HURRICANE INUNDATION AREAS

- Inundation Area A
- Inundation Area B
- Inundation Area C

NOTES:

1. Inundation areas were derived from the National Hurricane Center's application of the SLOSH (Sea, Lake and Overland Surges from Hurricanes) model. Inundation areas reflect "WORST CASE" combinations of hurricane direction, forward speed, landfall point, and high astronomical tide.

2. Hurricane categories 1 through 4 refer to the Saffir-Simpson scale of hurricane intensity.

3. Shaded land areas represent areas with coastal flooding potential from hurricanes of the categories and forward speeds referenced by the inundation matrix shown above. Inland areas that may only be subjected to freshwater flooding are not identified.

4. "WORST CASE" hurricane surge elevations delineated for each inundation area are given in the surge tide profiles provided on Plate iii.

5. Nauset Beach, Shooter's Island, and Monomoy Island are not shown due to the continuous topographic changes caused by erosion and deposition of migratory sands. These locations are susceptible to complete inundation from all hurricane scenarios depicted by the inundation matrix shown above.
