Suggested UCL to Use	
95% Student's-t UCL	0.595

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

nu hat (MLE)	33.25	nu star (bias corrected)	27.46
Mean (detects)	0.463		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.058	Mean	0.439
Maximum	2.38	Median	0.27
SD	0.559	CV	1.274
k hat (MLE)	1.301	k star (bias corrected MLE)	1.099

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

95% Student's-t UCL	0.0772

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

UCL Statistics for Data Sets with Non-Detects

User Selected Options

5% K-S Critical Value	0.258	Detected data appear Gamma Distributed at 5% Significance Level

Detected data appear Gamma Distributed at 5% Significance Level

Gamma Statistics on Detected Data Only

k hat (MLE)	2.205	k star (bias corrected MLE)	1.664
Theta hat (MLE)	0.00292	Theta star (bias corrected MLE)	0.00387
nu hat (MLE)	48.51	nu star (bias corrected)	36.61
Mean (detects)	0.00645		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	8.30E-04	Mean	0.00805
Maximum	0.0114	Median	0.01
SD	0.00328	CV	0.407
k hat (MLE)	3.323	k star (bias corrected MLE)	2.858
Theta hat (MLE)	0.00242	Theta star (bias corrected MLE)	0.00282
nu hat (MLE)	132.9	nu star (bias corrected)	114.3
Adjusted Level of Significance (β)	0.038		
Approximate Chi Square Value (114.30, α)	90.62	Adjusted Chi Square Value (114.30, β)	88.96
95% Gamma Approximate UCL (use when n>=50)	0.0101	95% Gamma Adjusted UCL (use when n<50)	0.0103

Theta hat (MLE)	0.278	Theta star (bias corrected MLE)	0.373
nu hat (MLE)	30.18	nu star (bias corrected)	22.46
Mean (detects)	0.419		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	0.253
Maximum	1.5	Median	0.106
SD	0.361	CV	1.427
k hat (MLE)	0.664	k star (bias corrected MLE)	0.59
Theta hat (MLE)	0.381	Theta star (bias corrected MLE)	0.429

DL/2 Statistics

DL/2 Normal		DL/2 Log-Transformed	
Mean in Original Scale	0.302	Mean in Log Scale	-1.678
SD in Original Scale	0.343	SD in Log Scale	1.038
95% t UCL (Assumes normality)	0.442	95% H-Stat UCL	0.631

DL/2 is not a recommended method, provided for comparisons and historical reasons

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Normal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (t) UCL	0.441

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

RA_SE_VOCs|2-Butanone (MEK)|mg/kg

General Statistics

Total Number of Observations	6	Number of Distinct Observations	6
Number of Detects	5	Number of Non-Detects	1
Number of Distinct Detects	5	Number of Distinct Non-Detects	1
Minimum Detect	0.0083	Minimum Non-Detect	0.0319
Maximum Detect	0.0422	Maximum Non-Detect	0.0319
Variance Detects	2.01E-04	Percent Non-Detects	16.67%
Mean Detects	0.0212	SD Detects	0.0142
Median Detects	0.0175	CV Detects	0.67
Skewness Detects	0.868	Kurtosis Detects	-0.469
Mean of Logged Detects	-4.043	SD of Logged Detects	0.693

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use
guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.
For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Mean (detects)	0.156		

Gamma ROS Statistics using Imputed Non-Detects
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use	
95% Student's-t UCL	12.29

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

nu hat (MLE)	44.95	nu star (bias corrected)	23.81
Mean (detects)	0.64		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	0.32
Maximum	1.1	Median	0.248

ISM Calculator for 1-sided Upper Confidence Limit (UCL) for the Mean

Note on Selecting a UCL Method. This worksheet can be used to calculate a 95UCL from ISM data using both the Chebyshev and Student's-t methods. If you have discrete data or other knowledge that indicates the variability in contaminant concentrations within the DU is low, use the Student's t method. If discrete data or other knowledge suggests that the variability may be high or the variability is unknown, use the Chebyshev method. Because the Chebyshev method tends to yield higher UCL values for the same data set, it's statistical performance is desirable - it achieves the desired 95% coverage of the mean under conditions when the variability of concentrations throughout the DU are moderate or high (See Table 4-4). One drawback of this performance is that the Chebyshev will tend to more severely overestimate the true mean than Student's t. Nevertheless, if no discrete data are available to estimate this variability, then Chebyshev is generally preferred over Student's t. Do not mistake the standard deviation (SD) of replicates as a measure of this variability. The SD of replicates is a measure of consistency in estimates of the mean - this is considered a reliable indicator of the laboratory processing steps, but not an indicator of the degree of variability in the distribution of concentrations throughout the DU.

	Replicate Results Per Sampling Unit (mg/kg)						
	ISM-BG1		ISM-BG5		ISM-UPS		
Replicate Number	0 - 1 ft	1 - 3 ft	0 - 1 ft	1 - 3 ft	0 - 1 ft	1 - 3 ft	Notes
1	0.41	0.38	0.12	0.079	0.25	0.097	If you have replicate ISM results, enter data in the first section "Replicate Results"
2	0.22	0.42	0.17	0.077	0.27	0.11	If you have summary statistics, enter data in the second section "Summary Statistics"
3	0.32	0.26	0.20	0.061	0.19	0.072	
arithmetic mean	0.32	0.35	0.16	0.072	0.24	0.093	sample mean of replicate results
standard deviation	0.095	0.083	0.040	0.010	0.042	0.019	sample standard deviation of replicate results
CV = SD / mean	0.30	0.24	0.25	0.14	0.18	0.21	CV gives a measure of spread of the replicates, which is different from CV of underlying distribution
count (r)	3	3	3	3	3	3	For ISM, the sample size in the UCL calculation is the number of replicates, not the number of increments.
alpha (95% = 0.05)	0.05	0.05	0.05	0.05	0.05	0.05	standard choice is alpha = 0.05
t(alpha, df=r-1)	2.92	2.92	2.92	2.92	2.92	2.92	from Student's t distribution
Student's t UCL	0.48	0.49	0.23	0.089	0.31	0.13	Note that the UCL for these relatively small sample sizes will typically exceed the maximum.
Chebychev UCL	0.56	0.56	0.27	0.10	0.34	0.14	The calculated UCL should be used (do not use the maximum).
Selected UCL (a)	0.48	0.49	0.23	0.089	0.31	0.13	If the CV > 35% (indicating high variability), the Chebychev UCL is selected, if the CV < 35% (indicating low variability), the Student's t UCL is selected.

Notes:
All results are presented in milligram per kilogram (mg/kg).
% = percent.
CV = coefficient of variation.
df = degrees of freedon.
ft = feet.
ISM = incremental sampling methodology.
ITRC = Interstate Technical Regulatory Council.
r = count.
RSD = relative standard deviation.
SD = standard deviation.
UCL = upper confidence limit.

1. Introduction

An evaluation of representative soil, hydric soil, and sediment background chemistry data was conducted in support of the Remedial Investigation/Feasibility Study (RI/FS) for the Former Blue Beach Disposal Area Formerly Used Defense Site (FUDS) in North Kingstown, Rhode Island (the Project). The purpose of the background evaluation was to distinguish Site-related conditions from conditions that are naturally occurring or due to anthropogenic influences that are not Site-related. The background evaluation focused on constituents of potential concern (COPCs) that were identified in the baseline human health risk assessment (HHRA) and ecological risk assessment (ERA).

The background evaluation was performed in accordance with the methodologies detailed in the Updated Risk Assessment Work Plan (RAWP) provided as Appendix E of the Quality Assurance Project Plan (QAPP) (Mabbett, 2018). These methods are in accordance with the United States Environmental Protection Agency (USEPA) Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and United States Army Corp of Engineers (USACE) risk assessment guidance specific to the evaluation of background media, as available/applicable.

Representative soil, hydric soil, and sediment background chemistry data were collected for comparison to Site-specific data in the risk assessment. The relevant available background data were compiled and compared with Site-specific data to distinguish Site-related impacts from non-Site-related background conditions (naturally occurring or anthropogenic). The background evaluation was conducted as a tiered process in conjunction with the risk assessment to determine which COPCs identified by the HHRA and ERA are Site-related, in accordance with the Tri-Service Position Paper on Background Levels in Risk Assessment (USACE, 2011).

1.1 Report Organization

This background evaluation attachment is organized into the following sections:

- Section 1.0: Introduction
- Section 2.0: Data Used in Background Evaluation – A description of the data included in the background evaluation, which includes data collected in background areas and Site-specific data collected in the On-Project and Off-Project areas.
- Section 3.0: Background Evaluation Methodology – The methods used to evaluate the presence of outliers, calculate background threshold values, compare Site and background data with two-sample hypothesis tests, and conduct the geochemical analysis.
- Section 4.0: Background Evaluation Results – The results of the background evaluation are presented for each exposure media and by exposure area.
- Section 5.0: Summary and Conclusions – A summary of results and conclusions of the background evaluation.

2. Background Data

This section presents the background data collected at background sampling locations and the Site data that are included in the background evaluation. Also, the process of COPC selection for inclusion in the background evaluation is presented.

2.1 Background Sampling Locations

The environmental data evaluated in the risk assessment, which includes both Site and background data, is described in Section 2 of the Risk Assessment and presented in Attachment A. The available Site data selected for evaluation in the risk assessment were grouped into one of the following exposure areas:

- On-Project Blue Beach area – within the Former Blue Beach Disposal Area FUDS (e.g., within the jurisdictional Blue Beach FUDS boundary)
- Off-Project Red Maple Swamp / tidal stream area – within the tidal marsh referred to as “Red Maple Swamp” and the adjacent public walking path from Circuit Drive to Blue Beach
- Off-Project Narragansett Bay and Beachfront area – within the Narragansett Bay and beachfront

Representative background soil, hydric soil, and sediment were collected in May 2020 at Rome Point State Park in North Kingstown, Rhode Island, and in the upstream portion of the Off-Project Red Maple Swamp / tidal stream area (Figure 2-X of risk assessment). Both areas are deviations from background sampling locations identified in the RAWP, as described in the *Draft Trip Report for the Comprehensive Remedial Investigation Former Blue Beach Disposal Area FUDs* (“Trip Report”; Mabbett, 2020), because permission was not granted for access to previously identified background areas. Rome Point State Park is located on Narragansett Bay with similar shoreline features to the former Blue Beach Disposal Area but has not been impacted by past military operations. The portion of the tidal stream where the background sediment samples were collected is upgradient and outside of the Site-related influence.

Background soil samples were collected at twenty locations and the data were divided into two different depth intervals for evaluation, consistent with Site soil samples. Background surface soil is defined as the soil collected at a depth within 0 to 1 foot (ft) below ground surface (bgs). Background subsurface soil was collected at a depth interval of 1 to 3 ft bgs.

Background hydric soil samples were collected at ten sample locations within a coastal wetland area in Rome Point State Park. Consistent with Site hydric soil samples, background hydric soil samples were collected in two depth intervals: surface samples were collected at a depth within 0 to 1 ft bgs and subsurface samples were collected at a depth within 1 to 2 ft bgs.

Background sediment samples were collected in two areas. Ten sediment samples were collected at a depth of 0 to 1 ft bgs in the intertidal zone along the shoreline of the beach at Rome Point State Park for comparison with the Off-Project Narragansett Bay and Beachfront Area. Five sediment samples were collected at a depth of 0 to 0.5 ft bgs at five locations in the upstream portion of the tidal stream between Circuit Drive/Outfall 025 and Outfall 026 for comparison with the Off-Project Red Maple Swamp / tidal stream area. The latter five sediment samples were collected concurrently with the Off-Project Red Maple Swamp / tidal stream area Site samples (SED-331, SED-333, SED-335, SED-337, and SED-339) and were submitted with these Site samples for the analyses of sediment quality including sediment chemistry, bioassays, and macroinvertebrate community. The sediment quality evaluation is presented in the ERA.

2.2 Data Treatment

Background and Site data were validated and qualified prior to use in the risk assessment and the background evaluation as described in Section 2 of the risk assessment. Summary statistics, treatment of duplicate samples, and the calculation of totals for polycyclic aromatic hydrocarbon (PAHs), polychlorinated biphenyl (PCB) Aroclors, and xylenes of background data were conducted consistent with Site data.

2.3 COPC Selection

Preliminary COPCs were identified for inclusion in the background evaluation based on the initial screening of Site data in the HHRA and ERA. The list of COPCs for each exposure media and exposure area, for which relevant background data are available, are presented below.

Preliminary COPCs Identified for the Background Evaluation

Exposure Media	Exposure Area	Preliminary COPCs			
Surface Soil	On-Project Blue Beach Area	**Inorganics**		**Organics**	
		Aluminum	Lead	Anthracene	
		Antimony	Manganese	Benzo(a)Pyrene	
		Arsenic	Mercury	Dibenzo(a,h)Anthracene	
		Cadmium	Nickel	Total High Molecular Weight (HMW) PAHs	
		Chromium	Silver	Total PAHs	
		Cobalt	Thallium		
		Copper	Vanadium		
		Iron	Zinc		
	Off-Project Red Maple Swamp / Tidal Marsh Area	**Inorganics**		**Organics**	
		Aluminum	Manganese	Anthracene	Dibenzo(a,h)Anthracene
		Arsenic	Mercury	Benzo(a)Anthracene	Indeno(1,2,3-cd)Pyrene
		Chromium	Thallium	Benzo(a)Pyrene	Pyrene
		Cobalt	Vanadium	Benzo(b)Fluoranthene	Total HMW PAHs
		Iron	Zinc	Benzo(g,h,i)Perylene	Total PAHs
		Lead		Chrysene	
Subsurface Soil	On-Project Blue Beach Area	**Inorganics**		**Organics**	
		Aluminum	Copper	Benzo(a)Pyrene	
		Antimony	Iron		
		Arsenic	Lead		
		Cadmium	Manganese		
		Cobalt	Thallium		
	Off-Project Red Maple Swamp / Tidal Marsh Area	**Inorganics**		**Organics**	
		Arsenic		Benzo(a)Pyrene	Naphthalene
Sediment	Off-Project Red Maple Swamp / Tidal Marsh Area	**Inorganics**		**Organics**	
		Aluminum	Lead	Total PCB Aroclors	Fluorene
		Arsenic	Manganese	1-Methylnaphthalene	Indeno(1,2,3-cd)Pyrene
		Barium	Mercury	2-Methylnaphthalene	Naphthalene
		Beryllium	Nickel	Acenaphthene	Phenanthrene
		Cadmium	Selenium	Acenaphthylene	Pyrene
		Chromium	Silver	Anthracene	Total HMW PAHs
		Cobalt	Thallium	Benzo(a)Anthracene	Total Low Molecular Weight (LMW) PAHs
		Copper	Vanadium	Benzo(a)Pyrene	
		Iron	Zinc	Benzo(b)Fluoranthene	Total PAHs
				Benzo(g,h,i)Perylene	Bis-(2-Ethylhexyl)-Phthalate
				Benzo(k)Fluoranthene	Carbazole
				Chrysene	2-Butanone (MEK)
				Dibenzo(a,h)Anthracene	Acetone
				Fluoranthene	Carbon Disulfide
	Off-Project Narragansett Bay and Beachfront Area	**Inorganics**			
		Aluminum	Iron		
		Arsenic	Manganese		
		Cobalt	Thallium		
Hydric Surface Soil	Off-Project Red Maple Swamp / Tidal Marsh Area	**Inorganics**		**Organics**	
		Aluminum	Lead	Total PCB Aroclors	Benzo(k)Fluoranthene
		Antimony	Manganese	1-Methylnaphthalene	Chrysene
		Arsenic	Mercury	2-Methylnaphthalene	Dibenzo(a,h)Anthracene
		Chromium	Selenium	Anthracene	Indeno(1,2,3-cd)Pyrene
		Cobalt	Thallium	Benzo(a)Anthracene	Naphthalene
		Copper	Vanadium	Benzo(a)Pyrene	Pyrene
		Iron	Zinc	Benzo(b)Fluoranthene	Total HMW PAHs
				Benzo(g,h,i)Perylene	Total PAHs
Hydric Subsurface Soil	Off-Project Red Maple Swamp / Tidal Marsh Area	**Inorganics**		**Organics**	
		Aluminum	Iron	Total PCB Aroclors	
		Arsenic	Thallium		
		Cobalt	Vanadium		

3. Background Evaluation Methods

As described in the RAWP, the background evaluation consisted of a tiered process that includes evaluation of the background datasets for potential outliers, derivation of background threshold values (BTVs), hypothesis testing to compare the mean background concentration with Site-related concentrations, and geochemical analysis each COPC. This section presents the methodologies used to identify the presence of outliers, calculate BTVs, conduct the two-sample hypothesis tests between Site and background, and conduct the geochemical analysis. The results of each evaluation are presented in Section 4 for each exposure media and area. The statistical test output for the calculation of BTVs and the two-sample hypothesis tests is presented in Attachment D-1. The geochemical analysis output is presented in Attachment D-2.

3.1 Outlier Determination

Per the RAWP, the background datasets were evaluated for the presence of outliers using the default outlier tests (Dixon's Test) in USEPA's ProUCL software (Version 5.1, USEPA, 2015, 2016). These statistical tests can identify "extreme" values in the background datasets; however, extreme values were not identified as outliers unless additional justification was evident. This approach for determining if elevated values should be removed from the background dataset is consistent with the USACE Tri-Service Paper on Background (USACE, 2011), which cites both the USEPA CERCLA guidance on background (USEPA, 2002) and US Navy guidance on background (NAVFAC, 1999). The US Navy 1999 guidance is specific on this topic:

> "If the [outlier] test indicates the suspect value(s) are indeed larger than expected, relative to the remaining data, the outliers should be examined to determine if they are mistakes or errors. If they are, they should be removed from the data set. Otherwise, they should not be removed, even though the statistical test indicated they were outliers."

In order to determine whether any of the background samples identified as extreme values had evidence of errors, the "Deviations from the QAPP/FSP" and "Data Validation" sections of the Trip Report were reviewed for information on any quality control failures for the laboratory analysis or field collection effort errors that would have affected background samples. No such errors were reported for any of the background samples included in this evaluation. Therefore, no background samples identified as extreme values were excluded on the basis of field collection or laboratory analysis errors.

Datasets with background samples identified as extreme values were further evaluated by conducting outlier tests with data transformations. The ProUCL outlier tests are parametric tests and as such, the tested dataset is assumed to be normal following the removal of the outlier(s). Because environmental datasets are often not normally distributed, these parametric tests can erroneously identify elevated values as outliers. To further examine this possibility, data transformations including a natural log transformation and a gamma correction (x^(1/3)) were applied to the datasets for which extreme values were identified and the default outlier tests were performed again. If the extreme values were not identified by the outlier test based on the transformed datasets, then it is likely that the values were identified in error (based on the non-transformed dataset tests) because the datasets are not normally distributed. In these cases, the values were not removed from the datasets.

If, however, the values were identified as extreme values based on outlier test results of both the non-transformed dataset and one of the transformed datasets (i.e., lognormal or gamma), the values were further examined to determine if the same sample was identified as an extreme value for other COPCs in the same chemical group (e.g., metals, PAHs). If a sample was identified as an extreme value and the same sample was identified for other COPCs in the same chemical group, the value was removed from the dataset prior to the BTV calculation, the two-sample hypothesis test, and the geochemical analysis.

3.2 Background Threshold Values

BTV statistics were calculated in ProUCL Version 5.1 (USEPA, 2015, 2016) for preliminary COPCs identified in the HHRA and ERA with at least five detected concentrations available. As detailed in Section 3.1, values determined to be outliers were removed from the dataset prior to the calculation of BTVs.

The 95% upper tolerance limit (95UTL), which is calculated such that 95% of observations from the background dataset are less than or equal to the statistic (which is the 95% upper confidence limit of the 95th percentile of the dataset) with 95% confidence, was selected as the BTV statistic. The 95UTL statistic selected was based on the distribution of the detected concentrations of each dataset (i.e., if the detected concentrations followed a normal, lognormal, or gamma distribution, then the normal, lognormal, or gamma 95UTL was selected, respectively), or in cases of no discernible distribution, the nonparametric 95UTL statistic was selected. If the dataset included non-detects, the Kaplan-Meier BTV statistics were selected based on the distribution of the detected concentrations. The BTV statistics output from ProUCL is presented in Attachment D-1.

3.3 Two-Sample Hypothesis Tests

For COPCs for which Site concentrations exceed the BTVs (as presented in the risk assessment), two-sample hypothesis tests were conducted when a minimum of five samples with four detected concentrations were available in both the Site and background datasets. The two-sample hypothesis test compares the central tendency (i.e., the mean or median) of COPC concentrations measured in Site samples (i.e., the Site population) with the central tendency of COPC concentrations measured in background (i.e., the background population). These tests provide information on whether the COPCs concentrations in the Site and background populations are consistent.

The two-sample hypothesis tests were conducted with the following steps. First, the distributions of COPC concentrations detected in the Site and background datasets were tested for normality using the Shapiro-Wilk test (significance level of 0.05). Next, a two-sample test was selected depending upon the distribution and the presence/absence of non-detect values in each dataset. For the purposes of the two-sample hypothesis tests non-detects were included at the limit of detection (LOD). When both the Site and the background datasets were normally distributed with no non-detect values, a parametric test (t-test) was conducted. When the Site and/or the background datasets were not normally distributed, a non-parametric test was selected as follows: the Wilcoxon test was selected when no more than one LOD was present in either dataset and the Tarone-Ware test was selected when one or both datasets had more than one LOD value present. All two-sample hypothesis tests were conducted on non-transformed data.

The two-sample comparison tests assume that the Site concentrations arise from the same distribution as the background concentrations. The null and alternative hypotheses are defined as:

> *Ho* (null): The Site mean/median concentration is less than or equal to the mean/median concentration in the background areas ($p > 0.05$: fail to reject Ho)
>
> *Ha* (alternative): The Site mean/median concentration is greater than the mean/median concentration in the background area ($p < 0.05$: reject Ho)

For all tests (t-test, Wilcoxon, or Tarone-Ware), Site concentrations were determined to be less than or equal to background concentrations at a significance level of 0.05 and the COPC was not retained for the risk assessment. If null hypothesis was rejected, and the alternative hypothesis (i.e., Site concentrations are higher than background concentrations) was accepted, the COPC was retained in the risk assessment.

The two-sample hypothesis test output is presented in Attachment D-1. For media/chemicals for which requirements for conducting a statistical evaluation are not met (e.g., Site or background dataset consist of mainly non-detects), a qualitative/graphical comparison (using box plots) will be performed.

3.4 Geochemical Analysis

For metal COPCs for which the two-sample hypothesis tests (Section 3.3) concluded Site concentrations were greater than background, a geochemical analysis was conducted. The methodology used in the geochemical analysis is based on processes that transport and redistribute naturally-occurring chemicals, particularly metals, in the geologic environment (Battelle Memorial Institute et al., 2002). During soil formation, primary minerals weather (break down) and secondary minerals form. The secondary minerals have large surface areas (on a microscopic basis), and therefore can be highly adsorptive. Constituents can also incorporate within secondary minerals. In addition to silica, the three main components of the secondary minerals are aluminum, iron, and manganese. These constituents occur as oxide, hydroxide, and oxyhydroxide minerals and as aluminum in clays. A strong correlation between one of these

three constituents (“reference elements”) and trace constituents (COPCs such as arsenic or copper) is an indicator that the trace metal is present due to natural soil forming processes.

Correlations between the reference elements and COPCs were examined using scatterplots and pairwise correlations. Scatterplots of metal COPCs plotted against aluminum, iron, and manganese are included in Attachment D-2. On the scatterplots a red hollow triangle was used to indicate a background data point and a black hollow circle was used to indicate a Site data point. The x-axis and y-axis on the scatterplots are shown in logarithmic (base 10) scale due to the large range of concentration values observed for most metals (one or more orders of magnitude).

The scatterplots were examined to determine whether the background data points lined up on a trend line from the lower-left corner to the upper-right corner on the scatterplot, which would be expected if a positive geochemical correlation exists between the two given metals in background. If the background data points formed a positive trend line and the Site data points generally followed this trend line, then the strength of the correlation was investigated further with pairwise correlation, as discussed below. If, however, the background data points were scattered throughout the plots with no clear pattern, then no positive geochemical correlation exists between the two given metals in background and the metal was retained as a COPC.

The pairwise correlation between two metals was assessed using the Kendall’s tau (τ) correlation coefficient (Kendall 1938, 1975). The Kendall’s tau correlation coefficient was selected as the method to assess the strength of correlations because tau is a non-parametric, rank-based statistical method that is not sensitive to the effect of a small number of unusual values, such as outliers, and is suitable for variables that exhibit skewness around the general relationship or for a range of values that spans several orders of magnitude (Helsel and Hirsch 2002). The Kendall’s tau correlations were computed using Stata version IC/11.0, developed by StataCorp LP (StataCorp LP 2009), and the resulting correlation coefficients are shown under each pairwise scatterplot in Attachment D-2. A two-sided hypothesis test for correlation was also performed to test for the significance of tau, and the associated p-values are also presented in Attachment D-2 for reference.

The Kendall’s tau correlation coefficient and associated p-value were used to determine the correlation strength between two given metals. A qualitative classification of correlation strength based on tau is presented in the USACE Environmental Statistics guidance (USACE 2013) and summarized below**.** Based on the qualitative classification, a Kendall’s tau correlation coefficient of at least 0.5 with an associated p-value of less than 0.05 was required to indicate a moderate correlation. If a moderate correlation was present between a COPC and at least one of the reference elements, then it was concluded that the COPC is naturally occurring and eliminated from the HHRA and ERA.

Qualitative Classification of Correlation Strength for Kendall’s Tau

Absolute value of correlation coefficient (Kendall’s tau)	Degree of relationship
$\tau < 0.30$	Extremely Weak
$0.30 < \tau < 0.50$	Weak
$0.50 < \tau < 0.75$	Moderate
$0.75 < \tau < 0.90$	Moderately Strong
$0.90 < \tau < 0.95$	Strong
$0.95 < \tau < 1.00$	Very Strong

4. Results

This section presents the results of the background evaluation including the identification of outliers, the calculation of BTVs, the two-sample hypothesis tests between Site and background, and the geochemical analyses. The results are reported separately for each background medium and area.

4.1 Background Surface Soil

4.1.1 Outlier Determination – Surface Soil

The results of the outlier tests identified extreme upper-tail values for antimony, arsenic, mercury (a lower-tail value [i.e., minimum] was also identified), nine individual PAH compounds, total HMW PAHs, and total PAHs (Table 1). Based on review of the Trip Report, no errors were reported for the samples for which extreme values were identified. The extreme values for the listed COPCs were further evaluated by transforming the COPC datasets using natural log transformation and gamma correction and performing the outlier tests again on the transformed datasets.

- The extreme values identified for arsenic and mercury were not outliers based on the tests performed with the transformed datasets, which suggests that the not normal distribution of the datasets are influencing the outlier test outcome and the values identified are not true outliers for those datasets. Therefore, the values were not removed as outliers for arsenic and mercury.
- The extreme value for antimony was also identified as an outlier based on the transformed datasets, but no outlier values were identified for other metal COPCs for this sample (SB-406), with the exception of arsenic which is discussed above, and therefore, the value was not removed as an outlier for antimony.
- The extreme values identified for individual and total PAHs was identified for the same sample (SB-412). The extreme value was identified as an extreme value based on one or both of the outlier test results of the transformed datasets for anthracene, benzo(b)fluoranthene, chrysene, dibenzo(a,h)anthracene, pyrene, total HMW PAHs, and total PAHs. Therefore, the values for these COPCs were removed from the dataset.
- For the remaining PAHs, the extreme value was not identified based on both outlier test results of the transformed datasets for benzo(a)anthracene, benzo(a)pyrene, benzo(g,h,i)perylene, and indeno(1,2,3-cd)pyrene, which suggests that the distribution of the datasets are influencing the outlier test outcome and the values identified are not true outliers for these datasets. Therefore, the values were not removed as outliers from these datasets.

Therefore, the outlier values were determined for anthracene, benzo(b)fluoranthene, chrysene, dibenzo(a,h)anthracene, pyrene, total HMW PAHs, and total PAHs and these values were removed from the datasets prior to BTV calculation, two-sample hypothesis test, and the geochemical analysis.

4.1.2 Background Threshold Values – Surface Soil

BTVs were calculated for the preliminary COPCs for background surface soil as described in Section 3.2 and are presented in Table 1. BTVs were used in the risk assessment to compare against Site concentrations. Any preliminary COPC for which the maximum detected concentrations in Site surface soils exceed the BTVs were retained for the two-sample hypothesis test.

4.1.3 Two-Sample Hypothesis Test – Surface Soil

A two-sample hypothesis test was conducted for each COPC retained following the comparison of BTVs to Site concentrations in the risk assessment (Table 2). Most of Site and background datasets were not normally distributed. Therefore, nonparametric tests (Wilcoxon or Tarone-Ware tests) were selected based on the presence of non-detects in the dataset as detailed in Section 3.3. Both Site and background datasets were normally distributed for cobalt, lead, and manganese, and therefore, parametric t-tests were performed for those datasets.

The following table presents the COPCs for which the central tendency (i.e., median or mean concentrations) of Site and background surface soil datasets are consistent and were not retained for further evaluation in the risk

assessment. For all other COPCs, Site surface soil concentrations are significantly higher than background and were retained as COPCs.

Two-Sample Hypothesis Test Outcome	COPCs Not Retained
Null hypothesis accepted: Site concentration < or = background	**On-Project Blue Beach Area**: chromium, cobalt, manganese, mercury, nickel, silver, anthracene, benzo(a)pyrene, total HMW PAHs, total PAHs **Off-Project Red Maple Swamp / Tidal Stream Area**: chromium, lead, zinc, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, chrysene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, pyrene, total HMW PAHs, total PAHs

4.1.4 Geochemical Analysis – Surface Soil

A geochemical evaluation was performed for metals retained as COPCs based on the results of the two-sample hypothesis tests which concluded Site concentrations were greater than background. The metal COPCs retained in background surface soil include antimony, cadmium, copper, lead, and zinc.

Attachment D-2 presents the scatterplot examined for each metal COPC, the Kendall's tau correlation coefficient, its associated p-value, and the rationale to retain or eliminate the given metal COPC. No apparent geochemical correlations were observed for any of the metal COPCs evaluated in background surface soil. Therefore, these metals are retained as COPCs in the risk assessment.

4.2 Background Subsurface Soil

4.2.1 Outlier Determination – Subsurface Soil

The results of the outlier tests identified extreme values for arsenic and benzo(a)pyrene (Table 3). Based on review of the Trip Report, no errors were reported for the samples for which these values were identified. The extreme values were further evaluated by transforming the COPC datasets using natural log transformation and gamma correction and performing the outlier tests again on the transformed datasets.

- The extreme value identified for arsenic was also identified as an extreme value based on the transformed datasets, but no extreme values were identified for other metal COPCs for this sample (SB-404). Therefore, the value was not removed from the dataset.
- The extreme value identified for benzo(a)pyrene was not identified as an extreme value based on the log-transformed dataset. In addition, no extreme values were identified for other PAH COPCs for this sample (SB-411). Therefore, the value was not removed from the dataset.

4.2.2 Background Threshold Values – Subsurface Soil

BTVs were calculated for the preliminary COPCs for background subsurface soil as described in Section 3.2 and are presented in Table 3. BTVs were used in the risk assessment to compare against Site concentrations. Any preliminary COPC for which the maximum detected concentrations in Site surface soils exceed the BTVs were retained for the two-sample hypothesis test.

4.2.3 Two-Sample Hypothesis Test – Subsurface Soil

A two-sample hypothesis test was conducted for each COPC retained following the comparison of BTVs to Site concentrations (Table 4). Most of Site and background datasets were not normally distributed. Therefore, nonparametric tests (Wilcoxon or Tarone-Ware tests) were selected based on the presence of non-detects in the dataset as detailed in Section 3.3. Both Site (Off-Project Red Maple Swamp / Tidal Stream Area) and background datasets were normally distributed for arsenic, and therefore, a parametric t-test was performed for those datasets.

The following table presents the COPCs for which the central tendency (i.e., median or mean concentrations) of Site and background subsurface soil datasets are consistent and were not retained for further evaluation in the risk assessment. For all other COPCs, Site subsurface soil concentrations are significantly higher than background and were retained as COPCs.

Two-Sample Hypothesis Test Outcome	COPCs Not Retained
Null hypothesis accepted: Site concentration < or = background	**On-Project Blue Beach Area**: arsenic, copper, lead, manganese

A two-sample hypothesis test could not be conducted for benzo(a)pyrene due to low frequency of detection in Site samples. Site and background concentrations (including LODs for non-detects) were compared in a boxplot (Attachment D-2). The range of concentrations of both Site and background samples overlap, but the detected concentrations range higher in Site samples.

4.2.4 Geochemical Analysis – Subsurface Soil

A geochemical evaluation was performed for metals retained as COPCs in subsurface soil based on the results of the two-sample hypothesis tests which concluded Site concentrations were greater than background. The metal COPCs retained in background subsurface soil include antimony, arsenic, and cadmium.

Attachment D-2 presents the scatterplot examined for each metal COPC, the Kendall's tau correlation coefficient, its associated p-value, and the rationale to retain or eliminate the given metal COPC. The results of the analysis are summarized below.

- For subsurface soil in the On-Project Blue Beach Area, antimony and cadmium were evaluated. No apparent geochemical correlations were observed for any of the metals and they were retained as COPCs in the risk assessment.
- Although the two-sample hypothesis test conducted for arsenic in subsurface soil in the Off-Project Red Maple Swamp / Tidal Stream Area concluded Site concentrations were greater than background, Site concentrations of aluminum, iron, and manganese were not available and geochemical analysis could not be conducted.

4.3 Background Sediment – Tidal Stream North

4.3.1 Outlier Determination – Sediment (Tidal Stream)

The results of the outlier tests identified extreme values for copper, lead, and selenium (Table 5). Based on review of the Trip Report, no errors were reported for the samples for which these values were identified. The extreme values were further evaluated by transforming the COPC datasets using natural log transformation and gamma correction and performing the outlier tests again on the transformed datasets.

- The extreme values identified for copper, lead, and selenium were not identified as extreme values based on the tests performed with the transformed datasets, which suggests that the distribution of the datasets are influencing the outlier test outcome and the values identified are not true outliers for those datasets. In addition, no other extreme values were identified for metals COPCs for these samples. Therefore, the values were not removed from the datasets.

4.3.2 Background Threshold Values – Sediment (Tidal Stream)

BTVs were calculated for the preliminary COPCs for background sediment (tidal stream area) as described in Section 3.2 and are presented in Table 5. BTVs were used in the risk assessment to compare against Site concentrations. Any preliminary COPC for which the maximum detected concentrations in Site sediment in the Off-Project Red Maple Swamp / Tidal Stream Area exceed the BTVs were retained for the two-sample hypothesis test.

4.3.3 Two-Sample Hypothesis Test – Sediment (Tidal Stream)

A two-sample hypothesis test was conducted for each COPC retained following the comparison of BTVs to Site concentrations (Table 6). Most of Site and background datasets were not normally distributed. Therefore, nonparametric tests (Wilcoxon or Tarone-Ware tests) were selected based on the presence of non-detects in the dataset as detailed in Section 3.3. Both Site and background datasets were normally distributed for beryllium, and therefore, a parametric t-test was performed on those datasets.

The following table presents the COPCs for which the central tendency (i.e., median or mean concentrations) of Site and background sediment (tidal stream area) datasets are consistent and were not retained for further evaluation in the risk assessment. For two COPCs, cadmium and zinc, Site sediment concentrations are significantly higher than background and were retained as COPCs.

Two-Sample Hypothesis Test Outcome	**COPCs Not Retained**
Null hypothesis accepted: Site concentration < or = background	**Off-Project Red Maple Swamp / Tidal Stream Area**: aluminum, arsenic, barium, beryllium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenuium, silver, thallium, vanadium, and fluorene

4.3.4 Geochemical Analysis – Sediment (Tidal Stream)

A geochemical evaluation was performed for two metals retained as COPCs based on the results of the two-sample hypothesis tests which concluded Site concentrations were greater than background. The metal COPCs retained in background sediment (tidal stream area) include cadmium and zinc.

Attachment D-2 presents the scatterplot examined for each metal COPC, the Kendall's tau correlation coefficient, its associated p-value, and the rationale to retain or eliminate the given metal COPC. A positive, significant geochemical correlation was found between both metals and the reference element manganese. Therefore, cadmium and zinc were eliminated as COPCs in the risk assessment.

4.4 Background Sediment – Beachfront Area

4.4.1 Outlier Determination – Sediment (Beachfront Area)

The results of the outlier tests identified one extreme value for cobalt (Table 7). Based on review of the Trip Report, no errors were reported for the sample for which the extreme value was identified. This extreme value was further evaluated by transforming the COPC dataset using natural log transformation and gamma correction and performing the outlier tests again on the transformed datasets.

- The extreme value identified for cobalt was not an extreme value based on the tests performed with the transformed datasets, which suggests that the distribution of the dataset is influencing the outlier test outcome and the value identified is not a true outlier for this dataset. In addition, no other extreme values were identified for metals COPCs for this sample. Therefore, the value was not removed from the dataset.

4.4.2 Background Threshold Values – Sediment (Beachfront Area)

BTVs were calculated for the preliminary COPCs for background sediment (beachfront area) as described in Section 3.2 and are presented in Table 7. BTVs were used in the risk assessment to compare against Site concentrations. Any preliminary COPC for which the maximum detected concentrations in Site sediment in the Off-Project Narragansett Bay / Beachfront Area exceed the BTVs were retained for the two-sample hypothesis test.

4.4.3 Two-Sample Hypothesis Test – Sediment (Beachfront Area)

A two-sample hypothesis test was conducted for each COPC retained following the comparison of BTVs to Site concentrations (Table 8). Site datasets were not normally distributed. Therefore, nonparametric tests (Wilcoxon tests) were selected based on the presence of non-detects in the dataset as detailed in Section 3.3.

The following table presents the COPCs for which the central tendency (i.e., median or mean concentrations) of Site and background sediment (beachfront area) datasets are consistent and were not retained for further evaluation in the risk assessment.

Two-Sample Hypothesis Test Outcome	**COPCs Not Retained**
Null hypothesis accepted: Site concentration < or = background	**Off-Project Narragansett Bay / Beachfront Area**: aluminum, arsenic

4.5 Background Hydric Surface Soil

4.5.1 Outlier Determination – Hydric Surface Soil

The results of the outlier tests identified extreme values for arsenic, chromium, cobalt, copper, iron, manganese, mercury, benzo(a)fluoranthene, chrysene, pyrene, total HMW PAHs, and total PAHs (Table 9). Based on review of the Trip Report, no errors were reported for the samples for which extreme values were identified. The listed COPCs were further evaluated by transforming the COPC datasets using natural log transformation and gamma correction and performing the outlier tests again on the transformed datasets.

- The extreme values identified for arsenic, chromium, cobalt, copper, iron, and manganese were identified as extreme values for the same sample (SSH-313) based on the tests performed with the transformed datasets. Therefore, these values were determined to be outliers for these COPCs and were removed from the datasets.
- The extreme value for mercury was not identified as an extreme value based on the transformed datasets, and no extreme values were identified for other metal COPCs for this sample (SSH-314). Therefore, the value was not removed from the dataset.
- The extreme values identified for benzo(a)fluoranthene, chrysene, pyrene, total HMW PAHs, and total PAHs were identified for the same sample (SSH-315). However, these values were not identified as extreme values based on the tests performed with the transformed datasets, which suggests that the distribution of the datasets are influencing the outlier test outcome and the values identified are not true outliers for these datasets. Therefore, the values were not removed from these datasets.

The extreme values identified for arsenic, chromium, cobalt, copper, iron, and manganese were determined to be outliers and the values removed from the datasets prior to BTV calculation, two-sample hypothesis test, and the geochemical analysis.

4.5.2 Background Threshold Values – Hydric Surface Soil

BTVs were calculated for the preliminary COPCs for background surface soil as described in Section 3.2 and are presented in Table 9. BTVs were used in the risk assessment to compare against Site concentrations. Any preliminary COPC for which the maximum detected concentrations in Site hydric surface soils exceed the BTVs were retained for the two-sample hypothesis test.

4.5.3 Two-Sample Hypothesis Test – Hydric Surface Soil

A two-sample hypothesis test was conducted for each COPC retained following the comparison of BTVs to Site concentrations (Table 10). Most of Site and background datasets were not normally distributed. Therefore, nonparametric tests (Wilcoxon or Tarone-Ware tests) were selected based on the presence of non-detects in the dataset as detailed in Section 3.3. Both Site and background datasets were normally distributed for arsenic, chromium, copper, iron, lead, vanadium, and zinc, and therefore, parametric t-tests were performed for those datasets.

The following table presents the COPCs for which the central tendency (i.e., median or mean concentrations) of Site and background hydric surface soil datasets are consistent and were not retained for further evaluation in the risk assessment. For all other COPCs, Site hydric surface soil concentrations are significantly higher than background and were retained as COPCs.

Two-Sample Hypothesis Test Outcome	**COPCs Not Retained**
Null hypothesis accepted: Site concentration < or = background	**Off-Project Red Maple Swamp / Tidal Stream Area**: manganese, anthracene, benzo(a)anthracene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, pyrene, total HMW PAHs

A two-sample hypothesis test could not be conducted for thallium due to low frequency of detection in background samples. Site and background concentrations (including LODs for non-detects) were compared in a boxplot (Attachment D-2). The range of concentrations of both Site and background samples overlap, but the detected concentrations are higher in Site samples.

4.5.4 Geochemical Analysis – Hydric Surface Soil

A geochemical evaluation was performed for metals retained as COPCs based on the results of the two-sample hypothesis tests which concluded Site concentrations were greater than background. The metal COPCs retained in background hydric surface soil include aluminum, arsenic, chromium, cobalt, copper, iron, lead, manganese, mercury, selenium, vanadium, and zinc.

Attachment D-2 presents the scatterplot examined for each metal COPC, the Kendall's tau correlation coefficient, its associated p-value, and the rationale to retain or eliminate the given metal COPC. The results of the evaluation are summarized below:

- A positive, significant geochemical correlation with one or more of the reference elements was found for aluminum, chromium, cobalt, iron, manganese, vanadium, and zinc. These metals were eliminated as COPCs in the risk assessment.
- No apparent geochemical correlations were observed for arsenic, copper, lead, mercury, and selenium. These metals are retained as COPCs in the risk assessment.

4.6 Background Hydric Subsurface Soil

4.6.1 Outlier Determination – Hydric Subsurface Soil

The results of the outlier tests identified extreme values for arsenic, cobalt, and iron (Table 11). Based on review of the Trip Report, no errors were reported for the sample for which these values were identified. The extreme values were further evaluated by transforming the COPC datasets using natural log transformation and gamma correction and performing the outlier tests again on the transformed datasets.

- The extreme values identified for arsenic, cobalt, and iron were identified as extreme values for the same sample (SSH-313) based on the tests performed with the transformed datasets. Therefore, these extreme values were removed from the dataset.

The extreme values identified for arsenic, cobalt, and iron were determined to be outliers and were removed from the datasets prior to BTV calculation, two-sample hypothesis test, and the geochemical analysis.

4.6.2 Background Threshold Values – Hydric Subsurface Soil

BTVs were calculated for the preliminary COPCs for background surface soil as described in Section 3.2 and are presented in Table 11. BTVs were used in the risk assessment to compare against Site concentrations. Any preliminary COPC for which the maximum detected concentrations in Site hydric subsurface soils exceed the BTVs were retained for the two-sample hypothesis test.

4.6.3 Two-Sample Hypothesis Test – Hydric Subsurface Soil

A two-sample hypothesis test was conducted for each COPC retained following the comparison of BTVs to Site concentrations (Table 12). Background datasets for arsenic and iron were not normally distributed and therefore, nonparametric tests (Wilcoxon tests) were selected based on the presence of non-detects in the dataset as detailed in Section 3.3. Both Site and background datasets were normally distributed for cobalt and vanadium, and therefore, parametric t-tests were performed for those datasets.

For all COPCs, Site hydric subsurface soil concentrations are significantly higher than background and were retained as COPCs.

A two-sample hypothesis test could not be conducted for thallium due to low frequency of detection in background samples. Site and background concentrations (including LODs for non-detects) were compared in a boxplot

(Attachment D-2). The range of concentrations of both Site and background samples overlap, but the detected concentrations are higher in Site samples.

4.6.4 Geochemical Analysis – Hydric Subsurface Soil

A geochemical evaluation was performed for metals retained as COPCs based on the results of the two-sample hypothesis tests which concluded Site concentrations were greater than background. The metal COPCs retained in background hydric subsurface soil include arsenic, cobalt, iron, and vanadium.

Attachment D-2 presents the scatterplot examined for each metal COPC, the Kendall's tau correlation coefficient, its associated p-value, and the rationale to retain or eliminate the given metal COPC. A positive, significant geochemical correlation with one or more of the reference elements was found for arsenic, cobalt, iron, and vanadium. These metals were eliminated as COPCs in the risk assessment.

5. Summary and Conclusions

This appendix presents the results of the background evaluation. Specifically, it provides a description of the background sediment samples collected upstream of the site that were selected to represent background conditions. In addition, the methodology and results of the background conditions data evaluation are presented, including the identification of outlier values, the comparison of Site and background datasets, and the calculation of BTVs.

Representative soil, hydric soil, and sediment background were collected in May 2020 at Rome Point State Park in North Kingstown, Rhode Island, which is located on Narragansett Bay with similar shoreline features but has not been impacted by past military operations as the former Blue Beach Disposal Area. Representative sediment was also collected in the upstream portion of the Off-Project Red Maple Swamp / tidal stream area, which is upgradient and outside of the Site-related influence. Soil and sediment background samples were collected at the same depth intervals as Site samples. The background datasets were validated and qualified prior to use in the risk assessment and the background evaluation, and statistics and totals were calculated in the same manner as Site data.

Preliminary COPCs were identified for each exposure media and area in the risk assessment. The background datasets for these preliminary COPCs were evaluated for the presence of outliers based both on the statistical outlier tests and on additional evidence including evidence of field sampling or laboratory analysis errors, an evaluation of data transformations on the outcome of the outlier tests, and the presence of other outliers identified within the same chemical group (e.g., metals, PAHs) for the same sample. Outlier values were identified for three samples: a surface soil sample, a hydric surface soil sample, and a hydric subsurface soil sample, and extreme values determined to be outliers for these samples were removed from the datasets prior to BTV calculation, two-sample hypothesis test, and the geochemical analysis.

Media	**COPCs with Outlier Values Removed from Datasets**
Surface soil (SB-412)	Anthracene, benzo(b)fluoranthene, chrysene, dibenzo(a,h)anthracene, pyrene, total HMW PAHs, and total PAHs
Hydric surface soil (SSH-313)	Arsenic, chromium, cobalt, copper, iron, and manganese
Hydric subsurface soil (SSH-313)	Arsenic, cobalt, and iron

BTVs were calculated for preliminary COPCs and compared to Site concentrations in the risk assessment. Any preliminary COPC for which Site concentrations are less than the BTVs were eliminated from the risk assessment.

A two-sample hypothesis test was conducted for each COPC retained following the comparison of BTVs to Site concentrations in the risk assessment. The two-sample hypothesis test compared the central tendency (i.e., the mean or median) of the Site and background datasets and identify the COPCs for which Site and background concentrations are consistent. The following table presents the COPCs for which the central tendency (i.e., median or mean concentrations) of Site datasets are less than or equal to background datasets and were not retained for further evaluation in the risk assessment. COPCs were eliminated for all exposure media and areas with the exception of hydric subsurface soil for which no COPCs were eliminated based on the two-sample hypothesis test results.

Media	COPCs Not Retained Based on Two-Sample Hypothesis Tests
Surface Soil	**On-Project Blue Beach Area**: chromium, cobalt, manganese, mercury, nickel, silver, anthracene, benzo(a)pyrene, total HMW PAHs, total PAHs **Off-Project Red Maple Swamp / Tidal Stream Area:** chromium, lead, zinc, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, chrysene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, pyrene, total HMW PAHs, total PAHs
Subsurface Soil	**On-Project Blue Beach Area:** arsenic, copper, lead, manganese
Sediment	**Off-Project Red Maple Swamp / Tidal Stream Area:** aluminum, arsenic, barium, beryllium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenuium, silver, thallium, vanadium, and fluorene **Off-Project Narragansett Bay / Beachfront Area:** aluminum, arsenic
Hydric Surface Soil	**Off-Project Red Maple Swamp / Tidal Stream Area:** manganese, anthracene, benzo(a)anthracene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, pyrene, total HMW PAHs

The last step in the background evaluation was the geochemical evaluation, which was performed for metals retained as COPCs based on the results of the two-sample hypothesis tests which concluded Site concentrations were greater than background. This evaluation is based on processes that transport and redistribute naturally-occurring chemicals, particularly metals, during soil formation whereby constituents can incorporate with secondary minerals including aluminum, iron, and manganese (reference elements). Correlations between the reference elements and COPCs were examined using scatterplots and pairwise correlations. Significant, positive correlations between reference elements and COPCs in background and Site indicated the COPC is naturally occurring and eliminated from the HHRA and ERA. The following COPCs were eliminated from the risk assessment on the basis of the geochemical evaluation as follows:

Media	COPCs Not Retained Based on Two-Sample Hypothesis Tests
Sediment	**Off-Project Red Maple Swamp / Tidal Stream Area:** cadmium and zinc
Hydric Surface Soil	**Off-Project Red Maple Swamp / Tidal Stream Area:** aluminum, chromium, cobalt, iron, manganese, vanadium, and zinc
Hydric Subsurface Soil	**Off-Project Red Maple Swamp / Tidal Stream Area:** arsenic, cobalt, iron, and vanadium

Notes:

BTV - Background Threshold Value.

COPC - Chemical of Potential Concern.

FOD - Frequency of Detection. The number of detected concentrations: the total number of samples.

HMW - High Molecular Weight.

ATTACHMENT D TABLE 1
OUTLIER DETERMINATION AND CALCULATION OF BACKGROUND THRESHOLD VALUES FOR COPCS IN BACKGROUND SURFACE SOIL
BACKGROUND EVALUATION
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

COPC	Background FOD (a)	Maximum Detected Concentration (mg/kg) (a)	Extreme Value (mg/kg) (b)	Sample Identification of Extreme Value	Outlier Determination (c)	BTV (mg/kg) (d)	BTV Statistic

KM - Kaplan Meier.

mg/kg - milligrams per kilogram.

PAH - Polycyclic aromatic hydrocarbons.

SVOCs - Semivolatile organic compounds.

USEPA - United States Environmental Protection Agency.

UTL - Upper Threshold Value.

(a) The maximum detected concentration and FOD of the background dataset following removal of outlier values.

(b) Extreme values identified by the default outlier test in ProUCL (version 5.1; USEPA, 2016) was conducted (Dixon's test for under 25 samples).

(c) Extreme values were further evaluated by data transformations (natural log and gamma correction): if the value was identified as an extreme value following the data transformations and additional extreme values were identified for the sample for the same group of COPCs (e.g., SVOCs), this value was determined to be an outlier and removed from the dataset. If the value was not identified as an extreme value based on the outlier test results of the transformed datasets and additional extreme values were not identified for the sample for the same group of COPCs, the value is not an outlier and was not removed from the dataset.

(d) BTVs were calculated in ProUCL (version 5.1; USEPA, 2016). The 95UTL was selected based on the distribution of the detected concentrations in the dataset.
If the dataset includes non-detects, the non-detects were included at the full value of the detection limit and the BTV was selected from the Kaplan-Meier (KM) statistics.
For gamma UTLs, the Wilson Hilferty (WH) statistic was selected.

(e) The value was identified as an extreme value based on the outlier test results of the transformed datasets. However, the sample was not identified as an extreme value for most other metals (with the exception of arsenic discussed below). Therefore, the value was not removed from the dataset.

(f) The values were not identified as extreme values based on the outlier test results of the transformed datasets. In addition, extreme values were not identified for most (with exception of antimony) or all other metals of this sample. Therefore, the value was not removed from the dataset.

(g) The value was identified as an extreme value based on the outlier test results of the transformed datasets. Therefore, the value was removed from the dataset.

(h) The value was not identified as an extreme value based on the outlier test results of the transformed datasets. Therefore, the value was not removed from the dataset.

ATTACHMENT D TABLE 2

COMPARISON OF CHEMICAL CONCENTRATIONS IN BACKGROUND AND SITE SURFACE SOIL

BACKGROUND EVALUATION

BLUE BEACH DISPOSAL AREA

NORTH KINGSTOWN, RHODE ISLAND

COPC (a)	FOD		Distribution		Mean/Median (SD) (mg/kg)		Population Test	p-value	Reject the Null Hypothesis? (c)
	Site	Background	Site	Background	Site (b)	Background (b)			

Notes:

COPC - Chemical of Potential Concern.

FOD - Frequency of Detection. The number of detected concentrations: the total number of samples.

HMW - High Molecular Weight.

mg/kg - milligrams per kilogram.

PAH - Polycyclic aromatic hydrocarbons.

SD - Standard deviation.

SVOCs - Semivolatile organic compounds.

WMW - Wilcoxon test.

(a) COPCs retained after comparison of Site maximum detect concentrations to background threshold values in the risk assessment.

(b) The mean (calculated for COPCs for which a t-test was conducted), median (calculated for COPCs for which a Wilcoxon or Tarone-Ware test was conducted) and the standard deviation (in parentheses) of the detected concentrations in Site and background.

(c) The null and alternative hypotheses of the hypothesis test are:

H_o (null): the Site mean concentration is less than or equal to the mean concentration in the background area ($p > 0.05$: fail to reject H_o)

H_a (alternative): The Site mean concentration is greater than the mean concentration in the background area ($p < 0.05$: reject H_o)

Benzo(a)Pyrene	11 / 20	0.80	0.80	SB-411	Not outlier (e)	0.52	Lognormal: 95% KM UTL 95% Coverage
Naphthalene	5 / 20	0.014	--	--	--	0.0133	Normal: 95% KM UTL with 95% Coverage

Notes:

BTV - Background Threshold Value.

COPC - Chemical of Potential Concern.

FOD - Frequency of Detection. The number of detected concentrations: the total number of samples.

HMW - High Molecular Weight.

KM - Kaplan Meier.

mg/kg - milligrams per kilogram.

PAH - Polycyclic aromatic hydrocarbons.

SVOCs - Semivolatile organic compounds.

USEPA - United States Environmental Protection Agency.

UTL - Upper Threshold Value.

(a) The maximum detected concentration and FOD of the background dataset following removal of outlier values.

(b) Extreme values identified by the default outlier test in ProUCL (version 5.1; USEPA, 2016) was conducted (Dixon's test for under 25 samples).

(c) Extreme values were further evaluated by data transformations (natural log and gamma correction): if the value was identified as an extreme value following the data transformations and additional extreme value were identified for the sample for the same group of COPCs (e.g., SVOCs), this value was determined to be an outlier and removed from the dataset. If the value was not identified as an extreme value based on the outlier test results of the transformed datasets and additional extreme values were not identified for the sample for the same group of COPCs, the value is not an outlier and was not removed from the datase

(d) BTVs were calculated in ProUCL (version 5.1; USEPA, 2016). The 95UTL was selected based on the distribution of the detected concentrations in the dataset.

If the dataset includes non-detects, the non-detects were included at the full value of the detection limit and the BTV was selected from the Kaplan-Meier (KM) statistics.

For gamma UTLs, the Wilson Hilferty (WH) statistic was selected.

(e) The value was not identified as an extreme value based on the outlier test results of the transformed datasets. In addition, extreme values were not identified for other COPCs in the same group (metals or SVOCs) of this sample. Therefore, the value was not removed from the dataset.

BTV - Background Threshold Value.

COPC - Chemical of Potential Concern.

FOD - Frequency of Detection. The number of detected concentrations: the total number of samples.

HMW - High Molecular Weight.

KM - Kaplan Meier.

mg/kg - milligrams per kilogram.

PAH - Polycyclic aromatic hydrocarbons.

PCBs - Polychlorinated biphenyl.

SVOCs - Semivolatile organic compounds.

USEPA - United States Environmental Protection Agency.

UTL - Upper Threshold Value.

NC - Not calculated.

(a) The maximum detected concentration and FOD of the background dataset following removal of outlier values.

(b) Extreme values identified by the default outlier test in ProUCL (version 5.1; USEPA, 2016) was conducted (Dixon's test for under 25 samples).

(c) Extreme values were further evaluated by data transformations (natural log and gamma correction): if the value was identified as an extreme value following the data transformations and additional extren were identified for the sample for the same group of COPCs (e.g., SVOCs), this value was determined to be an outlier and removed from the dataset. If the value was not identified as an extreme value bas on the outlier test results of the transformed datasets and additional extreme values were not identified for the sample for the same group of COPCs, the value is not an outlier and was not removed from the

(d) BTVs were calculated in ProUCL (version 5.1; USEPA, 2016). The 95UTL was selected based on the distribution of the detected concentrations in the dataset.
If the dataset includes non-detects, the non-detects were included at the full value of the detection limit and the BTV was selected from the Kaplan-Meier (KM) statistics.
For gamma UTLs, the Wilson Hilferty (WH) statistic was selected.

(e) The value was not identified as an extreme value based on the outlier test results of the transformed datasets. In addition, extreme values were not identified for other COPCs in the same group (metals) of this sample. Therefore, the value was not removed from the dataset.

OUTLIER DETERMINATION AND CALCULATION OF BACKGROUND THRESHOLD VALUES FOR COPCS IN BACKGROUND HYDRIC SURFACE SOIL
BACKGROUND EVALUATION
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Chemical	Background FOD (a)	Maximum Detected Concentration (mg/kg) (a)	Extreme Value (mg/kg) (b)	Sample Identification of Extreme Value	Outlier Determination (c)	BTV (mg/kg) (d)	Statistic

Notes:
BTV - Background Threshold Value.
COPC - Chemical of Potential Concern.
FOD - Frequency of Detection. The number of detected concentrations: the total number of samples.
HMW - High Molecular Weight.
KM - Kaplan Meier.
mg/kg - milligrams per kilogram.
PAH - Polycyclic aromatic hydrocarbons.
SVOCs - Semivolatile organic compounds.
USEPA - United States Environmental Protection Agency.
UTL - Upper Threshold Value.
NC - Not calculated.
(a) The maximum detected concentration and FOD of the background dataset following removal of outlier values.
(b) Extreme values identified by the default outlier test in ProUCL (version 5.1; USEPA, 2016) was conducted (Dixon's test for under 25 samples).
(c) Extreme values were further evaluated by data transformations (natural log and gamma correction): if the value was identified as an extreme value following the data transformations and additional extreme values were identified for the sample for the same group of COPCs (e.g., SVOCs), this value was determined to be an outlier and removed from the dataset. If the value was not identified as an extreme value on the outlier test results of the transformed datasets and additional extreme values were not identified for the sample for the same group of COPCs, the value is not an outlier and was not removed from the dataset.
(d) BTVs were calculated in ProUCL (version 5.1; USEPA, 2016). The 95UTL was selected based on the distribution of the detected concentrations in the dataset.
If the dataset includes non-detects, the non-detects were included at the full value of the detection limit and the BTV was selected from the Kaplan-Meier (KM) statistics.
For gamma UTLs, the Wilson Hilferty (WH) statistic was selected.
(e) The value was identified as an extreme value based on the outlier test results of the transformed datasets. In addition, extreme values were identified other metal COPCs for the same sample. Therefore, the value was removed from the dataset.
(f) The values were not identified as extreme values based on the outlier test results of the transformed datasets. In addition, extreme values were not identified for other metals of this sample. Therefore, the value was not removed from the dataset.
(g) The values were not identified as extreme values based on the outlier test results of the transformed datasets. In addition, extreme values were not identified for other PAHs of this sample. Therefore, the value was not removed from the dataset.

(a) The maximum detected concentration and FOD of the background dataset following removal of outlier values.

(b) Extreme values identified by the default outlier test in ProUCL (version 5.1; USEPA, 2016) was conducted (Dixon's test for under 25 samples).

(c) Extreme values were further evaluated by data transformations (natural log and gamma correction): if the value was identified as an extreme value following the data transformations and additional extreme values were identified for the sample for the same group of COPCs (e.g., SVOCs), this value was determined to be an outlier and removed from the dataset. If the value was not identified as an extreme value b on the outlier test results of the transformed datasets and additional extreme values were not identified for the sample for the same group of COPCs, the value is not an outlier and was not removed from the dataset.

(d) BTVs were calculated in ProUCL (version 5.1; USEPA, 2016). The 95UTL was selected based on the distribution of the detected concentrations in the dataset.
If the dataset includes non-detects, the non-detects were included at the full value of the detection limit and the BTV was selected from the Kaplan-Meier (KM) statistics.
For gamma UTLs, the Wilson Hilferty (WH) statistic was selected.

(e) The value was identified as an extreme value based on the outlier test results of the transformed datasets. In addition, extreme values were identified other metal COPCs for the same sample. Therefore, the value was removed from the dataset.

ATTACHMENT D TABLE 12
COMPARISON OF CHEMICAL CONCENTRATIONS IN BACKGROUND AND SITE HYDRIC SUBSURFACE SEDIMENT
BACKGROUND EVALUATION
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

COPC (a)	FOD		Distribution		Mean/Median (SD) (mg/kg)		Population Test	p-value	Reject the Null Hypothesis? (c)
	Site	Background	Site	Background	Site (b)	Background (b)			
Off-Project Red Maple Swamp / Tidal Stream Area									
Inorganics									
Arsenic	16 / 16	9 / 9	Normal	Not Normal	5.1 (2.838)	1.3 (0.95)	WMW	0.00031	Yes
Cobalt	10 / 10	9 / 9	Normal	Normal	2.69 (1.289)	1.85 (0.41)	t-test	0.04	Yes
Iron	10 / 10	9 / 9	Normal	Not Normal	9201 (4560)	6120 (1939)	WMW	0.047	Yes
Thallium	5 / 10	2 / 10	Normal	NC	0.1 (0.04)	0.13 (0.003)	NC	NC	NC
Vanadium	10 / 10	10 / 10	Normal	Normal	26.96 (11.3)	12.51 (5.842)	t-test	0.001	Yes

Notes:

COPC - Chemical of Potential Concern.

FOD - Frequency of Detection. The number of detected concentrations: the total number of samples.

mg/kg - milligrams per kilogram.

NC - Not calculated.

SD - Standard deviation.

WMW - Wilcoxon test.

(a) COPCs retained after comparison of Site maximum detect concentrations to background threshold values in the risk assessment.

(b) The mean (calculated for COPCs for which a t-test was conducted), median (calculated for COPCs for which a Wilcoxon or Tarone-Ware test was conducted) and the standard deviation (in parentheses) of the detected concentrations in Site and background.

(c) The null and alternative hypotheses of the hypothesis test are:

H_o (null): the Site mean concentration is less than or equal to the mean concentration in the background area ($p > 0.05$: fail to reject H_o)

H_a (alternative): The Site mean concentration is greater than the mean concentration in the background area ($p < 0.05$: reject H_o)

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

95% USL	17600		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	32.2	99% Percentile	19.32
95% USL	19.6		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	0.188	99% Percentile	0.141
95% USL	0.16		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.

Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	20	95% UTL with95% Coverage	0.28
Approx, f used to compute achieved CC	1.053	Approximate Actual Confidence Coefficient achieved by	0.642
Approximate Sample Size needed to achieve specified C	59	95% UPL	0.271
95% USL	0.28	95% KM Chebyshev UPL	0.322

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics
Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	19	95% UTL with95% Coverage	0.021
Approx, f used to compute achieved CC	1	roximate Actual Confidence Coefficient achieved by UTL	0.623
pproximate Sample Size needed to achieve specified CC	59	95% UPL	0.021
95% USL	0.021	95% KM Chebyshev UPL	0.0275

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

Approx, f used to compute achieved CC	1.053	Approximate Actual Confidence Coefficient achieved by U	0.642
		Approximate Sample Size needed to achieve specified CC	59
95% Percentile Bootstrap UTL with 95% Coverage	13300	95% BCA Bootstrap UTL with 95% Coverage	13300
95% UPL	13290	90% Percentile	12740
90% Chebyshev UPL	16159	95% Percentile	13110
95% Chebyshev UPL	18981	99% Percentile	13262
95% USL	13300		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	326	99% Percentile	217.8
95% USL	218		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	20	95% UTL with95% Coverage	0.014
Approx, f used to compute achieved CC	1.053	Approximate Actual Confidence Coefficient achieved by U	0.642
Approximate Sample Size needed to achieve specified C	59	95% UPL	0.014
95% USL	0.014	95% KM Chebyshev UPL	0.0191

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

95% Chebyshev UPL	19.6	99% Percentile	10.77
95% USL	10.8		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	0.182	99% Percentile	0.12
95% USL	0.12		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

		Approximate Sample Size needed to achieve specified CC	59
95% Percentile Bootstrap UTL with 95% Coverage	7.2	95% BCA Bootstrap UTL with 95% Coverage	7.2
95% UPL	7.2	90% Percentile	6.9
90% Chebyshev UPL	12.82	95% Percentile	7.05
95% Chebyshev UPL	16.45	99% Percentile	7.17
95% USL	7.2		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	8.923	99% Percentile	4.325
95% USL	4.4		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	24.1	99% Percentile	13.35
95% USL	13.4		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data

represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	7	95% UTL with95% Coverage	0.4
Approx, f used to compute achieved CC	0.368	Approximate Actual Confidence Coefficient achieved by U	0.302
Approximate Sample Size needed to achieve specified C	59	95% UPL	0.4
95% USL	0.4	95% KM Chebyshev UPL	0.104

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

SD in Original Scale	0.00836	SD in Log Scale	0.362
95% UTL95% Coverage	0.094	95% BCA UTL95% Coverage	0.035
95% Bootstrap (%) UTL95% Coverage	0.035	95% UPL (t)	0.054
90% Percentile (z)	0.039	95% Percentile (z)	0.0445
99% Percentile (z)	0.057	95% USL	0.0475

Statistics using KM estimates on Logged Data and Assuming Lognormal Distribution

KM Mean of Logged Data	-3.742	95% KM UTL (Lognormal)95% Coverage	0.11
KM SD of Logged Data	0.413	95% KM UPL (Lognormal)	0.0583
95% KM Percentile Lognormal (z)	0.0468	95% KM USL (Lognormal)	0.0503

Background DL/2 Statistics Assuming Lognormal Distribution

Mean in Original Scale	0.0403	Mean in Log Scale	-3.588
SD in Original Scale	0.0403	SD in Log Scale	0.975
95% UTL95% Coverage	1.027	95% UPL (t)	0.231
90% Percentile (z)	0.0965	95% Percentile (z)	0.137
99% Percentile (z)	0.267	95% USL	0.163

DL/2 is not a Recommended Method. DL/2 provided for comparisons and historical reasons.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	6	95% UTL with95% Coverage	0.239
Approx, f used to compute achieved CC	0.316	Approximate Actual Confidence Coefficient achieved by U	0.265
Approximate Sample Size needed to achieve specified C	59	95% UPL	0.239
95% USL	0.239	95% KM Chebyshev UPL	0.0678

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

MLE Sd (bias corrected)	0.2	95% Percentile of Chisquare (2kstar)	8.339

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.09	Mean	0.254
Maximum	0.6	Median	0.22
SD	0.164	CV	0.643

Nonparametric Upper Limits for Background Threshold Values

Order of Statistic, r	10	95% UTL with 95% Coverage	221
Approx, f used to compute achieved CC	0.526	Approximate Actual Confidence Coefficient achieved by U	0.401
		Approximate Sample Size needed to achieve specified CC	59
95% Percentile Bootstrap UTL with 95% Coverage	221	95% BCA Bootstrap UTL with 95% Coverage	221
95% UPL	221	90% Percentile	184.1
90% Chebyshev UPL	263.3	95% Percentile	202.6
95% Chebyshev UPL	313.5	99% Percentile	217.3
95% USL	221		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects
GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.0717	Mean	0.0963

95% Chebyshev UPL	0.561	99% Percentile	0.33
95% USL	0.33		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	0.447	99% Percentile	0.216
95% USL	0.22		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

90% Chebyshev UPL	1.131	95% Percentile	0.704
95% Chebyshev UPL	1.552	99% Percentile	0.917
95% USL	0.97		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20. Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.

The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

Order of Statistic, r		9	95% UTL with 95% Coverage	2.67
Approx, f used to compute achieved CC		0.474	pproximate Actual Confidence Coefficient achieved by UTL	0.37
			Approximate Sample Size needed to achieve specified CC	59
95% Percentile Bootstrap UTL with	95% Coverage	2.67	95% BCA Bootstrap UTL with 95% Coverage	2.67
	95% UPL	2.67	90% Percentile	2.542
	90% Chebyshev UPL	3.29	95% Percentile	2.606
	95% Chebyshev UPL	3.876	99% Percentile	2.657
	95% USL	2.67		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.0039	Mean	0.0211

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	10	95% UTL with95% Coverage	0.016
Approx, f used to compute achieved CC	0.526	Approximate Actual Confidence Coefficient achieved by U	0.401
Approximate Sample Size needed to achieve specified C	59	95% UPL	0.016
95% USL	0.016	95% KM Chebyshev UPL	0.0274

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Upper Limits for Background Threshold Values

	Order of Statistic, r	9	95% UTL with	95% Coverage	10700
	Approx, f used to compute achieved CC	0.474	Approximate Actual Confidence Coefficient achieved by UTL		0.37
			Approximate Sample Size needed to achieve specified CC		59
95% Percentile Bootstrap UTL with	95% Coverage	10700	95% BCA Bootstrap UTL with	95% Coverage	10700
	95% UPL	10700		90% Percentile	9276
	90% Chebyshev UPL	12759		95% Percentile	9988
	95% Chebyshev UPL	15536		99% Percentile	10558
	95% USL	10700			

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data represents a background data set and when many onsite observations need to be compared with the BTV.

t-Test Sample 1 vs Sample 2 Comparison for Uncensored Full Data Sets without NDs

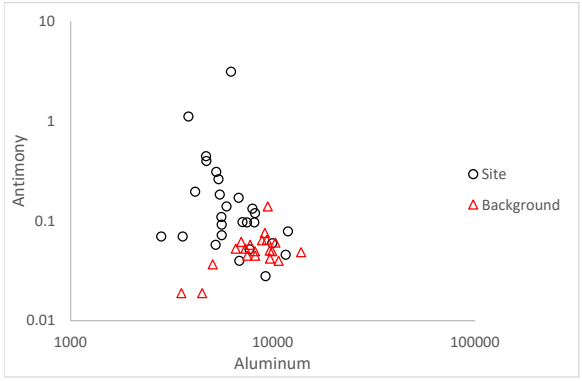
Geochemical Analysis and Graphical Comparisons

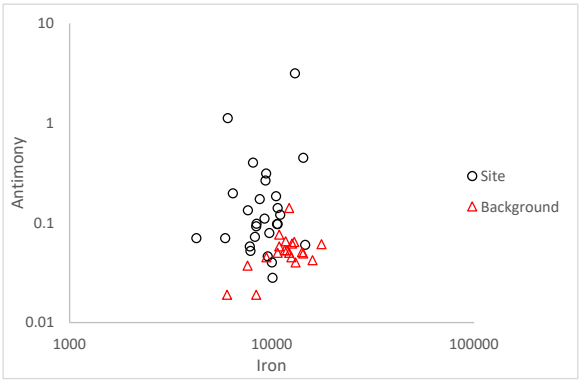
Surface Soil - On-Project Blue Beach Area - Antimony

Surface Soil, Antimony-Aluminum



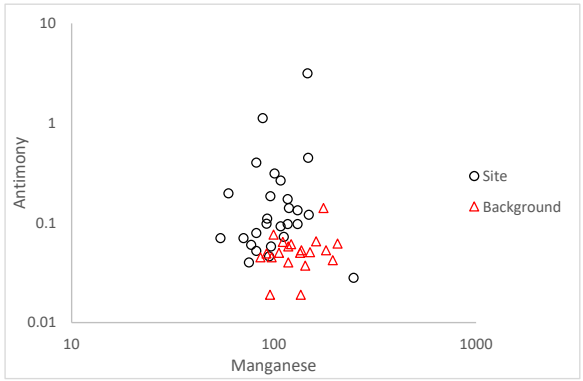
Kendalls' Tau Statistics	Kendall's tau coeff:	-0.2675
	p-value:	0.0085

Surface Soil, Antimony-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	-0.1025
	p-value:	0.3172

Surface Soil, Antimony-Manganese

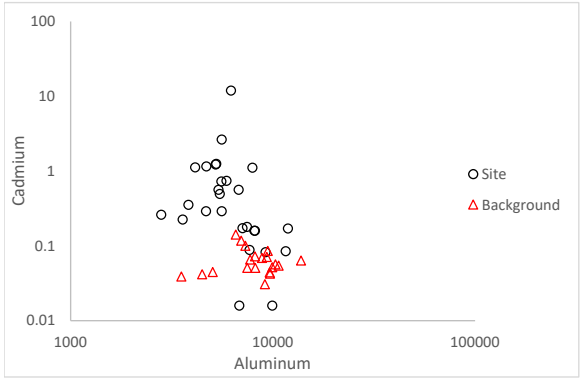


Kendalls' Tau Statistics	Kendall's tau coeff:	-0.068
	p-value:	0.5088

- The concentration trends on the regression graphs for antimony with the reference metals (aluminum, iron, and manganese) do not indicate consistent relationships and the Kendall's tau coefficients are < 0.3, indicating the relationships are extremely weak. Therefore, antimony is retained as a COPC in surface soil in the On-Project Blue Beach Area.

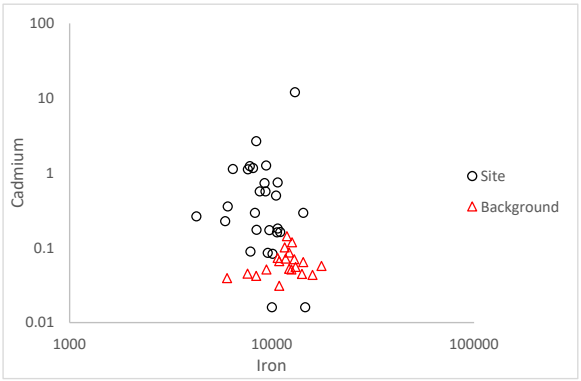
Surface Soil - On-Project Blue Beach Area - Cadmium

Surface Soil, Cadmium-Aluminum



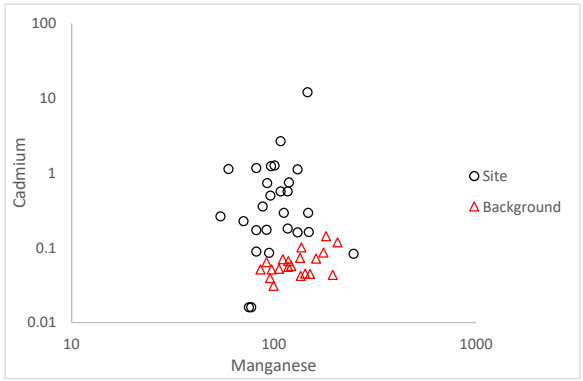
Kendalls' Tau Statistics	Kendall's tau coeff:	-0.3539
	p-value:	0.0005

Surface Soil, Cadmium-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	-0.3028
	p-value:	0.0029

Surface Soil, Cadmium-Manganese

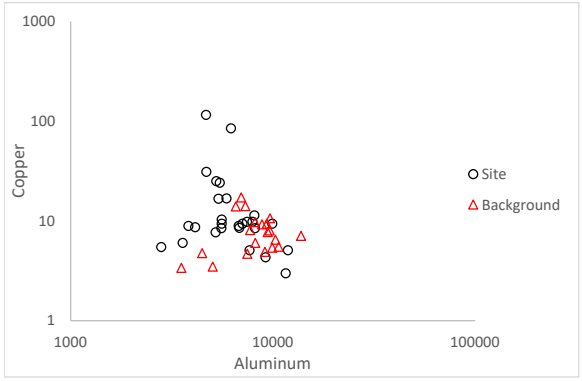


Kendalls' Tau Statistics	Kendall's tau coeff:	-0.0659
	p-value:	0.5208

- The concentration trends on the regression graphs for cadmium with the reference metals (aluminum, iron, and manganese) do not indicate consistent relationships and the Kendall's tau coefficients are < 0.3, indicating the relationships are extremely weak. Therefore, cadmium is retained as a COPC in surface soil in the On-Project Blue Beach Area.

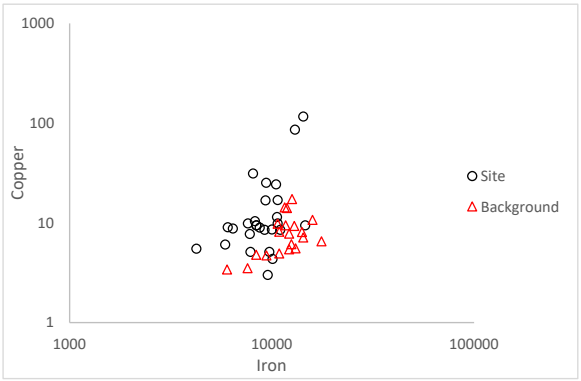
Surface Soil - On-Project Blue Beach Area - Copper

Surface Soil, Copper-Aluminum



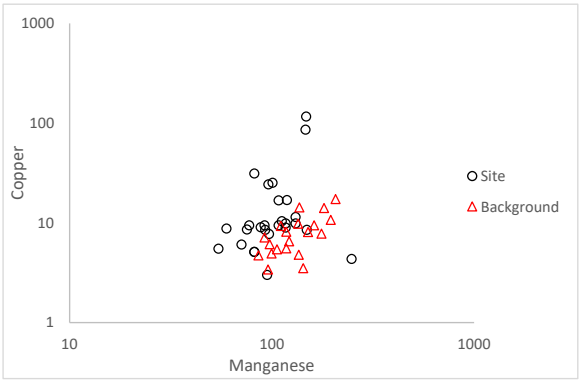
Kendalls' Tau Statistics	Kendall's tau coeff:	-0.1925
	p-value:	0.0576

Surface Soil, Copper-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.1448
	p-value:	0.1551

Surface Soil, Copper-Manganese

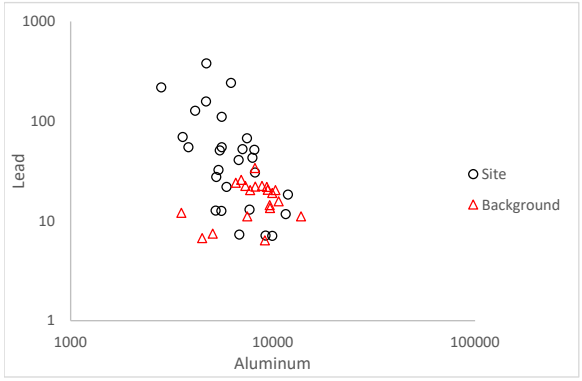


Kendalls' Tau Statistics	Kendall's tau coeff:	0.1781
	p-value:	0.0798

- The concentration trends on the regression graphs for copper with the reference metals (aluminum, iron, and manganese) do not indicate consistent relationships and the Kendall's tau coefficients are < 0.3, indicating the relationships are extremely weak. Therefore, copper is retained as a COPC in surface soil in the On-Project Blue Beach Area.

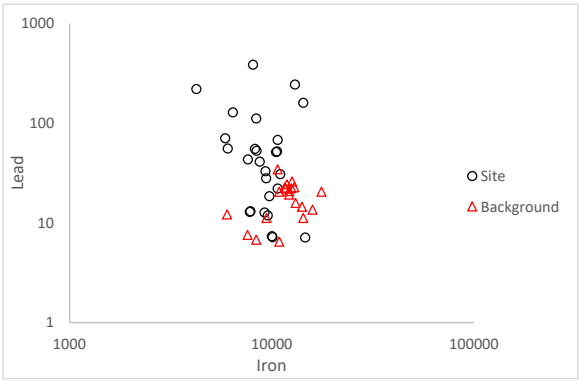
Surface Soil - On-Project Blue Beach Area - Lead

Surface Soil, Lead-Aluminum



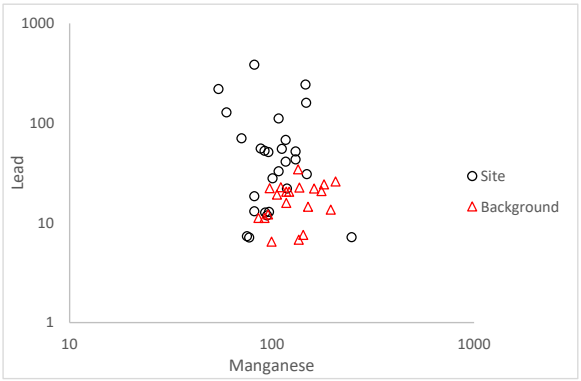
Kendalls' Tau Statistics	Kendall's tau coeff:	-0.339
	p-value:	0.0008

Surface Soil, Lead-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	-0.1839
	p-value:	0.0707

Surface Soil, Lead-Manganese

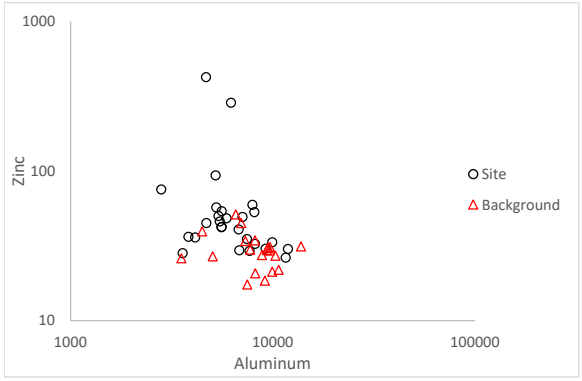


Kendalls' Tau Statistics	Kendall's tau coeff:	-0.0195
	p-value:	0.8544

- The concentration trends on the regression graphs for lead with the reference metals (aluminum, iron, and manganese) do not indicate consistent relationships and the Kendall's tau coefficients are < 0.3, indicating the relationships are extremely weak. Therefore, lead is retained as a COPC in surface soil in the On-Project Blue Beach Area.

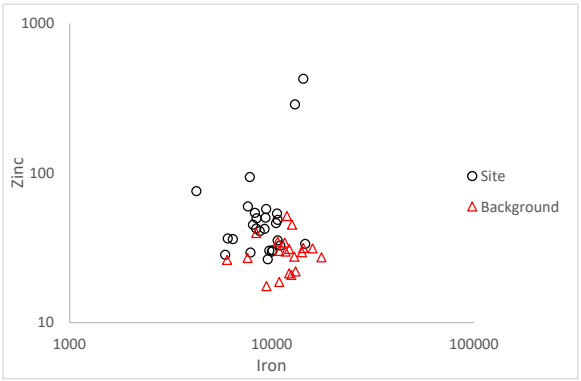
Surface Soil - On-Project Blue Beach Area - Zinc

Surface Soil, Zinc-Aluminum



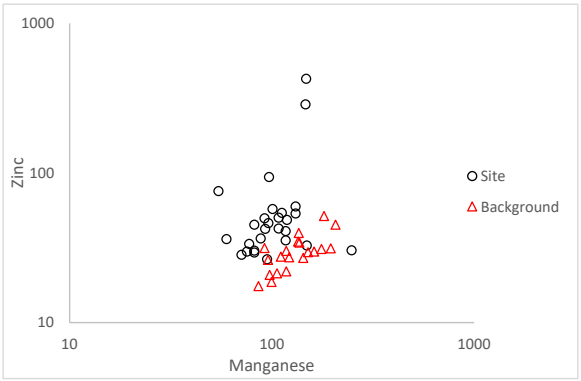
Kendalls' Tau Statistics	Kendall's tau coeff:	-0.3395
	p-value:	0.0008

Surface Soil, Zinc-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	-0.1401
	p-value:	0.1688

Surface Soil, Zinc-Manganese

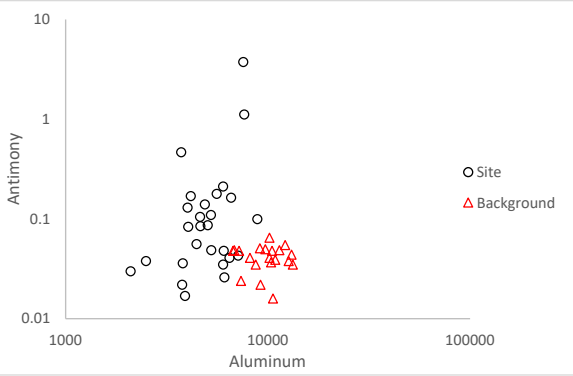


Kendalls' Tau Statistics	Kendall's tau coeff:	0.0705
	p-value:	0.4915

- The concentration trends on the regression graphs for zinc with the reference metals (aluminum, iron, and manganese) do not indicate consistent relationships and the Kendall's tau coefficients are < 0.3, indicating the relationships are extremely weak. Therefore, zinc is retained as a COPC in surface soil in the On-Project Blue Beach Area.

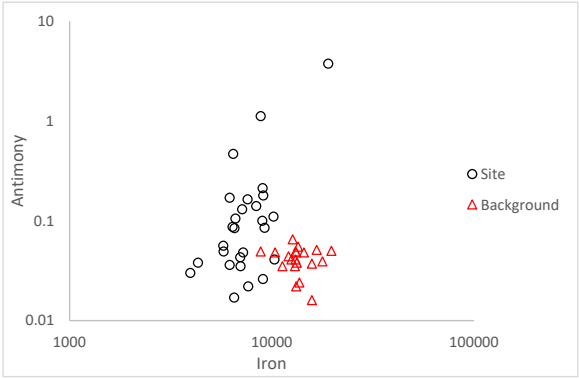
Subsurface Soil - On-Project Blue Beach Area - Antimony

Subsurface Soil, Antimony-Aluminum



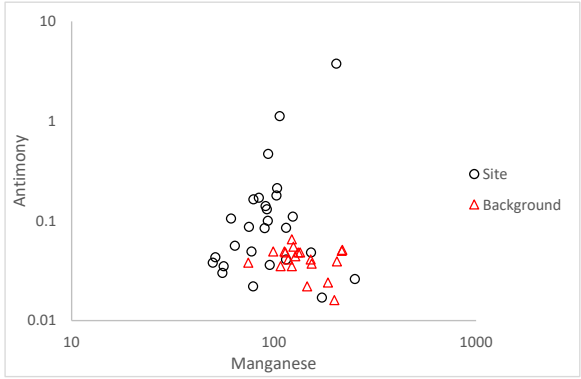
Kendalls' Tau Statistics	Kendall's tau coeff:	-0.1437
	p-value:	0.1602

Subsurface Soil, Antimony-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	-0.1158
	p-value:	0.2588

Subsurface Soil, Antimony-Manganese

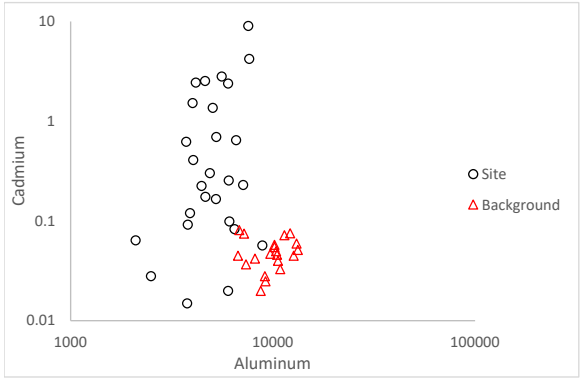


Kendalls' Tau Statistics	Kendall's tau coeff:	-0.1531
	p-value:	0.1346

- The concentration trends on the regression graphs for antimony with the reference metals (aluminum, iron, and manganese) do not indicate consistent relationships and the Kendall's tau coefficients are < 0.3, indicating the relationships are extremely weak. Therefore, antimony is retained as a COPC in subsurface soil in the On-Project Blue Beach Area.

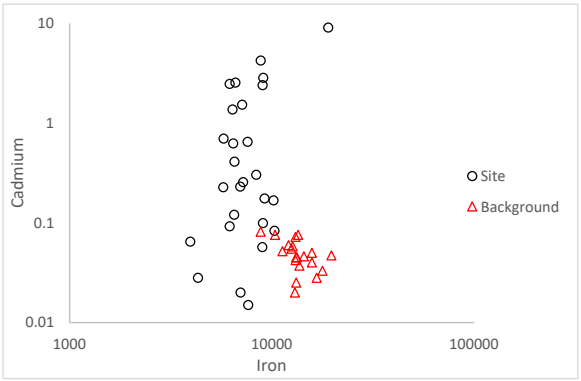
Subsurface Soil - On-Project Blue Beach Area - Cadmium

Subsurface Soil, Cadmium-Aluminum



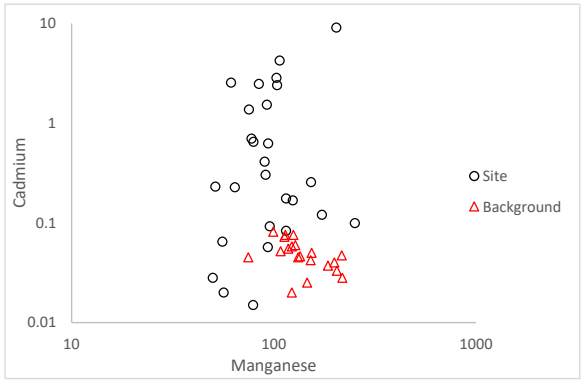
Kendalls' Tau Statistics	Kendall's tau coeff:	-0.2726
	p-value:	0.0072

Subsurface Soil, Cadmium-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	-0.3619
	p-value:	0.0004

Subsurface Soil, Cadmium-Manganese

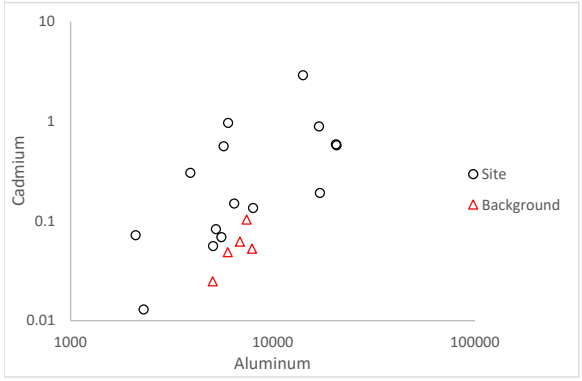


Kendalls' Tau Statistics	Kendall's tau coeff:	-0.2318
	p-value:	0.0224

- The concentration trends on the regression graphs for cadmium with the reference metals (aluminum, iron, and manganese) do not indicate consistent relationships and the Kendall's tau coefficients are < 0.3, indicating the relationships are extremely weak. Therefore, cadmium is retained as a COPC in subsurface soil in the On-Project Blue Beach Area.

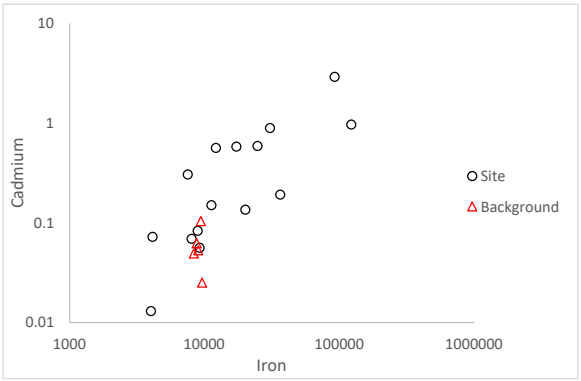
Sediment Tidal - Off-Project Red Maple Swamp / Tidal Stream Area - Cadmium

Sediment Tidal, Cadmium-Aluminum



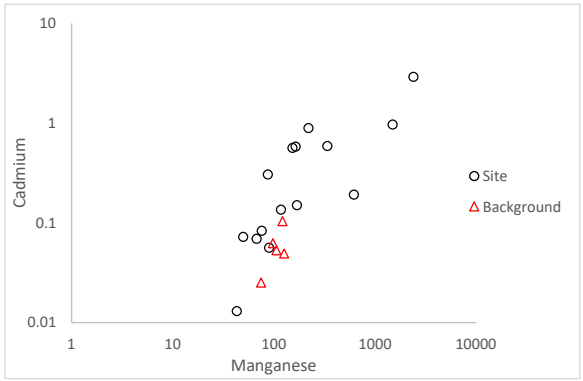
Kendalls' Tau Statistics	Kendall's tau coeff:	0.4
	p-value:	0.015

Sediment Tidal, Cadmium-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.5789
	p-value:	0.0004

Sediment Tidal, Cadmium-Manganese

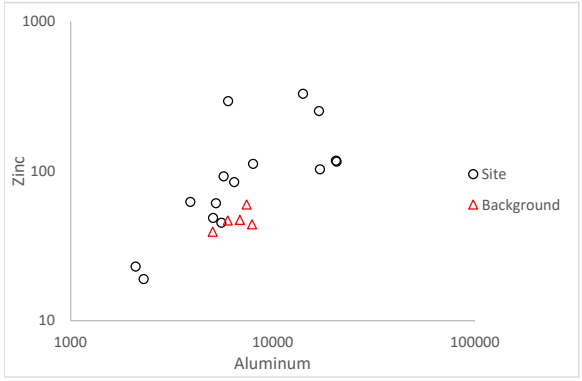


Kendalls' Tau Statistics	Kendall's tau coeff:	0.6
	p-value:	0.0002

- The concentration trend on the regression graph and Kendall's tau coefficient of 0.6 for cadmium and manganese indicate a consistent relationship between these constituents. Therefore, cadmium is eliminated as a COPC in tidal sediment in the Off-Project Red Maple Swamp / Tidal Stream Area.

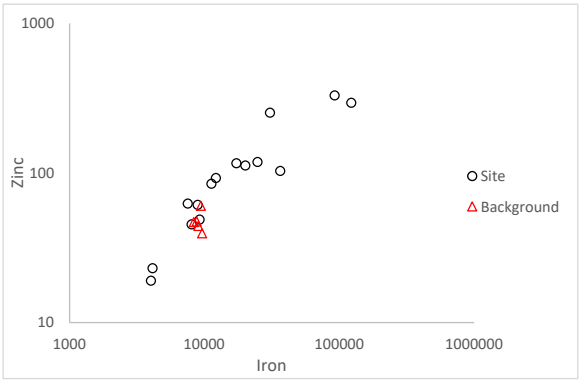
Sediment Tidal - Off-Project Red Maple Swamp / Tidal Stream Area - Zinc

Sediment Tidal, Zinc-Aluminum



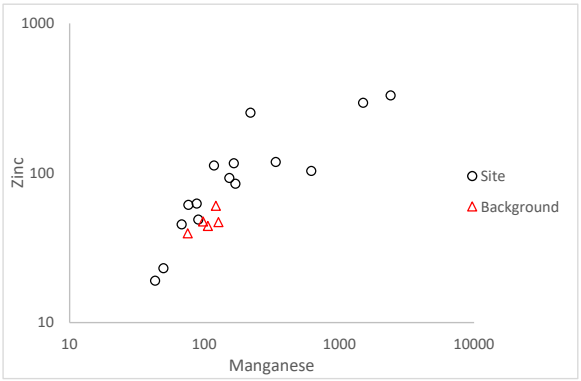
Kendalls' Tau Statistics	Kendall's tau coeff:	0.4947
	p-value:	0.0026

Sediment Tidal, Zinc-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.7158
	p-value:	0

Sediment Tidal, Zinc-Manganese

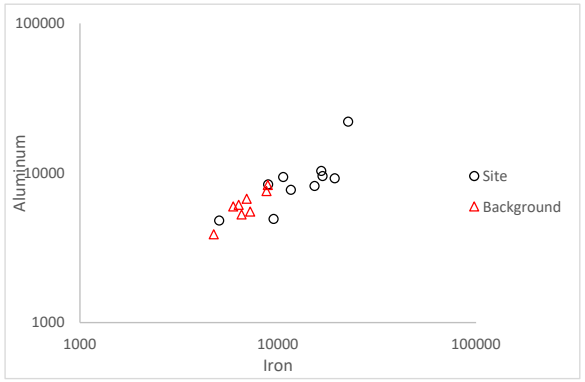


Kendalls' Tau Statistics	Kendall's tau coeff:	0.6947
	p-value:	0

- The concentration trend on the regression graph and Kendall's tau coefficient of 0.69 for zinc and manganese indicate a consistent relationship between these constituents. Therefore, zinc is eliminated as a COPC in tidal sediment in the Off-Project Red Maple Swamp / Tidal Stream Area.

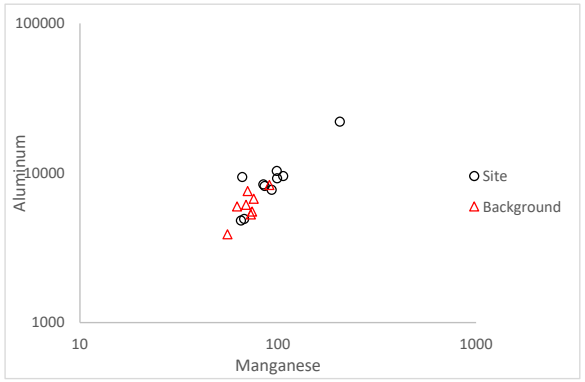
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Aluminum

Hydric Surface Soil, Aluminum-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.6993
	p-value:	0.0001

Hydric Surface Soil, Aluminum-Manganese

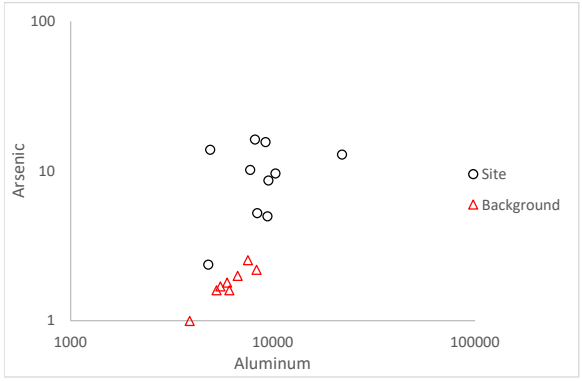


Kendalls' Tau Statistics	Kendall's tau coeff:	0.6471
	p-value:	0.0002

- The concentration trend on the regression graph and Kendall's tau coefficient of > 0.6 for aluminum and iron and aluminum and manganese indicate a consistent relationship between these constituents. Therefore, aluminum is eliminated as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

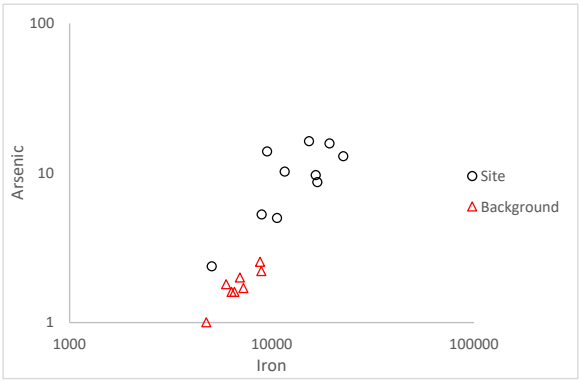
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Arsenic

Hydric Surface Soil, Arsenic-Aluminum



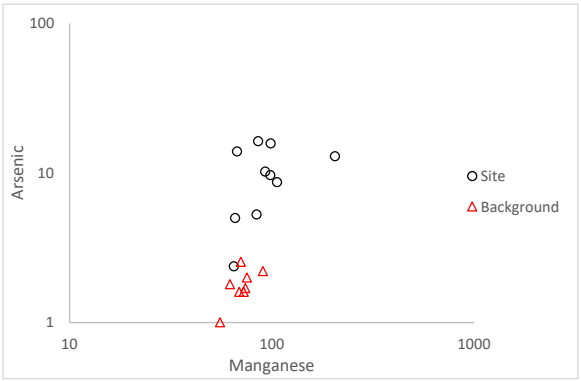
Kendalls' Tau Statistics	Kendall's tau coeff:	0.4852
	p-value:	0.0057

Hydric Surface Soil, Arsenic-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.6689
	p-value:	0.0001

Hydric Surface Soil, Arsenic-Manganese

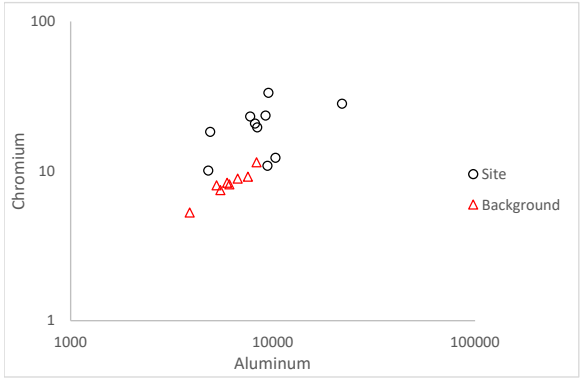


Kendalls' Tau Statistics	Kendall's tau coeff:	0.459
	p-value:	0.0089

- Although the Kendall's tau coefficient is 0.67 for arsenic and iron, the site samples lie off the trend formed by the background samples for these constituents. Therefore, arsenic is retained as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

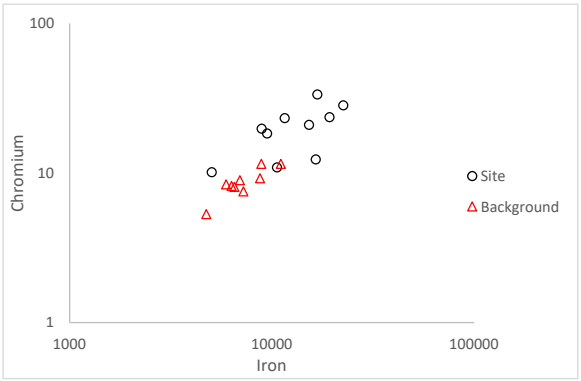
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Chromium

Hydric Surface Soil, Chromium-Aluminum



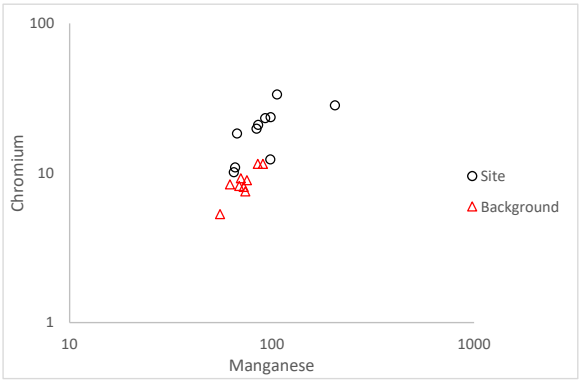
Kendalls' Tau Statistics	Kendall's tau coeff:	0.5686
	p-value:	0.0011

Hydric Surface Soil, Chromium-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.6921
	p-value:	0

Hydric Surface Soil, Chromium-Manganese

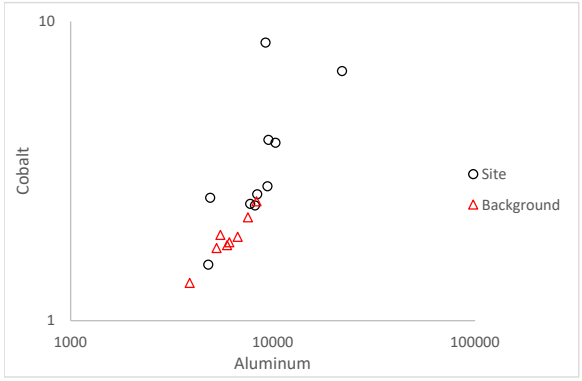


Kendalls' Tau Statistics	Kendall's tau coeff:	0.5982
	p-value:	0.0004

- The Kendall's tau coefficient is 0.69 for chromum and iron. Although many of the site samples have higher chromium than background samples, the site samples lie on the trend line for chromium and iron formed by the background samples. Therefore, chromium is eliminated as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

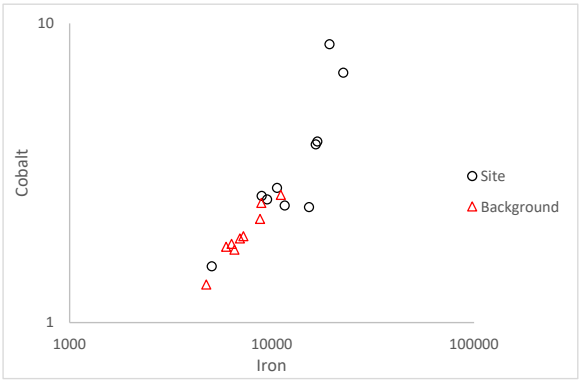
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Cobalt

Hydric Surface Soil, Cobalt-Aluminum



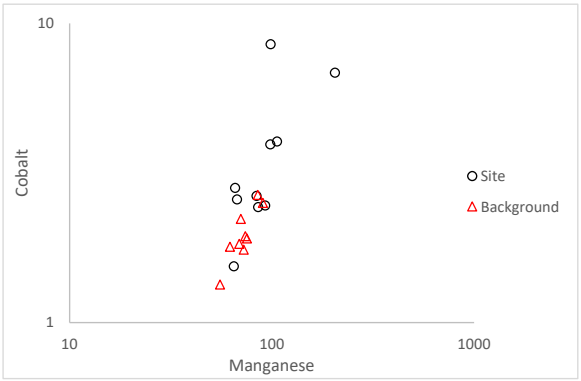
Kendalls' Tau Statistics	Kendall's tau coeff:	0.7647
	p-value:	0

Hydric Surface Soil, Cobalt-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.8129
	p-value:	0

Hydric Surface Soil, Cobalt-Manganese

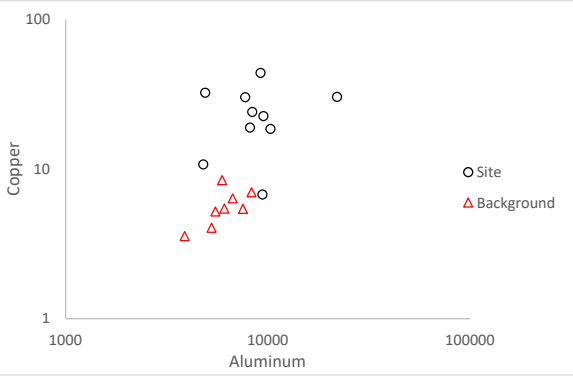


Kendalls' Tau Statistics	Kendall's tau coeff:	0.5906
	p-value:	0.0005

- The concentration trend on the regression graph and Kendall's tau coefficient of 0.81 for cobalt and iron indicate a consistent relationship between these constituents. Therefore, cobalt is eliminated as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

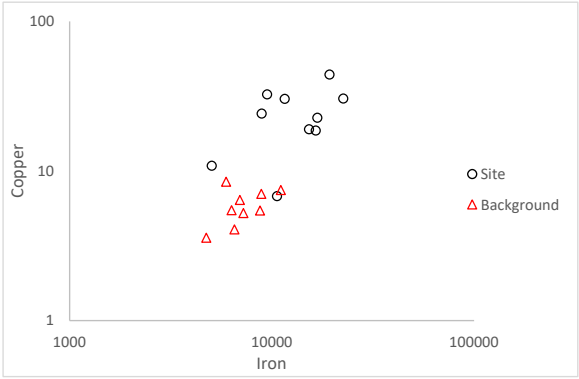
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Copper

Hydric Surface Soil, Copper-Aluminum



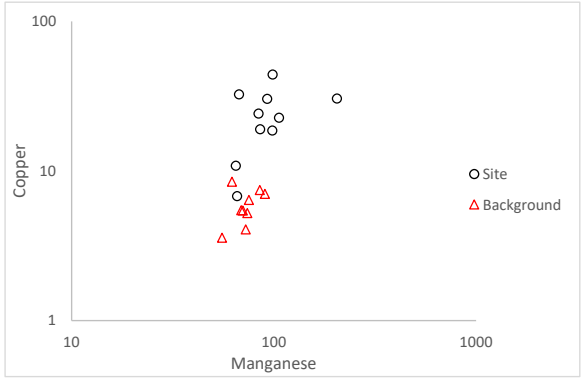
Kendalls' Tau Statistics	Kendall's tau coeff:	0.3856
	p-value:	0.028

Hydric Surface Soil, Copper-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.5322
	p-value:	0.0016

Hydric Surface Soil, Copper-Manganese

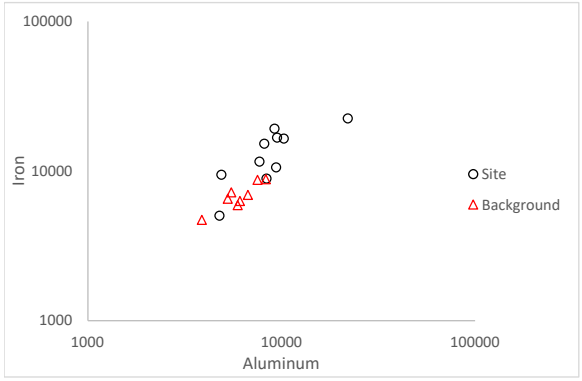


Kendalls' Tau Statistics	Kendall's tau coeff:	0.4035
	p-value:	0.0174

- Although the Kendall's tau coefficient is 0.53 for copper and iron, the site samples lie off the trend formed by the background samples for these constituents. Therefore, copper is retained as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area

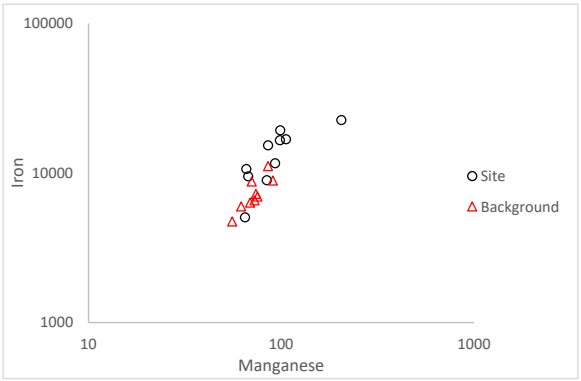
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Iron

Hydric Surface Soil, Iron-Aluminum



Kendalls' Tau Statistics	Kendall's tau coeff:	0.6993
	p-value:	0.0001

Hydric Surface Soil, Iron-Manganese

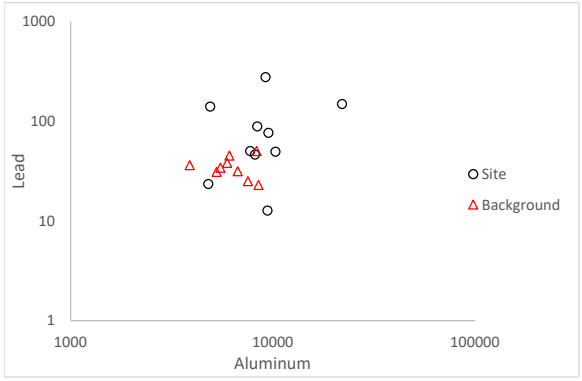


Kendalls' Tau Statistics	Kendall's tau coeff:	0.7076
	p-value:	0

- The concentration trend on the regression graph and Kendall's tau coefficient of > 0.6 for iron and aluminum and iron and manganese indicate a consistent relationship between these constituents. Therefore, iron is eliminated as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

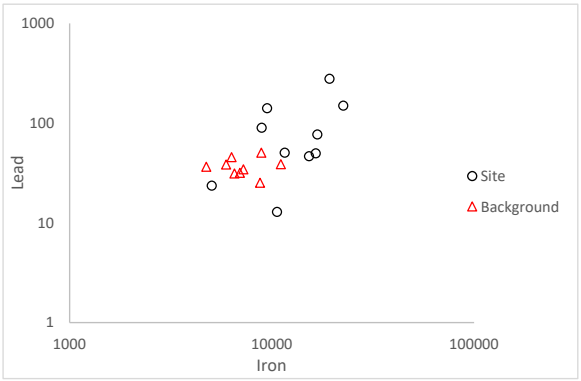
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Lead

Hydric Surface Soil, Lead-Aluminum



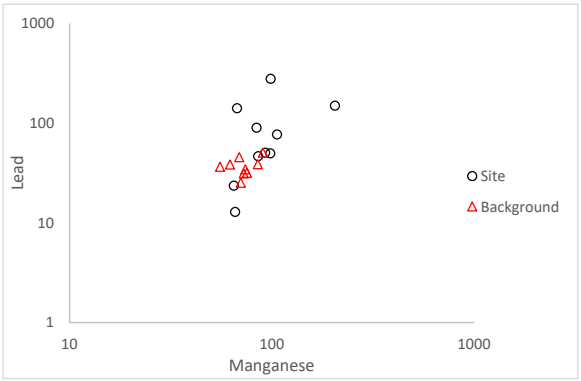
Kendalls' Tau Statistics	Kendall's tau coeff:	0.2632
	p-value:	0.1237

Hydric Surface Soil, Lead-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.4854
	p-value:	0.0041

Hydric Surface Soil, Lead-Manganese

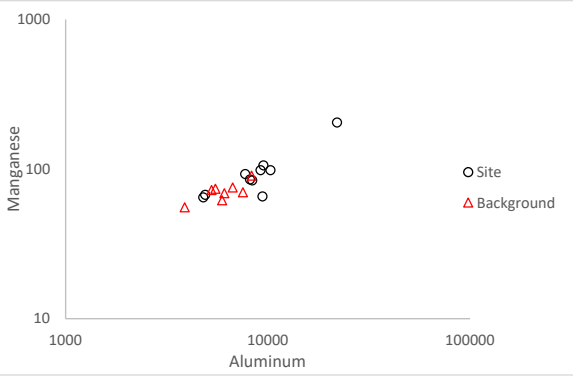


Kendalls' Tau Statistics	Kendall's tau coeff:	0.5205
	p-value:	0.0021

- Although the Kendall's tau coefficient is 0.52 for lead and manganese, background samples do not show a trend for these constituents. Therefore, lead is retained as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area

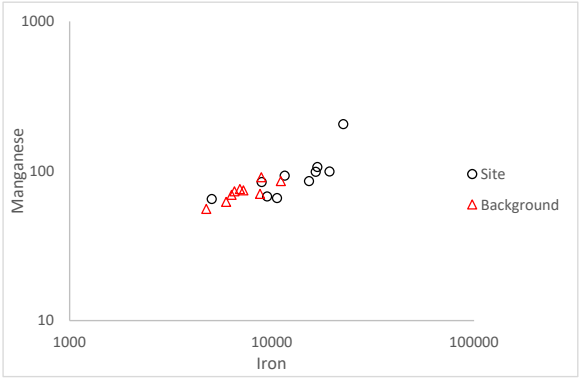
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Manganese

Hydric Surface Soil, Manganese-Aluminum



Kendalls' Tau Statistics	Kendall's tau coeff:	0.6471
	p-value:	0.0002

Hydric Surface Soil, Manganese-Iron

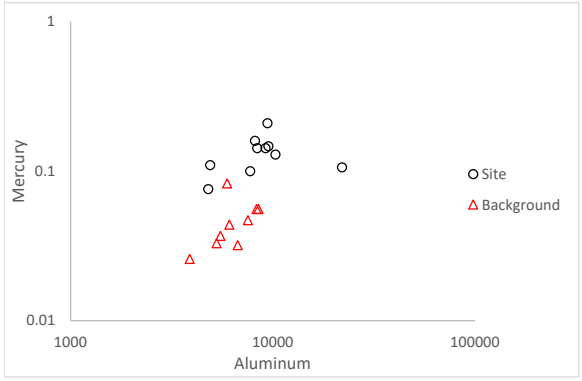


Kendalls' Tau Statistics	Kendall's tau coeff:	0.7076
	p-value:	0

- The concentration trend on the regression graph and Kendall's tau coefficient of > 0.6 for manganese and aluminum and manganese and iron indicate a consistent relationship between these constituents. Therefore, manganese is eliminated as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

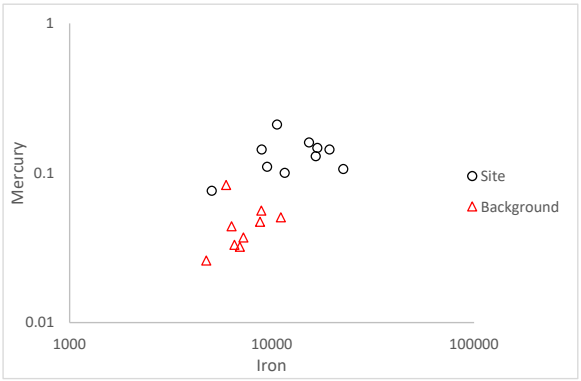
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Mercury

Hydric Surface Soil, Mercury-Aluminum



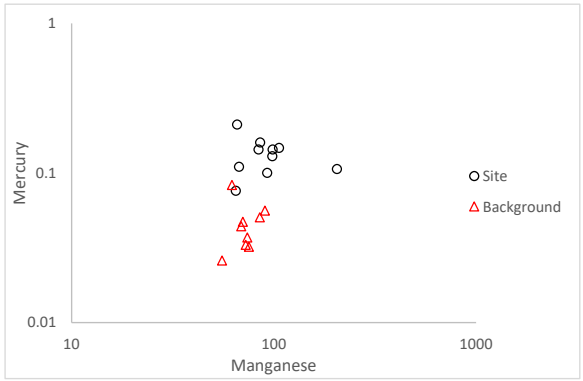
Kendalls' Tau Statistics	Kendall's tau coeff:	0.4647
	p-value:	0.0063

Hydric Surface Soil, Mercury-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.5044
	p-value:	0.0029

Hydric Surface Soil, Mercury-Manganese

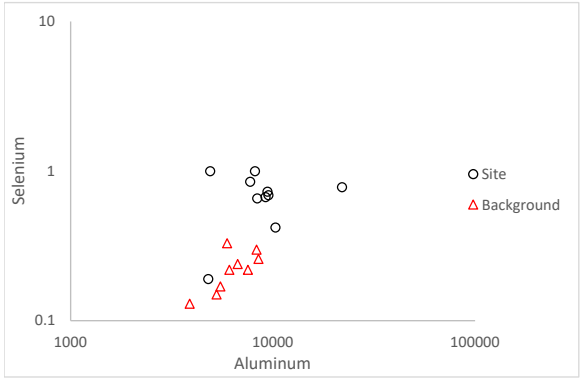


Kendalls' Tau Statistics	Kendall's tau coeff:	0.2815
	p-value:	0.0999

- Although the Kendall's tau coefficient is 0.5 for mercury and iron, the site samples lie off the trend formed by the background samples for these constituents. Therefore, mercury is retained as a COPC in hydric surface soil in the Off-Projec Red Maple Swamp / Tidal Stream Area

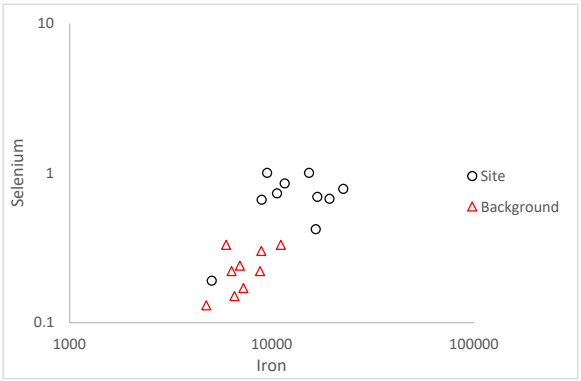
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Selenium

Hydric Surface Soil, Selenium-Aluminum



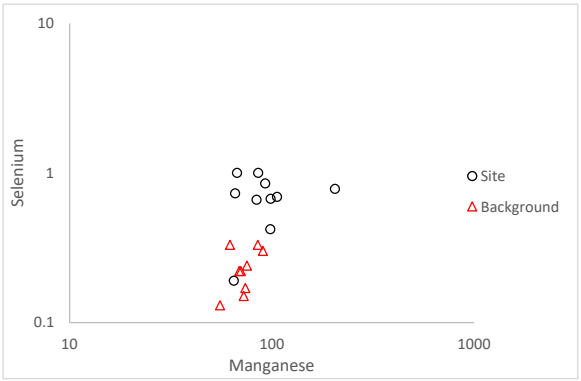
Kendalls' Tau Statistics	Kendall's tau coeff:	0.4529
	p-value:	0.0078

Hydric Surface Soil, Selenium-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.59
	p-value:	0.0005

Hydric Surface Soil, Selenium-Manganese

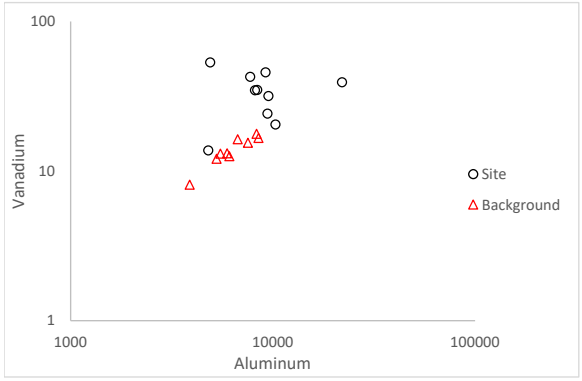


Kendalls' Tau Statistics	Kendall's tau coeff:	0.3894
	p-value:	0.0227

- Although the Kendall's tau coefficient is 0.59 for selenium and iron, the site samples lie off the trend formed by the background samples for these constituents. Therefore, selenium is retained as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area

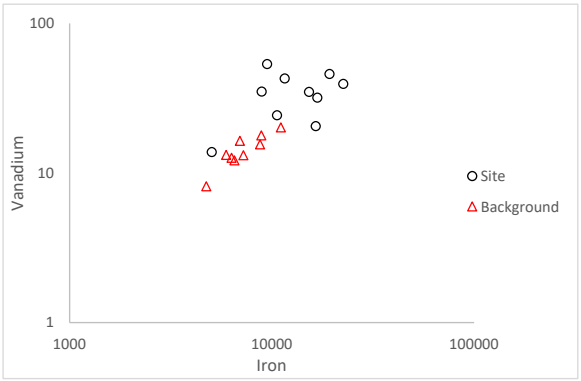
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Vanadium

Hydric Surface Soil, Vanadium-Aluminum



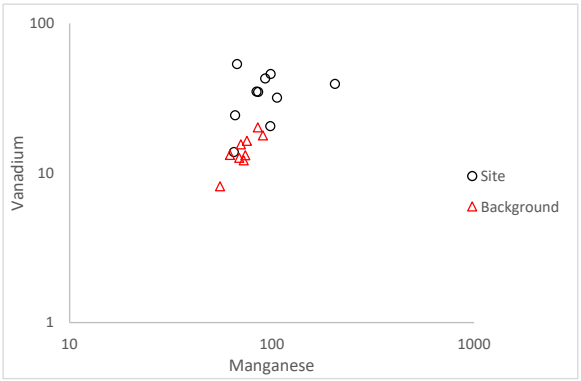
Kendalls' Tau Statistics	Kendall's tau coeff:	0.4503
	p-value:	0.0078

Hydric Surface Soil, Vanadium-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.6257
	p-value:	0.0002

Hydric Surface Soil, Vanadium-Manganese

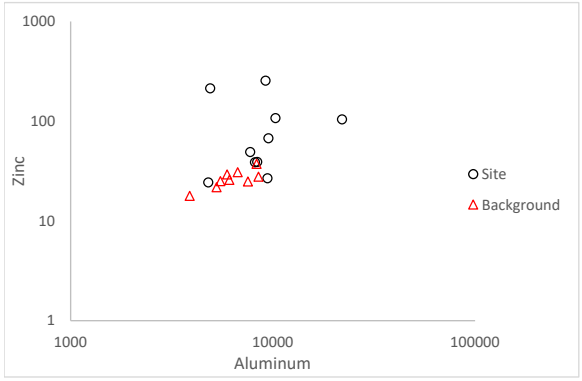


Kendalls' Tau Statistics	Kendall's tau coeff:	0.4737
	p-value:	0.0051

- The Kendall's tau coefficient is 0.63 for vanadium and iron. Although many of the site samples have higher vanadium than background samples, the site samples generally lie on the trend for vanadium and iron formed by the background samples. Therefore, vanadium is eliminated as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

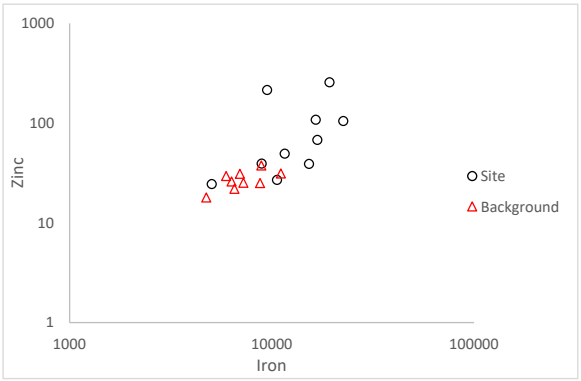
Hydric Surface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Zinc

Hydric Surface Soil, Zinc-Aluminum



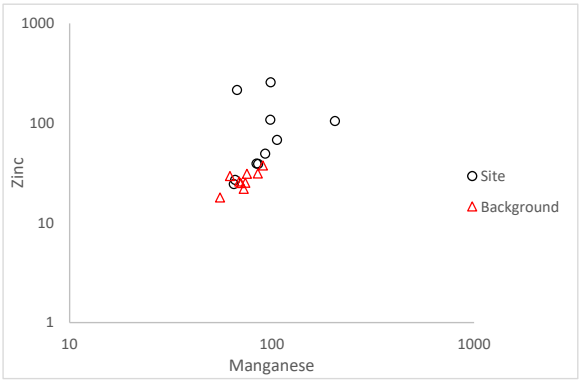
Kendalls' Tau Statistics	Kendall's tau coeff:	0.4971
	p-value:	0.0033

Hydric Surface Soil, Zinc-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.6608
	p-value:	0.0001

Hydric Surface Soil, Zinc-Manganese

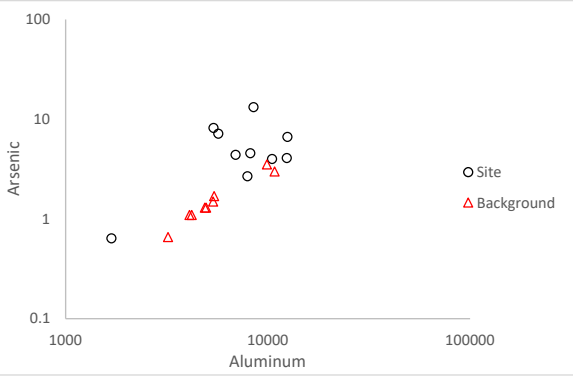


Kendalls' Tau Statistics	Kendall's tau coeff:	0.5789
	p-value:	0.0006

- The Kendall's tau coefficient is 0.66 for zinc and iron and most of the site samples lie on the trend formed by the background samples for these constituents. Therefore, zinc is eliminated as a COPC in hydric surface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

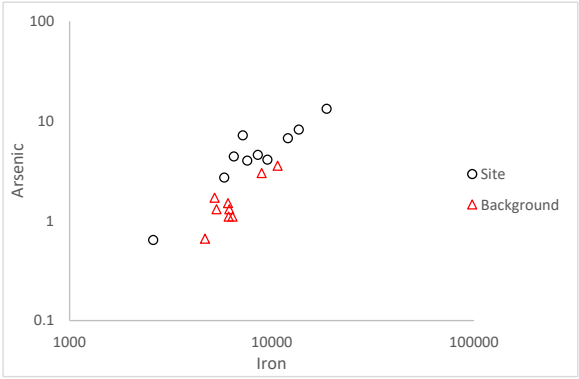
Hydric Subsurface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Arsenic

Hydric Subsurface Soil, Arsenic-Aluminum



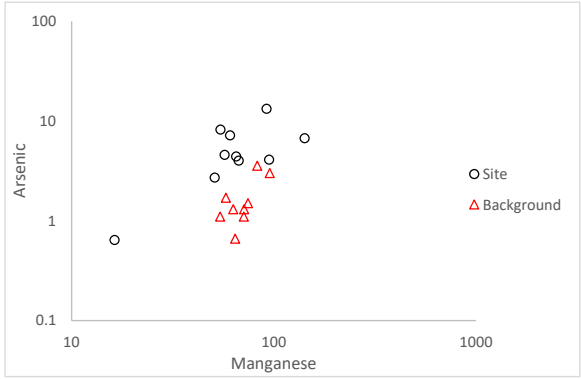
Kendalls' Tau Statistics	Kendall's tau coeff:	0.5941
	p-value:	0.0005

Hydric Subsurface Soil, Arsenic-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.6294
	p-value:	0.0002

Hydric Subsurface Soil, Arsenic-Manganese

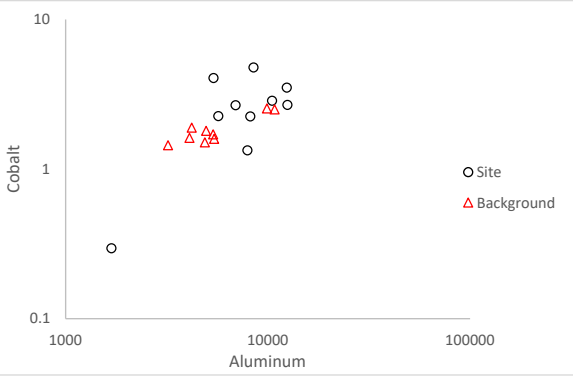


Kendalls' Tau Statistics	Kendall's tau coeff:	0.1941
	p-value:	0.2623

- The concentration trend on the regression graph and Kendall's tau coefficient of 0.63 for arsenic and iron indicate a consistent relationship between these constituents. Therefore, arsenic is eliminated as a COPC in hydric subsurface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

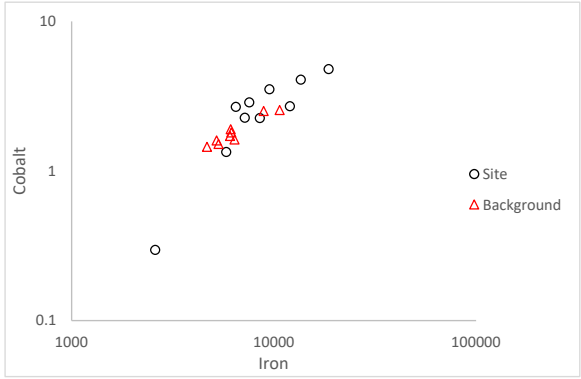
Hydric Subsurface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Cobalt

Hydric Subsurface Soil, Cobalt-Aluminum



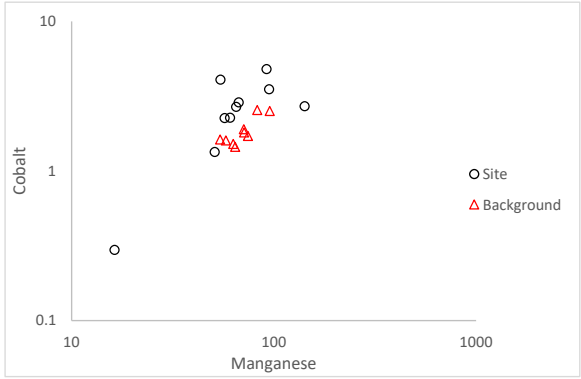
Kendalls' Tau Statistics	Kendall's tau coeff:	0.5205
	p-value:	0.0021

Hydric Subsurface Soil, Cobalt-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.7778
	p-value:	0

Hydric Subsurface Soil, Cobalt-Manganese

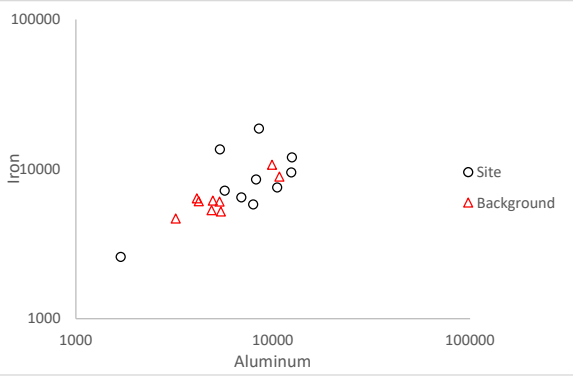


Kendalls' Tau Statistics	Kendall's tau coeff:	0.4035
	p-value:	0.0174

- The concentration trend on the regression graph and Kendall's tau coefficient of 0.78 for cobalt and iron indicate a consistent relationship between these constituents. Therefore, cobalt is eliminated as a COPC in hydric subsurface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

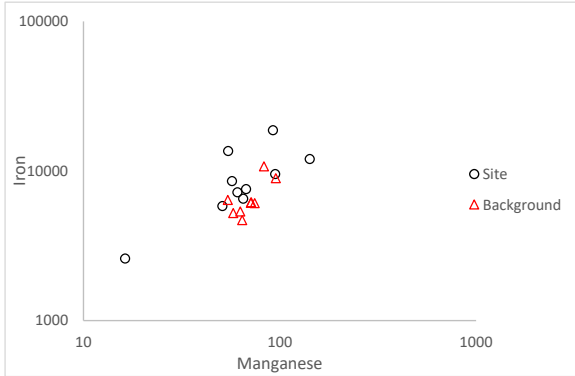
Hydric Subsurface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Iron

Hydric Subsurface Soil, Iron-Aluminum



Kendalls' Tau Statistics	Kendall's tau coeff:	0.5556
	p-value:	0.001

Hydric Subsurface Soil, Iron-Manganese

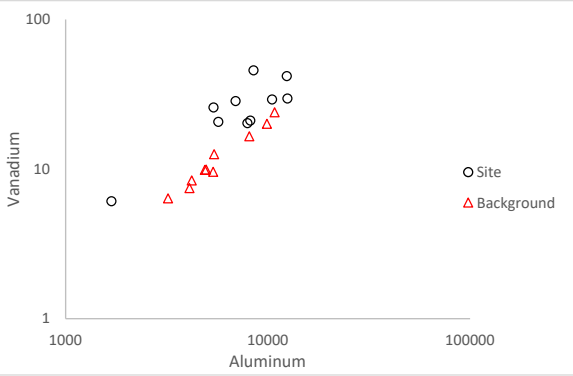


Kendalls' Tau Statistics	Kendall's tau coeff:	0.3684
	p-value:	0.0301

- The concentration trend on the regression graph and Kendall's tau coefficient 0.56 for iron and aluminum indicate a consistent relationship between these constituents. Therefore, iron is eliminated as a COPC in hydric subsurface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

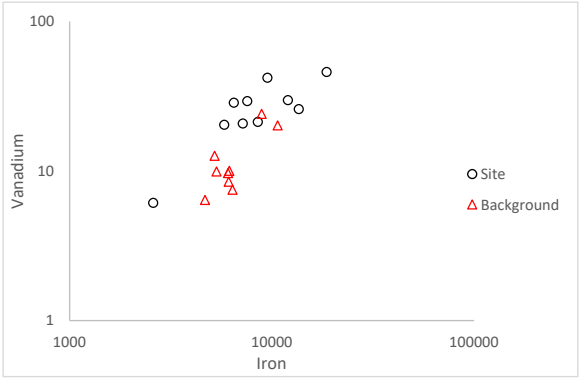
Hydric Subsurface Soil - Off-Project Red Maple Swamp / Tidal Stream Area - Vanadium

Hydric Subsurface Soil, Vanadium-Aluminum



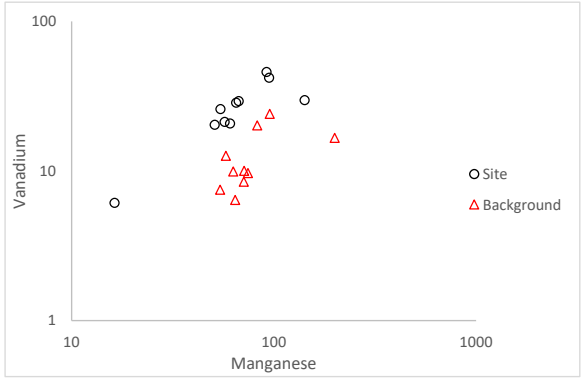
Kendalls' Tau Statistics	Kendall's tau coeff:	0.7158
	p-value:	0

Hydric Subsurface Soil, Vanadium-Iron



Kendalls' Tau Statistics	Kendall's tau coeff:	0.614
	p-value:	0.0003

Hydric Subsurface Soil, Vanadium-Manganese



Kendalls' Tau Statistics	Kendall's tau coeff:	0.2842
	p-value:	0.0855

- The concentration trend on the regression graph and Kendall's tau coefficient of 0.72 for vanadium and aluminum indicate a consistent relationship between these constituents. Therefore, vanadium is eliminated as a COPC in hydric subsurface soil in the Off-Project Red Maple Swamp / Tidal Stream Area.

Notes:

-- = Not Applicable/Not Available.

CAS = Chemical Abstracts Service.

SVOCs = semivolatile organic compounds.

USEPA, 2004 = United States Environmental Protection Agency (USEPA) Risk Assessment Guidance for Superfund. Vol. 1, Part E. July, 2004.

VOCs = volatile organic compounds.

(a) USEPA, 2004. Exhibit B-3 (Organics).

(b) USEPA, 2004. Exhibit 3-1. (Inorganics)

(c) Default for all other inorganics.

(d) Calculated. See equations below.

(e) USEPA, 2004. Equation A-4. Default value.

(f) USEPA, 2004. Exhibit B-2.

(g) Chemical identified as outside the effective prediction domain (EPD). Therefore, the dermal exposure pathway is not quantitatively evaluated, as discussed in the report text.

(h) See risk assessment report text for the evaluation of lead in groundwater.

(i) USEPA, 2020. Regional Screening Levels (RSLs) Calculator. May 2020.

(j) Value for trivalent chromium.

(k) Value for naphthalene.

(l) Value for 1,2,4-trichlorobenzene.

(m) Value for trans-1,2-dichloroethene.

Equations:

USEPA, 2004. Risk Assessment Guidance for Superfund. Volume 1, Part E, Supplemental Guidance for Dermal Risk Assessment

Equation 3.8:	$\text{Log Kp} = -2.80 + 0.66 \log \text{Kow} - 0.0056 \text{MW}$
Equation A.1:	$B = Kp \times MW^{0.5}/2.6$
Equation A.2:	$\text{Log Dsc/lsc} = -2.8-0.0056 \text{MW}$, where lsc = 1E-3 cm. Solving for Dsc: $Dsc = 10^{-2.8-0.0056\ MW} * lsc$.
Equation A.4:	$t = lsc^2/(6*Dsc)$
Equation A.5:	If $B \leq 0.6$, Equation A.5: $t^* = 2.4* t$
Equation A.6:	If $B > 0.6$: $t^* = (b- (b^2-c^2)^{0.5}) * l^2sc/(Dsc)$
Equation A-7:	$b = (2*(1+B)^2/p) -c$
Equation A-8:	$c = (1+3B+3B^2)/(3*(1+B))$

Definitions:

B - Relative Contribution of Permeability Coefficient.
Dsc - Effective diffusion coefficient through stratum corneum.
FA - Fraction Absorbed.
Kow - Octanol-Water Partition Coefficient.
Kp - Dermal Permeability Coefficient.
lsc - Apparent thickness of stratum corneum.
MW - Molecular Weight.
t - lag time (hr/event).
t* - Time to reach steady state.

Shower Air Modeling

Shower Air Modeling

The showering inhalation pathway requires modeling to derive exposure point concentrations. Foster and Chrostowski (1987) have presented a predictive model to estimate an indoor (bathroom) concentration. This theoretical approach is based on the experimental work of Andelman (1985), who measured air concentrations of trichloroethylene and chloroform in a bench scale shower assembly.

The shower model utilizes several assumptions, including a 12 cubic meter (m^3) bathroom volume and instant equilibrium in the air between the shower stall and the rest of the bathroom. The volumetric flow rate through the bathroom was assumed to be 0.1 m^3/min. This gives an effective air change rate of 0.5 air changes/hour (ACH). This value represents a reasonably conservative estimate given that median values for homes with closed windows is about 0.5 ACH (TRJ Environmental, 2002), and bathrooms with showers generally need a greater air exchange rate to remove moisture. No modifications were made to the model assumptions for this evaluation.

The model calculates the maximum concentrations, assuming that exposure time equals duration of the shower use. In reality, an individual would experience an integrated exposure that would gradually increase during shower usage and decrease again after the water was turned off. It was conservatively assumed that the peak concentration would persist for the entire duration of exposure.

The equation to calculate air concentrations in the bathroom is shown below:

$$C_{VOC} = \frac{S\,(e^{RDs} - 1)(e^{-Rt})}{R} \qquad \text{(Eq. 1)}$$

where:

C_{VOC}	=	bathroom VOC air concentration, ug/m^3
S	=	VOC source generation rate, ug/m^3- minute
R	=	air exchange rate of bathroom, min^{-1}
t	=	time at which concentration is being calculated, min
D_s	=	duration of shower, min

R, the air exchange rate, is calculated as the volumetric flow rate through the bathroom (m^3/min) divided by the volume of the bathroom (m^3).

S, the VOC source generation rate, is calculated based on the concentration of the compound in the water, emission of compound from a droplet, flow rate of water, and volume of room for dilution. S is calculated from the following series of equations:

$$S = \frac{C_{wd}\,Fr}{S_v} \qquad \text{(Eq. 2)}$$

where:

S	=	VOC source generation rate, ug/m^3-min
C_{wd}	=	concentration of VOC leaving the shower droplet, µg/l
F_r	=	water flow rate in shower, 10 liters/min
S_v	=	shower volume, 2.94 m^3

C_{wd} is calculated as follows:

$$C_{wd} = C_{wc} * (1 - e^{[(-KaL)(ts)/600d]}) \qquad \text{(Eq. 3)}$$

Where:

C_{wc} = concentration of VOC in water, µg/l
K_{aL} = temperature-connected mass transfer coefficient, cm/hr
t_s = shower droplet drop time, 2 sec
d = droplet diameter, 0.1 cm
1/600d = 6/d (mm) * (1 hr/3600 sec)

K_{aL} is calculated according to:

$$K_{aL} = K_L * [(T_1 * u_s)/(T_s * u_1)]^{-0.5} \quad \text{(Eq. 4)}$$

Where:

K_L = mass transfer coefficient at reference conditions (20°C and 1 atm), cm/hr
T_1 = reference temperature, 293°K
T_s = temperature of shower water, 318°K
u_1 = viscosity of water at reference temperature, 1.002 cp
u_s = viscosity of water at shower temperature, 0.5960 cp

K_L is calculated according to:

$$K_L = 1/[1/k_l + RT/(H\ k_g)] \quad \text{(Eq. 5)}$$

Where:

k_l = liquid-film mass transfer, cm/hr
k_g = gas-film mass transfer, cm/hr
H = Henry's Law constant, atm-m^3/mole
R = molar gas constant, 8.191×10^{-5} atm-m^3/mole-k
T = temperature, 293°K

The input values of k_l and k_g are based on the mass transfer coefficients of carbon dioxide (CO_2) and water. They are calculated for the particular chemical of potential concern (COPC) according to the following equations:

$$k_l = (kCO_2)\ [(44g/mole)/MW_{VOC}]^{0.5} \quad \text{(Eq. 6)}$$

$$k_g = (kH_2O)\ [(18g/mole)/MW_{VOC}]^{0.5} \quad \text{(Eq. 7)}$$

where:

kCO_2 = 20 cm/hr
kH_2O = 3,000 cm/hr
MW = molecular weight of COPC, g/mole

These equations were used to calculate bathroom air VOC concentrations derived from VOCs in groundwater, as presented in the table following this text. The air VOC concentrations were then used to calculate potential inhalation risks for the adult and child resident.

Uncertainties

There are uncertainties associated with the modeling of VOC volatilization from indoor water use for showering. Activity parameters that have uncertainty associated with them include shower durations and time spent in the room after a shower. Uncertain elements related to the modeling include chemical-specific input parameters (e.g., Henry's law constants), flow rate and temperature assumptions, and calculation of mass transfer coefficients. Measurement uncertainty is associated with some input parameters used in the model (e.g.,

droplet size) as well as the experimental data used to validate the model. Although the main source of VOCs in the air while showering is expected to be the shower spray itself, the conceptualization of the model as falling droplets only may result in an underestimation of modeled indoor concentrations (Foster and Chrostowski, 2003). The model also makes several conservative assumptions such as assuming exposure time equals duration of shower use and not accounting for the actual decrease in concentration after the water is turned off. Therefore, when all of the exposure and modeling assumptions are combined, it is much more likely that potential risks are significantly overestimated rather than underestimated.

Attachment E-4

Excavation Trench Air Modeling

CALCULATION OF EXCAVATION AIR VOC ATTENUATION FACTORS FROM STANDING WATER-EXCAVATION TRENCH

Excavation trench air concentrations of a COPC resulting from volatilization from groundwater and leachate infiltrating an excavation trench can be predicted by the use of the method recommended by USEPA (1994) for predicting volatilization from standing water.

Air Concentration

In this model, the air concentration of a COPC is estimated at the downwind boundary of the water. For the purposes of calculating this concentration, a rectangular box with the base corresponding to the water surface is considered. The height of the box, H_b, is the height to which the chemical emissions from the water surface are uniformly mixed with the air. W_b is the width of the box perpendicular to the airflow. If U is the wind speed along the length of the trench, then, by conservation of mass, the air concentration, C_a, of chemical within the box is given by:

$$C_a = \frac{Q}{H_b W_b U} \quad (1)$$

The diffusion height, Hb, above the water surface is approximately equal to 5% of the length of the trench, i.e., parallel to the wind flow (Jackson, 1976). If the length of the trench is expressed as the surface area of the water on the bottom of the trench divided by the trench width, the equation for the air concentration becomes:

$$C_a = \frac{Q}{0.05\,AU} \quad (2)$$

where:

Q = chemical emission rate (g/s)

A = water surface area (m^2)

U = wind speed along the trench (m/s)

The chemical emission rate, Q, can be expressed as follows:

$$Q = KAC_L \quad (3)$$

where:

Q = chemical emission rate (g/s)

K = overall mass transfer coefficient (m/s)

A = water surface area (m^2)

C_L = chemical concentration in water (g/m^3)

With the substitution of equation (3) into equation (2), the equation for air concentration simplifies to:

$$C_a = \frac{KC_L}{0.05\,U} \quad (4)$$

For the purpose of calculating the concentration in air from a given concentration in water, it is convenient to use this equation to define an attenuation factor, α, defined as the ratio of the airborne concentration of the COPC above the water to the COPC concentration in the water. If the air and water COPC concentrations are in the same units α is dimensionless. If, as is common practice, the concentration in water is expressed in mass units per liter (L) and the air concentration is expressed as mass units per cubic meter (m^3), then the attenuation factor can be expressed as:

$$\alpha\,(L/m^3) = \frac{20000K}{U} \qquad (5)$$

In applying the attenuation factor, the computation of the COPC air concentration requires the COPC concentration in water, wind speed and mass transfer coefficient.

Mass Transfer Coefficient

Volatilization is considered the primary pathway of mass transfer from the liquid to the vapor phase. It occurs when molecules of a dissolved substance escape to the gas phase due to a concentration gradient. The mass transfer coefficient is defined by USEPA (1994) as follows:

$$K = \left[\frac{1}{k_l^o \left(\frac{D_l^c}{D_l^o} \right)^m} + \frac{RT}{(10^6) H \; k_g^w \left(\frac{D_g^c}{D_g^w} \right)^n} \right]^{-1} \qquad (6)$$

Where:

k_l^o = mass transfer coefficient of oxygen in water, cm/s;

D_l = diffusivity of the chemical (c) or oxygen (o) in water, cm^2/s;

m = liquid turbulence exponent, 0.5 to 1, dimensionless;

R = ideal gas constant, atm cm^3/ (mol.K);

T = temperature, K;

H = Henry's law constant, atm m^3/mol;

k_w^g = mass transfer coefficient for water vapor in air, cm/s;

D_g = diffusivity of the chemical (c) or water (w) in air, cm^2/s;

n = gas turbulence exponent, 0.5 to 1.0, dimensionless

The elements of this equation can be described by:

$$K = \left[\frac{1}{K_L} + \frac{1}{K_G K_{eq}} \right]^{-1} \qquad (7)$$

where,

K_L = Liquid phase mass transfer coefficient, cm/s;

K_G = Gas phase mass transfer coefficient, cm/s;

K_{eq} = Equilibrium mass transfer coefficient, unitless;

K_L, K_G and K_{eq} may be expressed as follows:

$$K_{eq} = \frac{H}{RT} \quad (8)$$

$$K_L = k_l^o \left(\frac{D_l^c}{D_l^o} \right)^m \quad (9)$$

$$K_G = k_g^w \left(\frac{D_g^c}{D_g^o} \right)^n \quad (10)$$

Equation 6 requires values of diffusion coefficients and Henry's law constants which are presented in the accompanying table. The constants used in Equation 6 are presented below.

Values of Constants for use in Equation 6 (Source: USEPA (1994), Table 2-1):

Constant	Value for Lakes
k_l^o (cm/s)	0.0005
m	1.0
T (K)	293
RT (cm^3.atm/mol)	24042.4
k_w^g (cm/s)	0.58
n	0.7

Model Applications and Results

The accompanying table provides model inputs and the intermediate steps in the process of modeling the attenuation factor. A surface wind speed of 2.25 m/s was applied (ASTM, 1994).

DEVELOPMENT OF ATTENUATION FACTORS FOR THE GROUNDWATER TO EXCAVATION TRENCH AIR PATHWAY
BLUE BEACH DISPOSAL AREA
HUMAN HEALTH RISK ASSESSMENT
NORTH KINGSTOWN, RHODE ISLAND

Assumption: Losses from a trench occur in a manner similar to volatilization losses from a lake; using equation 2-4 from the "Air Emissions Models for the Waste and Wastewater"; EPA, Nov. 1994. The overall mass transfer coefficient, K is calculated as follows:

$$K = [1/(k_l^{\circ} * (D_l^{c}/D_l^{\circ})^{m}) + (RT/(10^{6}*H*K_g^{w}*(D_g^{c}/D_g^{w})^{n}))]^{-1} \text{ ------ (1) (a)}$$

$$K = (B+C)^{-1} \text{ ; Where}$$

$$B = 1/(k_l^{\circ} * (D_l^{c}/D_l^{\circ})^{m}) \text{ and}$$

$$C = (RT/(10^{6}*H*K_g^{w}*(D_g^{c}/D_g^{w})^{n}))$$

General Notes:

BW - Body Weight g - grams

DW - Dry Weight kg - kilograms

FIR - Food Ingestion Rate L - liters

Notes continued on following page.

Notes for American robin

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for insectivorous birds developed by Nagy, 2001 [FIR (gdw/day) = $0.540*BW^{0.705}$] using average body weight.

[c] Diet assumed to be exclusively soil invertebrates.

[d] In the absence of data for the robin, the incidental soil ingestion rate is based on 50th percentile value for woodcock (USEPA, 2007a).

[e] Home range listed by USEPA (1993) ranges from 0.27 to 1.04 acres with an average of 0.6095 acres.

ATTACHMENT G-1 TABLE 1
EXPOSURE PARAMETERS FOR WILDLIFE RECEPTORS FOR ON-PROJECT BLUE BEACH AREA
ECOLOGICAL RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Notes for Bobwhite quail

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for quail birds developed by Nagy, 2001 [FIR (gdw/day) = $0.088*BW^{0.891}$] using average body weight.

[c] Diet assumed to be exclusively plants.

[d] In the absence of data for the quail, the incidental soil ingestion rate is based on 50th percentile value for mourning dove (USEPA, 2007a).

[e] Home range listed by USEPA (1993) ranges from 8.9 to 41.3 acres with an average of 24.7 acres.

Notes for Raccoon

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for omnivorous mammals developed by Nagy, 2001 [FIR (g_{dw}/day) = $0.432*BW^{0.678}$] using average body weight.

[c] Diet composition based on the average of seasonal diets for raccoon in a Maryland forested bottomland (USEPA, 1993). Amphibian component of diet (12%) added to soil invertebrat

[d] The incidental soil ingestion rate is based on the value identified by Beyer (1994) for raccoons.

[e] Home range listed by USEPA (1993) ranges from 96 to 6325 acres with an average of 1558 acres.

Meadow vole

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for herbivorous mammals developed by Nagy, 2001 [FIR (kg_{dw}/day) = $0.859*BW^{0.628}$] using average body weight.

[c] Diet is expected to be composed entirely of plants.

[d] The incidental soil ingestion rate is based on 50th percentile value for vole (USEPA, 2007a).

[e] Home range listed by USEPA (1993) ranges from 0.000494 to 0.2051 acres with an average of 0.0659 acres.

Notes for Short-tailed Shrew

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for insectivorous mammals developed by Nagy, 2001 [FIR (kg_{dw}/day) = $0.373*BW^{0.622}$] using average body weight.

[c] An exclusive soil invertebrate diet was selected.

[d] The incidental soil ingestion rate is based on 50^{th} percentile value for shrew (USEPA, 2007a).

[e] Average home range for short-tailed shrew in Michigan, Manitoba, and New York (USEPA, 1993).

TOTAL PCB AROCLORS	0.48	6.667	[c]	3.2	0.106	[e,f]	0.0509

Notes:
Maximum EPCs for screening level evaluation represent maximum detected concentrations.

COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
HMW - High Molecular Weight.
LMW - Low Molecular Weight.
PAHs - Polycyclic Aromatic Hydrocarbons.
PCBs - Polychlorinated Biphenyls.
USEPA - United States Environmental Protection Agency.

[a] Value presented is the maximum detected surface soil concentration in the On-Project Blue Beach area. Total PCB results are associated with soil samples collected from three decision units (DUs) using an incremental sampling methodology (ISM). The highest of the DU-specific 95% upper confidence limits was selected for use as it is higher than the maximum detect (Attachment C).
[b] Soil-to-invertebrate uptake factors and regression equations recommended by USEPA in development of Ecological Soil Screening Levels (USEPA, 2007a)

arsenic	ln(tissue concentration) = 0.706 * ln(soil concentration) - 1.421
cadmium	ln(tissue concentration) = 0.795 * ln(soil concentration) + 2.114
lead	ln(tissue concentration) = 0.807 * ln(soil concentration) - 0.218
selenium	ln(tissue concentration) = 0.733 * ln(soil concentration) - 0.075
zinc	ln(tissue concentration) = 0.328 * ln(soil concentration) + 4.449

[c] Soil-to-earthworm uptake factors from Sample, et al (1998) - median value from Table 11.
[d] Soil-to-plant uptake factors and regression equations recommended by USEPA in development of Ecological Soil Screening Levels (USEPA, 2007a)

cadmium	ln(tissue concentration) = 0.546 * ln(soil concentration) - 0.475
copper	ln(tissue concentration) = 0.394 * ln(soil concentration) + 0.668
lead	ln(tissue concentration) = 0.561 * ln(soil concentration) - 1.328
nickel	ln(tissue concentration) = 0.748 * ln(soil concentration) - 2.223
selenium	ln(tissue concentration) = 1.104 * ln(soil concentration) - 0.677
zinc	ln(tissue concentration) = 0.554 * ln(soil concentration) + 1.575
Total LMW PAHs	ln(tissue concentration) = 0.4544 * ln(soil concentration) - 1.3205
Total HMW PAHs	ln(tissue concentration) = 0.9469 * ln(soil concentration) - 1.7026

[e] Soil-to-plant uptake factor obtained from Los Alamos National Laboratory (LANL) EcoRisk database version 4.1 (LANL, 2017).
[f] Value for Aroclor 1254 used for Total PCBs.

TOTAL PCBs	0.18	estimated NOAEL	reproduction	chronic	pheasant	Dahlgren et al., 1972 [b]	Sample et al., 1996

Notes:
LOAEL values from USEPA Eco-SSL documents were calculated as the geometric mean of growth and reproduction LOAEL values.
NOAELs were estimated if a NOAEL was not identified in the literature. The LOAEL was divided by 10 to derive an estimated NOAEL.

COPC - Chemical of Potential Concern.
HMW - High Molecular Weight.
LMW - Low Molecular Weight.
NOAEL - No Observed Adverse Effects Level.
PAHs - Polycyclic Aromatic Hydrocarbons.
PCBs - Polychlorinated Biphenyls.
TRV - Toxicological Reference Value

[a] The avian TRVs for the HMW and LMW PAHs are based on 7,12-dimethylbenz(a)anthracene.
[b] TRVs for Total PCBs are based on Aroclor 1254.

POTENTIAL RISKS TO THE SHORT-TAILED SHREW IN THE ON-PROJECT BLUE BEACH AREA
ECOLOGICAL RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

ASSUMPTIONS FOR THE SHORT-TAILED SHREW	
Average Body Weight (kg)	0.016
Exposure Duration	1
Area Use Factor	1
Soil Consumption Rate (kg_{dw}/day)	0.000019
Soil Invertebrate Consumption Rate (kg_{dw}/day)	0.0021

$$\text{Total Daily Dose} = \frac{\Sigma([IR_f \times C_f] + [IR_s \times C_s] + [IR_w \times C_w] \times ED \times AUF}{\text{Average Body Weight (kg)}}$$

Where:
IR_f = Ingestion rate of food (kg/day)
IR_s = Incidental ingestion rate of sediment or soil (kg/day)
IR_w = Drinking water ingestion rate(L/day)
C_f = Concentration of COPC in food (mg/kg)
C_s= Concentration of COPC in sediment or soil (mg/kg)
C_w= Concentration of COPC in water(mg/L)
ED = Exposure duration (fraction of time receptor spends within exposure area)

Notes:
COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
HQ - Hazard Quotient (Dose/TRV).
NOAEL - No Observed Adverse Effects Level.
TRV - Toxicity Reference Value.
HQs above 1 are bolded and highlighted.

Notes:
Maximum EPCs for screening level evaluation represent maximum detected concentrations. Total PCB results are associated with soil samples collected from three sampling units (SUs) using an incremental sampling methodology (ISM). The highest of the SU-specific 95% upper confidence limits was selected for use as it is higher than the maximum detect (Attachment C).
Potential risk is calculated using the maximum detected concentrations and NOAEL-based TRVs.
HQs above 1 are bolded and highlighted.

COPC - Chemical of Potential Concern.
EPC - Exposure Point Concentration.
HMW - High Molecular Weight.
HQ - Hazard Quotient (Dose/TRV).
LMW - Low Molecular Weight.
NOAEL - No Observed Adverse Effect Level.
PAHs - Polycyclic Aromatic Hydrocarbons.
PCBs - Polychlorinated Biphenyls.
TRV - Toxicity Reference Value.

Short-tailed shrew *(Blarina brevicauda)*	0.0161 [a]	0.0021 [b]	100% [c] 0.0021	-- --	0.9% [d] 0.000019	0.96 [e]

General Notes:

BW - Body Weight g - grams

DW - Dry Weight kg - kilograms

FIR - Food Ingestion Rate

Notes for Marsh Wren

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for insectivorous birds developed by Nagy, 2001 [FIR (g_{dw}/day) = 0.540*$BW^{0.705}$] using average body weight.

[c] Diet assumed to be exclusively benthic invertebrates.

[d] In the absence of data for the wren, the incidental soil ingestion rate is based on 50th percentile value for shrew (consuming 100% earthworms; USEPA, 2007a).

[e] Home range for freshwater wetlands listed by USEPA (1993) ranges from 0.17 to 0.42 acres with an average of 0.295 acres.

Notes for Raccoon

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for omnivorous mammals developed by Nagy, 2001 [FIR (g_{dw}/day) = 0.432*$BW^{0.678}$] using average body weight.

[c] Diet composition based on the average of seasonal diets for raccoon in a Maryland forested bottomland (USEPA, 1993). Amphibian component of diet (12%) added to benthic invertebrate component.

[d] The incidental soil ingestion rate is based on the value identified by Beyer (1994) for raccoons.

[e] Home range listed by USEPA (1993) ranges from 96 to 6325 acres with an average of 1558 acres.

Meadow vole

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for herbivorous mammals developed by Nagy, 2001 [FIR (kg_{dw}/day) = 0.859*$BW^{0.628}$] using average body weight.

[c] Diet is expected to be composed entirely of plants.

[d] The incidental soil ingestion rate is based on 50th percentile value for vole (USEPA, 2007a).

[e] Home range listed by USEPA (1993) ranges from 0.000494 to 0.2051 acres with an average of 0.0659 acres.

Notes for Short-tailed Shrew

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for insectivorous mammals developed by Nagy, 2001 [FIR (kg_{dw}/day) = 0.373*$BW^{0.622}$] using average body weight.

[c] An exclusive soil invertebrate diet was selected.

[d] The incidental soil ingestion rate is based on 50th percentile value for shrew (USEPA, 2007a).

[e] Average home range for short-tailed shrew in Michigan, Manitoba, and New York (USEPA, 1993).

Notes:
Maximum EPCs for screening level evaluation represent maximum detected concentrations.

COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
HMW - High Molecular Weight.
LMW - Low Molecular Weight.
PAHs - Polycyclic Aromatic Hydrocarbons.
PCBs - Polychlorinated Biphenyls.
USEPA - United States Environmental Protection Agency.

[a] Value presented is the maximum detected concentration from the following off-Project datasets:
surface soil from the off-Project Red Maple Swamp walking path, hydric surface soil from the off-Project Red Maple Swamp, and surface sediment from the off-Project tidal stream.
[b] Benthic invertebrate uptake factors obtained from Bechtel Jacobs (1998; Table 2; all data). Value selected is median uptake factor for depurated and non-depurated invertebrates combined expressed on a dry weight basis.

Invertebrate tissue $_{dw}$ = (uptake factor x sediment concentration)

[c] Median biota-sediment accumulation factor (BSAF) and lipids content for benthic invertebrates obtained from BSAF Data Set available at http://www.epa.gov/med/Prods_Pubs/bsaf.htm. See Table 3 for data.

Median lipid values from supporting studies and median site-specific sediment organic carbon used to determine tissue levels.

Median lipid levels for benthic invertebrates were -
0.424% (0.00424 fraction lipids) for HMW PAHs
0.415% (0.00415 fraction lipids) for LMW PAHs
4.2% (0.042 fraction lipids) for PCBs

Median site-specific TOC is 13% (0.13 fraction organic carbon) based on samples collected from 20 locations in 2011 and 2019 (see Attachment A for data).

Invertebrate tissue $_{dw}$ = [BSAF x sediment concentration x (fraction lipid/fraction organic carbon)]/(1-% moisture)

[d] Sediment-to-invertebrate factors obtained from Los Alamos National Laboratory (LANL) EcoRisk database version 4.1 (LANL, 2017).

Invertebrate tissue $_{dw}$ = (uptake factor x sediment concentration)

[e] Soil-to-plant uptake factors and regression equations recommended by USEPA in development of Ecological Soil Screening Levels (USEPA, 2007a)

cadmium	ln(tissue concentration) = 0.546 * ln(soil concentration) - 0.475
copper	ln(tissue concentration) = 0.394 * ln(soil concentration) + 0.668
lead	ln(tissue concentration) = 0.561 * ln(soil concentration) - 1.328
nickel	ln(tissue concentration) = 0.748 * ln(soil concentration) - 2.223
selenium	ln(tissue concentration) = 1.104 * ln(soil concentration) - 0.677
zinc	ln(tissue concentration) = 0.554 * ln(soil concentration) + 1.575
Total LMW PAHs	ln(tissue concentration) = 0.4544 * ln(soil concentration) - 1.3205
Total HMW PAHs	ln(tissue concentration) = 0.9469 * ln(soil concentration) - 1.7026

[f] Soil-to-plant uptake factor obtained from Los Alamos National Laboratory (LANL) EcoRisk database version 4.1 (LANL, 2017).
[g] Value for Aroclor 1254 used for Total PCBs.

					MEDIAN FOR TOTAL PCBs	**0.72**	**0.042**

Notes:
Source of information is the BSAF Data Set available at http://www.epa.gov/med/Prods_Pubs/bsaf.htm.
Information presented for whole body freshwater and marine invertebrates.

HMW - High Molecular Weight.
LMW - Low Molecular Weight.
NETC - Naval Education & Training Center
NR - Not Reported.
PAHs - Polycyclic Aromatic Hydrocarbons.
PCBs - Polychlorinated Biphenyls.

TOTAL PCBs	0.18	estimated NOAEL	reproduction	chronic	pheasant	Dahlgren et al., 1972 [b]	Sample et al., 1996

Notes:
NOAELs were estimated if a NOAEL was not identified in the literature. The LOAEL was divided by 10 to derive an estimated NOAEL.

COPC - Chemical of Potential Concern.
HMW - High Molecular Weight.
LMW - Low Molecular Weight.
LOAEL - Lowest Observed Adverse Effects Level.
NOAEL - No Observed Adverse Effects Level.
PAHs - Polycyclic Aromatic Hydrocarbons.
PCBs - Polychlorinated Biphenyls.
TRV - Toxicological Reference Value

[a] The avian TRVs for the HMW and LMW PAHs are based on 7,12-dimethylbenz(a)anthracene.
[b] TRVs for Total PCBs are based on Aroclor 1254.

ATTACHMENT G-2 TABLE 5
POTENTIAL RISKS TO THE MARSH WREN IN THE OFF-PROJECT RED MAPLE SWAMP / TIDAL STREAM AREA
ECOLOGICAL RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

ASSUMPTIONS FOR THE MARSH WREN	
Average Body Weight (kg)	0.011
Exposure Duration	1
Area Use Factor	1
Hyd. Soil/Sediment Consumption Rate (kgdw/day)	0.000026
Wetland Invertebrate Consumption Rate (kg_{dw}/day)	0.0029

Notes:
COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
HQ - Hazard Quotient (Dose/TRV).
NOAEL - No Observed Adverse Effects Level.
TRV - Toxicity Reference Value.
HQs above 1 are bolded and highlighted.

$$\text{Total Daily Dose} = \frac{\Sigma([IR_f \times C_f] + [IR_s \times C_s] + [IR_w \times C_w] \times ED \times AUF}{\text{Average Body Weight (kg)}}$$

Where:
IR_f = Ingestion rate of food (kg/day)
IR_s = Incidental ingestion rate of sediment or soil (kg/day)
IR_w = Drinking water ingestion rate(L/day)
C_f = Concentration of COPC in food (mg/kg)
C_s= Concentration of COPC in sediment or soil (mg/kg)
C_w= Concentration of COPC in water(mg/L)
ED = Exposure duration (fraction of time receptor spends within exposure area)

POTENTIAL RISKS TO THE RACCOON IN THE OFF-PROJECT RED MAPLE SWAMP / TIDAL STREAM AREA
ECOLOGICAL RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

ASSUMPTIONS FOR THE RACCOON	
Average Body Weight (kg)	5.78
Exposure Duration	1
Area Use Factor	1
Hyd. Soil/Sediment Consumption Rate (kg_{dw}/day)	0.0144
Wetland Plant Consumption Rate (kg_{dw}/day)	0.0645
Wetland Invertebrate Consumption Rate (kg_{dw}/day)	0.089

Notes:
COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
HQ - Hazard Quotient (Dose/TRV).
NOAEL - No Observed Adverse Effects Level.
TRV - Toxicity Reference Value.
HQs above 1 are bolded and highlighted.

$$\text{Total Daily Dose} = \frac{\Sigma([IR_f \times C_f] + [IR_s \times C_s] + [IR_w \times C_w] \times ED \times AUF}{\text{Average Body Weight (kg)}}$$

Where:
IR_f = Ingestion rate of food (kg/day)
IR_s = Incidental ingestion rate of sediment or soil (kg/day)
IR_w = Drinking water ingestion rate(L/day)
C_f = Concentration of COPC in food (mg/kg)
C_s= Concentration of COPC in sediment or soil (mg/kg)
C_w= Concentration of COPC in water(mg/L)
ED = Exposure duration (fraction of time receptor spends within exposure area)
AUF = Area use factor (ratio of the receptor's home range relative to the size of exposure area)

Notes:

Maximum EPCs for screening level evaluation represent maximum detected concentrations.

Potential risk is calculated using the maximum detected concentrations and NOAEL-based TRVs.

HQs above 1 are bolded and highlighted.

COPC - Chemical of Potential Concern.

HMW - High Molecular Weight.

HQ - Hazard Quotient (Dose/TRV).

LMW - Low Molecular Weight.

NOAEL - No Observed Adverse Effect Level.

PAHs - Polycyclic Aromatic Hydrocarbons.

PCBs - Polychlorinated Biphenyls.

TRV - Toxicity Reference Value.

Notes:
COPC - Chemical of Potential Concern.
EPC - Exposure Point Concentration.
ISM - Incremental Sampling Methodology.
ITRC - Interstate Technical Regulatory Council.
mg/kg - Milligrams per kilogram.
NC - Not Calculated.
UCL - Upper Confidence Limit.
USEPA - United States Environmental Protection Agency.

[a] Upper Confidence Limit (UCL) on the arithmetic mean concentration calculated using USEPA ProUCL Version 5.1. The UCL suggested by ProUCL is used, unless otherwise noted.
In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
[b] With 3 or fewer detected results, a reliable UCL cannot be calculated. The maximum detected concentration was selected as the EPC.
[c] Total PCB results for the on-Project Blue Beach area are associated with soil samples collected from three sampling units (SUs) using an incremental sampling methodology (ISM). Selected EPC is equal to the weighted mean UCL concentration of the SU-specific 95% UCL based on SU size (calculated using the ITRC ISM calculator; see Attachment C).

ECOLOGICAL RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Receptor Species	Body Weight (kg)	Food Ingestion Rate (kg_{dw}/day)	Dietary Assumptions (% kg_{dw}/day)		Incidental Soil Ingestion (% kg_{dw}/day)	Average Home Range (acres)
			Soil Invertebrates	Terrestrial Plants		
Birds						
American robin *(Turdus migratorius)*	0.0804 [a]	0.0119 [b]	100% [c] 0.0119	-- --	6.4% [d] 0.0008	0.6095 [e]
Mammals						
Raccoon *(Procyon lotor)*	5.78 [a]	0.1535 [b]	58% [c] 0.0890	42% [c] 0.0645	9.4% [d] 0.014	1558 [e]
Short-tailed shrew *(Blarina brevicauda)*	0.0161 [a]	0.0021 [b]	100% [c] 0.0021	-- --	0.9% [d] 0.000019	0.96 [e]

General Notes:

BW - Body Weight g - grams

DW - Dry Weight kg - kilograms

FIR - Food Ingestion Rate

Notes continued on following page.

Notes for American robin

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for insectivorous birds developed by Nagy, 2001 [FIR (gdw/day) = $0.540*BW^{0.705}$] using average body weight.

[c] Diet assumed to be exclusively soil invertebrates.

[d] In the absence of data for the robin, the incidental soil ingestion rate is based on 50th percentile value for woodcock (USEPA, 2007a).

[e] Home range listed by USEPA (1993) ranges from 0.27 to 1.04 acres with an average of 0.6095 acres.

Notes for Raccoon

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for omnivorous mammals developed by Nagy, 2001 [FIR (g_{dw}/day) = $0.432*BW^{0.678}$] using average body weight.

[c] Diet composition based on the average of seasonal diets for raccoon in a Maryland forested bottomland (USEPA, 1993). Amphibian component of diet (12%) added to soil invertebrate component.

[d] The incidental soil ingestion rate is based on the value identified by Beyer (1994) for raccoons.

[e] Home range listed by USEPA (1993) ranges from 96 to 6325 acres with an average of 1558 acres.

Notes for Short-tailed Shrew

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for insectivorous mammals developed by Nagy, 2001 [FIR (kg_{dw}/day) = $0.373*BW^{0.622}$] using average body weight.

[c] An exclusive soil invertebrate diet was selected.

[d] The incidental soil ingestion rate is based on 50th percentile value for shrew (USEPA, 2007a).

[e] Average home range for short-tailed shrew in Michigan, Manitoba, and New York (USEPA, 1993).

ATTACHMENT G-4 TABLE 2

MEDIA AND TISSUE CONCENTRATIONS IN THE ON-PROJECT BLUE BEACH AREA
ECOLOGICAL RISK ASSESSMENT

Notes:
Maximum EPCs represent the 95% upper confidence limit (UCL) on the arithmetic mean.
PCB soil data are from incremental sampling and the EPC represents the area weighted mean concentration calculated based on three sampling unit-specific UCLs (see Attachment C).

COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
PCBs - Polychlorinated Biphenyls.
UCL - Upper Confidence Limit.
USEPA - United States Environmental Protection Agency.

[a] Value presented is the selected surface soil EPC in the On-Project Blue Beach area (see Attachments B & C).
[b] Soil-to-invertebrate uptake factors and regression equations recommended by USEPA in development of Ecological Soil Screening Levels (USEPA, 2007a)
cadmium ln(tissue concentration) = 0.795 * ln(soil concentration) + 2.114
lead ln(tissue concentration) = 0.807 * ln(soil concentration) - 0.218
zinc ln(tissue concentration) = 0.328 * ln(soil concentration) + 4.449
[c] Soil-to-earthworm uptake factors from Sample, et al (1998) - median value from Table 11.
[d] Soil-to-plant uptake factors and regression equations recommended by USEPA in development of Ecological Soil Screening Levels (USEPA, 2007a)
cadmium ln(tissue concentration) = 0.546 * ln(soil concentration) - 0.475
copper ln(tissue concentration) = 0.394 * ln(soil concentration) + 0.668
lead ln(tissue concentration) = 0.561 * ln(soil concentration) - 1.328
zinc ln(tissue concentration) = 0.554 * ln(soil concentration) + 1.575
[e] Soil-to-plant uptake factor obtained from Los Alamos National Laboratory (LANL) EcoRisk database version 4.1 (LANL, 2017).
[f] Value for Aroclor 1254 used for Total PCBs.

TOTAL PCBs	*1.8*	*LOAEL*	*reproduction*	*chronic*	*pheasant*	*Dahlgren et al., 1972 [a]*	*Sample et al., 1996*

Notes:
LOAEL values from USEPA Eco-SSL documents were calculated as the geometric mean of growth and reproduction LOAEL values.
NOAELs were estimated if a NOAEL was not identified in the literature. The LOAEL was divided by 10 to derive an estimated NOAEL.

COPC - Chemical of Potential Concern.
LOAEL - Lowest Observed Adverse Effects Level.
NOAEL - No Observed Adverse Effects Level.
PCBs - Polychlorinated Biphenyls.
TRV - Toxicological Reference Value

[a] TRVs for Total PCBs are based on Aroclor 1254.

ATTACHMENT G-4 TABLE 4
POTENTIAL RISKS TO THE AMERICAN ROBIN IN THE ON-PROJECT BLUE BEACH AREA - REFINED FOOD WEB MODEL
ECOLOGICAL RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

ASSUMPTIONS FOR THE AMERICAN ROBIN	
Average Body Weight (kg)	0.080
Exposure Duration	1
Area Use Factor	1
Soil Consumption Rate (kg_{dw}/day)	0.000762
Soil Invertebrate Consumption Rate (kg_{dw}/day)	0.0119

$$\text{Total Daily Dose} = \frac{\Sigma([IR_f \times C_f] + [IR_S \times C_S] + [IR_w \times C_w] \times ED \times AUF}{\text{Average Body Weight (kg)}}$$

Where:
IR_f = Ingestion rate of food (kg/day)
IR_s = Incidental ingestion rate of sediment or soil (kg/day)
IR_w = Drinking water ingestion rate(L/day)
C_f = Concentration of COPC in food (mg/kg)
C_S= Concentration of COPC in sediment or soil (mg/kg)
C_w= Concentration of COPC in water(mg/L)
ED = Exposure duration (fraction of time receptor spends within exposure area)

Notes:
COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
HQ - Hazard Quotient (Dose/TRV).
LOAEL - Lowest Observed Adverse Effects Level.
NOAEL - No Observed Adverse Effects Level.
TRV - Toxicity Reference Value.
HQs above 1 are bolded and highlighted.

Maximum EPCs represent the 95% upper confidence limit (UCL) on the arithmetic mean (Attachment G-3).
Soil EPC for PCBs is based on incremental sampling and represents the area-wide weighted mean concentration (see Attachment C).
Area Use Factor set at 1. Exposure area size of 3.2 acres is larger than receptor home range shown in Table 1.

Notes:
Maximum EPCs represent the 95% upper confidence limit (UCL) on the arithmetic mean (Attachment G-3).
PCB soil data are from incremental sampling and the EPC represents the area-wide weighted mean concentration calculated based on three sampling unit-specific UCLs (see Attachment C).
Potential risk is calculated using the maximum EPC and both NOAEL-and LOAEL-based TRVs.
HQs above 1 are bolded and highlighted.

COPC - Chemical of Potential Concern.
EPC - Exposure Point Concentration.
HQ - Hazard Quotient (Dose/TRV).
LOAEL - Lowest Observed Adverse Effect Level.
NOAEL - No Observed Adverse Effect Level.
PCBs - Polychlorinated Biphenyls.
TRV - Toxicity Reference Value.

ECOLOGICAL RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Receptor Species	Body Weight (kg)	Food Ingestion Rate (kg_{dw}/day)	Dietary Assumptions (%; kg_{dw}/day)		Incidental Sediment Ingestion (%; kg_{dw}/day)	Average Home Range (acres)
			Wetland Invertebrates	Wetland Plants		
Birds						
Marsh Wren *(Cistothorus palustris)*	0.0106 [a]	0.0029 [b]	100% 0.0029	-- --	0.9% [d] 0.000026	0.295 [e]
Mammals						
Raccoon *(Procyon lotor)*	5.78 [a]	0.1535 [b]	58% [c] 0.0890	42% [c] 0.0645	9.4% [d] 0.014	1558 [e]
Meadow vole *(Microtus pennsylvanicus)*	0.033 [a]	0.0077 [b]	-- --	100% [c] 0.0077	1.2% [d] 0.000093	0.066 [e]
Short-tailed shrew *(Blarina brevicauda)*	0.0161 [a]	0.0021 [b]	100% [c] 0.0021	-- --	0.9% [d] 0.000019	0.96 [e]

General Notes:

BW - Body Weight g - grams

DW - Dry Weight kg - kilograms

FIR - Food Ingestion Rate

Notes for Marsh Wren

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for insectivorous birds developed by Nagy, 2001 [FIR (g_{dw}/day) = 0.540*$BW^{0.705}$] using average body weight.

[c] Diet assumed to be exclusively benthic invertebrates.

[d] In the absence of data for the wren, the incidental soil ingestion rate is based on 50th percentile value for shrew (consuming 100% earthworms; USEPA, 2007a).

[e] Home range for freshwater wetlands listed by USEPA (1993) ranges from 0.17 to 0.42 acres with an average of 0.295 acres.

Notes for Raccoon

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for omnivorous mammals developed by Nagy, 2001 [FIR (g_{dw}/day) = 0.432*$BW^{0.678}$] using average body weight.

[c] Diet composition based on the average of seasonal diets for raccoon in a Maryland forested bottomland (USEPA, 1993). Amphibian component of diet (12%) added to benthic invertebrate component.

[d] The incidental soil ingestion rate is based on the value identified by Beyer (1994) for raccoons.

[e] Home range listed by USEPA (1993) ranges from 96 to 6325 acres with an average of 1558 acres.

Meadow vole

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for herbivorous mammals developed by Nagy, 2001 [FIR (kg_{dw}/day) = 0.859*$BW^{0.628}$] using average body weight.

[c] Diet is expected to be composed entirely of plants.

[d] The incidental soil ingestion rate is based on 50th percentile value for vole (USEPA, 2007a).

[e] Home range listed by USEPA (1993) ranges from 0.000494 to 0.2051 acres with an average of 0.0659 acres.

Notes for Short-tailed Shrew

[a] Average of adult body weights listed by USEPA (1993).

[b] Food ingestion rate calculated using algorithm for insectivorous mammals developed by Nagy, 2001 [FIR (kg_{dw}/day) = 0.373*$BW^{0.622}$] using average body weight.

[c] An exclusive soil invertebrate diet was selected.

[d] The incidental soil ingestion rate is based on 50th percentile value for shrew (USEPA, 2007a).

[e] Average home range for short-tailed shrew in Michigan, Manitoba, and New York (USEPA, 1993).

ATTACHMENT G-5 TABLE 2

Organics							
TOTAL PCB AROCLORS	0.8	0.72	[c]	0.84	0.106	[f, g]	0.084

Notes:
Maximum EPCs represent the 95% upper confidence limit (UCL) on the arithmetic mean.

COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
PCBs - Polychlorinated Biphenyls.
USEPA - United States Environmental Protection Agency.

[a] Value presented is the 95 UCL from the following off-Project datasets: surface soil from the off-Project Red Maple Swamp walking path, hydric surface soil from the off-Project Red Maple Swamp, and surface sediment from the off-Project tidal stream (Attachment G-3).
[b] Benthic invertebrate uptake factors obtained from Bechtel Jacobs (1998; Table 2; all data). Value selected is median uptake factor for depurated and non-depurated invertebrates combined expressed on a dry weight basis.
Invertebrate tissue $_{dw}$ = (uptake factor x sediment concentration)
[c] Median biota-sediment accumulation factor (BSAF) and lipids content for benthic invertebrates obtained from BSAF Data Set available at http://www.epa.gov/med/Prods_Pubs/bsaf.htm. See Table 3 for data.
Median lipid values from supporting studies and median site-specific sediment organic carbon used to determine tissue levels.
Median lipid levels for benthic invertebrates were -
4.2% (0.042 fraction lipids) for PCBs
Median site-specific TOC is 13% (0.13 fraction organic carbon) based on samples collected from 20 locations in 2011 and 2019 (see Attachment A for data).
Invertebrate tissue $_{dw}$ = [BSAF x sediment concentration x (fraction lipid/fraction organic carbon)]/(1-% moisture)
[d] Sediment-to-invertebrate factors obtained from Los Alamos National Laboratory (LANL) EcoRisk database version 4.1 (LANL, 2017).
Invertebrate tissue $_{dw}$ = (uptake factor x sediment concentration)
[e] Soil-to-plant uptake factors and regression equations recommended by USEPA in development of Ecological Soil Screening Levels (USEPA, 2007a)

copper	ln(tissue concentration) = 0.394 * ln(soil concentration) + 0.668
lead	ln(tissue concentration) = 0.561 * ln(soil concentration) - 1.328
nickel	ln(tissue concentration) = 0.748 * ln(soil concentration) - 2.223
selenium	ln(tissue concentration) = 1.104 * ln(soil concentration) - 0.677

[f] Soil-to-plant uptake factor obtained from Los Alamos National Laboratory (LANL) EcoRisk database version 4.1 (LANL, 2017).
[g] Value for Aroclor 1254 used for Total PCBs.

TOTAL PCBs	*1.8*	*LOAEL*	*reproduction*	*chronic*	*pheasant*	*Dahlgren et al., 1972 [a]*	*Sample et al., 1996*

Notes:
LOAEL values from USEPA Eco-SSL documents were calculated as the geometric mean of growth and reproduction LOAEL values.
NOAELs were estimated if a NOAEL was not identified in the literature. The LOAEL was divided by 10 to derive an estimated NOAEL.

Notes:
NOAELs were estimated if a NOAEL was not identified in the literature. The LOAEL was divided by 10 to derive an estimated NOAEL.

COPC - Chemical of Potential Concern.
LOAEL - Lowest Observed Adverse Effects Level.
NOAEL - No Observed Adverse Effects Level.
PCBs - Polychlorinated Biphenyls.
TRV - Toxicological Reference Value

[a] TRVs for Total PCBs are based on Aroclor 1254.

ATTACHMENT G-5 TABLE 5
POTENTIAL RISKS TO THE MARSH WREN IN THE OFF-PROJECT RED MAPLE SWAMP / TIDAL STREAM AREA - REFINED FOOD WEB MODEL
ECOLOGICAL RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

ASSUMPTIONS FOR THE MARSH WREN	
Average Body Weight (kg)	0.011
Exposure Duration	1
Area Use Factor	1
Hyd. Soil/Sediment Consumption Rate (kgdw/day)	0.000026
Wetland Invertebrate Consumption Rate (kg_{dw}/day)	0.0029

$$\text{Total Daily Dose} = \frac{\Sigma([IR_f \times C_f] + [IR_S \times C_S] + [IR_W \times C_W] \times ED \times AUF}{\text{Average Body Weight (kg)}}$$

Where:
IR_f = Ingestion rate of food (kg/day)
IR_S = Incidental ingestion rate of sediment or soil (kg/day)
IR_W = Drinking water ingestion rate(L/day)
C_f = Concentration of COPC in food (mg/kg)
C_S= Concentration of COPC in sediment or soil (mg/kg)
C_W= Concentration of COPC in water(mg/L)
ED = Exposure duration (fraction of time receptor spends within exposure area)

Notes:
COPC - Chemical of Potential Concern.
dw - Dry Weight.
EPC - Exposure Point Concentration.
HQ - Hazard Quotient (Dose/TRV).
LOAEL - Lowest Observed Adverse Effects Level.
NOAEL - No Observed Adverse Effects Level.
TRV - Toxicity Reference Value.
HQs above 1 are bolded and highlighted.
Maximum EPCs represent the 95% upper confidence limit (UCL) on the arithmetic mean (Attachment G-3).
Area Use Factor set at 1. Exposure area size of 7.6 acres is larger than receptor home range shown in Table 1.

Mabbett Purchase Order #5582

Leptocheirus plumulosus 28 Day Sediment Evaluation

1.0 INTRODUCTION

This report presents the results of toxicity tests carried out on sediment samples collected from the Blue Beach FUDS site located in Quonset Point, Rhode Island. Samples were provided by Mabbett & Associates, Stoneham, Massachusetts. Biological testing was based on programs and protocols developed by the US Environmental Protection Agency, (USEPA 2001, 1994) and ASTM (2019). Potential toxicological impacts of the samples were determined by conducting 28-day toxicity tests with the estuarine amphipod, *Leptocheirus plumulosus*. All testing, toxicological and analytical, was performed at Enthalpy Analytical, LLC (Enthalpy), Hampton, New Hampshire.

Toxicity tests expose groups of organisms to environmental samples, reference sites and laboratory control samples for a specified period to assess potential impacts. Analysis of variance techniques are used to determine if differences in a measured endpoint for organisms exposed to a test sample are significantly different from responses obtained from organisms exposed to field reference sites or laboratory control samples. Endpoints evaluated as part of these assays include survival, growth and reproduction.

2.0 MATERIALS AND METHODS

2.1 General Methods, Biological Evaluations

Toxicological and analytical protocols used in this program follow procedures outlined in *Standard Test Method for Measuring the Toxicity of Sediment-Associated Contaminants with Estuarine and Marine Invertebrates* (ASTM 2019), *Methods for Assessing the Chronic Toxicity of Marine and Estuarine Sediment-associated Contaminants with the Amphipod, Leptocheirus plumulosus* (USEPA 2001), *Methods for Assessing the Toxicity of Sediment-Associated Contaminants with Estuarine and Marine Amphipods* (USEPA 1994), and *Standard Methods for the Examination of Water and Wastewater*, 22nd Edition (APHA 2012). These protocols provide standard approaches for physical and chemical analyses and for the evaluation of toxicological effects of sediments on aquatic invertebrates.

2.2 Test Species

Leptocheirus plumulosus were obtained from cultures maintained by Aquatic BioSystems, Incorported (ABS) of Fort Collins, Colorado. The organisms used in the assay were size selected from those that pass through a 600μm sieve and are retained by a 500 μm screen at the start of the test.

2.3 Test Samples

Sediment samples collected for this project were received at Enthalpy in 2-gallon polyethylene buckets under chain of custody. Once received, samples were inspected to determine integrity, given unique sample numbers and logged into the laboratory sample management database. Samples were stored in a refrigerator maintained at 4$\pm$2°C. A listing of sample sites, sample collection, and receipt information is summarized in Table 1.

Sediment for the laboratory control treatment was collected from the Hampton-Seabrook Estuary, Hampton, New Hampshire. The area is not known to receive any direct industrial inputs and has been used as laboratory control sediment in the testing of marine sediments since 1978.

Overlying seawater used in the assays is pumped in from the Hampton-Seabrook Estuary and stored in holding tanks. Seawater is obtained through a filter system located on the bottom of the estuary at a point approximately 1 mile from the open ocean. Water in the holding tanks is re-circulated, which helps to ensure proper mixing and provides aeration. Water from the estuary has been used for the culture and maintenance of test organisms at Enthalpy since 1978.

Prior to testing samples, all samples were press sieved through a 2-mm stainless steel sieve (US Standard #10 sieve) to remove large stones, sticks, roots, man-made material and indigenous organisms. Once sieved, the sediment was homogenized and placed in test chambers. Overlying water was added immediately and the chambers were allowed to stabilize. During this period, the chambers received one volume addition daily and the pore water was measured for ammonia. The published threshold for *Leptocheirus* in waters with a pH of 7.7 is <60mg/L, measured as total ammonia, and <0.8mg/L, measured as unionized ammonia. Once the pore water ammonia was sufficiently below these levels, the assay proceeded.

2.4 *L. plumulosus* 28 Day Sediment Evaluation Methods

The 28-day amphipod sediment tests were conducted according to the methods provided in the ASTM (2019) and USEPA (2001, 1994). Endpoints measured at the completion of the assays were survival, growth and reproduction. Growth was measured as dry weight and dry biomass. Reproduction was measured as juvenile production per surviving amphipod and juvenile production per surviving female amphipod.

Test vessels were 1000 mL glass beakers containing approximately 175 mL of sediment and approximately 725 mL of overlying water. Test vessels were drilled at a consistent height, approximately 3 cm below the lip, and the drilled hole covered with nylon screen to facilitate water exchange without the loss of test organisms. Vessels were maintained in a water bath during the test. Depth of the water in the bath was set below the drain hole in the test vessel to eliminate flow of water from the bath into the test vessel. Test chambers were block randomized by replicate and placed in the water bath after addition of test sediments. Placement locations were generated by the CETIS™ v1.9.6.3 software program. The randomization order is included in Appendix A. The water bath was maintained in a limited access, temperature controlled room. Temperatures in the room and water bath were independently set at a temperature of 25°C. Temperature was recorded on an hourly frequency using a temperature logger placed in a surrogate vessel. The photoperiod in the test chamber was set at 16:8 hour light:dark. Lighting was supplied by cool white fluorescent and/or LED bulbs.

Each treatment group included 8 replicates with 20 randomly selected organisms per replicate, as well as a surrogate test chamber. The surrogate chamber was used to obtain water qualities during the assay without disturbing the test animals, and were treated the same as actual test chambers with the addition of animals and food but were not used to determine endpoint data.

Each day during the test, chambers received 1 volume of new seawater having similar salinity and temperature as the overlying water in the vessels. Water exchanges were facilitated by use of a distribution system designed to provide equal and regulated flow to each chamber. The system was activated manually by the addition of water during the test. Overlying water dissolved oxygen, pH, salinity, specific conductivity and temperature were measured daily in a surrogate chamber for each treatment. Test chambers were aerated in order to maintain dissolved oxygen levels at ≥60% saturation. Water quality measurements were completed prior to overlying water renewals. The total ammonia concentration of the overlying and pore water was measured on days 0, 7, 14, 21 and 28. In order to calculate the unionized ammonia levels in the pore water, the temperature, pH and salinity were also measured.

Test chambers were observed daily and any organisms found floating on the surface were noted on

the data sheets. Organisms were fed three times weekly with a 20 mg/mL suspension of flake fish food, dried alfalfa leaves, wheat grass powder and shrimp maturation feed. During the first 2 weeks of the assay, amphipods in each replicate were fed 1mL of the suspension at each feeding. The amount of food was increased to 2mL for the last 2 weeks of the assay.

After the 28 days exposure, organisms were recovered from the sediments. Each test chamber was gently swirled to loosen the sediments and the test material was dumped into stacked 8" stainless steel sieves with 710 and 355 μm mesh (US Standard #25 and #45) sieves. The sediments were washed through the sieve using water and material left on the screen was sorted to recover all amphipods. This process was continued until the entire sample was evaluated. Juvenile *L. plumulosus* were discarded once they were counted. Adult *L. plumulosus* were differentiated from juveniles following sieving (adults are retained on the larger top sieve) and based on a visual inspection of size. Adult organisms were preserved with formalin solution and sexed. Adults were then placed on tared weighing pans and dried overnight at $104 \pm 6^{\circ}$C to obtain dry weight to the nearest 0.01 mg. The mean weight of surviving adult organisms was determined to assess growth.

2.5 Statistical Analysis

Survival, growth and reproduction data were analyzed using CETIS™ v. 1.9.6.3 software to determine significant differences between the test sediments and the associated laboratory control and reference locations. Data sets were evaluated to determine normality of distribution and homogeneity of sample variance. Data sets were subsequently evaluated using the appropriate parametric or non-parametric Analysis of Variance (ANOVA) statistic. If outliers were found in the data set, then the analysis was conducted both with and without the outlier included in the data set. Statistical comparisons were made for the following endpoints: survival, dry weight, dry biomass, juvenile production per surviving amphipod (CETIS endpoint “reproduction”) and juvenile production per surviving female. Pair-wise comparisons were made using the appropriate statistical evaluation. Statistical difference was evaluated at $\alpha = 0.05$.

2.6 Reference Toxicant Evaluation

As part of the laboratory quality control program, reference toxicant evaluations are conducted by Enthalpy on a regular basis for each test species. These results provide relative health and response data while allowing for comparison with historic data sets. Results are summarized in Table 2.

3.0 RESULTS AND DISCUSSION

Table 3 provides a summary of assay acceptability criteria and laboratory control achievement, and Table 4 provides a summary of exposure conditions. Table 5 summarizes the endpoint performances for each reference site. Tables 6 through 11 summarize assay endpoints and detailed statistical results for individual endpoints, and Table 12 summarizes the findings of significant effects on amphipods for all endpoints. Tables 13 and 14 summarize ammonia data in overlying water and pore water, respectively.

3.1 Laboratory Control Performance

Following the 28-day exposure period, mean amphipod survival in the laboratory control sediment was 91%, had a coefficient of variation (CV) of 14% and a minimum inter-replicate survival rate of 60%. Test acceptability criteria require ≥80% survival on day 28 with no individual replicate having <60% survival. The mean dry weight of surviving amphipods at the end of the assay was 1.07 mg/organism. The mean dry weight of 40 randomly selected amphipods at the start of the assay was 0.253 mg/organism. The overall mean juvenile production was calculated to be 2.4 juveniles/surviving amphipod. Protocol requires that organisms must show some evidence of growth and reproduction (ASTM, USEPA). Based on the data, the amphipods are considered healthy and the overlying water was determined to have had no adverse impact on the outcome of the assay.

Mean reference site survival ranged from 56% (Sed-325) to 86% (Sed-324), and all reference site samples showed evidence of growth and reproduction.

3.2 Water Quality Data

Tables 4, 13 and 14 summarize water quality data collected during the assay. Temperature data collected during the daily water quality observations documented a mean value of 24.8°C with a range of 20.0 to 26.1°C. Confirmation temperature data collected on an hourly basis from a data logger documented a mean value of 23.8°C with a range of 19.7 to 25.6°C. Salinity levels ranged from 17.8 to 22.0‰ with a mean value of 20.5‰. Dissolved oxygen ranged from 55% to 97%. Target exposure conditions are a mean temperature of 25±1°C with maximum temporary fluctuations of 25±3°C, salinity within a range of 20±2‰ and dissolved oxygen ≥60%. See Section 3.3.2 for a discussion of the temperature and dissolved oxygen excursions.

3.3 Protocol Deviations and Exposure Condition Excursions

3.3.1 Protocol Deviations

Review of data generated during the 28-day exposure period revealed one deviation from the method protocol or Enthalpy's SOP. There were a few instances (replicate 2 of Sed-339 and replicate 6 of Sed-333) in which 21 adult amphipods were found in a test chamber at assay termination, therefore the same number were presumed to have been added at the start of the assay for purposes of the statistical analyses. This is a reasonable assumption as technicians are checked for their ability to count live organisms and the staff on hand have documented a high degree of counting accuracy. Despite this, counting errors can occur. These impacts are mitigated by the test design. Testing incorporated 8 replicates for each sample, thereby reducing the impact of a single replicate on the overall assessment. It is the opinion of Enthalpy's study director that this deviation did not adversely affect the outcome of the assay.

3.3.2 Exposure Condition Excursions

Review of data generated during the 28-day exposure period revealed that temperature readings recorded by the hourly temperature logger dropped below Enthalpy's standard protocol range of 25±3°C for a period of 22 hours, from 11:53:16 AM on June 30th to 9:53:16 AM on July 1st (days 13 and 14 of the assay). The hourly temperatures dropped to a low of 19.7°C, and daily readings confirmed that temperatures fell below the target range in all treatments on day 14. The low readings were the result of a short circuit in the power connection, causing the GFC protection to trip and the water bath pump to turn off. The problem was fixed upon discovery the next morning, the pump was turned back on and temperatures climbed back into the target range. These values are still within the normal temperature range tolerated by *L. plumulosus*, and the mean temperature fell within the target range indicating that overall, the exposure condition objectives were achieved. It is the opinion of Enthalpy's technical director that this excursion had no adverse impact on the result of the assay.

A single dissolved oxygen measurement recorded in Sed-331 on June 25th (day 8 of the assay) fell slightly below the target lower threshold of 60% identified in Enthalpy's SOP. Nearly all of the remaining measurements were upwards of 80%. There was a notation on the daily record on day 8 indicating that an airline had fallen out of that sample and was put back into the water upon discovery. This isolated excursion had no adverse impact on the results of the assay.

4.0 SUMMARY

This program utilized protocols developed by the USEPA and ASTM to assess the potential toxicological impacts that exposure to sediments from the Blue Beach FUDS site would have on aquatic invertebrates. The results of the statistical analyses indicate that there was a pattern of significant adverse effects on amphipods following exposure to site samples Sed-331, Sed-335 and Sed-339 as compared to the laboratory control and most reference sites (all except reference sample Sed-321). Survival was significantly impacted in only one site sample (Sed-335), however all 3 samples had significant negative effects on amphipod growth and reproduction. There were no significant effects on amphipods following exposure to site samples Sed-333 or Sed-337 for any of the endpoints measured.

Note: Data were analyzed to determine significant differences between test sediments, reference sediments, and the laboratory control. Statistical difference was evaluated at α=0.05.

- "Y" Indicates that a statistical difference was identified.
- "-" Indicates that statistical analysis was not conducted.
- " " An empty cell indicates that a statistical difference was not found.
- "*" Indicates that the analysis was completed both with and without a statistical outlier and the findings were split (Yes and No).

Cc: James Provencher <james.provencher@enthalpy.com>, Kirk Cram <kirk.cram@enthalpy.com>, "Martin W, David" <martin@mabbett.com>, Herbert Jordan <Herbert@mabbett.com>, "Archer, Christine" <Christine.Archer@aecom.com>

Thank you Renee.

For our purposes, the reference samples will be SED-321, SED-322, SED-323, SED-324, and SED-325.

Thanks,

Steve

Subject: Re: Blue Beach FUDS Toxicity Testing

Greetings,

We received 10 sediment samples for the Blue Beach study today, and all samples were received in good condition.

I have attached a copy of the sample receipt documents for your reference.

Could you let me know if any of these samples should be treated as reference samples?

Please let me know if you have any questions.

Regards,

Renée Ashley McIsaac

Project Manager

Test Sediment Preparation Notes

Study: 34122

Client: Mabbett & Associates

Project: Blue Beach FUDS Site, Quonset, RI

Lab Code	Field ID	Sample Number	Initials & Date	Notes
34122-001	Sed-321-C120-0-0.5	001	PBS 06/02	2 gal bucket sieved. About 750 mL of roots detritus & earthworms removed. moist dark sediment throughout sample
34122-002	Sed-322-C120-0-0.5	002	BG 06/02/20	~2 gal sieved. ≈1.5L excluded of rocks, roots, and a couple of earthworms. Sediment was very soil-like in that it was trapped in roots and fairly well moistened.
34122-003	Sed-323-C120-0-0.5	003	PBS 06/04/20	2 gal bucket sieved. 600 mL of rock + roots removed moist dark sediment.
34122-004	Sed-324-C120-0-0.5	004	JTP 06/02/20	2 gallons sieved. ≈ 1/2 gallon excluded. Small rocks, sticks. Granular, high moisture.
34122-005	Sed-325-C120-0-0.5	005	BG 06/02/20	2 gallons sieved. ≈ 1/2 gallon excluded of pebbles and roots. Sandy, high moisture.
34122-006	Sed-331-C120-0-0.5	006	JTP 06/03/20	2 gallons sieved, ≈ 1/2 gallon excluded. Sticks & reeds. Very high moisture, "jet" black color
34122-007	Sed-333-C120-0-0.5	007	BG 06/03/20	2 gallons sieved @ 4hm. ≈ 1/2 gallon excluded of roots and debris. Entire sample was a root ball with very fine sediment.
34122-008	Sed-335-C120-0-0.5	008	JTP 06/03/20	2 gallons sieved, ≈ 1/2 gallon excluded. Roots, Sticks, leaves. High moisture, black.
34122-009	Sed-337-C120-0-0.5	009	BG 06/03/20	2 gallons sieved. ≈ 100mL excluded of roots and debris. Black fine sediment, high moisture.
34122-010	Sed-339-C120-0-0.5	010	JTP 06/03/20	2 gallons sieved. ≈ 3/4 gallon excluded. All large rocks, Sandy / granular.

Note: Samples are to be sieved using a 2mm screen.

Notes:

Attachment 2 - Formulas Used to Derive Un-Ionized Ammonia (UIA) Fractions and USEPA Ammonia Criteria (Engle 2010)
Consistent with USEPA AWQC (1989) and Whitfield (1974).

Where: I = Ionic Strength (19.9273*N11)/(1000-1.005109*N11)
pKa = ionization constant of ammonium ion in aqueous saline solution (+9.245+0.116*Q11)
F_{NH3} = fraction of UIA (+1/(1+10^(R11+0.0324*(298-P11)+((0.0415*1)/P11)-M11)))
Tot NH3 = total ammonia, or QLimit if ND
pressure in F_{NH3} assumed to be 1 atm

Notes:

Attachment 2 - Formulas Used to Derive Un-Ionized Ammonia (UIA) Fractions and USEPA Ammonia Criteria (Engle 2010) Consistent with USEPA AWQC (1989) and Whitfield (1974).

Where: I = Ionic Strength (19.9273*N11)/(1000-1.005109*N11)

pKa = ionization constant of ammonium ion in aqueous saline solution (+9.245+0.116*Q11)

F_{NH3} = fraction of UIA (+1/(1+10^(R11+0.0324*(298-P11)+((0.0415*1)/P11)-M11)))

Tot NH3 = total ammonia, or QLimit if ND

pressure in F_{NH3} assumed to be 1 atm

Attachment J-1

Spearman Rank Order Correlation Tests

1.0 Introduction

The following sections present the statistical correlation tests conducted to support the Ecological Risk Assessment (ERA) for Former Blue Beach Disposal Area Formerly Used Defense Site (FUDS) in North Kingstown, Rhode Island.

Samples for sediment toxicity testing and macroinvertebrate community surveys were co-located with each other and with sediment chemistry samples. A statistical correlation test (Spearman's Rho) was conducted on the co-located samples to evaluate if sediment chemistry or physical data could be the cause of observed toxicity or degraded community.

As described in Section 4.6.2.3 of the ERA, 28-day sediment toxicity tests were conducted on 5 upstream reference samples and 5 downstream Site samples using the amphipod (*Leptocheirus. plumulosus*). All samples locations were also submitted for macroinvertebrate community survey metrics.

Chemicals of potential concern (COPCs) identified in the ERA as potential causes of sediment toxicity (polychlorinated biphenyls [PCBs], metals, and polycyclic aromatic hydrocarbon [PAHs]) were included in the correlation tests. The probable effect concentration quotient (PEC-Q) for freshwater and effects range-median quotient (ERM-Q) for marine sediment for each sample (i.e., concentration divided by PEC) were included along with hazard quotients (HQs) and measures of bioavailability for divalent metals (sum of simultaneously extracted metals [SEM] subtracted by acid volatile sulfides [AVS] divided by fraction organic carbon [f_{oc}], expressed as $\sum$SEM-AVS/f_{oc}). In addition, physical parameters (total organic carbon [TOC] and fines).

Non-parametric Spearman rank correlations were conducted using the co-located sediment chemistry, sediment toxicity test, and macroinvertebrate community survey metrics results to evaluate potential relationships between chemistry, toxicity, and community. The following endpoints and metrics were included in the correlations:

- Toxicity Test Endpoints: 28-day survival, 28-day biomass, 28-day growth, or 28-day reproduction for the amphipod
- Macroinvertebrate Community Survey Metrics: Shannon Diversity, Hilsenhoff Biotic Index (HBI), total richness, and total density
- Physical parameters: TOC and fines
- Measures of bioavailability: $\sum$SEM-AVS/f_{oc}
- Sediment chemistry:
    - HQs for probable effect total HMW PAHs, total LMW PAHs, and total PAHs
    - PEC-Qs for total PAHs and total PCB Aroclors and mean metals PEC-Qs
    - Mean PEC-Qs calculated for metals and total PAHs and metals, total PAHs, and total PCB Aroclors
    - ERM-Qs for total PAHs and total PCB Aroclors and mean metals ERM-Qs

- Mean ERM-Qs calculated for metals and total PAHs and metals, total PAHs, and total PCB Aroclors

Correlations were conducted using the statistical software Minitab (version 18.1). Mean toxicity test results (not individual replicate results) were used for all the test endpoints. Non-detected sediment chemistry concentrations were included at the limit of detection. Correlations were significant if the p-value was less than 0.05.

2.0 Correlation Results

The results of the correlation tests are presented in **Table 1**. Supporting calculations and a summary of the input data used for the correlation tests are presented in **Tables 2, 3, 4, and 5**.

The correlation tests did not show significant relationships ($p<0.05$) for any paired chemistry, toxicity test, and macroinvertebrate community survey metrics results. In addition, physical parameters (TOC and fines) or measures of bioavailability ($\sum$SEM-AVS/f_{oc}) were not significantly correlated with toxicity test results or macroinvertebrate community survey metrics.

Notes:
All results reported in milligrams per kilogram (mg/kg).
HMW - High Molecular Weight.
ERM - Effects Range-Median (Buchman, 2008).
ERM-Q - ERM-quotient (concentration/ERM).
LMW - Low Molecular Weight.
PAH - Polycyclic Aromatic Hydrocarbon.
PEC - Probable Effects Concentration (MacDonald, et al, 2000).
PEC-Q - PEC-quotient (concentration/PEC).
Probable Effect HQ - Probable Effect Hazard Quotient (concentration/UET). Calculated when PECs were not available.
UET - Upper Effects Threshold (Buchman, 2008).

Derivation of Reference Envelope Values and Application in Sediment Quality Triad Evaluation

1.0 Introduction

The following sections provide a summary of the derivation of reference envelope values and the use of these values in a sediment quality triad as part of the Ecological Risk Assessment (ERA) for the tidal stream located within the off-Project Red Maple Swamp/tidal stream area of the Former Blue Beach Disposal Area Formerly Used Defense Site (FUDS) in North Kingstown, Rhode Island (the Project).

Bulk sediment chemistry data, toxicity testing results, and macroinvertebrate community survey results are available from ten sampling locations within the tidal stream: five located between Circuit Drive and outfall 025 and five located between outfall 025 and Narragansett Bay. For the interpretation of these data in the ERA, the upstream portion of the stream located between Circuit Drive and outfall 025 represents the upstream background/reference area and the samples located downstream from outfall 025 are referred to as Site.

A sediment quality triad evaluation was conducted to determine if Site sample results for bulk sediment chemistry, toxicity testing, and biological community surveys are impacted for benthic invertebrate communities compared to the upstream background/reference conditions. The data collected upstream from outfall 025 are representative of local conditions in the absence of Project-related contaminants and were used as reference samples in the evaluation of the biological data. As described below, reference envelope values (REVs) were derived using data from the upstream background/reference samples and the REVs were used to identify potential Project-related impacts in Site samples using the sediment quality triad approach identified by Chapman (1992).

2.0 Reference Envelope Derivation

A reference envelope approach was used in the sediment quality triad to incorporate the spatial and temporal variation observed in the upstream background/reference samples (Hunt et al., 2001). REVs were derived for bulk sediment chemistry, toxicity testing endpoints, and community survey metrics using data from the five upstream background/reference samples to represent reference conditions for comparisons against the Site sample responses.

The Site and reference samples included in the REV derivation and sediment quality triad included those samples for which a complete and consistent dataset are available for bulk sediment chemistry, toxicity tests, and macroinvertebrate community survey. Samples for which bulk sediment chemistry data were available, but not toxicity test or macroinvertebrate community survey data, were excluded.

The lower or upper limit REVs were derived based on tolerance limits or the minimum or maximum observed values in the dataset as follows. Lower or upper tolerance limits were calculated for each line of evidence following an approach detailed by Hunt et al. (2001). Lower tolerance limits (LTLs) were used for endpoints where a lower value indicates impact (e.g., growth or reproduction in the toxicity test). Upper tolerance limits (UTLs) were used for endpoints where a higher value indicated impact (e.g., community metrics like Hilsenhoff Biotic Index [HBI] or bulk sediment related values).

If these lower or upper bounds exceeded the minimum or maximum observed values in the reference dataset, respectively, then the latter (i.e., the minimum or maximum observed reference value) was selected as the REV. Therefore, the selected REV for an endpoint falls within the range of responses observed for the reference dataset. Site test results that fall below or above the REVs indicate the Site benthic community is adversely impacted compared to the reference conditions.

The following toxicity test endpoints and benthic macroinvertebrate community survey metrics were selected for inclusion in the REV derivation:

- 28-day amphipod (*Leptocheirus plumulosus*) sediment toxicity – Mean biomass endpoint and reproduction endpoint (as mean juveniles per surviving amphipod) as sensitive measures of impacts in the toxicity tests (these endpoints showed the most frequent individual statistical differences [see Table 4-19 in the ERA]).

    - For both endpoints, a negative relationship indicates an adverse impact and a lower limit REV was selected

- Benthic Macroinvertebrate Community – Total richness, total density, and HBI as measures of diversity and pollution tolerance.

    - For total density and total richness, a negative relationship indicates an adverse impact and a lower limit REV was selected

    - For HBI, a positive relationship indicates an adverse impact and an upper limit REV was selected

Bulk sediment data for potentially Project-related chemicals were also included in the REV derivation. These chemicals include polychlorinated biphenyls (PCBs), metals, and polycyclic aromatic hydrocarbon (PAHs). These data were considered by calculating probable effect concentration quotients (PEC-Q) based on freshwater benchmarks and effects range-median quotients (ERM-Q) based on marine benchmarks. These PEC-Qs and ERM-Q were calculated in Attachment J-1 as the chemical concentration in a sample divided by the associated PEC (MacDonald et al., 2000) or ERM (Buchman, 2008). For metals, the mean PEC-Q (and ERM-Q) metals were determined as the average of the individual metals PEC-Q (and the average of the individual metals ERM-Qs). The REV considered the following two parameters for bulk sediment chemistry:

- mean of the Total PAHs, Total PCBs, and mean metals PEC-Qs

- mean of the Total PAHs, Total PCBs, and mean metals ERM-Qs

For both parameters, a positive relationship indicates an adverse impact and an upper limit REV was selected.

Table 1 presents the data evaluations and REV derivations for the toxicity test endpoints, community metrics, and bulk sediment chemistry, respectively. LTL and UTL statistics were calculated in Minitab (Version 18) and the output is presented at the end of this attachment. The data used in the REV derivations is presented in Attachment J-1 (Table 5).

Prior to the derivation of the REVs, each dataset was tested for a normal distribution using the Shapiro-Wilk test. All datasets were found to be normally distributed. Lower or upper tolerance limits were calculated as the lower or upper bound of a one-tailed tolerance interval (alpha of 0.05) with at least 90% of the population covered (Hunt et al., 2001). For all toxicity test and bulk sediment chemistry endpoints and benthic macroinvertebrate community metrics, the lower or upper tolerance limits were less than the minimum or greater than the maximum observed values, respectively. Therefore, the observed values (minimum or maximum) were selected as the REVs.

3.0 Sediment Quality Triad Evaluation

The REVs provided in **Table 1** were used to evaluate the results of co-located bulk sediment chemistry, sediment toxicity tests, and benthic invertebrate community surveys conducted on five Site samples collected within the tidal stream. The sediment quality triad approach identified by Chapman (1992) was

used to evaluate the potential for Project-related sediment impacts on the biological community within the tidal stream.

Table 2 provides a comparison of each REV against each of the individual Site endpoints for sediment contamination, sediment toxicity, and benthic alteration (i.e., benthic macroinvertebrate community impacts). Results that are outside the REV (i.e., above or below the REV as described in Section 2.0) and indicative of a potential adverse impact on the benthic community are identified with a positive ('+') symbol. A negative ('–') symbol indicates a result that is within the REV for the endpoint.

The three triad elements (i.e., sediment contamination, sediment toxicity, benthic alteration) are each scored with '+' or '-' depending upon whether an individual endpoint for that element was outside the REV. Each triad element was assigned a '+' if any of the included individual endpoints was outside the REV. A triad element was assigned a '–' if all of the individual endpoints were within the REV. The evaluation of the individual endpoints identified the following findings for each triad element:

- **Sediment contamination** – Two samples (SED-331 and SED-335) were identified as outside the REV. SED-331 was outside the REV for marine benchmarks (ERM-Qs) but not for freshwater benchmarks (PEC-Qs). SED-335 was outside the REV for both freshwater and marine benchmarks.

- **Sediment Toxicity** – Three samples (SED-331, SED-335, SED-339) were identified as outside the REV based on the results of the 28-day sediment toxicity test. SED-331 and SED-339 were outside the REV for the reproduction endpoint, but not for biomass. SED-335 was outside the REV for both biomass and reproduction.

- **Benthic alteration** – Only one sample (SED-337) was identified as outside the REV based on the benthic invertebrate community metrics. SED-337 was outside the REV for the HBI metric (higher values are indicative of more pollution tolerant communities). None of the samples were outside the REV for total richness or total density.

The findings for each element of the triad were interpreted based on a matrix provided by Chapman (1992) and are provided in **Table 2**. The matrix shown below identifies the eight possible outcomes for each sample depending upon the findings from each of the triad elements.

Outcome Number	Sediment Contamination	Toxicity	Benthic Alteration	Possible Conclusions
1	+	+	+	Strong evidence for pollution-induced degradation
2	-	-	-	Strong evidence that there is no pollution induced degradation
3	+	-	-	Chemicals are not bioavailable
4	-	+	-	Unmeasured chemicals or conditions exist with the potential to cause degradation
5	-	-	+	Alteration is not due to toxic chemicals
6	+	+	-	Toxic chemicals are stressing the system
7	-	+	+	Unmeasured toxic chemicals are causing degradation
8	+	-	+	Chemicals are not bioavailable or alteration is not due to toxic chemicals
+ Indicates response was outside the REV. - Indicates response was within the REV.				

Based on the categories identified by Chapman (1992) and comparisons to REVs, the sediment quality triad evaluation indicates that:

- None of the samples showed adverse impacts for all three elements of the triad.

- SED-333 did not show adverse impacts relative to the reference envelope values for any of the triad components which, according to Chapman (1992), provides "strong evidence that there is no pollution induced degradation."

- The remaining four samples showed an impact relative to the REVs with respect to at least one element of the triad but did not necessarily support an indication of COPC-related benthic invertebrate community impacts.

    - SED-331 and SED-335 showed impacts to the sediment chemistry and toxicity portions of the triad but not to the macroinvertebrate community.

    - SED-339 showed impacts to the toxicity portion of the triad (based on reproduction only) but not to sediment chemistry or macroinvertebrate community.

    - SED-337 showed impacts to the macroinvertebrate community portion of the triad (based on HBI only) but not to sediment chemistry or toxicity.

According to Chapman (1992), based on the impacts for two triad components including sediment chemistry, the findings for SED-331 and SED-335 suggest that "toxic chemicals are stressing the system."

Although sediment chemistry results are part of the sediment quality triad evaluation, comparisons to bulk sediment benchmarks such as the PECs or ERMs may overestimate potential risks to the benthic community. Consideration of additional information that accounts for bioavailability of contaminants (e.g., sulfides, organic carbon) is also useful in evaluating whether Project-related COPCs explain observed biological impacts.

The ERA indicated the Total PCBs were the only COPC retained in the Step 3a refined screening for tidal stream sediments (see Table 4-17 in the ERA). A sample-by-sample review of Total PCB concentrations, shows that PCBs were not detected in the SED-331 sample and the Total PCB concentration for SED-335 was 1.5 mg/kg (above the PEC and ERM, but well below the sample-specific 10% benthic injury benchmark; see Table 4-25 in the ERA). In addition, PCBs were analyzed but not detected in total or dissolved phase porewater collected from five sediment locations in and near the tidal stream in 2011 (data presented in Attachment A). These results suggest that PCBs are not likely to be the cause of impacts at these locations (or other locations in the stream).

A review of the PEC-Q and ERM-Qs calculated in Attachment J-1 show that the quotients based on metals and Total PAHs for these two samples were less than 1, suggesting that these chemicals are not likely to result in adverse impacts to the benthic community.

In addition, the evaluation of co-located simultaneously extracted metals (SEM), acid volatile sulfides (AVS), total organic carbon (TOC) data, indicated that the divalent metals were not likely to be bioavailable at any locations in the stream (see Table 4-18 in the ERA). These two samples did have among the highest TOC levels in the stream, 44% for SED-331 and 19% for SED-335, which suggests samples were collected from depositional areas.

Although the sediment quality triad indicated the potential for COPC-related impacts, primarily related to PCBs, the sample-by-sample PCB evaluation and the lack of statistical correlations between biological responses and PCBs (or other chemical stressors) suggests that observed impacts are not associated with Project-related chemicals.

3.1 Sediment Quality Triad Conclusions

The evaluation of bulk sediment chemistry, sediment toxicity testing, and benthic invertebrate community survey results found that none of the samples showed adverse impacts for all three elements of the triad. One sample (SED-333) did not show impacts relative to the REVs for any of the triad components.

The remaining samples showed impacts for one or two components. SED-339 showed an impact for the toxicity component and SED-337 showed an impact for the invertebrate community component; however, neither sample showed an impact for sediment chemistry, so impacts are not Project-related.

SED-331 and SED-335 showed impacts for two triad components including sediment chemistry, suggesting that impacts could be related to chemicals detected in the sediment. However, a review of PCB benchmark exceedances, individual PEC-Qs, ERM-Qs, and SEM, AVS, TOC results, and a lack of significant correlations with chemical stressors, suggests that observed impacts are not associated with Project-related chemicals.

Notes:
ERM-Q - Effects Range Median Quotient (marine benchmark evaluation).
LTL - Lower Tolerance Limit
PEC-Q - Probable Effect Concentration Quotient (freshwater benchmark evaluation).
REV - Reference Envelope Value
UTL - Upper Tolerance Limit

The upstream background/reference dataset includes the following samples : SED-321, SED-322, SED-232, SED-324, and SED-325.
The LTL is calculated as one-sided lower-bound tolerance interval with 95% confidence with at least 90% of population covered.
If the LTL is lower than the minimum observed value, then the minimum was selected as the REV.
The UTL is calculated as one-sided upper-bound tolerance interval with 95% confidence with at least 90% of population covered.
If the UTL is higher than the maximum observed value, then the maximum was selected as the REV.

SED-337	0.32	0.61	1.4	3.8	4	84	9.8	-	-	+	Alteration is not due to toxic chemicals
SED-339	0.077	0.20	0.63	0.34	15	175	7.3	-	+	-	Unmeasured chemicals or conditions exist with the potential to cause degradation.

Notes:
Shading indicates a response outside the reference envelope.
A result above the reference envelope is assigned a + (impacted) for these endpoints: mean PEC-Qs, mean ERM-Qs, and HBI.
A result below the reference envelope is assigned a + (impacted) for these endpoints: biomass and juveniles per amphipod endpoints from the toxicity tests, total richness, and total density.

PEC-Q - Probable Effect Concentration Quotient (freshwater benchmark evaluation).
ERM-Q - Effects Range Median Quotient (marine benchmark evaluation).

In the summary of responses for each triad component:
+ Indicates response was outside the reference envelope for at least one endpoint.
- Indicates response was within the reference envelope for all endpoints.
Interpretation of triad responses (Chapman, 1992).

Outcome Number	Sediment Contamination	Toxicity	Benthic Alteration	Possible Conclusions
1	+	+	+	Strong evidence for pollution-induced degradation
2	-	-	-	Strong evidence that there is no pollution induced degradation
3	+	-	-	Chemicals are not bioavailable
4	-	+	-	Unmeasured chemicals or conditions exist with the potential to cause degradation
5	-	-	+	Alteration is not due to toxic chemicals
6	+	+	-	Toxic chemicals are stressing the system
7	-	+	+	Unmeasured toxic chemicals are causing degradation
8	+	-	+	Chemicals are not bioavailable or alteration is not due to toxic chemicals
