FINAL
Comprehensive Remedial Investigation Report

FORMER BLUE BEACH DISPOSAL AREA FUDS

North Kingstown, Rhode Island

Formerly Used Defense Sites (FUDS)
Property and Project Number D01RI0488 01

October 2024

Prepared for

U.S. Army Corps of Engineers
New England District
696 Virginia Road
Concord, MA 01741

Contract No. W912WJ-19-D-0005
Delivery Order No. W912WJ-23-F-0029

TABLE OF CONTENTS

SECTION **PAGE**

1.0 INTRODUCTION 1-1
1.1 Regulatory Framework 1-1
1.2 Project and Property Definition 1-1
1.3 Purpose of Report 1-2
1.4 Report Organization 1-3
2.0 SITE BACKGROUND 2-1
2.1 Site History 2-1
2.2 Site Description 2-1
2.2.1 Former Blue Beach Disposal Area FUDS Project (On-Project) 2-1
2.2.2 Walking Path and Blue Beach Recreational Beachfront (Off-Project) 2-2
2.2.3 Red Maple Swamp (Off-Project) 2-3
2.3 Demographics 2-3
2.4 Groundwater Resource Use and Classification 2-3
2.5 Environmental Land Use Restrictions 2-4
3.0 SUMMARY OF HISTORICAL AND RECENT SITE INVESTIGATIONS 3-1
3.1 Historical Investigations and Remedial Measures 3-2
3.1.1 Drum Removal & Soil Investigation, 1984 3-2
3.1.2 Contaminant Confirmation Study, 1988 3-2
3.1.3 Soil Gas Survey at Blue Beach Disposal Site, 1992 3-3
3.1.4 Engineering Evaluation of Contamination, 1993 3-3
3.1.5 Supplemental Engineering Evaluation of Contamination, Kiefer Park/Blue Beach, 1994 3-5
3.1.6 Remediation and Disposal of Buried Drums at Blue Beach Disposal Site, 1996 3-6
3.1.7 Blue Beach PCB Remediation and Debris Consolidation, 1998-1999 3-6
3.1.8 Phase I/II Environmental Site Assessment, 2001 3-6
3.1.9 Geotechnical Investigation for the Proposed Goldline Controls Building, July 2001 3-7
3.1.10 Phase III Investigation and Remediation Activities, 2001-2002 3-8
3.1.11 Limited Site Seepage Investigation, 2002 3-8
3.1.12 Geophysical Survey, 2009 3-9
3.1.13 USACE Groundwater Monitoring, 2005-2009 3-9
3.1.14 Soil Vapor Sampling, 2006 3-10
3.1.15 Blue Beach/Kiefer Park – Quonset Point, Rhode Island, Examination of Historical Photography 3-10
3.2 Former Kiefer Park Tank Farm 3-11
3.2.1 Remedial Actions at the Former Kiefer Park Tank Farm FUDS 3-11
3.2.2 Former Kiefer Park Interceptor Trench 3-12
3.3 Recent Site Investigations, 2011-2020 3-13
3.3.1 2011 Investigation 3-13
3.3.2 2011 Geophysical Anomaly Area Findings and Debris Removal 3-14
3.3.3 2014 Investigation 3-16
3.3.4 2015 Investigation 3-17
3.3.5 2019-2020 Investigation 3-18
4.0 PHYSICAL CHARACTERISTICS OF THE SITE 4-1
4.1 Surface Features (Physiography) 4-1
4.1.1 Regional 4-1
4.1.2 Site 4-1

APPENDIX

A Draft Final Human Health and Ecological Risk Assessment Report

LIST OF ACRONYMS

ADR	Automated Data Review
ASTM	American Society for Testing Materials
avgas	Aviation Gasoline
AVS	Acid Volatile Sulfides
bgs	Below Ground Surface
BTEX	Benzene, Toluene, Ethylene, Xylene
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
COC	Contaminant of Concern
COPC	Contaminant of Potential Concern
CRMC	Coastal Resource Management Counsel
CSM	Conceptual Site Model
CTE	Central Tendency Exposure
CVOC(s)	Chlorinated Volatile Organic Compound(s)
CY	Cubic Yard
DCE	Dichloroethene
DERP	Defense Environmental Restoration Program
DNAPL	Dense Non-Aqueous Phase Liquids
DoD	Department of Defense
EDC	Economic Development Corporation
ELCR	Excess Lifetime Cancer Risk
ELUR	Environmental Land Use Restrictions
EM	Engineering Manual
EM-31	Electromagnetics-31
EOD	Explosive Ordnance Disposal
ER	Engineering Regulation
EP	Engineering Pamphlet
ERA	Ecological Risk Assessment
ERM	Environmental Resource Map
ESI	Environmental Sensitivity Index
ESV	Ecological Screening Value
FID	Flame Ionization Detector
FOD	Frequency of Detection
FS	Feasibility Study
FUDS	Formerly Used Defense Sites
GC	Gas Chromatograph
GPR	Ground Penetrating Radar
GSA	General Services Administration
HHRA	Human Health Risk Assessment
HI	Hazard Index
HQ	Hazard Quotient
HTRW	Hazardous, Toxic, and Radioactive Waste

LIST OF ACRONYMS (CONT.)

IDW	Investigation Derived Waste
ILOC	Interim Letter of Compliance
ISM	Incremental Sampling Methodology
LNAPL	Light Non-Aqueous Phase Liquids
LOAEL	Lowest Observed Adverse Effect Level
µg/L	Micrograms per liter
µg/kg	Micrograms per kilogram
µg/m3	Micrograms per Cubic Meter of Air
MCL	Maximum Contaminant Level
MEK	Methyl Ethyl Ketone/2-Butanone
mg/kg	Milligrams per kilogram
MSL	Mean Sea Level
MTBE	Methyl Tert-Butyl Ether
NAS	Naval Air Station
NCP	National Oil and Hazardous Substances Pollution Contingency Plan
NOAEL	No Observed Adverse Effect Level
NRCS	Natural Resources Conservation Service
OC	Organic Carbon
OSWER	Office of Solid Waste and Emergency Response
PA	Preliminary Assessment
PAH	Polycyclic Aromatic Hydrocarbon
PCB	Polychlorinated Biphenyl
PCE	Tetrachloroethene
PID	Photoionization Detector
ppmv	Parts Per Million by Volume
QA/QC	Quality Assurance/Quality Control
QDC	Quonset Development Corporation
RCRA	Resource conservation and Recovery Act
RI	Remedial Investigation
RIEDC	Rhode Island Economic Development Corporation
RICC	Rhode Island Commerce Corporation
RIDEM	Rhode Island Department of Environmental Management
RIPA	Rhode Island Port Authority
RME	Reasonable Maximum Exposure
RQD	Rock Quality Designations
RSL	Regional Screening Level
SAP	Sampling and Analysis Plan
SARA	Superfund Amendments and Reauthorization Act
SDWA	Safe Drinking Water Act
SEM	Simultaneously Extracted Metals
SI	Site Investigation
SLERA	Screening-Level Ecological Risk Assessment

LIST OF ACRONYMS (CONT.)

SMP	Soil Management Plan
SSDS	Subslab Depressurization System
SVOC	Semi-Volatile Organic Compound
TAL	Target Analyte List
TCA	Trichloroethane
TCL	Target Compound List
TCE	Trichloroethene
TOC	Total Organic Carbon
TPH	Total Petroleum Hydrocarbons
TRPH	Total Recoverable Petroleum Hydrocarbons
UU/UE	Unlimited Use/Unrestricted Exposure
UCL	Upper Concentration Limit (RIDEM) / Upper Confidence Limit (Risk Assessment)
USACE	U.S. Army Corps of Engineers
USAGC	U.S. Army Geospatial Center
USC	U.S. Code
USDA	U.S. Department of Agriculture
USEPA	U.S. Environmental Protection Agency
USGS	U.S. Geological Survey
UST	Underground Storage Tank
UXO	Unexploded Ordnance
VC	Vinyl Chloride
VOC	Volatile Organic Compounds

EXECUTIVE SUMMARY

This Comprehensive Remedial Investigation (RI) Report was prepared by Mabbett & Associates, Inc. (Mabbett) on behalf of the U.S. Army Corps of Engineers (USACE), New England District under Contract No. W912WJ-19-D-0005, Delivery Order No. W912WJ-23-F-0029. The Comprehensive RI was performed under the Defense Environmental Restoration Program (DERP) for Formerly Used Defense Sites (FUDS) in accordance with the requirements of USACE Engineering Regulation (ER) 200-3-1, dated 10 May 2004. Consistent with ER 200-3-1, the RI and risk assessments were performed in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). The Hazardous, Toxic, and Radioactive Waste (HTRW) risk assessments were performed in accordance with Engineering Pamphlet (EP) 200-1-15 for Standard Scopes of Work for Environmental Risk Assessments for the USACE.

The Former Blue Beach Disposal Area FUDS (Blue Beach Project) is located in North Kingstown, Rhode Island (Figure ES-1). The portion of FUDS property that was historically occupied by the Former Blue Beach Disposal Area is referred to in this report as the "Project" (Figure ES-2). The Site has since been redeveloped as part of a larger industrial park. Releases of chemical constituents to the environment from historical operations at the former Blue Beach Disposal Area were evaluated in this RI report. The nature and extent of constituents potentially originating from the Blue Beach Project include downgradient migration from the original source of release; the area impacted by site-related constituents is referred to in this RI as the "Site".

The Site encompasses an area approximately 21.5 acres in size and is comprised of the Former Blue Beach Disposal Area FUDS (Project Area) and the off-Project areas subsequently impacted by constituents migrating from the Project which include a walking path, tidal stream, Red Maple Swamp, and the Blue Beach recreational area (Figure ES-3).

Abutting the Site to the north and west, and immediately upgradient, is the Former Kiefer Park Tank Farm FUDS. In early investigations of this portion of the former Quonset Naval Air Station, the two sites were often investigated together, leading to the conclusion that the Former Kiefer Park Tank Farm FUDS is the primary source of petroleum-related constituents to the Blue Beach Project Area. Releases from the Former Kiefer Park Tank Farm appear to have impacted the western and northwestern portions of the Blue Beach Project and the adjacent Red Maple Swamp/tidal stream, whereas the Former Blue Beach Disposal Area (the subject of this RI) appears to be the primary source for metals, polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and chlorinated volatile organic compounds (CVOCs) released to the environment in the Red Maple Swamp/tidal stream. Petroleum-related constituents at the Blue Beach FUDS are being addressed through a RI Interim Letter of Compliance (ILOC) under FUDS Property and Project NO. D01RI002912, and therefore are not included as part of this RI.

Remedial measures have been taken on both FUDS and based on most recent data, appear to have mitigated on-going releases such that residual contaminant levels in environmental media are relatively low and either steady or decreasing. Remedial measures on the Former Blue Beach Project have included the excavation of PCB-containing soils and the consolidation of soils under an asphalt cap or transportation and disposal of soils at an off-site facility (1998-1999 and 2001), removal of unexploded ordnance (UXO) scrap items and other debris during a 1998-1999 removal action, and removal and off-site disposal of debris during a 2011 test pitting investigation within an apparent CVOC source area. Removal actions taken in response to the release of petroleum hydrocarbons from the Former Kiefer Park Tank Farm, which have also improved environmental conditions at the Former Blue Beach Disposal Area, included installation of a product recovery trench and light-non-aqueous-phase liquid (LNAPL) recovery system to remove petroleum product to the north and west (upgradient) of the Blue Beach Project Area.

Data from RI sampling events completed in 2014 and 2019 were selected as most representative of current Site conditions following the completion of remedial actions and source removal on both FUDS. These data were used

to characterize the nature and extent of constituents in on- and off-Property media and were used to support the human health and ecological risk assessments for the Site (the risk assessment did make use of environmental sampling results collected before 2014 to provide additional data to inform certain exposure scenarios). Constituents from both FUDS were identified in off-Property media, including in surface soils, subsurface soils, hydric soils, sediments, pore water, and groundwater. The risk assessments considered local and regional background concentrations of PAHs and metals to distinguish between FUDS contamination and natural or anthropogenic background levels of these constituents.

Although concentrations of Project-related constituents were detected in environmental media throughout the on-Project and off-Project areas, the human health and ecological risk assessments concluded that, under current and reasonably foreseeable land use scenarios, constituents from the Property a) do not pose human health risks above USEPA target values for noncarcinogenic or carcinogenic risks and b) were not identified as posing ecological risk or warranting further evaluation for ecological risk under CERCLA.

No residential use of the Site is reasonably anticipated, and therefore none of the exposure scenarios evaluated will require remedial action to address actionable risk. Potential future use of groundwater from the Site is already restricted through an Environmental Land Use Restriction (ELUR) that was implemented as part of the groundwater remedy for the Former Kiefer Park Tank Farm FUDS. Furthermore, RIDEM has classified groundwater in the developable portions of the Site as GB, indicating the water may not be suitable for consumption without treatment due to known or presumed degradation.

The comprehensive RI performed by USACE between approximately 2011 and 2020 concluded that the human health and ecological risks from constituents on the Project are within or below the USEPA's target risk range, with the exception of the potential future use of on-Project groundwater (i.e., drinking water and showering/bathing) under a hypothetical future residential exposure scenario. This scenario is not currently reasonably anticipated as a future use of the Site and an ELUR has been implemented as part of the groundwater remedy for the Former Kiefer Park Tank Farm FUDS that prohibits the use of groundwater as a potable supply.

While the risk assessments concluded no unacceptable risks to current and foreseeable receptors at the Site, a screening evaluation was conducted to ensure the protectiveness of groundwater resources at the Site that are classified for potable use. Off-Project groundwater in Red Maple Swamp is classified by RIDEM as GA, indicating that this groundwater is a groundwater resource known or presumed to be suitable for public or private drinking water use without treatment. While there are currently no drinking water wells present in this area and no foreseeable future plans to add a drinking water well, the analytical results for groundwater samples collected from the GA groundwater area were compared to RIDEM GA groundwater criteria (comprised of USEPA MCLs and state-specific standards for MtBE and naphthalene). Given the groundwater criteria exceedances (trichloroethene, vinyl chloride, benzo[a]pyrene, naphthalene, and lead), there remains potential for impacts to groundwater. To address this potential for impacts, remedial alternatives will be developed and evaluated for off-Project groundwater.

1.0 INTRODUCTION

This Comprehensive Remedial Investigation (RI) has been prepared by Mabbett & Associates, Inc. (Mabbett) for the U.S. Army Corps of Engineers (USACE), New England District under Contract Number W912WJ-16-D-0004, Task Order Number 0002. The Comprehensive RI was performed under the Defense Environmental Restoration Program (DERP) for Formerly Used Defense Sites (FUDS) in accordance with the requirements of Engineering Regulation (ER) 200-3-1, dated 10 May 2004.

The Former Blue Beach Disposal Area FUDS (Blue Beach Project) is located in North Kingstown, Washington County, Rhode Island. The FUDS identifying Property and Project number for the Blue Beach FUDS is D01RI0488 01 and the corresponding USACE New England District Project Number is 108369.

1.1 Regulatory Framework

The Department of Defense (DoD) has the responsibility to characterize and clean up former DoD facilities under the FUDS Program and the USACE is the lead agency responsible for environmental restoration of FUDS. The FUDS Program only covers properties transferred from DoD control prior to October 17, 1986. Investigations at the Blue Beach Disposal Area FUDS have been conducted under the FUDS Program since 1984.

The Comprehensive RI was conducted in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act §120 (42 United States Code (USC) § 9620) (CERCLA or Superfund) as amended by the Superfund Amendments and Reauthorization Act (SARA) and the National Oil and Hazardous Substances Pollution Contingency Plan; National Contingency Plan (NCP) (U.S. Environmental Protection Agency [USEPA], 1990), and pursuant to USACE ER 200-3-1 FUDS Program Policy (USACE, 2004). This RI also considered and is consistent with the groundwater restoration policy goals stated in the USEPA Office of Solid Waste and Emergency Response (OSWER) Directive 9283.1-33 Summary of Key Existing USEPA CERCLA Policies for Groundwater Restoration (USEPA, 2009a).

Oversight by the State of Rhode Island (State) for the project is provided by the Rhode Island Department of Environmental Management (RIDEM) Division of Land Revitalization and Sustainable Materials Management. The RIDEM Rules and Regulations for the Investigation and Remediation of Hazardous Material Releases, dated April 2020 (“Remediation Regulations”), Rules and Regulations for Groundwater Quality (“Groundwater Regulations”), and other relevant RIDEM regulations were considered in the development of the RI approach (i.e., groundwater classification, background sampling protocol, discussion of risk drivers).

1.2 Project and Property Definition

The portion of FUDS property number D01RI0488 01 historically occupied by the Former Blue Beach Disposal Area is referred to in this report as the “Project”. A map of the Project vicinity is provided on Figure 1-1; the location of the Project within the Quonset Point portion of North Kingstown is provided on Figure 1-2. Releases of chemical constituents to the environment from historical operations at the former Blue Beach Disposal Area were evaluated in this RI report. The nature and extent of constituents potentially originating from the Project include downgradient migration; the area impacted by site-related constituents is referred to in this RI as the “Site”.

A map of the Site showing permanent structures and key ecological habitats within its boundary is provided on Figure 1-3. Also shown on Figure 1-3, the Former Kiefer Park Tank Farm FUDS (Project and Property Number D01RI0029 12) is not included as part of the Former Blue Beach FUDS. The petroleum constituents associated with releases from the Former Kiefer Park Tank Farm were addressed separately under the USACE Former Kiefer Park Tank Farm FUDS Project and are discussed in this RI only to provide context for constituents that are attributed to the Former Kiefer Park Tank Farm. Full details regarding the Former Kiefer Park Tank Farm FUDS Project history and investigations, nature and extent of contamination, and remedial actions are available in the Former Kiefer Park Tank Farm FUDS Project repository.

1.3 Purpose of Report

The objective of this Comprehensive RI is to determine the nature and extent of DoD-related contamination at the Site, to evaluate the fate and transport of that contamination, and to quantify potential human health and ecological risks associated with residual environmental contamination. This RI includes the results of historical investigations as well as recent investigations conducted by Mabbett since 2011. The recent investigations were conducted to address data gaps identified in the Conceptual Site Model (CSM) originally developed for the Site in 2011 (Watermark, 2011) and to provide additional environmental data to refine human health and ecological risk estimates.

Recent investigations were completed in two separate events in 2014-2015 and 2019-2020. In 2014-2015, Mabbett implemented a field investigation to achieve the following objectives:

- Characterize the nature and extent of chlorinated volatile organic compounds (CVOCs) in soil and groundwater in the eastern, southern, and western portions of the Site.
- Investigate a geophysical anomaly area for potential CVOC sources on the western side of the Hayward facility.
- Characterize the nature and extent of environmental contamination in pore water, sediment, surface water, hydric soil, and shallow soil at the Site resulting from historical operations at the Project.

After review of the 2014 environmental data and estimation of potential human health and environmental risks, Mabbett and USACE identified data gaps and uncertainties that prevented the development of representative exposure point concentrations for the risk assessment. Therefore, in 2019-2020 Mabbett implemented a supplemental field event designed to achieve the following objectives:

- Obtain a sufficient quantity of data to represent an average concentration in media with 95 percent confidence for certain site areas.
- Assess the extent of PCBs in soil in the western portion of the Site and in the central portion of the Site within the grassy shoulder of Hayward's parking lot on the western side of Whitecap Drive.
- Assess the extent of SVOCs in the immediate vicinity of the isolated southwestern portion of the Project.
- Further assess the concentrations of PCBs, SVOCs, and metals in surficial soil along the walking path.
- Further assess the concentrations of PCBs and metals in sediments located along the Blue Beach shoreline of Narragansett Bay.
- Further assess the concentrations of PCBs, SVOCs, and metals in sediments located in the Red Maple Swamp tidal stream.
- Further assess the concentrations of PCBs, SVOCs, and metals in hydric soil within Red Maple Swamp.
- Collect total organic carbon (TOC), grain size, toxicity testing, and macroinvertebrate samples from soil/sediment to support the ecological risk assessment.
- Collect background soil, hydric soil, and sediment samples in order to determine natural and anthropogenic background concentrations of key constituents so that they can be distinguished from FUDS-related contamination.
- Revise human health and ecological risk assessment estimates by evaluating historical and current analytical data collected at the Site.

The results of the 2011, 2014, 2015, and 2019-2020 field investigations are summarized in this Comprehensive RI Report. These data were used to perform baseline human health and ecological risk assessments, the results of which are described in this report and presented in detail in Appendix A.

1.4 Report Organization

The Comprehensive RI Report is organized in general accordance with the USEPA's "Interim Final Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA" (USEPA, 1988). The ensuing sections of the report are organized as follows:

- Section 1 – Introduction
- Section 2 – Site Background
- Section 3 – Summary of Historical and Recent Site Investigations
- Section 4 – Physical Characteristics of the Site
- Section 5 – Nature and Extent of Contamination
- Section 6 – Contaminant Fate and Transport
- Section 7 – Baseline Risk Assessment
- Section 8 – Summary and Conclusions
- Section 9 – References

Tables and Figures are included in their own sections at the end of this report. The human health and ecological risk assessment prepared for this Site is included as Appendix A.

2.0 SITE BACKGROUND

In this section, the site history and current site description are provided. Land use, demographics, resource use, and other characteristics of the Site are described.

2.1 Site History

The Site is located in the southwestern portion of the Quonset Business Park (formerly the Quonset Point Naval Air Station [NAS]) in the Town of North Kingstown, Washington County, Rhode Island, approximately 20 miles south of Providence, Rhode Island. The Quonset Business Park is a State of Rhode Island asset that is managed by the Quonset Development Corporation (QDC), a development and management subsidiary of the RI Commerce Corporation (RICC). The Site is accessed by a paved road named Whitecap Drive, which is located off Circuit Drive (Figure 1-3).

The NAS was acquired in 1940 by the DoD for use as a training and support facility. Prior to construction of the NAS, the Site and surrounding area were used as farmland and residential land (at the time, a residential development to the west of the Site was called “Kiefer Park”), with a number of summer cottages located near the shoreline of Quonset Point (US Army Geospatial Center [USAGC], 2010). During construction of the NAS, these residential properties were apparently demolished, and extensive grading and filling occurred in the area, especially to the east of the Site, where streams and ponds draining to Narragansett Bay were filled.

The NAS was active during the World War II, Korean, and Vietnam conflicts. During operation of the NAS, the Blue Beach Disposal Area was used as a salvage yard for the storage and disposal of vehicle parts, machinery, construction debris, drummed materials, and miscellaneous wastes. However, no written records of the specific quantities of wastes are available for the Project. The wastes disposed of are presumed to have contributed to the constituents identified in various media on the Site.

In 1974, the NAS was deactivated and reported to General Services Administration (GSA) for disposal. GSA conveyed the site to the Rhode Island Port Authority (RIPA) and Economic Development Corporation (EDC) in November 1978 (GZA, September 1996). Following conveyance, the Quonset Business Park was developed and improved with light industrial manufacturing facilities and supporting infrastructure. In general, the current land use to the north and east of the Site is industrial/commercial; to the west of the Site are residential and commercial properties; and to the south is Narragansett Bay.

2.2 Site Description

The Site encompasses an area approximately 21.5 acres in size and is comprised of the Former Blue Beach Disposal Area FUDS (Project Area) and the off-Project areas subsequently impacted by constituents migrating from the Project which include a walking path, tidal stream, Red Maple Swamp, and Blue Beach. These areas are depicted on the Site map provided on Figure 1-3 and described in detail in the following sections. As previously noted, the Site does not include the Former Kiefer Park Tank Farm FUDS Project.

2.2.1 Former Blue Beach Disposal Area FUDS Project (On-Project)

The Former Blue Beach Disposal Area FUDS Project occupies approximately 13.4 acres of the Site. The Project boundary overlaps five real parcels, as depicted on Figure 2-1 and in the following summary matrix. The Project is alternatively described as “on-Project” in the risk assessment discussion.

North Kingstown Tax Assessor ID	Address	Owner	Features/Total Acreage	Name used in RI Report
Lot 179-025	Circuit Drive	Goldline Properties, LLC	Vacant, parking lot; 4.77 acres	Blue Beach FUDS Project

North Kingstown Tax Assessor ID	Address	Owner	Features/Total Acreage	Name used in RI Report
Lot 179-028	61 Whitecap Drive	Goldline Properties, LLC	Light manufacturing, offices, parking lot; 7.71 acres	Blue Beach FUDS Project
Lot 185-008	50 Whitecap Drive	Vantage Point Properties, LLC	Roadway southeast from Whitecap Drive, offices, parking lot; 2.64 acres	Blue Beach FUDS Project
Lot 185-020	66 Whitecap Drive	Falvey Realty, LLC	Offices, parking lot; PCB-cap area; 3.85 acres	Blue Beach FUDS Project
Lot 185-021	40 Whitecap Drive	Vantage Point Properties, LLC	Offices, parking lot; 3.4 acres	Blue Beach FUDS Project

2.2.1.1 61 Whitecap Drive

Hayward Industries, Inc. (Hayward), under Goldline Properties, LLC, owns and operates a pool products manufacturing and warehouse facility at 61 Whitecap Drive, occupying much of the western portion of the Project. The Hayward facility extends across two parcels (Lot 179-25 and Lot 179-28). The area to the east of the Hayward facility is improved with an asphalt parking lot for workers and delivery trucks. The remaining grounds around the Hayward facility are landscaped with grass and native vegetation.

The northern portion of the Project at 61 Whitecap Drive is adjacent to the Former Kiefer Park Tank Farm FUDS Project, which is located on portions of Lot 179-025 and Lot 179-028.

A seawall constructed with concrete and large boulders is located along the southern boundary of 61 Whitecap Drive. Construction design documents for the seawall were not available for the RI.

2.2.1.2 66 Whitecap Drive

Falvey Realty, LLC owns and operates an office building and parking lot at 66 Whitecap Drive. This parcel occupies the southeast portion of the Project that borders Narragansett Bay. The seawall along the southern boundary of 61 Whitecap Drive also extends along the shoreline at 66 Whitecap Drive.

The USACE-managed asphalt cap covering polychlorinated biphenyl (PCB)-contaminated soils is located at the southern end of Whitecap Drive, midway between the Hayward and Falvey facilities. Details of the PCB remedial action and constructed cap are summarized in Section 3.0.

2.2.1.3 40 and 50 Whitecap Drive

The Project also extends over small portions of 40 and 50 Whitecap Drive, both of which are owned by Vantage Point Properties, LLC. Vantage Point Properties LLC, leases the buildings for general office use by various tenants, including DuPont Water Technology, Clarke Valve, and AmWINS Group Benefits, Inc.

2.2.2 Walking Path and Blue Beach Recreational Beachfront (Off-Project)

Immediately west of the Project is the Walking Path/Blue Beach Recreational Beachfront parcel, which is owned by RICC. As its name implies, the parcel includes a public walking path that provides access to the Blue Beach recreational beachfront. The path was constructed and is maintained by QDC. The path is approximately 8-feet wide and covered with pea-stone and has an approximately 8-foot wide grass-covered shoulder on either side. The path begins at an asphalt-paved public parking lot to the south of Circuit Drive and extends south for

approximately 1,200 feet until reaching its terminus at the Blue Beach recreational beachfront along Narragansett Bay. The size of this parcel is approximately 1.50 acres.

North Kingstown Tax Assessor ID	Address	Owner	Features	Name used in RI Report
Lot 179-022	Listed as 0 Whitecap Drive (accessible from Circuit Drive)	RICC	Walking path Public beach	Off-Project Walking Path Off-Project Beachfront

2.2.3 Red Maple Swamp (Off-Project)

The western portion of the Site contains a coastal zone estuarine emergent wetland and scrub-deciduous forest (commonly referred to as "Red Maple Swamp"), which is owned by RICC. Red Maple Swamp is tidally-influenced via the Red Maple Swamp tidal stream, connected to the south to Narragansett Bay. The size of this parcel is approximately 7.74 acres.

North Kingstown Tax Assessor ID	Address	Owner	Features	Name used in RI Report
Lot 179-024	Listed as 0 Circuit Drive	RICC	Wetland with a tidally-influenced stream	Off-Project Red Maple Swamp

2.3 Demographics

The Site is located within the Town of North Kingstown, which is in southeast Rhode Island along the western shore of Narragansett Bay. North Kingstown is located in Washington County, which is comprised of several villages, of which Wickford is the largest. The other villages that comprise the Town of North Kingstown are Allentown, Belleville, Davisville, Hamilton, Lafayette, Saunderstown, and Slocum. North Kingstown covers a total area of approximately 43.5 square miles.

The area which is now North Kingstown was first settled in 1641 and was incorporated as Kings Towne in 1674, in honor of King Charles II. In 1722, Kingstown was divided into North Kingstown and South Kingstown. This area was a battleground for King Philip's War in 1675.

According to 2019 US Census data, North Kingstown has a population of 26,323 (US Census Quick Facts, 2020). The male population comprises 48.8 percent of the total population, whereas 51.2 percent of the population is female. Median household income is $89,874. According to 2019 US Census data, the four most highly represented races in North Kingstown are White (93.1%), Asian (1.5%), Hispanic (2.8%), and Black or African American (0.8%). Only 6.3 percent of the population speaks a language other than English at home. Accordingly, translation services do not appear to be necessary when circulating information regarding the Site.

2.4 Groundwater Resource Use and Classification

The RIDEM *Rules and Regulations for Groundwater Quality* (RIDEM, 2005) classify the State's groundwater into four classes (GAA, GA, GB, and GC) and establish groundwater quality standards for each class (RIDEM, 2009). The classifications provide a system for setting groundwater resource priorities in the State's regulatory and enforcement programs. Groundwater under the Site has two different RIDEM classifications: GA (off-Project to the west) and GB (on-Project and to the east), as depicted on Figure 2-2.

Groundwater classified by RIDEM as GB, including the water underlying the Site up to the border with Red Maple Swamp, indicates the groundwater may not be suitable for consumption without treatment due to known or presumed degradation. RIDEM states that GB groundwater shall not threaten public health or the environment;

adversely impact current or future uses of property, groundwater, or surface water; or violate any surface water quality standards or surrounding groundwater quality standards.

To the west of the Project (e.g., walking path, Blue Beach, Red Maple Swamp, tidal stream), RIDEM classifies groundwater as GA, indicating that this groundwater is a groundwater resource known or presumed to be suitable for public or private drinking water use without treatment. Likewise, RIDEM classifies groundwater as GA underlying the residential areas west of Red Maple Swamp. The Groundwater Quality Objectives for GA groundwater are generally equivalent to USEPA's Maximum Contaminant Levels (MCLs), plus state specific standards for naphthalene and methyl tert-butyl ether (MtBE), which do not have MCLs (RIDEM, 2009).

According to the RIDEM Groundwater Resource Map, the Site and areas within a 1-mile radius have no community or non-community wellhead protection areas, no sole source aquifers, no surface water protection areas, and no groundwater reservoirs or groundwater recharge zones (Figure 2-3).

Potable water is provided to the Site and throughout the Quonset Business Park by the RICC Water District; this water is obtained from three gravel-packed municipal groundwater wells developed in the Hunt Aquifer, and the wells are located approximately 3 miles upgradient from the Site. The residential neighborhoods located to the west of the Site are served by municipal water pumped from 11 gravel-packed wells distributed by North Kingstown Water District. There were no potable water supply wells identified within the Site boundary.

2.5 Environmental Land Use Restrictions

Environmental Land Use Restrictions (ELUR) that prohibit unrestricted residential activity and potable use of groundwater have been recorded on the deeds in the Town of North Kingstown Land Records for several of the parcels comprising the Site. These ELURs include Soil Management Plans (SMP) to control and limit the handling and exposure of potentially contaminated soil by workers. The parcels with existing ELUR/SMPs include:

- Plat 185, Lots 8 and 21 (50 and 40 Whitecap Drive); recorded April 11, 2005.
- Plat 179, Lots 28 and 29 (61 Whitecap Drive); recorded January 15, 2004 and April 28, 2008.
- Plat 179, Lots 25, 26 and 27 (61 Whitecap Drive); recorded January 31, 2007.
- Plat 185, Lot 20 (66 Whitecap Drive); recorded March 24, 2009.

Under the separate Former Kiefer Park Tank Farm FUDS Project, USACE submitted ELURs/SMPs for the parcel containing the Walking Path/Blue Beach beachfront (Lot 179-022), for the parcel containing Red Maple Swamp (Lot 179-024), and for the Circuit Drive Public Parking Lot (Lot 179-033). The ELURs prohibit unrestricted residential activity and potable groundwater use, and the SMPs are intended to control and limit the handling and exposure of contaminated soil by workers. RICC, as the owner of these parcels, recorded the ELUR/SMPs on the deeds with the North Kingstown Tax Assessor on April 16, 2018. Evidence of the recordings can be found in the North Kingstown Town Clerk's records in Book 3117 beginning on Page 1 (Lot 179-022), in Book 3116 beginning on Page 285 (Lot 179-24), and in Book 3116 beginning on Page 301 (Lot 179-33).

Although these existing ELURs prohibit residential use and potable groundwater use at these parcels, as a conservative measure the hypothetic future residential exposure scenario was evaluated in the human health risk assessment (Appendix A).

3.0 SUMMARY OF HISTORICAL AND RECENT SITE INVESTIGATIONS

Since 1984, USACE and others have conducted investigations to identify Project-related hazardous substances and potential sources of release to the environment. Findings from selected historical investigations performed prior to 2011 as well as more recent investigations conducted since 2011 at the Site are summarized in the following sections. Additional details about the recent investigations completed between 2011 and 2020 are available in the respective trip reports (Mabbett, 2012; Mabbett, 2016; Mabbett, 2020).

Because the Site is adjacent to the Former Kiefer Park Tank Farm FUDS Project, the scope and extent of many historical investigations have overlapped both FUDS Projects (Figure 1-3). Accordingly, the historical (pre-2011) investigations focused primarily on dissolved-phase petroleum and light non-aqueous phase liquid (LNAPL) constituents associated with the Former Kiefer Park Tank Farm FUDS Project as well as pesticides, PCBs, CVOCs, and metals. These historical investigations involved the collection of approximately 800 samples of groundwater, sediment, hydric soil, surface soil (0-2 ft bgs), subsurface soil (>2 ft bgs), surface water, and soil vapor. Additionally, bedrock cores were collected from five borings during these historical investigations (MW-19, MW-20, OW-1, OW-3, and OW-4; GZA, 1993; GZA, 1997).

During historical investigations, solid wastes such as wire cable, rubber tires, parts of jet engines, drums containing transformer oil, miscellaneous wood and metal, and training non-explosive ordnance were also found and subsequently removed from the Project and the Former Kiefer Park Tank Farm FUDS.

The historical investigations provided a substantial understanding of the physical characteristics and the nature and extent of contamination at the Site. In 2011, the historical data were used to develop a preliminary CSM and data gap evaluation (Watermark, 2011). This preliminary CSM served as the basis for the 2011 RI/FS Work Plan and the subsequent investigations conducted in 2011 through 2015. Additional data gaps identified after completion of the 2014-2015 investigations were resolved during the 2019-2020 portion of the RI.

The following is a timeline of the historical investigation and remedial activities reports conducted between 1984 and 2012:

- **1984**: Evaluation of drums of transformer oil and PCB contaminated surficial soils in the salvage yard (original source unknown).
- **1984**: Preliminary Assessment (PA) completed by NUS Corporation for USEPA Region I (NUS, 1984).
- **1988**: Quonset Point Confirmation Study by Sirrine Environmental Corp. (SEC, 1988).
- **1992**: Soil gas Survey of Blue Beach Disposal Site (GZA, 1992).
- **1993**: Engineering Evaluation of Contamination (GZA, 1993).
- **1994**: Supplemental Engineering Evaluation of Contamination (GZA, 1997).
- **1996**: Final Site Inspection Prioritization Report for Blue Beach (CDM Federal, 1996).
- **1997**: Delineation, Remediation, and Disposal of Buried Drums at Blue Beach Disposal Site (Weston, 1997).
- **1998**: Environmental Assessment and Finding of No Significant Impact for general environmental restoration work under DERP at the Quonset Point Naval Air Station (IEP, Inc., 1988).
- **1998-1999**: Blue Beach PCB Remediation and Debris Consolidation, Install PCB Cap (ECC, 1999).
- **2001**: Phase I and Phase II Site Assessment of Blue Beach Property (NE&C, 2001a).
- **2001**: Geotechnical Investigation for the Proposed Goldline Controls Building (NE&C, 2001b).
- **2001-2002**: Phase III Investigation and PCB Remediation Activities, (ECC, 2003).

- **2002**: CDW performed a limited investigation of the walking path to determine if residual petroleum hydrocarbons from the Kiefer Park FUDS Project were migrating at the beachfront (CDW, 2002, CDW, 2003).
- **2005-2009**: USACE performed groundwater sampling for VOCs at selected monitoring wells throughout the Site (USACE, 2009).
- **2009**: Geophysical Survey on the Blue Beach FUDS Project (Hager-Richter, 2009).
- **2010**: Examination of historical photography at the former Blue Beach disposal area and Kiefer Park Tank Farm (USAGC, 2010).
- **2006-2012:** Groundwater chemical analysis data (CVOCs and cadmium) collected from five wells at the Falvey Realty Property.

Summaries of the pertinent points and findings of these investigations, remedial activities, and how they focused subsequent investigations are provided in the following sections. Section 3.1 discusses historical studies and interim removal efforts and how they influenced the Site recognizing that many of the earlier work was done on both the Former Kiefer Park Tank Farm Site and on the Former Blue Beach Disposal Area Site (the subject of this RI). The most recent investigations were the basis for describing current Site conditions in this RI (Section 3.2) and were therefore the data used in the baseline risk assessments.

3.1 Historical Investigations and Remedial Measures

Historical investigations and remedial measures are discussed in this section to provide context for existing conditions. Section 3.2 below describes more recent investigations that are used to define current conditions on the Site. Investigations from 2014 and 2019 described in Section 3.2 were the basis for the baseline risk assessments discussed in Section 7.0.

3.1.1 Drum Removal & Soil Investigation, 1984

In 1984, the RIPA removed 16 to 18 drums, which reportedly had been left by the Navy, of transformer oil from the southeast corner of their salvage yard (Figure 3-1) (described in GZA, 1993). The oil in the drums was tested and reportedly did not contain PCBs. However, surficial soil samples were collected from six locations within the former drum storage area of the salvage yard and PCBs were detected in several of these samples. The summary report for this investigation is not available.

3.1.2 Contaminant Confirmation Study, 1988

Sirrine Environmental Consultants (SEC) completed a Contamination Confirmation Study in 1988 (SEC, 1988). As part of the evaluation, three test borings were advanced to depths between 21 to 26 feet below ground surface (Figure 3-2). Each of these soil borings were completed as monitoring wells (BMW-1 through BMW-3), which are located in the southern portion of the former Navy salvage yard along the former fence line. Groundwater samples were collected from these wells and analyzed for VOCs, metals, petroleum hydrocarbons, total organic carbon, organic halides, total phenols, pesticides/PCBs. Low levels of VOCs were identified in the groundwater samples. Metals were reportedly not detected at elevated levels.

Six surface soil samples and one background soil sample were also collected and analyzed for the presence of VOCs, total recoverable metals, total recoverable hydrocarbons (TRPHs), total organic carbon (TOC), total organic halides, total phenols, pesticides/PCBs and selected metals (BG-1 through BG-7). PCBs and metals were detected in these soil samples.

3.1.3 Soil Gas Survey at Blue Beach Disposal Site, 1992

As the initial phase of its Engineering Evaluation of Contamination at the Blue Beach Disposal Site, GZA completed a soil gas survey covering the Former Blue Beach Disposal Area (Figure 3-3) (GZA, 1992a). A similar soil gas survey was performed at the Former Kiefer Park FUDS Project at the same time (GZA, 1992b). Soil vapor samples were collected in a grid formation with grid nodes placed at 60-foot intervals. Based on reported groundwater depths of 7 to 13 feet, a soil gas sampling depth of 3.5 feet below surface grade was used for the survey.

A total of 119 points were sampled at the Former Blue Beach Disposal Area. Of these, 83 (70 percent) were found to contain detectable VOC soil gas concentrations of trace to 67 ppm. Of the 83 "detect" locations, 64 were identified as containing CVOCs, ten contained benzene, toluene, ethylene, and xylene (BTEX) compounds, and ten contained unknown compounds.

Forty-one (64 percent) of the samples containing CVOCs exhibited total CVOC concentrations of less than 0.1 ppm. Thirteen locations (20 percent) yielded aggregate concentrations of greater than 0.25 ppm, and only five (8 percent) had an aggregate CVOC concentration of greater than 1 ppm (ranging from 1.2 to 46 ppm). Identified CVOCs included trichloroethene (TCE); tetrachloroethene (PCE); 1,1,1-trichloroethane (TCA); 1,1-dichloroethene (DCE); and 1,2-DCE. The highest CVOC concentration at each location was generally TCE or PCE. The highest CVOC concentrations were detected in the southeastern and southwestern survey areas in the vicinity of the former Navy salvage yard.

Non-chlorinated VOCs, including BTEX, were identified at 10 locations in two main portions of the survey area. These compounds are the volatile constituents of lighter fraction fuels, including aviation and jet fuels. The highest concentrations (up to 67 ppm) were observed at soil gas locations in the north-central portion of the survey area adjacent to the Former Kiefer Park Tank Farm. The chromatograms for these samples indicated that the constituents might be from a volatile petroleum in the range of aviation fuel.

The second identified area of detected BTEX concentrations was in the south-central portion of the survey area. BTEX concentrations ranging from trace to 24 ppm were detected in seven samples collected from this area. Gas chromatograph (GC) analysis of these samples indicated that the VOCs in this area are primarily benzene or xylene compounds, which is consistent with the GC results from the northern VOC area described above. The characteristics of the chromatograms for samples from this area also suggest the presence of volatile petroleum in the range of aviation and jet fuels.

3.1.4 Engineering Evaluation of Contamination, 1993

In 1993, GZA completed the Engineering Evaluation of Contamination at the Blue Beach Disposal Site (GZA, 1993). The objective of this evaluation was to assess the lateral and vertical extent of constituents in soil and groundwater which may have been released from the operation of the disposal site, as well as at the adjacent, upgradient former underground jet fuel and aviation gas storage tank farm (Former Kiefer Park Tank Farm). The evaluation included a soil gas survey (Section 3.1.3), test pit excavation, advancement of soil borings and installation of groundwater monitoring wells, *in situ* permeability testing, and soil and groundwater sampling and analysis.

Twenty test pits were excavated to evaluate the horizontal and vertical extent of contamination in the unsaturated zone and to investigate for the presence of buried debris (Figure 3-4). With two exceptions, the excavation depth of each test pit was 6 feet. Test pit TP-6 was continued to a depth of 12 feet due to the discovery of buried debris (including three crushed drums) and TP-14 was excavated to a depth of 8 feet to investigate the depth of the fill at that location.

The drilling program consisted of a series of soil borings to further evaluate the horizontal and vertical extent of constituents at the site. A total of 16 soil borings were advanced (Figure 3-4). Eleven of the soil borings were converted to monitoring wells (OW-1 through OW-11). Seven of the wells were advanced to depths of 20 to 22

feet and screened across the water table (OW-2, OW-5, OW-6, OW-7, OW-9, OW-10, and OW-11). Three intermediate-depth (OW-1, B-1, and B-5) and one deep soil boring (B-8) were advanced on site. The depth of these borings ranged from approximately 33 to 65 feet below ground surface. Boring B-8 was completed as monitoring well OW-3, which was screened from depth of 12 to 22 feet. A separate boring was advanced next to boring B-5 and completed as monitoring well OW-8A, which was screened between 12 and 22 feet. The OW-1 boring was completed as monitoring well OW-1 with a screened interval from a depth of 6 to 16 feet. Hydraulic conductivity testing was conducted in each of the observation wells (OW series).

Based on photoionization detector (PID) screening, one soil sample, with the highest PID reading, from each boring was submitted for laboratory analysis. Groundwater sampling was performed at the eleven OW-series monitoring wells and three previously existing monitoring wells (BMW series). No NAPLs were observed during sampling of the monitoring wells.

Key findings of GZA's studies can be summarized as follows:

- The soil gas survey identified TCE, PCE, and BTEX compounds in soil gas within the former Navy salvage/material storage yard. There were two general areas of TCE and PCE detections, with higher concentrations in the southwestern portion of the salvage/material storage yard, and lower levels in the southeastern portion. BTEX compounds were detected in the south-central portion of the salvage/material storage yard.
- Constituents detected in soil and groundwater at the site included VOCs, SVOCs, petroleum hydrocarbons, pesticides, PCBs, and metals. The highest concentrations were detected in the area of the buried drums encountered in the southeastern portion of the former Navy salvage/material storage yard, where concentrations of petroleum, PCBs, and heavy metals were detected in soil and/or groundwater samples.
- The highest concentrations of CVOCs were detected in the groundwater sample collected from monitoring well OW-9, installed within the area of CVOCs identified by the soil gas survey.
- Pesticides and metals (mercury and cadmium) were detected in soil samples collected throughout the investigation area, with no identified source(s) other than general conditions associated with historical site usage. PCBs (Aroclor 1260) were also detected in soil samples from throughout the salvage/material storage yard and in shallow soils from the beach area, along the south fence line of the salvage/material storage yard. PCB concentrations were less than 1.0 ppm.
- The GZA study identified at least two additional potential onsite sources of contamination to groundwater: the buried drum area (TP-6) and the area of CVOCs in soil in the southwestern portion of the salvage/material storage yard (OW-9). These two areas were in addition to the former PCB/waste oil drum storage area located in the southeastern portion of the former Navy salvage/material storage yard, as described in Section 3.1.1 and depicted on Figure 3-1.
- GZA also identified two off-site potential sources to groundwater: the former General Dynamics salvage/material storage yard and the Former Kiefer Park Tank Farm, both of which are located hydraulically upgradient of the Site. Low-level petroleum hydrocarbons were detected in saturated soils in a boring in the northcentral portion of the former Navy salvage/material storage yard, which was suspected to have migrated from the Kiefer Park Tank Farm. Furthermore, CVOCs (TCE and PCE) detected in groundwater samples collected from the eastern portion of the Site were attributed to migration from the former General Dynamics salvage/material storage yard, which was part of the Blue Beach Disposal Site during its operation by the NAS. The location of the former General Dynamics salvage/material storage yard is shown on Figure 3-4.

3.1.5 Supplemental Engineering Evaluation of Contamination, Kiefer Park/Blue Beach, 1994

The objectives of the Supplemental Engineering Evaluation of Contamination (SEEC) were to further evaluate the presence of buried drums and/or debris at the site; perform additional field investigations and laboratory testing to provide supplementary information concerning the lateral and vertical extent of previously identified soil and groundwater contamination (GZA, 1997).

The SEEC was performed in 1994 and involved investigations in both the former Kiefer Park Tank Farm and the Blue Beach Disposal Area (Figures 3-5 and 3-6). Specific activities undertaken during the SEEC included the excavation of test pits, trench excavations, and soil borings, the installation and sampling of monitoring wells, soil and groundwater screening and analyses, *in situ* permeability testing, measurement of groundwater levels in wells, and site surveys.

A series of thirty-five test pits and approximately 200 linear feet of trenching were excavated to further investigate the presence and nature of buried debris within the former salvage yard. The test pits were designated TP94-1 through TP94-35. The trenching program was performed in the southeast portion of the former Navy salvage yard, in the area in which three crushed drums were previously encountered. Three main trenches were completed, along with five supplementary pits excavated to better define the lateral extent of the debris fill observed in the trenches.

The first trench, Trench-1, commenced northeast of former test pit TP-6, where crushed drums were encountered during the Engineering Evaluation (Section 3.1.4), and extended approximately 50 feet to the southwest. The exploration encountered miscellaneous fill, a mixture of soil and debris, to a depth of approximately 14 feet below grade. The debris included charred timbers, glass bottles, bricks, concrete, scrap metal (including gears, gauges, and pipes), an empty rubber fuel tank, and 25 steel drums. Of the 25 drums, approximately six were the remains of crushed drums, and 19 were relatively intact. Drums were removed from the excavation and temporarily stockpiled on polyethylene sheeting.

Trench-2 was excavated along the eastern fence of the former Navy salvage yard, extending to the north until natural soil was encountered at shallow depth approximately 70 feet south of the former General Dynamics salvage yard boundary. Trench-3 was excavated along the General Dynamics salvage yard boundary, extending to the west until natural soil was encountered approximately 74 feet west of the corner of the former Navy salvage yard. Only one empty drum was encountered (2 feet below ground surface) and removed from Trench-3.

After the completion of Trench-3, USACE decided not to continue drum excavation, but rather to complete the remainder of the 35 test pits and then expand the exploratory program to the General Dynamics portion of the site in an effort to characterize and delineate the area of drum fill. This decision was made recognizing that buried drums would likely remain in the ground following completion of the exploratory program. However, after encountering military ordnance at boring location B94-20, the determination was made to discontinue subsurface exploration work within the salvage yard portion of the site. Section 3.1.6 below describes additional drum removal conducted by Roy F. Weston in 1997.

A total of 16 surface soil samples, designated SS-1 through SS-16, were also collected from the former PCB storage area in the northeast corner of the former Navy salvage yard and from the waterfront/recreation area (Figure 3-5). No VOCs were detected in the soil samples collected from any of the test pits and soil borings. Aroclor-1260 was detected in eight surface soil samples collected from the Blue Beach Disposal Site. Three samples were reported with concentrations of PCBs above 20.0 mg/kg.

To evaluate groundwater quality in Red Maple Swamp, GZA installed 15 manually-driven wellpoints. The wellpoints were designated WP-1 through WP-15 (Figure 3-6). Each wellpoint consisted of a 3-foot long, 2-inch I.D., stainless steel well screen (0.020-inch slot size). Each well extended approximately 3-feet below ground surface.

Six surface water samples were also collected from the wetland, drainage swale, and former interceptor trench. Twelve sediment samples were collected from seven locations within Red Maple Swamp and the former interceptor trench. These samples were collected to evaluate whether petroleum and other site constituents had migrated to the wetland and impacted sediments, and to provide inputs to the human health and ecological risk assessments to evaluate potential risks from exposures to the wetlands. The sample locations were designated SED-1 through SED-7 (Figure 3-5). Except for SED-6 and SED-7, both shallow and deep sediment samples were collected from each sample location.

3.1.6 Remediation and Disposal of Buried Drums at Blue Beach Disposal Site, 1996

Roy F. Weston, Inc. (Weston) completed the drum removal project in the summer of 1996 (Weston, 1997). That project is described in Weston's January 31, 1997 draft project completion report entitled "Delineation, Remediation, and Disposal of Buried Drums at Blue Beach Disposal Site, North Kingstown, Rhode Island." According to that report, Weston transported and disposed of 18 drums, two 30-yard roll-off containers of residual materials associated with the drums, and 25 square feet of non-friable asbestos debris.

3.1.7 Blue Beach PCB Remediation and Debris Consolidation, 1998-1999

The objectives of the 1998-1999 remediation effort were to perform test pit excavations to define the limits of excavation required within Areas 1 and 2 (Figure 3-7); consolidate two debris areas into one consolidated pile; place gravel and a bituminous concrete cap over the debris pile; install a stone-lined toe; and remove, sample, and dispose of PCB/PAH contaminated soils from the Blue Beach FUDS Project (ECC, 1999).

A total of eleven test pits were excavated. Excavation, segregation, and removal of items from test pits was performed concurrently with removal activities at Area 1. Soil and debris from Area 1 were excavated and stockpiled. The stockpiled material was placed in either a reuse stockpile or a disposal stockpile. The material was screened using visual, olfactory, and headspace (flame ionization detector [FID] and PID) methods for total petroleum hydrocarbons (TPH). Soil that had a headspace reading of less than 10 parts per million by volume (ppmv) by PID and 100 ppmv by FID was stockpiled for reuse. The remaining soil was stockpiled to be placed in Area 2 and capped. A total of 1,800 cubic yards (CY) of soil was stockpiled and placed under the cap in Area 2.

During excavation activity in Area 1, 1,114 pieces of unexploded ordinance (UXO) scrap items were uncovered in the area referred to as the explosive ordinance disposal (EOD) pit. Ordnance related scrap was described as inert (USACE, 1999). Soils encountered on the floor of the excavation (10 to 12 ft bgs) displayed characteristics of petroleum contamination at a location approximately in the center of Area 1 and 50 feet south of the north edge of Area 1 and were attributed to the Former Kiefer Park Site and were left in place (USACE, 1999).

Soil excavated from Area 1 was placed, compacted, and capped in Area 2 on November 5, 1999. After the material from Area 1 was placed, compacted, and tested, a 12-inch layer of gravel sub-base was placed over the soil to ensure proper drainage. A 6-inch stone lined toe layer was installed on the west end of the Area 2 cap on top of the gravel sub-base. Stone was placed along the perimeter of the cap to ensure erosion control. A bituminous concrete pavement cap was placed over the subbase material. This work effort was labeled "Phase 2 PCB Remediation" and the PCB characterization results are termed Phase 2 delineation.

3.1.8 Phase I/II Environmental Site Assessment, 2001

In 2001, Northeast Engineers & Consultants (NEC) conducted an ASTM Phase I/II Environmental Assessment on Lots 179-28 and 179-29 (later combined into Lot 179-28) to identify the presence or likely presence of hazardous substances or petroleum (Figure 3-8) (NEC, 2001a). The Phase I Environmental Assessment focused on a document review, including past investigations of both the Former Blue Beach Disposal Area and the Former Kiefer Park Tank Farm, and site reconnaissance.

The Phase I Assessment identified the following concerns:

- Previous environmental investigations of the Kiefer Park Tank Farm identified a plume of LNAPL on the surface of the groundwater table that extended onto the northwestern portion of the Blue Beach Disposal Area Site. The extent of the plume required additional investigation.
- The potential impact to groundwater in the vicinity of the previously remediated Areas 1 and 2 required additional investigation.
- TCE was detected at a concentration of 1,100 µg/L, which was above the RIDEM GB Groundwater Objective of 540 µg/L, in a groundwater sample collected from monitoring well OW-9 in 1996.

To evaluate these data gaps, NEC completed a field investigation program consisting of the advancement of test borings and installation of monitoring wells, measuring relative groundwater elevations, and collecting and analyzing soil and groundwater samples. NEC advanced eight borings; four of the borings in the northeastern portion of the site were advanced to 20 feet and completed as groundwater monitoring wells (NEC-2, NEC-4, NEC-5, and NEC-6). These monitoring wells, along with wells installed during the 1994 Engineering Evaluation (W94-6, MW-12, MW-21/DB-14, MW-11, W94-15, and W94-16), were gauged and sampled (Figure 3-8). Measurable LNAPL thickness was not observed in any of the ten wells gauged; however, petroleum sheen was observed in six of the wells. The results of the laboratory analyses indicate that VOCs were not detected above the GB Groundwater Objective in any of the samples, although levels of TPH were reported.

One soil boring was also competed as groundwater monitoring well (NEC-1) on the northeastern portion of the Project downgradient from former debris Area 1. VOCs and SVOCs were not detected in soil samples collected from this boring. The groundwater sample collected from NEC-1 was reported with petroleum related compounds, but none were detected above RIDEM GB Groundwater Objectives. No LNAPL was detected, but a sheen was noted in NEC-1 during sampling. NEC concluded that the modest impacts observed in NEC-1 were not due to Area 1 but rather to the nearby Former Kiefer Park Tank Farm.

Boring NEC-3 was completed as a groundwater monitoring well in the northeastern portion of the Project, downgradient from former debris Area 2, which is the location where soil was consolidated during the Phase 2 PCB Remediation in 1998-1999. The groundwater sample collected from NEC-3 was reported with detected concentrations of VOCs. Analysis of groundwater samples from nearby monitoring wells BMW-2 and OW-11 were non-detect for VOCs. Based on these results, NEC concluded that groundwater had not been significantly impacted by the debris buried beneath the Area 2 cap.

Consistent with previous findings, the groundwater samples collected from OW-8 and OW-9 during the 2001 Phase II ESA were reported with concentrations of TCE and PCE.

Based on the findings of this investigation, NEC concluded that the groundwater beneath the northern portion of the Project had been impacted by petroleum contamination originating from the Former Kiefer Park Tank Farm. In addition, the groundwater in the vicinity of well OW-9 was impacted by CVOCs.

3.1.9 Geotechnical Investigation for the Proposed Goldline Controls Building, July 2001

NEC completed a geotechnical investigation to explore subsurface conditions below the proposed building site (the current Hayward facility) in order to develop recommendations for site preparation and foundation design (Figure 3-9) (NEC, 2001b). The field exploration program consisted of drilling and logging nine geotechnical borings ranging from 2 to 22 feet in depth. No evidence of a release was noted in any of these soil borings.

These borings provided the basis for a detailed description of subsurface materials beneath and surrounding the Hayward Building. The borings generally encountered sandy soils that become finer with more silt and denser with depth. The upper layer encountered in each boring (except B-9) is a well-graded sand that is likely to be previously placed fill from the original site development in the 1940s. Boring B-9 was drilled to the south of the former Quonset Hut location and may represent original surface soils consisting of fine sand. In the other borings,

fine sand was encountered beneath the well-graded sand, with increasing amounts of silt. The well-graded sand is generally medium dense in consistency, and the underlying fine sand is generally medium dense to very dense. There were a few areas of loose sand encountered in Borings B-7 and B-9 between layers of denser sands.

Three of the soil borings were advanced to refusal. The deepest boring (B-4) encountered very dense sand and silt with rock fragments below 25 feet that was interpreted to be glacial till. This boring met refusal at 32.3 feet, which may be bedrock or a boulder in the till. The shallower depths of refusal in the other two borings are believed to be due to boulders or very dense till.

3.1.10 Phase III Investigation and Remediation Activities, 2001-2002

A Phase III investigation was conducted in March 2001 (EEC, 2003). The purpose of this investigation was to delineate the extent of PCBs in soils beneath the paved access roads and additional areas identified during the Phase II sampling. Fifty-nine surface soil samples were collected. Samples were collected beneath the asphalt at 100-foot intervals along the centerline of the access roads and from the area south of the scale house at 50-foot intervals (Figure 3-10).

Based on recommendations in the Final PCB Letter Report (ECC, 2001), Phase III remediation activities were initiated in 2001. During October 2001, a total of 822 CY of PCB-containing material was excavated and disposed off-site. After excavation of the initial volumes, laboratory confirmation sampling indicated further remediation was necessary. A second excavation was conducted in November 2001 to complete the removal of soils with PCB concentrations above 10 mg/kg. A total of 1,660 CY of PCB-contaminated soils were removed and disposed during the two excavation events.

3.1.11 Limited Site Seepage Investigation, 2002

In 2002, an investigation was performed to evaluate the continuing observations of petroleum seepage along a section of beachfront downgradient from the disposal area (Figure 3-11) (CDW, 2002; CDW, 2003). The study area was established as an approximately 750 foot long by 30-foot wide pathway, from a former interceptor trench adjacent to the former Kiefer Park Tank Farm, along an abandoned sewer line, to an abandoned sewer line manhole adjacent to the beachfront.

The 24-inch-diameter abandoned sewer line was constructed of vitrified clay in 2-foot-long sections with mortared joints and no gravel bedding. The abandoned sewer line was previously used to discharge wastewater that originated from a water treatment plant at the North Kingstown Municipal Golf Course and overflow from a main sanitary sewer line on Roger Williams Way. Most of the abandoned sewer line was removed at an unknown time (but prior to 1983), leaving behind a portion of the line along the western boundary of the Kiefer Park FUDS Project (south of Circuit Drive). In 1983, RIPA reportedly evacuated 4,200 gallons of a water/sewage/jet fuel mixture, including approximately 200 gallons of jet fuel, from the abandoned sewer line. In 1992, USACE filled this remaining portion of the abandoned sewer line with concrete slurry introduced through a brick manhole located at the southern end of the sewer line, near the southern end of the walking path.

Twelve soil borings were advanced in the study area, and six of these were completed as 1-inch diameter groundwater monitoring wells. Soil and groundwater samples were submitted for laboratory analysis of TPH. Analysis of soil samples identified TPH concentrations in specific isolated areas adjacent to the abandoned sewer line. These limited areas of contamination were not contiguous, suggesting that breaks in the abandoned sewer line allowed jet fuel to enter the soil from within the line. It did not appear that the contamination was traveling along the bedding of the abandoned sewer line itself.

TPH was also detected in groundwater samples collected throughout the length of the abandoned sewer line at generally low, but consistent levels. The concentrations of TPH in wells near the former interceptor trench at the

Kiefer Park Tank Farm FUDS Project were considerably higher than concentrations along the abandoned sewer line.

Source area remediation further inland was recommended as a remedial effort. It was believed that excavation and off-site disposal of soil in the area within and immediately west and south of the former interceptor trench would eliminate an apparently isolated area of contamination. It was determined that other areas of contamination along the abandoned sewer line could have been responsible for the periodic seepage observations at the beach, however, as constituent concentrations did not exceed RIDEM standards, a decision was made not to remove these apparently isolated areas of TPH in soils.

The Limited Site Investigation concluded that the existing wells at the Site should be monitored periodically to indicate whether LNAPL or sheens were present in any of the wells, and under what conditions the LNAPL appears. A long-term monitoring program was also recommended for use in developing a trend of LNAPL occurrences and contaminant concentration fluctuations in groundwater along the abandoned sewer line.

3.1.12 Geophysical Survey, 2009

Several lines of evidence indicated that the source of the COVCs in groundwater was in the western side of the Project Area. This premise was based on a combination of information sources, including but not limited to: the historical aerial photograph interpretation study (USAGC, 2010); historical data for CVOCs in soil gas (GZA, 1992); and the CVOC plume in groundwater geometry emanating from this side of the Project (e.g., GZA, 1992; EA, 2006; USACE, 2009).

In October 2009, a geophysical survey was performed to identify possible underground storage tanks (USTs), buried drums, or other sources of TCE and related CVOCs (Figure 3-12) (Hager-Richter, 2009). The geophysical survey was conducted by Hager-Richter Geoscience using ground-penetrating radar (GPR) and electromagnetic methods (EM-61). This investigation focused on the area around OW-9, which is to the west of the Hayward building. This area was selected based on historical soil gas and groundwater data, which indicated this area contained the highest TCE concentrations. The subsurface survey was able to penetrate to a depth of between 8 to 10 feet below the ground surface. The following conclusions were drawn based on the results of the geophysical survey:

- Two broad areas of high amplitude EM anomalies not attributable to surface metal, but attributed to buried metal, were identified. These areas were further investigated via GPR.
- GPR results showed eight large unidentified buried metal objects in the survey area, at depths of approximately 2 to 4 feet. The GPR reflections were consistent with those expected from a possible drum or small UST.
- Four large unidentified buried non-metallic objects were present in the survey area. The GPR reflections were consistent with those expected from a possible non-metal drum or small UST.
- Several possible utility segments and many small unidentified buried objects were detected in the survey area.

Based on these results, a geophysical anomaly investigation was conducted in 2011 (Mabbett, 2012). The results of that investigation are described in Section 3.2.1.

3.1.13 USACE Groundwater Monitoring, 2005-2009

USACE sampled selected groundwater monitoring wells for VOC analysis in 2005, 2006, 2007, 2008, and 2009 (USACE, 2009). Additionally, groundwater samples were analyzed for metals in 2008. Notably, over this 4-year period the TCE concentration in monitoring well OW-9 was 262 µg/L in 2005, decreased to 89.5 µg/L in 2007, was 273 µg/L in 2008, and 212 µg/L in 2009 (average concentration of 218 µg/L). Additionally, the monitoring event in

2005 was the first time a groundwater sample was collected from monitoring well W98-1, which is located on the far western border of Red Maple Swamp. From 2005-2009, the TCE concentration in W98-1 ranged from 24.4 µg/L to 31.0 µg/L.

3.1.14 Soil Vapor Sampling, 2006

Based on the soil vapor investigations conducted at the Blue Beach FUDS Project and Kiefer Park FUDS Project in 1992 (GZA, 1992), the locations of TCE and PCE in soil vapor samples collected at approximately 3 feet bgs and 6 feet bgs generally corresponded to the locations of the underlying TCE and PCE CVOC groundwater plumes. Two distinct areas of TCE and PCE in soil vapor samples were observed: on the western side of the Project (near the geophysical anomaly area and where the Hayward facility was later constructed), and on the eastern side of the Project south of the former General Dynamics salvage yard and near the Phase 2 PCB Remediation Area.

CVOCs were not detected in soil vapor samples collected from the Kiefer Park FUDS Project (GZA, 1992). These results served as the basis for many of the subsequent investigations to assess the nature and extent of contamination and identify potential source areas at the Site (e.g., GZA, 1994; GZA, 1997). It is also noted that subsequent to these investigations, the Hayward facility was constructed in 2004/2005 with a sub-slab depressurization system (SSDS) to mitigate potential vapor intrusion risk.

In 2006, a soil vapor investigation was performed in the areas where Hayward planned to expand their building footprint (EA, 2006). Soil vapor samples were collected from ten locations at a depth interval of 8 to 12 feet bgs and analyzed for VOCs and TPH. Of these ten samples, six were located on the Blue Beach FUDS Project, and four on the Kiefer Park FUDS Project.

One sample (EA04VP) was located just east of the geophysical anomaly area, under what is now the expanded Hayward facility (Figure 3-13). Soil vapor in this sample contained PCE at 6.2 micrograms per cubic meter of air (µg/m^3); other CVOC concentrations in this sample were non-detect (Table 3-1). In total, PCE was detected in soil vapor samples collected from two locations, ranging from 3.3 to 6.7 µg/m^3, on the western and central areas of the Project. However, in the northeast portion of the Blue Beach Project, between the Kiefer Park FUDS Project and Whitecap Drive, soil vapor in sample EA27VP contained *cis*-1,2-DCE at a concentration of 51 µg/m^3, *trans*-1,2-DCE at a concentration of 18 µg/m^3, and vinyl chloride (VC) at a concentration of 180 µg/m^3.

It was unclear where the source of CVOCs detected in these samples was located. However, the source is possibly from general historic waste disposal activities in this area. It was noted that at each soil vapor sampling location, a separate soil sample was collected from the boring. None of the ten soil samples contained CVOCs above laboratory instrument method reporting limits. In the soil vapor sample EA26VP, located on northern portion of the Blue Beach FUDS Project and adjacent to the Kiefer Park Tank Farm FUDS Project, benzene was detected at a concentration of 160 µg/m^3. The source of benzene in the area is likely the former Kiefer Park Tank Farm.

3.1.15 Blue Beach/Kiefer Park – Quonset Point, Rhode Island, Examination of Historical Photography

The USAGC examined relevant historical aerial photography spanning 1938 to 2009 to assess potential areas of open storage as the source of TCE plume contamination (which had been previously investigated at the Project site) (USAGC, 2010). Other features such as buildings, storage tanks, ground scars, disturbed ground, fill areas, and ponds were also included in this report as findings.

Examination of aerial photos flown from 1945 to the 1960s offer findings which relate to the geographic location of an identified TCE plume source. The southern area of the Former Kiefer Park Tank Farm (prior to the installation of Tanks 538, 539, and 540) displays a grouping of three structures (1945-1949) located immediately south of an aircraft salvage yard (1945). Areas of ground scars are identified on late 1940s oblique aerial photography over the TCE plume area. A 13,500-barrel jet fuel storage tank (No. 538), installed in the early 1950s, lies within the northern-most section of the TCE plume. An activity area (type unknown) – a probable open storage area, is

observed on 1954 aerial photography. On aerial photos dated from the 1950s to the 1960s, there are various materials typical of salvage operations in open storage located within the plume area and extensively at the Blue Beach Salvage Yard lying just east of the TCE plume. A fuel truck loading stand, built circa 1963 and associated with Storage Tank No. 538, appears at the northern portion of the TCE plume. Finally, a review of 1970 aerial photography indicates a large amount of open storage over the TCE plume area.

3.2 Former Kiefer Park Tank Farm

The Former Kiefer Park Tank Farm FUDS Project, which borders the Site to the north and west, has been identified as the source of petroleum compounds impacting the Site (Watermark, 2011; Mabbett, 2015b). The Former Kiefer Park Tank Farm FUDS was the location of the former Kiefer Park Tank Farm, which housed three aviation gasoline (avgas) and three jet fuel USTs and associated transfer piping from 1940 to 1974. The removal of these USTs and associated piping in 1989/1990 eliminated any ongoing potential source of fuel oil releases to the Kiefer Park Tank Farm FUDS Project and the Site (Mabbett, 2015b). The source of the release of avgas and jet fuel at Kiefer Park appeared to be associated primarily with the former USTs (number 539 and 540), which were located in the southern portion of the former Kiefer Park Tank Farm (south of Circuit Drive), and from the former fuel truck loading area piping in the southeastern area of the former Tank Farm.

3.2.1 Remedial Actions at the Former Kiefer Park Tank Farm FUDS

In 2003-2004, USACE constructed a LNAPL recovery system spanning the southeastern portion of the Kiefer Park FUDS and the central portion of the Blue Beach FUDS (Figure 3-14; Conti, 2005). At that time, regulators and other consultants theorized that LNAPL that had been previously measured in groundwater monitoring wells was actively migrating in the subsurface vadose zone and groundwater toward the south/southwest from the former Tank Farm (CDW, 2002). As part of the LNAPL recovery system construction, USACE excavated nearly 1,400 CY of petroleum-contaminated soil, which was transported off-site for disposal (Conti, 2003; Conti, 2005). USACE began operating the LNAPL recovery system in 2004 (Conti, 2005). However, after approximately one year of operation, no LNAPL had migrated into the LNAPL recovery system (Conti, 2005). Accordingly, in 2005 USACE halted operation of the LNAPL recovery system, determining that the fluctuating levels of LNAPL previously measured in groundwater monitoring wells was not due to horizontal or vertical LNAPL migration, but was instead an artifact of lowering and rising groundwater levels (Conti, 2005).

To further assess LNAPL potential mobility and recoverability, USACE completed an LNAPL investigation of the former Kiefer Park Tank Farm in 2011 (Watermark, 2011) and a subsequent investigation for residual petroleum to the west of the Kiefer Park FUDS Project, along the northern portion of Red Maple Swamp in 2013 (Mabbett, 2015b). The 2011 investigation used water drive and centrifugal testing to conclude that the LNAPL present in subsurface soils was not readily mobile or recoverable, and that the historical intermittent observations of fluctuating LNAPL thicknesses in selected groundwater monitoring wells in vicinity of the former tanks and piping was an artifact of the physical mechanisms related to groundwater levels, soil porosity, and petroleum dynamics (Interstate Research Council, 2009; Watermark, 2010).

The 2013 investigation confirmed that LNAPL was not present beyond the western border of the Kiefer Park FUDS Project (Mabbett, 2015b). Based on these data, in 2014 USACE permanently decommissioned the shed housing the former LNAPL recovery system controls and removed the shed from the Hayward parking lot. Additionally, in 2015 USACE submitted a request to RIDEM for an Interim Letter of Compliance (ILOC), documenting that USACE has completed remedial efforts at the Kiefer Park FUDS Project; acknowledging that LNAPL and residual petroleum remained present at the Kiefer Park FUDS above RIDEM upper concentration limits (UCL) and leachability criteria; and that long-term monitoring of dissolved-phase petroleum in groundwater will continue until such time that applicable RIDEM soil and groundwater objectives are achieved (Mabbett, 2015b).

As part of the ILOC approval process requested by RIDEM in June 2015, USACE prepared an updated long-term monitoring plan for groundwater; and ELUR/SMPs for the parcels currently without these controls and where dissolved-phase petroleum from the Kiefer Park FUDS Project had migrated. These parcels include the Walking Path, Red Maple Swamp, the Blue Beach Public Parking Lot, and the parcel occupied by Hexagon Metrology. The owner of these parcels, RICC, submitted the ELUR/SMPs on the deeds of these properties on April 16, 2018. The ELURs prohibit unrestricted residential activity and groundwater for potable uses at each parcel, while the SMPs control future exposure to and handling of petroleum-contaminated soil.

The dissolved-phase petroleum compounds in groundwater associated with the Kiefer Park Tank Farm FUDS Project former tank farm source area include naphthalene, benzene, ethylbenzene, methylene chloride, and bis(2-ethylhexyl)phthalate, with co-mingled metals including arsenic, chromium, and lead. The RIDEM GA exceedances of the VOCs benzene, ethylbenzene, and methylene chloride are mostly found in the northern portion of the former Kiefer Park Tank Farm (north of Circuit Drive) and attenuate to below RIDEM GA Groundwater Objectives within Red Maple Swamp. Likewise, bis(2-ethylhexyl)phthalate and the metals attenuate to below RIDEM GA Groundwater Objectives in Red Maple Swamp. All of the groundwater samples collected by the Army Corps during the Blue Beach RI were collected using the EPA low-flow methodology. It is noted that the exceedances of the RIDEM GA Groundwater Objectives for metals are generally based on historical groundwater data, which may have been influenced by the turbidity. Therefore, the metals data may be biased high, and should be considered conservative from a risk evaluation standpoint. Additionally, groundwater data collected since 2008 from permanent monitoring wells using low stress/low-flow methods do not indicate significant levels of metals in groundwater.

Based on these soil and groundwater data, residual petroleum in vadose zone soils attributed to the Kiefer Park FUDS Project appears to act as a source of dissolved-phase petroleum compounds to groundwater, which migrates onto the Site (Mabbett, 2015b). The Former Blue Beach Disposal Area FUDS RI addresses these compounds in context of the risk assessment and nature and extent; however, by design a Feasibility Study for the Site would not include remedies to address contamination originating from the Kiefer Park Tank Farm FUDS Project.

3.2.2 Former Kiefer Park Interceptor Trench

Based on data from the 2011-2014 investigations and historical investigations, contaminated sediments present in the former interceptor trench installed by QDC, which is located within the Kiefer Park FUDS Project on its western border (Figure 3-15), appear to be a potential source of the contaminants present in Red Maple Swamp, namely pesticides, metals, petroleum, PCBs (Aroclor 1260), VOCs, and SVOCs. A summary of the former interceptor trench sediment and surface water analytical data is presented in Tables 3-2 and 3-3, respectively. During periods of high precipitation, the former interceptor trench becomes saturated, and sediments may become mobilized in the surface water column; as surface water flows westward out of the former interceptor trench, it carries sediment with it, migrating westward through the rip-rap-lined channel under the walking path foot bridge, then discharging near QDC Outfall 026 and ultimately transported further downgradient via the tidal stream in Red Maple Swamp.

Metals detected in sediment samples included aluminum, arsenic, barium, cadmium, chromium, cobalt, copper, lead, magnesium, manganese, mercury, vanadium, zinc (Table 3-2). Trace levels of PCBs were detected in sediment samples as Aroclor 1260. Trace levels of pesticides detected in sediment samples included 4,4'-DDD; 4,4'-DDE; 4,4'-DDT (in 1994 only), aldrin (in 1994 only), alpha-chlordane (in 1994 only), Endosulfan II, and Endosulfan sulfate (in 1994 only), endrin aldehyde (in 1994 only), endrin ketone, and gamma-chlordane (in 1994 only). SVOCs detected in sediment included PAHs, di-n-butyl phthalate, and dibenzofuran. VOCs detected in sediment included 1,2,4-trimethylbenzene, MEK, benzene, naphthalene, and total xylenes. TPH was also reported in sediment samples.

Surface water in the former interceptor trench was sampled in 1986, 1994, 2011, and 2012. Chemicals detected during one or more of these events included metals, VOCs, and SVOCs. A summary of the analytical data for surface samples collected from the former interceptor trench is provided in Table 3-3. Dissolved metals in surface water in the former interceptor trench included barium, cadmium, and chromium. Total metals detected in surface water included arsenic, barium, cadmium, and lead, and were detected at higher concentrations than dissolved metals, with the exception of arsenic (total = 0.8J µg/L, dissolved was nondetect at 2.5U µg/L) and chromium (total was nondetect at 10U µg/L and dissolved = 2.2J µg/L). Such inconsistencies around the reporting limits are not unusual and are not of concern. Dissolved metals detected in surface water in the former interceptor trench included barium, cadmium, and chromium. VOCs detected in surface water in the former interceptor trench included 1,2,4-trimethylbenzene; 1,3,5-trimethylbenzene; 4-isopropyltoluene; ethylbenzene; isopropylbenzene; n-propylbenzene; naphthalene, *sec*-butylbenzene; *tert*-butylbenzene; toluene; and p,m-xylenes. The only SVOC detected in surface water was di-n-butyl phthalate at 140 to 160 µg/L in 1994. A surface water sample collected in 1994 contained TPH at a concentration of 0.16 mg/L.

The source of the contaminants present in the former interceptor trench is believed to be from general historical activities at the former Kiefer Park Tank Farm.

3.3 Recent Site Investigations, 2011-2020

This section provides a summary of the recent investigations conducted by USACE under the FUDS program between 2011 and 2020 by Mabbett. The primary goals of the 2011-2020 investigations were to address specific data gaps identified in the prior investigations; to refine the preliminary CSM presented in the 2011 investigation/FS Work Plan (Watermark, 2011); to assess the geophysical anomaly area for sources of CVOCs and other constituents in groundwater; and to provide an environmental sampling dataset that is sufficiently robust to support a CERLCA-compliant human health and ecological risk assessment.

The 2011-2020 investigations were conducted in four tiered phases: the first phase was conducted in October-December 2011; the second phase in July-August 2014; the third phase in August-September 2015; and the fourth phase in 2019-2020. Each investigation was performed according to USACE-approved Work Plans (Watermark, 2011; Mabbett, 2014; Mabbett, 2015; Mabbett 2019). The specific methods used, and analytical data generated during these investigations is summarized in the 2011, 2014-2015, and 2019-2020 Trip Reports (Mabbett, 2012; Mabbett, 2016; Mabbett, 2020).

As described below, the 2011 investigations were conducted to identify the location and extent of source areas remaining on the Project Area following previous targeted remedial actions. Since 2011, additional waste materials were removed from the Project Area and additional remedial measures were taken on the Former Kiefer Park Tank Farm. Therefore, the data collected after these additional remedial measures (2014 and 2019) are most representative of current conditions and were the data set used for the baseline risk assessment discussed in Section 7.0.

3.3.1 2011 Investigation

3.3.1.1 Rationale

The primary goal of the 2011 investigation was to assess the geophysical anomaly area for potential sources of the constituents previously identified in groundwater. Additional goals of the 2011 investigation included expanding the monitoring well network and collecting additional groundwater, sediment, surface water, pore water, hydric soil, and surface and subsurface soil samples for analysis to better assess the nature and extent of contamination identified in previous investigations and address data gaps identified in the 2011 preliminary CSM. The 2011 investigation data were also to be evaluated in the CERCLA-compliant human health and ecological risk assessments in this RI. Details of the 2011 investigation were presented in the Field Trip Report (Mabbett, 2012).

3.3.1.2 Summary of Tasks

Tasks conducted during the 2011 investigation included the following:

- Two test pits were excavated where subsurface geophysical anomalies were identified in 2009 (Hager-Richter, 2009) (Figure 3-12). Several crushed, corroded 55-gallon metal drums were unearthed. Samples of *de minimis* amounts of residual "fluffy" material were collected from drums and analyzed for VOCs, semi-volatile organic compounds (SVOCs), polycyclic aromatic hydrocarbons (PAHs), PCBs, and metals. Likewise, subsurface soil samples under each drum were collected and analyzed for the same parameters. A sample of "white powder" from a full 55-gallon drum was analyzed for the same parameters. Yellow paint residue was also encountered in the base of one of the drums of which a sample was collected by Mabbett. A length of polyethylene sheeting was placed over the drums prior to backfill. Groundwater samples subsequently collected from OW-9 showed a decrease in TCE concentrations, a trend which continues to this day. A summary of the 2011 geophysical anomaly area observations is provided in Table 3-4. A summary of the waste profile chemical data is provided in Table 3-5. A summary of the soil chemical data is provided in Table 3-6.
- Eleven shallow overburden groundwater monitoring wells were installed to increase spatial coverage of groundwater across the Site. At least one subsurface (>2 feet bgs) soil sample was collected from each soil boring core and analyzed for VOCs, Resource Conservation and Recovery Act (RCRA) 8 metals, and biological parameters. The 11 new monitoring wells and 18 existing monitoring wells were sampled and analyzed for VOCs (Figure 3-16).
- Five pore water samples were collected within Red Maple Swamp and analyzed for VOCs, PCBs, and RCRA 8 metals (total and dissolved) (Figure 3-17).
- Three co-located shallow (0 to 0.5 foot bgs) sediment and surface water samples were collected from the Red Maple Swamp tidal stream; one from the surficial drainage ditch upgradient from the tidal stream; and one from the former interceptor trench on the Kiefer Park FUDS Project. Samples were analyzed for VOCs, PCBs, and RCRA 8 metals (total and dissolved for surface water samples) (Figure 3-17).
- Twelve shallow (0-1 foot bgs, 1-2 feet bgs) hydric soil samples were collected from six locations in Red Maple Swamp and analyzed for VOCs, PCBs, and RCRA 8 metals (Figure 3-18).
- Twelve shallow (0-1 foot bgs, 1-2 feet bgs) soil samples were collected from six locations along the Walking Path and analyzed for VOCs, PCBs, and RCRA 8 metals (Figure 3-18).
- A synoptic groundwater elevation survey was performed to assess and confirm groundwater flow directions indicated in historical investigations. Wells were also assessed for the presence and thickness of LNAPL and DNAPL.
- A ground elevation survey was conducted for sampling locations and relevant physical site features.

All samples submitted for laboratory analysis were analyzed by ESS Laboratory in Cranston, Rhode Island. The data collected during the 2011 investigation were qualified by the laboratory and validated by Mabbett using the USACE Automated Data Review (ADR) software. The validated analytical data collected during the 2011 investigation are presented in Section 5.0. Further discussions of sampling deviations, data quality, validation processes, and usability were presented in the 2011 Investigation Field Trip Report (Mabbett, 2012).

3.3.2 2011 Geophysical Anomaly Area Findings and Debris Removal

Two distinct areas were investigated during the subsurface excavation investigation of the geophysical anomaly area conducted as part of the 2011 investigation (Mabbett, 2012). During this subsurface investigation, the two areas were excavated to a depth of approximately 8 feet bgs. Observations during the investigation identified six

isolated crushed drums containing less than a handful of "fluffy" brown material, a hardened mass of yellow paint (equivalent to less than a 5 gallon container in size), an intact drum containing an unknown white powder, a metal 5-sided box containing approximately 0.5 to 1 cy of an unknown granular black media, an airplane landing arm with an attached wheel, and significant amounts of buried metal cable and metal, possibly siding from a Quonset hut. Other objects encountered included a refrigerator, a radiator, flexible pipe, and small metal containers appearing to contain electrical components suspected to be ship communication fuses wrapped in paper. Figure 3-19 shows the locations where debris was observed during the geophysical anomaly investigation. Table 3-4 presents a summary of these observations. Appendix C of the 2012 Mabbett report presents photographs of the geophysical anomaly investigation.

Samples were collected and analyzed of the different materials. Concentrations of VOCs and CVOCs were reported in the "fluffy" brown material, hardened paint, and granular media, and concentrations of metals were reported in the hardened paint, granular media, and at lower concentrations in the white powder. The geophysical anomaly waste sample chemical data are presented in Table 3-5. Two samples of the "fluffy" brown material were collected and contained elevated CVOC, VOC, and metal concentrations. Some of the higher CVOC concentrations included:

- PCE – 55,800 µg/kg
- TCE – 814,000 µg/kg and 120,000 µg/kg
- *cis*-1,2-DCE – 133,000 µg/kg

A sample of the hardened yellow paint contained TCE at a concentration of 85,700 µg/kg. The granular black media from the metal box had TCE at a concentration of 44.9 µg/kg.

Other detected VOCs in these wastes included 1,2,4-trimethylbenzene; 1,3,5-trimethylbenzene; 2-butanone/methyl ethyl ketone (MEK), 4-isopropyltoluene; 4-methyl-2-pentanone; BTEX; isopropylbenzene; methylene chloride; naphthalene; n-propyl benzene; and *sec*-butyl benzene. Detected metals in these wastes included arsenic, barium, cadmium, chromium, lead, mercury, and silver. Approximately 20 CY of metal and associated debris originating from the geophysical anomaly area were contained in a polyethylene-lined roll-off container and transported off-site for disposal.

Concurrently with the geophysical anomaly area investigation, soil samples were collected from the base of each test pit and underlying the buried drums. The soil samples were reported with CVOC, VOC, and metal concentrations. The soil sample analytical data from these test pits is presented in Table 3-6, with a comparison of analytical results to the EPA Regional Screening Levels (RSLs) for Resident Soil. CVOC concentrations included:

- PCE: detected in three soil samples at concentrations that ranged from 50.9 to 165 µg/kg.
- TCE: detected in six soil samples at concentrations ranging from 1.8 to 2,580 µg/kg; the two highest concentrations (2,140 and 2,580 µg/kg) were detected in soil samples collected from beneath the crushed drums containing brown "fluffy" debris.
- *cis*-1,2-DCE: detected in three soil samples at concentrations that ranged from 86.6 to 153 µg/kg.
- 1,1-DCA: detected in one soil sample at 48.5 µg/kg.

Other detected VOCs in these soil samples included 1,2,4-trimethylbenzene; 1,3,5-trimethylbenzene; MEK; 4-isopropyltoluene; 4-methyl-2-pentanone; BTEX; isopropylbenzene; methylene chloride; naphthalene; n-propyl benzene; and *sec*-butyl benzene. The same VOCs were detected in the waste materials present in the geophysical anomaly area. Detected metals in these soil samples included arsenic, barium, cadmium, chromium, and lead. These metals were also detected in the waste samples.

3.3.3 2014 Investigation

3.3.3.1 Rationale

The primary goal of the 2014 investigation was to better refine the horizontal and vertical extent of CVOCs in groundwater migrating south and west from the geophysical anomaly area, which is the presumed source of CVOCs in groundwater, by conducting a vertical groundwater profiling investigation upgradient and downgradient from the source area. Details of the 2014 investigation were presented in the 2014-2015 Trip Report (Mabbett, 2016). Additional goals included repeating the 2011 investigation sampling effort at permanent groundwater monitoring wells, pore water sample locations, and co-located sediment and surface water locations. Furthermore, the Blue Beach inter-tidal beachfront sediment was sampled and analyzed for constituents potentially migrating from groundwater to sediment. The 2014 investigation data was used to refine the CSM and the data were evaluated in the human health and ecological risk assessments for the Comprehensive RI.

3.3.3.2 Summary of Tasks

Tasks conducted during the 2014 investigation included the following:

- Five shallow (1 foot bgs) pore water samples were collected within Red Maple Swamp at similar locations as the 2011 investigation. The samples were analyzed for VOCs and RCRA 8 metals (filtered and non-filtered) (Figure 3-20).
- Co-located sediment and surface water samples were collected from three locations within Red Maple Swamp (Figure 3-21), similar to the 2011 investigation. The samples were analyzed for VOCs and RCRA 8 metals (filtered and non-filtered for aqueous media). Sediment samples were also collected from the surficial drainage ditch (between QDC Outfalls 025 and 026) and the former interceptor trench at the Kiefer Park Tank Farm FUDS and analyzed for VOCs, RCRA 8 metals, SVOCs, PCBs, and TPH; surface water was not present at these two locations when the sediment samples were collected.
- Shallow sediment (0 to 0.5 foot bgs) samples were collected from eight locations along the Blue Beach beachfront and analyzed for VOCs and RCRA 8 metals (Figure 3-22). The samples were spaced approximately evenly across the length of the beachfront parcel owned by QDC. The samples were collected during low tide between the mid-tide and low-tide lines.
- Groundwater samples were collected from 34 monitoring wells for analysis of VOCs and RCRA 8 metals (filtered and non-filtered) (Figure 3-23).
- Vertical groundwater profiling was performed at 22 locations (Figure 3-24). The objective of the vertical groundwater profiling task was to further delineate the vertical and horizontal extent of CVOCs and metals in groundwater migrating west and south from the geophysical anomaly area (the presumed CVOC source area). The samples were collected for VOCs and RCRA 8 metals (filtered and non-filtered).
- A synoptic groundwater elevation survey was performed to confirm prior groundwater flow directions. Wells were also assessed for the presence and thickness of LNAPL and DNAPL.
- A ground elevation survey was conducted of sampling locations and relevant physical site features.

All samples submitted for RCRA 8 metals, SVOCs, PCBs, and TPH were analyzed by ESS Laboratory in Cranston, Rhode Island. Samples for VOCs were analyzed by Mabbett's subcontracted on-site mobile laboratory operated by ECCS Nationwide Mobile Laboratory. The data collected during the 2014 investigation were qualified by each laboratory and validated by Mabbett using the USACE ADR software. The validated analytical data collected during the 2014 investigation are presented in Section 5.0.

3.3.4 2015 Investigation

3.3.4.1 Rationale

The primary goal of the 2015 investigation was to assess sediment, porewater, and surface water along the Blue Beach beachfront area for constituents that may have migrated to these media from upgradient groundwater. Details of the 2015 investigation were presented in the 2014-2015 Field Trip Report (Mabbett, 2016).

An additional goal was to conduct a seismic survey to assess the bedrock topography to the west and south of the source area. Although all previous investigations indicated low-level CVOC concentrations (e.g., low parts per billion [µg/L] levels not indicative of a DNAPL source) in groundwater, the seismic survey was requested by RIDEM out of concern that if bedrock depressions were present these depressions could be harboring pools of DNAPL, and the depressions would be the recommended locations for deep overburden groundwater wells, if needed. The 2015 investigation data were used to refine the CSM and evaluated in the human health and ecological risk assessments in the Comprehensive RI.

3.3.4.2 Summary of Tasks

Tasks conducted during the 2015 investigation included the following:

- On-shore shallow sediment (0- to 0.5-foot bgs) samples were collected from two locations along the Blue Beach beachfront and analyzed for VOCs and RCRA 8 metals (Figure 3-25). The samples were collected along a portion of the beachfront owned by QDC. The samples were collected between the mid-tide and low-tide lines, within the eastern portion of the beachfront. These two sediment samples increased the number of on-shore intertidal data points to 10, thereby facilitating the use of ProUCL for the CERCLA-compliant risk assessments.
- On-shore shallow (1-foot bgs) pore water samples were collected from 10 locations (co-located with the beachfront sediment samples) along the Blue Beach beachfront and analyzed for VOCs and RCRA 8 metals (filtered and non-filtered) (Figure 3-25). The porewater samples were collected between the mid-tide and low-tide lines during an outgoing tide.
- Off-shore shallow (0- to 0.5-foot bgs) sediment samples were collected from 10 locations approximately 50 feet off-shore and aligned with the 10 on-shore sediment sample locations. The samples were analyzed for VOCs and RCRA 8 metals (Figure 3-25).
- Off-shore shallow (1-foot bgs) porewater samples were collected from 10 locations co-located with the off-shore sediment samples. The porewater samples were analyzed for VOCs and RCRA 8 metals (filtered and non-filtered) (Figure 3-25).
- Off-shore surface water (mid-column) was collected from Narragansett Bay at three locations where off-shore sediment/pore water samples were collected. Surface water was collected 50 feet off-shore and at the eastern, western, and central areas of the off-shore sampling transect. The surface water samples were analyzed for VOCs and RCRA 8 metals (filtered and non-filtered) (Figure 3-25).
- Seismic survey to map bedrock topography in the western portion of the Site.
- A ground elevation survey of sampling locations and relevant physical site features.

All samples submitted for VOC and RCRA 8 metals were analyzed by Accutest Laboratory in Marlborough, Massachusetts. Details of the 2015 investigation were presented in the 2014-2015 Field Trip Report (Mabbett, 2016). The data collected during the 2015 investigation were qualified by each laboratory and validated by Mabbett using the USACE ADR software. The validated analytical data collected during the 2015 investigation are presented in Section 5.0.

3.3.5 2019-2020 Investigation

3.3.5.1 Rationale

The primary goal of the 2019-2020 investigation was to further assess upland soil, hydric soil, sediment, and groundwater to provide additional support to the risk assessments; and to provide additional data (sediment toxicity testing and an invertebrate survey) for the ecological risk assessment at on-Project and off-Project locations. In addition, a background sampling program was conducted to collect a representative data set for comparison with Site data to support the human health and ecological assessments and conclusions regarding naturally occurring or anthropogenic sources not associated with the Former Blue Beach Disposal area. Details of the 2019-2020 investigation were presented in the 2019-2020 Field Trip Report (Mabbett, 2020).

3.3.5.2 Summary of Tasks

Tasks conducted during the 2019-2020 investigation included the following:

- Discrete surface (0-1 foot bgs) and subsurface (1-3 foot bgs) soil samples were collected from on-Project upland soil locations BG-5 (SB-301 through SB-303) and BG-1 (SB-304 through SB-306). The samples were analyzed for SVOCs and TAL metals. A subset of samples was also submitted for laboratory analysis of TOC and grain size (Figure 3-26).
- Triplicate incremental sampling methodology (ISM) soil samples were collected from surface (0-1 foot) and subsurface (1-3 foot) soil at BG-1 and BG-5 (six samples total) and submitted for laboratory analysis of PCBs (Figure 3-26). The objective of these samples was to determine a representative average concentration of PCBs in soil at these 1988 sampling locations where PCBs were detected during the Contaminant Confirmation Study (Section 3.1.2).
- Surface (0-1 foot bgs) and subsurface (1-3 foot bgs) soil samples were collected from 20 upland soil boring locations (SB-307 through SB-326) along the southern and western portions of the Site. Soil samples were analyzed for VOCs, SVOCs, and TAL metals (Figure 3-26).
- Surface (0-1 foot bgs) and subsurface (1-3 foot bgs) ISM soil samples were collected from upland soils to the south of the Hayward building (UPS-1 through UPS-3). These ISM soil samples were submitted for laboratory analysis of PCBs (Figure 3-26).
- Ten shallow soil samples (0-1 foot bgs) were collected from the walking path leading from the Circuit Drive parking area to the shoreline of Narragansett Bay (SB-327 through SB-336) and analyzed for SVOCs/PAHs, PCBs, and TAL metals. A subset of these samples was also analyzed for TOC and grain size (Figure 3-26).
- Ten shallow sediment samples (0-1 foot bgs) were collected from the intertidal zone along the shoreline of Blue Beach (SED-301 through SED-310) for laboratory analysis of PCBs and TAL metals. A subset of the samples was also analyzed for TOC and grain size (Figure 3-26).
- 20 shallow sediment samples (0-0.5 foot bgs) were collected from the Red Maple Swamp tidal stream (SED-321 through SED-340) for laboratory analysis of SVOCs/PAHs, PCBs, and TAL metals. A subset of the samples was also analyzed for TOC and grain size (Figure 3-26).
- 20 hydric soil samples were collected from ten locations at the 0-1 and 1-2 foot bgs intervals from the Red Maple Swamp interior (SSH-301 through SSH-310). Samples were analyzed for SVOCs/PAHs, PCBs, and TAL metals. A subset of samples was also analyzed for TOC and grain size (Figure 3-26).
- Groundwater samples were collected from 38 monitoring wells for laboratory analysis of VOCs, SVOCs/PAHs, PCBs, and TAL metals (filtered and unfiltered) (Figure 3-27).

- Background upland surface (0- to 1-foot bgs) and subsurface (1- to 3-foot bgs) soil samples were collected from 20 locations at Rome Point State Park (SB-401 through SB-420) and submitted for analysis of PAHs and TAL metals. A subset of samples was also analyzed for TOC and grain size (Figure 3-28).
- Background hydric soil samples were collected from 2 depth intervals (0-1 and 1-2 foot bgs) from ten locations within a coastal wetland area at Rome Point State Park (SSH-311 through SSH-320). Soil samples were submitted for laboratory analysis of PAHs, PCBs, and TAL metals. A subset of the samples was also analyzed for TOC and grain size (Figure 3-28).
- Ten shallow sediment samples (0-1 foot bgs) were collected from the intertidal zone along the shoreline of the beach at Rome Point State Park (SED-311 through SED-320). Sediment samples were submitted for laboratory analysis of TAL metals. A subset of the samples was also submitted for laboratory analysis of TOC and grain size (Figure 3-28).
- Five off-Project upstream sediment samples (background) samples were collected for sediment toxicity testing, macroinvertebrates survey, and analysis for acid volatile sulfide/simultaneously extracted metals (AVS/SEM) to support the ecological risk assessment (SED-321 through SED-325 on Figure 3-26).

All environmental samples submitted for chemistry analysis were analyzed by Katahdin Analytical in Scarborough, Maine. Details of the 2019-2020 investigation were presented in the Field Trip Report (Mabbett, 2020). The data collected during the 2019-2020 investigation were qualified by Katahdin and validated by Laboratory Data Consultants (LDC) of Carlsbad, California using the USACE ADR software and in accordance with Stage 2A validation guidelines. The validated analytical data collected during the 2019-2020 investigation are presented in Section 5.0.

The sediment toxicity testing was performed by Enthalpy Analytical of Hampton, New Hampshire. Sediment samples collected for the macroinvertebrate survey were analyzed by Normandeau Associates of Bedford, New Hampshire.

4.0 PHYSICAL CHARACTERISTICS OF THE SITE

This section summarizes the physical characteristics of the Site and surrounding area, including topography, geology, and hydrology. Physical characteristics of the Site have been compiled using a combination of literature reviews, historical reports, and field measurements and observations from the 2011-2020 Mabbett investigation field programs.

4.1 Surface Features (Physiography)

4.1.1 Regional

The surface topography near the Site (from Quonset Point to a point approximately 5 miles west of Quonset Point) exhibits over 150 feet of relief in a series of north-south trending troughs/depressions and ridges (Figure 4-1). These troughs were developed by river and stream erosion and deepened by glacial activity. Surface drainage is not well developed, and swamps and marshes are extensive. Streams are small and, in most places, bordered by swamps.

Nearly all the surficial deposits are of glacial origin deposited during the Wisconsinan Glacial Stage of the Pleistocene Epoch. The glacial deposits record a single invasion of the ice sheet and are only slightly modified by post-glacial weathering and erosion (Schafer, 1961) (Figure 4-2). Portions of the land surface at the Quonset Business Park have undergone significant man-made modification, e.g., hills were leveled and depressions filled in as part of the original construction of the Base and during military training operations.

4.1.2 Site

Elevations in the general vicinity of the Site range from approximately 23 ft above mean sea level (MSL) at the northern end of the Site along Circuit Drive to mean sea level at the southern end of the Site along Narragansett Bay (Figure 4-3). Site topography generally slopes from north to south toward Narragansett Bay. The western border of the Project and the walking path are at slightly higher elevations than Red Maple Swamp.

4.2 Meteorology

The climate in eastern Rhode Island is considered humid continental with hot summers, cold winters, and high humidity year-round. The U.S. Department of Agriculture (USDA) classifies the area as Zone 6b (USDA, 2020). According to National Resources Conservation Service (NRCS) data for Washington County, from 1981-2010 the average temperature was 50.9°F; the average daily low temperature was 18.8°F (January); and the average daily high temperature was 69.9°F (July) (NRCS, 2020). The average humidity was 64 percent over a period between 2010 and 2020 (Wolfram Alpha, 2020). Average wind speed information collected from the Quonset State Airport (KOQU) between 2010 and 2020 was approximately 12 miles per hour (Wolfram Alpha, 2020). Similar to the rest of the northeastern seaboard, the North Kingstown area receives year-round precipitation. Average monthly precipitation ranges from a high of 5.54 inches in March to a low of 3.66 inches in July (The Weather Channel, 2020). Precipitation levels are generally lower in the summer months than in winter months. In winter months, powerful storms known as “nor’easters” can cause significant rain or snowfall and blizzard conditions.

4.3 Surface Water Features

4.3.1 General Surface Water Drainage

Surface water drainage flows southward across the Site toward Narragansett Bay by overland flow, with a component in the western portion of the Project flowing toward Red Maple Swamp due to the lower elevation of the latter. The tidal stream in Red Maple Swamp drains into Narragansett Bay near the Site's southwestern corner. Elsewhere on the Project, surface flow is likely influenced by the large areas of non-permeable surfaces (the majority of the Project is paved), and the permeability of the sandy surficial soil, as well as the topography.

Overland runoff from the area immediately upgradient from the Site flows generally eastward toward Narragansett Bay. Runoff originating from proximal areas between Roger Williams Way and Circuit Drive are directed to the site through a man-made earthen drainage channel (Figure 4-4). This earthen drainage channel begins south of Roger Williams Way and collects surficial storm water from landscaped areas between Roger Williams Way and Circuit Drive. The earthen drainage channel extends due south until Circuit Drive, where it travels beneath Circuit Drive through a concrete culvert. On the downstream side of the culvert (southern side of Circuit Drive), the drainage channel discharges to the northern portion of the Red Maple Swamp at QDC Outfall 025. The earthen drainage channel then continues south along the western border of the Blue Beach walking path, terminating at QDC Outfall 026, which is located at the northern head of the Red Maple Swamp tidal stream.

4.3.2 Red Maple Swamp

The Red Maple Swamp tidal stream extends south/southwest through Red Maple Swamp, turns west in the central portion of Red Maple Swamp, then turns south until it discharges into Narragansett Bay. During tidal cycles, Narragansett Bay seawater flows into the tidal stream, causing the tidal stream to reverse flow direction and become brackish up to Outfall 026. The tidal stream salinity, calculated as a function of temperature and conductivity, was measured most recently at three locations during an outgoing tide in 2014. The data indicated that salinity ranged from a maximum of 17.97 percent at location SW-5 located approximately 170 feet north from where the tidal stream discharges into Narragansett Bay; decreased to 0.15 percent at location SW-4 located approximately 650 feet upstream from SW-5; and was less than 0.01 percent at located SW-3 located at the northern head of the tidal stream at QDC Outfall 026 and approximately 400 feet upstream from SW-4 (Mabbett, 2016).

Red Maple Swamp also receives storm water originating from two storm drains on Roger Williams Way and one storm drain located in the landscaped grass field between Roger Williams Way and Circuit Drive (Figure 4-5) (QDC, 2012). The storm water is conveyed through an underground 36-inch diameter concrete pipe that passes underneath Circuit Drive and eventually discharges at QDC Outfall 026 (Figure 4-4).

Additional surface water inputs to the Red Maple Swamp include outflow from a surficial depression associated with a former interceptor trench located on the western side of the Kiefer Park FUDS Project. This man-made, shallow, seasonally-inundated depression is located between the western boundary of the former Kiefer Park Tank Farm and the Blue Beach public walking path. It is approximately 100 feet long (north to south), 10 to 20 feet wide (east to west), with an approximate area of 1,500 square feet. A man-made rip-rap lined surface water overflow discharge outlet is located on the southwestern end of the former interceptor trench. During periods of high precipitation and seasonal high groundwater elevation, surface water in the former interceptor trench flows west beneath the Blue Beach walking path foot bridge and merges with surface water just downstream from the QDC Outfall 026. Between 2002 and 2005 QDC constructed the elevated foot bridge and rip-rap lined drainage channel connecting the former interceptor trench to Red Maple Swamp. Prior to 2002-2005, the elevated grade of the earthen walking path served as a barrier to surface water in the former interceptor trench from flowing into Red Maple Swamp, except under conditions when “the area surrounding the interceptor trench remnant was inundated, with water flowing over the path toward the main body of the wetland [e.g., Red Maple Swamp]” (GZA, 1997).

Groundwater in the Red Maple Swamp is not considered to be accessible to residents due to non-CERCLA use restrictions, related to its status as a wetland, and existing provisions limiting earth disturbance in wetlands and recreation areas. Depth to groundwater exceeds the depth that could be caused by typical site use by visitors, recreators, adjacent residents, and adjacent site workers.

4.3.3 Onsite Interceptor Tench

In 1983, RIPA reportedly excavated all or a portion of the interceptor trench along the western border of the former Kiefer Park Tank Farm south of Circuit Drive (GZA, 1986). The trench was excavated to observe the presence of jet fuel breakouts at the toe of the slope. Absorbent pads were used to remove some jet fuel observed seeping from the excavated area at that time. The trench was not backfilled at that time and petroleum or water was never pumped from it. However, based on a comment letter dated November 28, 1995, from Rhode Island Economic Development Corporation (RIEDC; later became QDC) to USACE, and from a separate telephone interview between Mabbett and Mr. Luchka, the former QDC Engineer (Mabbett, 2013), the former interceptor trench was likely the remnant of a series of chambers constructed by the Navy in the 1950s. The chambers were constructed at different elevations and presumably separated by weirs, believed possibly to "separate product from water (probably tank bottoms) before discharging the water into the [Red Maple Swamp] further to the west". Based on this historical information, the other chambers were likely filled in prior to 1983—the date when RIPA performed their excavation in the area now referred to as the former interceptor trench.

During a site visit by USACE's ecological risk assessor in the fall of 2012, the former interceptor trench was observed to be vegetated with emergent wetland plants and contained a small area of shallow standing water. Plants noted growing in the trench included cattail, purple loosestrife, boneset, jewel weed, soft rush, sedges, and Phragmites australis. Surface water present in the depression was noted as having a distinct iron sheen. During four visits between 2011 and 2012, Mabbett observed surface water outflow from the former interceptor trench at a near "trickle" to a steady discharge; no surface water was present during site visits in the summer and fall of 2014 and 2015; a mixture of snow and ice was present in the winter of 2016. The outfall was dry during the September/October 2020 sampling event.

4.3.4 Stormwater Detection Basin

A man-made, unlined storm water detention basin (approximately 1.42 acres) is located adjacent to and west of the northwestern segment of the Blue Beach walking path (Figure 4-6). The detention basin is owned by Circuit Drive Drainage Association and operated by a consortium of the four companies that use it. The detention basin receives stormwater run-off from catch basins located at four businesses located to the northwest of the Site; the businesses include Dominion Diagnostics, Meister Abrasives, Inc., Supfina Machine Company, Inc., Emissive Energy, and Stanley Bostich. The stormwater in these catch basins is conveyed by gravity through underground conduits that discharge into the detention basin. An overflow spillway/weir is located midway along the eastern side of the detention basin. The spillway/weir reportedly drains into a conduit (dimensions not known) that discharges in the vicinity of QDC Outfall 026 (the conduit outfall has not been observed by Mabbett).

4.3.5 Surface Water Bodies

The Red Maple Swamp tidal stream is the only surface water body on Site. Narragansett Bay borders the southern boundary of the Site. There are no surface water features on the Blue Beach FUDS Project.

4.4 Geology

This section presents a discussion of regional and site geology. It is based on information from published literature and data gathered during the investigations conducted at the Site and adjacent areas.

4.4.1 Regional Geology

The Quonset Point area is located on the western flank of a glacially carved valley that forms the Western Passage of Narragansett Bay (Schafer, 1961) (Figure 4-2). Bedrock, consisting of meta-sedimentary rocks of the Pennsylvanian-age Rhode Island Formation, outcrops in the area in a series of discontinuous ridges, generally trending southward and partially covered by glacial deposits (Williams, 1964). Bedrock outcrops occur along Camp

Avenue, beginning approximately one-half mile north of Kiefer Park. The U.S. Geological Survey (USGS) groundwater map of the Wickford Quadrangle (1959) shows a bedrock ridge just west of the site, the eastern side of which slopes towards the east to depths of greater than 90 feet offshore of Quonset Point (Figure 4-7).

Bedrock is overlain by glacially derived ice-contact deposits, which consist of water-laid sands, gravels and silts deposited by streams or in lakes on top of or against thin sheets of ice. In some places these deposits include layers of till, consisting of dense, poorly sorted sands and gravels. Melting of the underlying ice resulted in collapse of these layers forming locally discontinuous sequences of sediments (Schafer, 1961).

In general, near the Narragansett Bay shoreline are localized areas of recent swamp and marsh deposits, and beach deposits. Most of the eastern portion of the Quonset Point area has undergone extensive reworking of near surface soils, especially during construction of the NAS and Quonset State Airport. Many swamps, marshes, streams, and ponds appear to have been filled and, in places, the shoreline has been extended eastward up to 1,000 feet by the placement of fill.

4.4.2 Site Geology

In general, subsurface conditions at the Site are consistent with the regional geologic sequence. The bedrock at the Site is overlain by glacial deposits. The overburden consists of a sequence of fill overlying sands that become increasingly dense and silty with depth. Layers of silt are found interbedded in the sands, and a dense, gravelly glacial till is found immediately overlying bedrock in select areas.

Initial investigations at the Project (GZA, 1993) indicated that surface soils consist of sand and silty sand and gravel fill varying in thickness from less than one foot to as much as 11 feet. The fill consists primarily of well-graded sands with up to about 40 percent fragments of metal, brick, wood, and glass, and, in some places, ash. The fill at Kiefer Park Tank Farm was initially found to be as deep as 14 feet. As discussed in Section 3.0, portions of the Project have been remediated to address environmental concerns, with some debris being removed and disposed off-site or consolidated on site.

The underlying natural soil strata generally consists of fine sand to depths of approximately 10 to 17 feet grading to a silty sand to depths of 27 to 39 feet. Typical of glacial deposits, the horizontal and vertical distribution of sands and silty sands are highly variable across the Site. The depth to silty sands is generally less in the glacial deposits overlying the bedrock ridge observed in the western portion of the Project area. Both sands and silty sands are interbedded with layers of silt. Sand sequences are generally thicker in the eastern portion of the Site. This type of upward-coarsening sequence is typical of a progradational shoreline, such as occurs along a high energy coastline, or of deltaic deposits.

In deeper borings along the eastern portion of the Project, a layer of glacial till was encountered at depths of approximately 30 feet bgs, beneath the silty fine sands. Till consisted mostly of very dense silty sands and gravel, with occasional boulders or boulder zones. Refusal was encountered in the intermediate and deep borings at depths ranging from 30 to 58 feet bgs. Some or all of the refusals at shallower depths, particularly to the southwest of the Hayward facility, may have been due to boulders or the bedrock ridge observed in the western portion of the Project area identified along. Within Red Maple Swamp, the overburden is approximately 15 to 30 feet thick; thickness increases toward the western border of Red Maple Swamp. Soil boring data from the MW-106 cluster indicate thick deposits of sand.

The stratigraphy at the Site is depicted in cross-sections provided in Figures 4-8A, 4-8B, and 4-8C. As shown on these figures, these cross-sections depict the stratigraphy extending west and south from OW-9.

Bedrock was penetrated and cored at five boring locations during the RI. Bedrock was encountered at 54 ft bgs, 49.5 to 54.5 ft bgs, 45-55 ft bgs, 32-42 ft bgs, and 55-60 ft bgs, respectively, at borings MW-19, MW-20, OW-4,

OW-3, and OW-1. Based on the cores obtained from these borings, the bedrock at the Site was observed to be fresh, to slightly weathered hard, fine-grained meta-sandstone. The rock quality designations (RQDs) for bedrock cores ranged from 66 percent to 98 percent. Fractures occurred along the bedding planes or at near vertical angles; most were filled with quartz and pyrite. In general, the bedrock appeared to have a low hydraulic conductivity relative to the overlying sediments.

The surface of the bedrock was delineated by five borings (MW-19, MW-20, OW-4, OW-3, and OW-1) and nine additional borings completed to refusal at the presumed bedrock depth. As noted in Section 3.3.4.2, a seismic survey was also performed in the western and southern portion of the Site in 2015 to evaluate the bedrock surface in these areas (Hager-Richter, 2015). Based on the survey and boring data, a ridge of bedrock appears to exist beneath the Site. The ridge is located parallel the western side of the Hayward facility, along the western boundary of the Project area (Figure 4-9). The ridge rises to an approximate elevation of -10 feet MSL. The ridge slopes downward to the east and west, with the lowest elevations of the bedrock surface at approximately -33 feet MSL on either side of the ridge. Additionally, the bedrock elevation north of the Circuit Drive also appears to be between approximately -33 and -36 feet MSL. The bedrock ridge appears to extend from the beachfront to at least the northern end of the Hayward facility.

The NRCS defines the soil at the adjacent Former Kiefer Park Project area as primarily consisting of the Udorthents-Urban land complex and Quonset gravelly sandy loam (Figure 4-10). However, much of the surface soils on the Project were reworked and graded during the initial construction of the NAS and since. As discussed above Section 3.0, initial historical investigations at the Project indicated that surface soils consisted of sand and silty sand and gravel fill, varying in thickness from less than one to as much as 11 feet. Beneath the historical fill and native materials appears to be the natural sequence of glacial deposits.

The forested portion of Red Maple Swamp consists of Quonset gravelly sandy loam; the tidal flat within Red Maple Swamp consists of Matunuck mucky peat; and the Blue Beach beachfront is defined as a beach, sandy surface.

Hydric soil is defined as soil present in Red Maple Swamp that becomes intermittently saturated during high tide; these samples were collected from the interior of Red Maple Swamp in 2019 (20 samples), 2011 (14 samples), and 1994 (2 samples). Sediment is defined generally as perpetually saturated media present in the tidal stream within Red Maple Swamp; the natural depressions and tidal creeks in the interior of Red Maple Swamp that are also generally perpetually saturated; and the Blue Beach beachfront sediments in the inter-tidal and sub-tidal areas along Narragansett Bay. Hydric soil and sediment samples were generally collected from 0 to 0.5 feet bgs or from 1-foot intervals between 0 and 2 feet bgs.

Red Maple Swamp receives surface water discharge from the QDC Outfall 025 at Circuit Drive, and at QDC outfall 026 at the head of the tidal stream. Surface flow between QDC Outfalls 025 and 026 is to the south. Within Red Maple Swamp, during an outgoing tide the surface water flow in the tidal stream is south toward Narragansett Bay. During an incoming tide, the surface water flow reverses, and Narragansett Bay surface water flows into tidal stream up to the QDC Outfall 026. Along the tidal stream flow path along the western border of Red Maple Swamp, the sediment appears to reflect this flow pattern, based on a defined channel and scouring. This scouring does not extend very far upstream of the dogleg (where the tidal stream turns to the east) or north toward QDC Outfall 026.

4.5 Hydrogeology

4.5.1 Regional

Regional groundwater flow in the area is generally toward the east and south, discharging to Narragansett Bay. The near-surface overburden aquifer is primarily in glacial deposits, with the bedrock surface acting as the lower aquifer boundary. The overburden aquifer thickness varies from zero near the western end of the Quonset Point

area to 60 or more feet near the eastern end (Johnson and Marks, 1959; Rosenshein et al., 1968). Reported hydraulic conductivities in the aquifer are generally quite high, with a transmissivity of 40,000 gpd/ft recorded in a former pumping well located near the Quonset Point Air Base control tower (Rosenshein et al., 1968). For an assumed 60-foot aquifer thickness, this rate is equivalent to a hydraulic conductivity of approximately 90 ft/day. It should, however, be noted that these aquifer values were derived from pumping wells which were developed in the more prolific portions of the aquifer. Consequently, these values may be higher than average values at the Site.

4.5.2 Site

Although variable in elevation due to seasonal and temporal effects, the water table in the Project area is generally encountered at depths ranging from 5.5 to 15 feet bgs. This depth generally coincides with the transition of the surface fill materials to natural sands. However, at some locations, particularly along the bedrock high running along the western boundary of the Project area, the water table lies just above or in the silty sands. Depths to groundwater are typically deeper within the Blue Beach Project area, in comparison to Red Maple Swamp where depth to groundwater is approximately 1.5 to 3 feet bgs during low tide, and 0 feet bgs during high tide (when Red Maple Swamp is partially flooded).

The potentiometric surface is depicted from water-level data from monitoring events in December 2011 on Figure 4-12, July 2014 on Figure 4-13, and September 2019 on Figure 4-14. As these figures indicate, the potentiometric surfaces were similar during each monitoring event, as would be expected from the synchronized water levels measurement collected at approximately the same interval in the tidal sequence (on an out-going tide). However, water levels were somewhat higher in 2011. As these data sets demonstrate, a groundwater divide is present in the western portion of the Project area, running roughly north-south. This groundwater divide coincides with the location of the bedrock high running beneath the western portion of the Project Area. The divide is more pronounced during the high-water conditions observed in 2011.

As these potentiometric surfaces indicate, groundwater flow direction is generally southerly across the Site, with a western and eastern component on either side of the Hayward facility, corresponding the location of the groundwater divide and bedrock ridge. Hydraulic gradients are variable across the Site with average horizontal hydraulic gradients of approximately 0.007. The gradient appears to be lower in the northern portion of the site (0.005), and steeper close to the southern site boundary (0.01) as groundwater approached the shoreline.

Based on the 2014 water levels depicted in Figure 4-12, the gradient on the southeastern portion of the Site is approximately 0.008. The gradient in the immediate area of monitoring well OW-09 is slightly less than 0.007. However, the gradient steepens immediately downgradient of OW-09 to approximately 0.02. The groundwater gradient subsequently dissipates as it enters the marsh area. Shallow groundwater flow appears to stagnate in the marsh although a slight gradient to the south toward Narragansett Bay is evident.

These changes in gradient are attributed to the subsurface geologic features of the Site. The saturated overburden in the area surrounding OW-9 is relatively thin and comprised of silty sand and poorly graded sand. These conditions restrict groundwater flow and require high gradients to transmit groundwater. In the swamp, extensive deposits of clean sand are present. The much higher permeability associated with such materials would not require strong gradient to transmit the limited flow coming from the northeast from the area of OW-09.

The potentiometric surfaces depicted in Figures 4-11 through 4-13 represent gradients in shallow groundwater. These gradients indicate shallow groundwater flows toward the center of the marsh from both the eastern and western borders of the marsh. However, groundwater sample data suggest Site-related constituents are present at depth along the western boundary of the Site in the vicinity of monitoring well W98-1.

Groundwater level data collected in 2014 was used to infer groundwater gradients in the deeper overburden deposits in the marsh. The water level measured on July 21, 2014 in the center of marsh at MW-106D (screened from -25 feet to -30 feet MSL) was 2.95 feet MSL. Water levels measured on the same date along the western boundary of the Marsh in monitoring wells W98-1 (screened at -20 to -25 feet MSL) and in PZ-2 (screened at -20 to -25 feet MSL) were 2.2 feet MSL and 2.38 feet MSL, respectively. Thus, there appears to be a modest gradient in the deep overburden deposit from the middle of the marsh to the western boundary of the Site. Comparison of water levels in MW-106D and M98-1 indicate a gradient in deep groundwater of 0.004 between these locations. Based on two separate 8-hour tidal studies in five wells (OW-1, OW-6, OW-7, OW-9, OW-10) on March 25 and 27, 1993 (GZA, 1993), the tidal flux was approximately 0.3 feet in the two wells (OW-6, OW-10) located within 20 feet upgradient from the seawall. The two wells (OW-7, OW-9) located farther inland, approximately 400 feet upgradient from the seawall, did not exhibit a substantial tidal impact (<0.05 feet). Monitoring well OW-1 located north of Circuit Drive also had no substantial tidal impact. Likewise, during two additional 8-hour tidal studies in five different wells (MW-10, MW-11, MW-12, MW-14, MW-16) on May 4 and 5, 1993 (GZA, 1993), the data confirmed there was no apparent tidal impact in any of the wells, including well MW-11, located approximately 650 feet upgradient from and the well closest to the shoreline. These data suggest tidal influence decreases with distance from the shoreline and are not significant at the Site.

Hydraulic conductivity testing using slug tests has been undertaken as part of several historical investigations in the Site area and adjacent Kiefer Park FUDS Project. GZA (1993) performed slug testing in eleven monitoring wells in OW-series shortly after their installation in the Blue Beach Salvage Area in 1993. The reported hydraulic conductivity values for the sand and silt deposits range from 1 to 112 feet/day ($3.5x10^{-4}$ cm/sec to $4.0x10^{-2}$ cm/sec). GZA (1994) performed slug testing in 21 wells in the MW-series shortly their installation in the Kiefer Park Tank Farm and adjacent area in 1993. The range of hydraulic conductivity reported for the 19 water table wells was 10.7 feet/day to 77.0 feet/day ($6x10^{-3}$ cm/sec to $2.7x10^{-2}$ cm/sec). However, GZA reported that the hydraulic conductivity in 11 of the 19 water-table wells ranged between 20 to 50 feet/day ($7x10^{-3}$ cm/sec to $2x10^{-2}$ cm/sec). The hydraulic conductivity for the two wells screened in the till ranged between 0.12 and 2.20 feet/day ($4.2x10^{-5}$ cm/sec to $2x10^{-4}$ cm/sec). GZA conducted hydraulic conductivity testing of 16 water-table monitoring wells in the W94 series shortly after their installation in Kiefer Park and adjacent Blue Beach areas in 1994. GZA (1997) reported that the results of the testing indicated a range of hydraulic conductivity measurements from 0.1 to 14 ft/day ($3.5x10^{-5}$ cm/sec to $5.0x10^{-3}$ cm/sec).

The hydraulic conductivity values determined for the MW-series water-table wells are clearly higher than the values determined for the W94-series of wells. The construction of the MW-series and W94-series wells is similar. This apparent inconsistency was evaluated by ENSR (2000) as a part of an evaluation of remedial technology undertaken for the Kiefer Park Tank Farm FUDS Project. ENSR observed that the hydraulic conductivity test done in the MW-series wells occurred during high water table conditions, while the test conducted during in W94-series wells was conducted during low water table conditions. ENSR observed that both set of water-table wells are screened across the transition from fine sand fill to nature silty sands. Thus, hydraulic testing during high water table conditions yielded measurements consistent with the more permeable fine sand fill and testing during low water table conditions yielded measurements consistent with the less permeable natural silty sands on Site. Therefore, the hydraulic conductivity measurements from the MW-series wells were judged to be more representative of fine sand fill materials and the measurements from W94-series wells were judged to be more representative of underlying, natural silt sands. This evaluation indicates that hydraulic conductivity measurements obtained from the OW-series well may be similarly impacted by groundwater elevation during the testing. Furthermore, when evaluating migration pathways and remedial options, the hydraulic properties of the overburden strata need to be carefully considered.

Groundwater flow rates across the Site can be estimated using an average horizontal gradient of 0.007 across the Site, average porosity of 0.30, and average hydraulic conductivity of 20 feet/day. The groundwater velocity can be calculated by substituting these parameter values into the following equation:

$$v=Ki/n,$$

where K = average hydraulic conductivity, i = the estimated flow gradient, and n = an assumed porosity.

The resulting ground water flow rate is 0.47 ft/day or 170 feet/year. However, caution is necessary when applying this flow water since it is representative of flow in the shallow fine sands at the Site. Using an equivalent gradient, flow through the less permeable silty sand may be an order of magnitude slower (e.g., 17 ft/year).

4.6 Land Use

As previously described, the Site is located within the Quonset Business Park (Figure 4-14). According to the North Kingstown Zoning Ordinance, "*The Quonset Business Park zoning district is established as a mixed-use center for economic activity, which may include residential and recreational uses. The Quonset Business Park is a performance-based development district that will focus on facilitating economic development that recognizes, is protective of, and is consistent with the overall community planning objectives of the town.*"

The Quonset Business Park, which is comprised of 3,207 acres and is the largest industrial park in Rhode Island by employment levels, consists of approximately 200 businesses and employs approximately 12,000 people (QDC, 2015). These businesses encompass a wide variety of fields, including office, research and development, manufacturing, warehouse and distribution, marine construction, and importation. The Quonset Business Park also includes a daycare facility (located 1.7 miles north/northwest of the Project), golf course, marina, ferry, airport, restaurants, public beaches, museums, and retail stores. The Quonset Airport, as well as open space and wetlands, comprise approximately 38 percent of the Quonset Business Park. The remaining 62 percent of the land is designated for development.

As previously described, land use at the Project is restricted to commercial/industrial activities by ELURs recorded on the deeds. ELURs were prepared separately under the Kiefer Park Tank Farm FUDs Project by RICC, the parcels' owner, for the Walking Path/Blue Beach beachfront lot, the Circuit Drive Public Parking Lot, and the Red Maple Swamp. The ELURs were submitted on April 16, 2018. Deed records can be found at the North Kingstown Town Clerk in Deed Books 3116 Page 285, Book 3116 Page 301, and Book 3117 Page 1, respectively. These ELURs prohibit residential use and limit activities to passive recreation at those parcels.

The five parcels located within the Project are within the "Quonset Light Industrial District" under the Quonset Land Use District plan (Figure 4-14) (QDC, 2018). To the west of the Project, the Walking Path/Blue Beach beachfront parcel is within the "Quonset Public and Recreation District," while the Red Maple Swamp parcel is within the "Quonset Open Space and Conservation District" under the Quonset Land Use District plan.

The Rhode Island Coastal Resources Management Council (CRMC) maintains jurisdiction over wetlands and coastal zone development at the Site.

4.6.1 Residential

There are no residences on the Site or at the Quonset Business Park. As previously discussed, unrestricted residential use is prohibited by ELURs recorded on the deeds for the parcels within the Project, and similar ELURs were filed in association with the Kiefer Park Tank Farm FUDS project for the walking path/Blue Beach beachfront, Circuit Drive Public Parking Lot, and for Red Maple Swamp.

Beyond the Site, the previously mentioned residential abutter to the west is the nearest residential area. This residence is located on the western border of Red Maple Swamp and is outside of the Quonset Business Park. As

a protected wetland, Red Maple Swamp is assumed to be unavailable for future residential development or use. Other residential areas are located outside of and to the west, north, and east of the Quonset Business Park.

4.6.2 Educational

There are no schools on the Site or on the Quonset Business Park. The nearest school is the Fishing Cove Elementary School, located approximately 0.8 miles west of the Site. Davisville Middle School and Forest Park Elementary School are located just over 2 miles north/northwest of the Site.

4.6.3 Recreational

The Blue Beach beachfront is a public beach located adjacent to the south/southwest border of the Project but within the boundary of the Site. Public access to Blue Beach beachfront is gained from the walking path, which originates on the southern side of Circuit Drive. The walking path/Blue Beach beachfront parcel is owned by RICC and maintained by QDC.

Other recreational areas at the Quonset Business Park include a bike path and three public beaches located on Quonset Point within 1 to 2 miles east of the Site: Calf Pasture Point, Compass Rose, and Spink's Neck Beach.

To the west of the Site is the natural saltwater inlet known as Fishing Cove, which is located within Wickford Harbor approximately 0.5 miles west of the Site.

4.7 Ecology

The regional and site ecological settings are described in this section.

4.7.1 Regional Ecology

The regional ecology is characterized as a mix of improved land (either developed or cleared) and non-improved land with forested uplands dominated by a diverse shrubby understory. Within the Quonset Business Park, developed areas are typically landscaped with grass and ornamental vegetation.

Additionally, RIDEM publishes the environmental sensitivity index (ESI) map for the marine and coastal areas of Rhode Island (Figure 4-15). The RIDEM ESI map is a compilation of information related to three main categories: shoreline habitats; sensitive biological resources; and human-use resources. The RIDEM ESI map include information on habitat and species present in the State. RIDEM has identified areas of critical habitat located near the Quonset airport, which is located approximately 0.85 miles northeast of the Site; in the upstream portion of Mill Creek, approximately 1 mile northwest of the Site; and in Mill Cove, located approximately 1 mile west of the Site (Figure 4-16).

4.7.2 Site Ecology

The RIDEM ESI and biodiversity resource maps that encompass the Site indicate no known sensitive species or area of critical habitat on the Site (Figure 4-15, 4-16). There are sensitive habitats for fish, waterfowl, and invertebrate species noted along Narragansett Bay, along the southern Site border. However, according to the RIDEM Environmental Resource Map (ERM), shellfishing is prohibited throughout the area of Narragansett Bay along the southern Site border (Figure 4-17).

The majority of wildlife that has been observed at the Site is within the Red Maple Swamp area. Wildlife observed has included white-tailed deer (Odocoileus virginianus), rabbits, rodents, amphibians, and birds (GZA, 1993; GZA, 1997; Mabbett, 2011; Mabbett, 2016). The forest and wetland resources at the Site are located within Red Maple Swamp, as depicted on the RIDEM Forest and Wetland Resources Map provided on Figure 4-18.

The dominant vegetation in the northern portion of Red Maple Swamp is a deciduous forest with a diverse shrubby understory; the central portion is dominated by Phragmites; and the southern portion is dominated by Spartina. RIDEM classifies the wetlands in Red Maple Swamp as estuarine emergent wetlands and forested deciduous

wetlands. The RIDEM Forest and Wetland Resources map indicates that the non-developed portions of the Site include wetland/marine estuarine and upland deciduous forest.

5.0 NATURE AND EXTENT OF CONTAMINATION

This section summarizes the results of characterization efforts and the current understanding of the nature and extent of Project-related constituents in environmental media at the Site. The nature and extent evaluation is based on more than ten historical investigations performed over the past 30 years, accounting for hundreds of environmental samples collected from soils, sediments, groundwater, surface water, and soil gas. These data provide a thorough understanding not only of the nature and extent of contamination at the Site, but also the source areas where contaminants may have been released.

5.1 Potential Source Areas of Contaminant Releases on the Blue Beach FUDS Project

Based on data from environmental samples analyzed during the 2011-2020 investigations and historical investigations, the principal chemicals identified at the Site include CVOCs, petroleum-related VOCs, SVOCs (PAHs), metals, and PCBs. Infrequent detections of pesticides were also present in soil and sediment at the Site. The presence of these chemicals in various media at the Site is attributed to chemical releases associated with the general waste handling activities during the time period when the Project was used as the Blue Beach Disposal Area from approximately 1941-1974.

Based on the horizontal and vertical extent of these chemicals within the Site, there appear to be at least two primary source areas present within the larger former disposal area: (1) the former PCB Removal Areas/former General Dynamics Salvage Yard/former Drum Storage Area on the eastern portion of the Project, where the majority of contaminants in soil have been removed and no longer act as a source area; and (2) the geophysical anomaly area on the western portion of the Project. Additionally, two areas at the Kiefer Park Tank Farm FUDS Project—the former tank farm area and the former interceptor trench area—appear to be the source of petroleum-related chemicals present at the Site. These source areas are described in the following section.

5.1.1 Blue Beach Disposal Area

Wastes identified during various investigations at the Blue Beach Disposal Area included salvaged aircraft, vehicle parts, machinery, construction debris, drummed materials, and other miscellaneous wastes (USAGC, 2010; GZA, 1993; GZA, 1997; Mabbett, 2011). However, there is no known documented inventory of wastes disposed of in the former Blue Beach Disposal Area. Constituents in soils may have been further dispersed due to apparent grading and earth-moving activities during operation of the former disposal area and during construction of the Hayward and Falvey facilities in circa 2003 and 2008, respectively. Transport of contaminants from the Project into Red Maple Swamp may have also occurred via wind and surface water run-off.

Within the Blue Beach Disposal Area, two primary source areas appear to be present as described in the following sections.

5.1.1.1 PCB Removal Areas/Former General Dynamics Salvage Yd/Former Drum Storage Area

The former PCB Removal Areas/former General Dynamics Salvage Yard/former Drum Storage Area is located on the eastern portion of the Project (Figures 3-1 and 3-7). Historical investigations identified concentrations of PCBs, VOCs, metals (e.g., arsenic), and benzo(a)pyrene in surface soils; and lead, selenium, cadmium, and naphthalene in groundwater in this area (ECC, 1999; ECC, 2003). Potential sources for these constituents included oiling of roads for dust control using oils containing PCBs, and from drums of transformer fluid historically stored in the eastern portion of the Project. The drums were subsequently removed in 1984, and the associated soils were removed during the PCB removal completed from 1998 to 2001 (ECC, 1999; ECC, 2003). As part of the PCB removal, contaminated soils were either transported off-site for disposal or consolidated and placed underneath the asphalt cap located at the southern end of Whitecap Drive, midway between the Hayward and Falvey facilities (Figure 3-7).

Groundwater data indicates the presence of CVOCs in the eastern portion of the Project, near the northern side of the Falvey facility. Former activities at either the Blue Beach Disposal Area and/or the former General Dynamics salvage yard appear to be the source of these CVOCs in groundwater in the eastern portion of the Project.

5.1.1.2 Geophysical Anomaly Area

The geophysical anomaly area on the western side of the Project is discussed in more detail in Sections 3.1.12 and 3.3.2. This area is presumed to be the potential source of CVOCs in this portion of the Site. Both large and small metallic and non-metallic unidentified buried objects were detected in the central eastern and central western portions of the survey area and removed for off-site disposal. Approximately 20 CY of metal and debris were removed from the geophysical anomaly area during the 2011 RI field activities.

Soil samples collected from the base of each test pit were submitted for laboratory analysis of VOCs and metals prior to backfilling (Table 3-6). Concentrations of VOCs and CVOCs were reported in these samples, with the highest concentrations detected being ethylbenzene and TCE in Test Pit 1. Other detected VOCs included 1,2,4-trimethylbenzene; 1,3,5-trimethylbenzene; BTEX; naphthalene; n-propyl benzene; and *sec*-butyl benzene. However, only ethylbenzene and TCE were detected above the EPA RSLs for Resident Soil. Detected metals in soil samples included arsenic, barium, cadmium, chromium, and lead. The concentration of arsenic detected in each soil sample exceeded the EPA RSL, however arsenic levels were at or near regional background levels.

During the 2014 investigation, the geophysical anomaly area was further assessed as the source of CVOC and VOCs present in downgradient groundwater by conducting a temporary vertical groundwater profiling investigation at locations hydraulically upgradient and downgradient from the geophysical anomaly area, with a specific focus throughout Red Maple Swamp, along the western boundary of the Project, and along the Blue Beach beachfront (Figure 3-24). The 2014 groundwater profiling locations were chosen, in part, to evaluate possible additional release locations. Based on the 2014 investigation groundwater profiling results, no other source areas were identified west or south of the geophysical anomaly area, and no DNAPL was found.

A summary of the groundwater profiling analytical data is provided in Table 5-1. The geophysical anomaly area may be a contributing source of metals in downgradient groundwater, based on generally higher concentrations of dissolved metals (arsenic, barium, cadmium, chromium, lead, and selenium) in groundwater profiling transects down gradient from the geophysical anomaly area (TS-3 series) compared with the two upgradient transects (UP-1 and UP-2 series). Based on these data, the geophysical anomaly area appears to have been the primary source of CVOC and some metals in soil and groundwater to the west and south of the geophysical anomaly area.

5.1.2 Former Kiefer Park Tank Farm FUDS Project

The Former Kiefer Park Tank Farm is a part of the Kiefer Park FUDS Project (Figure 1-3). The former tank farm operated as a Navy tank farm housing six cylindrical USTs, three of which were located to the north of Circuit Drive and three of which were located to the south of Circuit Drive. The three tanks located north of Circuit Drive each contained aviation gas (avgas), while the three tanks south of Circuit Drive contained jet fuel. Each tank measured 80 feet in diameter by 13 feet deep and stored approximately 565,000 gallons of fuel. The tanks and associated underground piping were removed in 1989 and 1990. Constituents associated with the Kiefer Park Tank Farm FUDS Project are primarily associated with residual petroleum in soil and dissolved petroleum in groundwater. Groundwater from the Kiefer Park Tank Farm FUDS Project that may have migrated to the Blue Beach FUDS Project was addressed by USACE under the separate Kiefer Park Tank Farm FUDS Project through implementation of ELURs to eliminate exposure pathways with the potential to pose significant risk to human health.

5.2 Identification of Chemicals of Potential Concern (COPC)

As specified in the Sampling and Analysis Plan (SAP) for the Comprehensive RI (Mabbett, 2019), the detected chemical concentrations in samples collected during the 2011-2020 investigations and during selected historical

investigations were compared to their relevant risk-based screening levels to identify COPCs, which are chemicals that exceed one or more of the risk-based screening criteria defined in the Risk Assessment Work Plan (provided as Appendix E of the SAP) and presented in the CERCLA-compliant baseline risk assessment (Tables 3-2 and 4-4 through 4-11 in Appendix A). Groundwater within the Red Maple Swamp has a different set of potential exposure scenarios due to existing restrictions related to the status of a tidal wetland, than on-Project groundwater and is evaluated separately as there are no exposure scenarios that include contact with the groundwater within Red Maple Swamp. The sample data used for these comparisons are summarized by medium and exposure area in Tables 5-2 through 5-16, as described in the table below.

Table	Medium	Exposure Area
5-2	Soil	On-Project Blue Beach Upland Area
5-3	Soil	Off-Project Walking Path/Red Maple Swamp
5-4	Soil	Off-Site Background
5-5	Hydric Soil	Off-Project Red Maple Swamp/Tidal Marsh
5-6	Hydric Soil	Off-Site Background
5-7	Sediment	Off-Project Red Maple Swamp/Tidal Marsh
5-8	Sediment	Off-Project Upstream/Background Tidal Stream
5-9	Sediment	Off-Project Narragansett Bay/Beachfront
5-10	Sediment	Off-Site Beachfront Background
5-11	Groundwater	On-Site (including Former Keifer Park Site,)
5-12	Groundwater	Off-Project (Red Maple/Tidal Marsh, and off-Project)
5-13	Pore Water	Off-Project Red Maple Swamp/Tidal Marsh
5-14	Pore Water	Off-Project Narragansett Bay/Beachfront
5-15	Surface Water	Off-Project Red Maple Swamp/Tidal Marsh
5-16	Surface Water	Off-Project Narragansett Bay/Beachfront

The chemicals that exceeded the risk-based screening levels were further evaluated relative to known and possible source areas and in comparison, to background (represented by background samples collected from Rome Point State Park or from upstream locations for tidal stream sediments). Based on the source profiles and screening comparison results, the COPCs for the Site were identified as metals, PCBs, SVOCs, CVOCs, and VOCs. Petroleum-related chemicals found on and near the Site are attributed to releases from the Kiefer Park FUDS Project.

Individual COPCs that were determined to be present above background were carried forward in the RI; a discussion of the results follows below. Rather than presenting an extensive discussion for each parameter analyzed during investigations, this section focuses on only the nature and extent of the COPCs that contribute to potential Site-specific risks, as indicated by the CERCLA-compliant human health and ecological risk assessments (Section 7.0 and Appendix A).

Concentrations of selected pesticides in hydric soil and sediment collected in Red Maple Swamp were above ecological risk-based screening criteria. However, pesticides were detected infrequently, and at concentrations and locations that are not indicative of a specific release from a source associated with historical operations at the Project. Pesticides are attributed to the historical application of these chemicals consistent with their labeling and were not considered further in this RI.

5.2.1 Metals

Metals detected in soils (Tables 5-2 and 5-3) and identified as COPCs in the HHRA for direct contact are antimony, arsenic, cadmium, and thallium. Those that present a risk to human health from groundwater in a potential future use scenario include antimony, arsenic, barium, cadmium, chromium, cobalt, iron, lead, and manganese. In

addition to those identified in the HHRA, copper, mercury, selenium, silver and zinc were identified as being above screening levels in the initial steps of the SLERA.

Although some concentrations of metals were reported above screening levels, it is possible that a significant source of relatively low concentrations of metals is naturally occurring or anthropogenic (regional) background. A more detailed evaluation of background conditions is discussed in the risk assessments (Section 7.0, Appendix A). The other sources of heavy metals in the environment are most likely from the former use of the Site as a disposal area and other industrial and defense site uses in the surrounding area. However, areas of buried metal and discolored soils were removed during previous remedial actions, leaving no evidence of an on-going source area and no pattern of distribution that would indicate absorbed or dissolved-phase migration from a source area.

Metals were identified above screening levels in multiple locations throughout the Site. Although metals were reported above screening levels, they were usually relatively low and reasonably consistent concentrations and somewhat sporadically located on and off the Project area. No evidence of a single source area was identified, nor was evidence of a migration pathway. To illustrate this point, the chemical tag maps provided on Figures 5-1 through 5-15 show the distribution of these metals in the environmental medium and exposure area for which they were identified as a COPC. As shown on these figures, exceedances of the screening levels are either sporadic and do not appear to be associated with a single point source, or screening levels are exceeded at most locations (e.g., lead) despite relatively low and consistent concentrations, because the screening levels are low for this type of industrial former use setting.

5.2.2 PCBs

Section 3.0 describes several PCB removal excavations from both On-Property and Off-Property areas and the consolidation of PCB-impacted material under the cap on the Project (Figure 3-7). Concentrations of PCBs under the cap reportedly range from 35 to 690 mg/kg. Other materials from the PCB excavations were removed and disposed of offsite. Soils with PCBs were delineated for removal using a 10 mg/kg cleanup goal for both surface and subsurface (excavation floor and sidewalls) soils. Given that PCB containing soils were consolidated under the cap and the likelihood that PCB residual concentrations less than 10 mg/kg remain in soils, detections of PCBs in on-Project and off-Project media are not unexpected.

Note that the concentrations for total PCBs discussed in this section of this RI report and presented on the tables and figures differ from those reported in the risk assessments in Section 7.0 and Appendix A. The difference is in the handling of reporting limits for non-detect values. In this section and on the associated Tables and Figures, total PCBs are reported as the sum of detected Aroclor concentrations, with non-detects treated as zero. If the sample is reported non-detect for each Aroclor, the lowest reporting limit for any given Aroclor is reported as the non-detect value for that sample. In the risk assessment calculations, the reporting limits for the non-detect Aroclors are added to each other or to the detected values to report the total PCBs. For low concentration and non-detect values, the non-detect limits add a significant proportion to the reported value. In the risk assessments, this is an added layer of conservatism that ensures that risk-based decisions are protective of human health and the environment.

5.2.2.1 PCBs in On-Project Soils

To characterize current conditions for on-Project accessible soils (i.e., not under the cap or building), ISM sampling for PCBs was conducted in 2019. ISM samples were collected from surface and subsurface soils from three locations (Figures 5-16A and 5-16B). PCBs were detected in each of the samples and an exposure point concentration of 0.31 mg/kg was calculated for on-Project surface soil and 0.13 mg/kg for on-Project subsurface soil (Table 3-3 in Appendix A). The maximum concentration of PCBs detected in any single ISM sample was 0.37 mg/kg, indicating that the cap and other on-Project improvements (buildings, parking lots, and raised medians) are effectively containing soils with concentrations of PCBs above 1 mg/kg.

5.2.2.2 PCBs in Off-Project Soils

PCB samples were also collected from nine discrete locations along the walking path (Figure 5-16C). PCBs were detected in three discrete surface soil samples and detected concentrations (Aroclor 1260) ranged from 0.056 to 0.19 mg/kg. As discussed for other off-Project areas and matrices, it is likely that the source for PCBs in off-Project areas was the known, uncontrolled areas of PCB storage and disposal on the Project. Since the on-Project areas have been excavated and materials either removed or placed under the cap, previous source areas are now controlled and additional releases are unlikely. The concentrations in off-Project soil areas are significantly below 1 mg/kg and are not expected to pose a risk to human or ecological receptors

5.2.2.3 PCBs in Groundwater

PCBs were detected at trace levels in groundwater from two adjacent monitoring wells in 2008 (BMW-3 at 0.07 µg/L and OW-3 at 0.05 µg/L). Samples from 38 groundwater monitoring wells were collected and analyzed for PCBs during the 2019 investigation, including BMW-3 and OW-3. PCBs were not detected in any of the 2019 groundwater samples. These data further confirm that current measures on the Site are effectively containing PCBs under the cap and under other Site improvements.

5.2.2.4 PCBs in Off-Project Sediment and Hydric Soils

To evaluate the potential impacts of PCBs to the off-Project areas, samples were collected from off-Project soils, wetland (hydric) soils, sediment, surface water and pore water. Hydric soil and sediment sample results are tabulated on Tables 5-5 through 5-10 (Tables 5-6, 5-8, and 5-10 include results for background hydric soils, tidal stream sediment, and beachfront sediment, respectively) and shown on Figures 5-16D (surface hydric soil), 5-16E (subsurface hydric soil), and 5-16F (sediment).

As shown on the figures referenced above, the highest concentration of PCBs detected in off-Project hydric soil samples was from 0.58 mg/kg (SSH-301) and the highest concentration of PCBs detected in off-Project sediment samples was from SED-335 (1.3 mg/kg). The exposure point concentration for PCBs in hydric soil within Red Maple Swamp was calculated to be 1.0 mg/kg and for sediment in the Red Maple Swamp/tidal stream area was 0.44 mg/kg. PCB were detected in each beachfront sediment samples at relatively low concentrations with a maximum detection of 0.025 mg/kg from sample SED-310.

The ecological risk assessment (Section 7.2, Appendix A) evaluated the PCB data from sediment and hydric soils from Red Maple Swamp and compared the results to several sediment quality benchmarks, including assessing the potential bioavailability of PCBs using organic carbon (OC)-normalized data and comparing with benchmarks that were also derived using OC-normalized data. This evaluation is presented in Table 4-25 in Appendix A and concludes that although most (23 of 34) sediment and hydric soil samples were greater than the Buchman (2008) effects range median concentration for marine sediment of 0.18 mg/kg, most samples (27 of 34) were below the MacDonald (2002) probable effects concentration of 0.676 mg/kg and all, except one sample, were below the OC normalized Finkelstein (2017) 10% injury benchmarks. Furthermore, if the total PCB results were calculated using detected concentrations only, or a single Aroclor limit for non-detects, as is a more conventional method (based on the overlap of Aroclors in the analytical method), no samples would exceed the OC-normalized (Finkelstein) benchmarks and only one sample (SED-335, 1.3 mg/kg) would exceed the MacDonald probable effects concentration.

Although the concentrations of PCBs in sediment and hydric soils in Red Maple Swamp and along the beachfront are most likely attributable to the historical presence of PCBs on the Project, it is likely that the release(s) of PCBs are historical in nature from when the PCBs on the Project were uncontrolled or, possibly, released with fugitive dust or surface water runoff during excavation, cap construction, and re-grading of excavated areas. As would be expected from relatively small, historical releases, the concentrations were low and below most ecological

benchmarks. Since the on-Project past source areas are now under control, it is likely that concentrations in off-Project areas will continue to decrease over time as a result of naturally occurring attenuation processes.

5.2.2.5 PCBs in Off-Project Pore Water and Surface Water

PCBs were not detected in any of the five pore water or four surface water samples collected from Red Maple Swamp in 2011 (Tables 5-12 and 5-14).

5.2.3 Semi-Volatile Organic Compounds (SVOC)

PAHs are commonly found, especially in urban areas, from the use, storage, and burning of fossil fuels and are expected to be found in a former disposal area associated with machinery and heavy equipment, such as the Site. PAHs are usually found together in different proportions depending on the source(s) for the PAHs. Because benzo(a)pyrene is often detected when PAHs are detected and because it is usually considered the most toxic (lowest screening level), it is a good indicator compound to assess the nature and extent of PAHs both on the on-Project and in off-Project areas.

A detailed description of the background analysis is provided in the risk assessment in Appendix A. In general, the concentrations of PAHs detected in samples collected from both on the on-Project and off-Project area are relatively low and consistent with the multiple sources of anthropogenic background both on and around the Site.

Although technically categorized as a PAH, naphthalene is a lighter weight compound and usually is detected as both a volatile and semi-volatile compound. Because of its nature and low molecular weight, the primary concerns with naphthalene are its mobility and volatility. Naphthalene is discussed further in Section 5.2.4.2 separately from the PAHs summarized in this section.

Bis(2-ethylhexyl)phthalate was identified as a COPC in on-Project surface soils and off-Project sediment in the ecological risk assessment. It was detected in 4 of 27 on-Project surface soil samples and in 9 of 21 off-Project sediment samples (Figures 5-17A and 5-17B). Bis(2-ethylhexyl)phthalate is commonly found in association with plasticizers and is not unexpected on a known disposal site such as the Blue Beach Project. Because of its somewhat ubiquitous uses, it is also a common field and laboratory contaminant. Because of its relatively low frequency of detection and the fact that it was not found to be a source of unacceptable risk, it is not discussed further in this RI.

5.2.3.1 PAHs in On-Project and Off-Project Soils

SVOCs were detected in surface soil samples collected in 1994, 1995, and 2019. Those SVOCs identified as the COPCs in soils reported above screening levels include benzoic acid (Figure 5-18) and the PAHs benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, chrysene and pyrene.

The distribution of benzo(a)pyrene detected in on-Project surface soil samples is shown on Figure 5-19A. PAHs are commonly found, especially in urban areas, from the use, storage, and burning of fossil fuels and are expected to be found in a former disposal area associated with machinery and heavy equipment, such as the Site. PAHs are usually found together in different proportions depending on the source(s) for the PAHs. Because benzo(a)pyrene is often detected when PAHs are detected and because it is usually considered the most toxic (lowest screening level), it is a good indicator compound to assess the nature and extent of PAHs both on the Project and in off-Project areas.

As shown on Figure 5-19A, benzo(a)pyrene is somewhat ubiquitous throughout the Project area. Although detected in most samples and usually at concentrations above the conservative human health risk-based screening level of 0.11 mg/kg, the concentrations were relatively low with a maximum concentration of 0.5 mg/kg (SB-311, 0-1 foot).

5.2.3.2 PAHs in Groundwater

PAHs have a low water solubility; therefore, the concentrations detected are most likely associated with fine particulate in groundwater, similar to metals and PCBs. Several PAHs were identified as COPCs in groundwater including benzo(a)pyrene (Figure 5-19D), dibenzo(a,h)anthracene (Figure 5-20B), 1-methylnaphthalene (Figure 5-21), 2-methylnaphthalene (Figure 5-22), benzo(a)anthracene (Figure 5-23), benzo(b)fluoranthene (Figure 5-24B), and naphthalene (Table 5-11).

5.2.3.3 PAHs in Off-Project Sediment and Hydric Soils

Slightly higher concentrations were detected in the off-Project area sediment and hydric soils. PAHs were detected in most sediment and hydric soil samples. Concentrations detected in association with the Site, including Red Maple Swamp, were consistent with and, possibly, slightly lower than in the background upstream sediment samples. The highest concentration in Site sediment was detected at SED-328 (0-0.5 feet), the maximum benzo(a)pyrene concentration was 1.7 mg/kg and the highest PAH compound detected was benzo(b)fluoranthene (3.6 mg/kg, screening level = 1.1 mg/kg). In hydric soils, the highest concentrations of most PAHs were found in the sample from SSH-304, (0-1 foot). The maximum benzo(a)pyrene detection was at this location (3.0 mg/kg). The maximum PAH concentration was also at this location and was for fluoranthene at 8.2 mg/kg (screening level of 240 mg/kg). Fewer PAHs were detected and at lower concentrations in the subsurface hydric soil samples, indicating that low levels of PAHs were probably adsorbed onto particulates, transported to the wetland area via surface water runoff and are generally sequestered in the upper foot of hydric soils.

5.2.4 Volatile Organic Compounds (VOCs)

Several VOCs have been identified on the Site from multiple known and, possibly, unknown source areas. Because of their volatility, solubility, and toxicity, VOCs are of most concern in source areas, groundwater, and in soil vapor. The remedial actions conducted on the Site and on the former Kiefer Park Tank Farm have largely mitigated the different source areas and resulted in significantly lower concentrations of VOCs in groundwater and soil vapor.

Previous investigations on the Site are summarized in Section 3.0 and discuss the remediation of the former Kiefer Park Tank Farm used for the storage of avgas and jet fuel (JP-4). LNAPL was identified and remediated in association with the former Kiefer Park Tank Farm. On the former Blue Beach Disposal Area Property, soils with concentrations of PCBs greater than 50 mg/kg were either removed and disposed of on-site under the cap or disposed of off-site. Other materials excavated and disposed of from the Blue Beach Property included intact and damaged drums, unusual materials (e.g., brown fluff, white powder) and other machinery and metal objects.

Because of the various remedial actions and the relatively high potential for mobility of the VOC compounds, this RI uses data most representative of current conditions, data from the 2014 and 2019 sampling events. For the purposes of evaluating potential source areas, patterns and extents of migration, and contributions from the former Kiefer Park Tank Farm, VOC compounds were divided into two categories:

- CVOCs, including PCE, TCE, *cis*- and *trans*-1,2-DCE, and VC, that appear to originate from disposal activities on the Blue Beach Property.
- Naphthalene and other aromatic compounds (BTEX and 1,2,4-trimethylbenzene) attributed to petroleum releases from the former Kiefer Park Tank Farm.

Although other VOC compounds were identified as preliminary COPCs based on exceedances of screening levels, the compounds listed above were the more prevalent and/or more toxic (lower screening levels) and were chosen for this discussion to illustrate the fate and transport mechanisms occurring on the Site. Other compounds that are not specifically discussed are expected to have the same transport mechanisms as evidenced by similar distribution patterns, but were of less concern in the risk assessments, due to low frequency of detection or otherwise not found to be of unacceptable risk.

5.2.4.1 Chlorinated VOCs

CVOCs were detected in groundwater samples collected from Red Maple Swamp. TCE was detected most frequently in 33 of the 53 samples collected in 2014 and 2019. A degradation product of TCE, *cis*-1,2-DCE, was detected in 30 samples. PCE was detected in 18 samples and other degradation products, *trans*-1,2-DCE and VC, were each detected in five samples (although not the same five samples). Each of these compounds except for *trans*-1,2-DCE were detected above the screening levels and were carried forward in the risk assessment evaluation. Each of these compounds also has an MCL higher than the screening value.

Figures 5-26B and 5-26C (TCE), Figure 27 (*cis*-1,2-DCE), Figures 5-28A and 5-28B (VC), Figure 5-29 (PCE), Figure 5-30 (1,1,2,2-tetrachloroethane), Figure 5-31 (1,1,2-trichloroethane), Figure 5-32 (1,1-dichloroethane), and Figure 5-33 (1,2-dichloropropane) show the distribution of CVOCs in groundwater that were retained as COPCs in the human health risk assessment.

TCE was detected in 33 of the 53 groundwater samples from 2014 and 2019 and was detected above the screening level of 0.28 µg/L in 32 of those samples and was above the MCL of 5 µg/L in 14 samples. TCE was reported in four on-Property monitoring wells (MW-108S, OW-3, OW-9, and BMW-3) in 2019 with concentrations of between 1.4 µg/L (MW-108S) and 46 µg/L (OW-3). Otherwise, TCE was not detected in on-Property or upgradient wells. The highest concentrations of TCE were detected in groundwater samples collected from monitoring wells in Red Maple Swamp adjacent to the Property and downstream from QDC Outfall 026. Maximum concentrations of TCE detected were 180 µg/L (TS-3-D) and 134 µg/L (OW-3-A). Other detected concentrations above the MCL of 5 µg/L ranged up to 75 µg/L.

The compound *cis*-1,2-DCE was detected in 30 of the 53 samples collected in 2014 and 2019 (Figure 5-27). Of these, it was detected above the screening level of 3.6 µg/L in 13 samples, and was not detected above the MCL of 70 µg/L. As with TCE, the higher concentrations were detected in the samples collected from Red Maple Swamp to the west of the Property and downstream from QDC Outfall 026.

VC was detected in 5 groundwater samples collected in 2014 and 2019 (Figure 5-28A and 5-28B). Where it was detected, it was above the screening level of 0.02 µg/L and one sample (MW-106S in 2019, 7 µg/L) was above the MCL of 2 µg/L.

PCE has a screening level of 4.1 µg/L and an MCL of 5 µg/L. Although detected in 18 of the 53 groundwater samples collected in 2014 and 2019 (Figure 5-29), it was only detected above the screening level and MCL in one sample (maximum concentration = 5.8 µg/L in MW-107 in 2014). The sample collected from this well in 2019 was non-detect for PCE. Based on the relatively low concentrations and limited detections of PCE, this compound does not appear to be of significant concern for the Site.

Based on these results, and the lack of detections in upgradient wells, it appears the Site was a former source area for CVOCs. Because the on-Property concentrations are relatively low and the highest concentrations are from wells located downgradient from the property in Red Maple Swamp, it is likely that the release(s) of CVOCs were historical and from materials previously disposed of on the Property. These materials have since been excavated and removed from the Property or placed under the asphalt cap on the property. Based on the relatively consistent concentrations and the locations of those concentrations from 2014 to 2019, it appears that soil and debris removal/consolidation has effectively mitigated the source area(s) on the property and that no further releases are occurring or likely to occur. It also appears that further downgradient migration and/or attenuation of CVOCs is occurring relatively slowly with not much change from 2014 to 2019.

Previous investigations (Section 3.1.14) identified concentrations of CVOCs in soil vapor that generally corresponded to the locations of the underlying TCE and PCE groundwater plumes. Two distinct areas of TCE and PCE in soil vapor samples were observed: on the western side of the Project (near the geophysical anomaly area and where the Hayward facility was later constructed), and on the eastern side of the Project south of the former

General Dynamics salvage yard and near the PCB Removal Area. Subsequent to these investigations, the Hayward facility was constructed in 2004/2005 with a sub-slab depressurization system (SSDS) to mitigate potential vapor intrusion risk.

Indoor air as an exposure pathway was evaluated in this RI and in the risk assessment (Section 7.0, Appendix A). Potential VOC concentrations in indoor air, without the benefit of treatment (e.g., SSDS) were evaluated based on concentrations in shallow groundwater. Although not determined to cause an unacceptable risk, VC was the only CVOC identified as requiring evaluation as COPCs for soil vapor (Figure 5-28C).

5.2.4.2 Naphthalene

Naphthalene is classified as a PAH; however, it also has some volatile organic properties (it is analyzed as both a heavy volatile compound and as an SVOC (Section 5.2.3). As it is a PAH, it is often found in association with the burning of fossil fuels or associated with coal tar. It is also commonly found as a component of unused fuel product, such as gasoline and jet fuel, as are the low molecular weight SVOC PAHs 1-methylnaphthalene and 2-methylnaphthalene. The latter two substituted-naphthalenes and 1,2,4-trimethylbenzene were also detected in Site groundwater and identified as COPCs. Naphthalene is discussed in this section as a representative example of the higher molecular weight aromatic volatile compounds, probably associated with the storage and use of petroleum related products.

Naphthalene is also of concern because it was also carried through the HHRA (Section 7.0) as presenting the highest risk to the hypothetical potential future resident of the Site who would be using groundwater for showering and drinking. The risks to indoor workers from soil vapor was also evaluated in the risk assessment and found to be within the USEPA target risk range(s). However, naphthalene was identified as a preliminary COPC in the indoor air evaluation, based on the concentrations in groundwater on the Property (BB-4, 250 µg/L).

The distribution of naphthalene in groundwater from 2014 and 2019 is shown on Figure 5-34B. As shown on the figure, the naphthalene in groundwater plume appears to be originating upgradient abutting the former Kiefer Park Tank Farm (BB-4, 250 µg/L), and in the two wells (MW-12 and W94-6; 270 µg/L and 170 µg/L, respectively) along the northern boundary of the western side of the Site and upgradient along the walking path (MW-8 and MW-10; 35 µg/L and 190 µg/L, respectively). The highest concentration of naphthalene in groundwater was detected in 2014 in well TS-3-A at 780 µg/L, downgradient from QDC Outfall 026. Concentrations around this location were lower (CDW-4, 22 µg/L; WP-5, 34 µg/L) in 2019. Concentrations further downgradient were non-detect or below screening values in both the 2014 and 2019 groundwater sampling events.

Naphthalene was not detected above screening levels in soils, hydric soils, or sediment indicating that the Site is not the source for the naphthalene in groundwater. The data indicate that the plume likely originated at the former Kiefer Park Tank Farm and that concentrations in groundwater are decreasing over time and distance, indicating that source control measures were effective and that natural attenuation processes are further reducing the concentrations in the red maple swamp groundwater.

5.2.4.3 Volatile Aromatic Hydrocarbons (BTEX)

Light molecular weight aromatic VOCs benzene, ethylbenzene, toluene and xylene are similar to naphthalene, 1-methylnaphthalene, 2-methylnaphthalene, and 1,2,4-trimethylbenzene in that they are most likely present in groundwater due to a release from the former Kiefer Park Tank Farm. Toluene was detected the most frequently in groundwater but has a relatively high screening value (MCL = 1,000 µg/L) and was not detected above the MCL in any groundwater samples, including those upgradient on and adjacent to the former Kiefer Park Tank Farm. Benzene was also not detected above its MCL of 5.0 µg/L.

The distributions of ethylbenzene and xylenes in groundwater are shown on Figures 5-43C and 5-44B, respectively. Ethylbenzene was detected above the screening level of 1.5 µg/L in eight of the wells sampled in 2014 and 2019.

Ethylbenzene was not detected above the MCL of 700 µg/L in any of the groundwater wells sampled. Xylene was detected above the screening level of 19 µg/l in three wells and was not detected above the MCL of 10,000 µg/L. As shown on Figures 5-43C and 5-44B, the highest concentrations of ethylbenzene (28 µg/L, MW-10) and xylene (130 µg/L, MW-8) tend to be on and abutting the former Kiefer Park Tank Farm and extending downgradient to COE-6 and TS-3-A west of the Blue Beach property.

Based on the distribution of concentrations of BTEX, the presence of these compounds in groundwater is attributed to the former Kiefer Park Tank Farm.

In addition to the CVOCs and naphthalene identified as requiring further evaluation for the soil vapor pathway in the risk assessment, 1,2,4-trimethylbenzene, ethylbenzene, and xylenes concentrations in shallow groundwater warranted further consideration as COPCs in indoor air.

6.0 CONTAMINANT FATE AND TRANSPORT

The source, fate and transport of COPCs are discussed in this Section.

6.1 Source Areas

Several potential source areas have been identified affecting both the on-Property and off-Property media. PCBs, metals, PAHs, and CVOCs have been identified in several on-Property areas in association with the use of the Property as a former disposal area. To the extent that they have been identified, on-Property areas have been remediated by excavation of materials and placement under a cap located on the Property, or by excavation, transportation, and off-site disposal. In addition, much of the on-Property area has been improved with buildings and parking lots, further limiting the infiltration of surface water and the potential for migration to groundwater. Most recent data discussed in Section 5.0 suggests that source control measures on the Property have been successful.

The second source area is on the Former Kiefer Park Tank Farm property to the north and upgradient of the Former Blue Beach Property and from the Red Maple Swamp. The Former Kiefer Park Tank Farm appears to be the primary source of petroleum related constituents including naphthalene; 1,2,4-trimethylbenzene; benzene; ethylbenzene; toluene; and xylene. Similar to the Former Blue Beach Property, remediation measures on the Former Kiefer Park Tank Farm have been effective in mitigating sources from this area.

6.2 Migration Pathways

Two primary migration pathways were identified for this Site:

- Surface water (precipitation) infiltration, dissolution, and leaching to groundwater, most applicable to the more soluble constituents: certain metals and VOCs
- Surface water overland flow (and possibly culverted storm drains) and transport of particulate matter with adsorbed metals, PAHs, and PCBs

In both cases, source control measures appear to have mitigated the potential for precipitation (surface water infiltration and run off) to readily come in contact with impacted materials. Therefore, both primary source areas and migration pathways have mitigated the potential for further releases and for those potential releases to further adversely impact off-Property areas.

Following mitigation of the primary sources and primary migration pathways is the potential for secondary sources to pose a migration pathway or exposure route. These secondary routes include:

- Constituents (primarily VOCs) in groundwater moving downgradient through Red Maple Swamp
- Constituents previously deposited in association with historical overland (or culverted) storm water runoff (metals, PAHs, and PCBs).

The VOC plumes follow the direction of groundwater flow, which appears to follow surface water to the tidal stream in the Red Maple Swamp

The latter constituents (metals, PAHs, and PCBs) are most likely associated with particulates sequestered in the Red Maple Swamp surface soils, hydric soils, and sediment and are most likely to be disturbed and dispersed via surface water under high flow (storm) events.

The data presented in this RI report (primarily from 2014 and 2019) indicates that the concentrations of COPCs in the secondary sources and pathways (Red Maple Swamp groundwater, soils, hydric soils, and sediment) are relatively low (concentrations do not pose a risk to human health or ecological receptors under current conditions). As current conditions do not pose an unacceptable risk, it is unlikely that, in the absence of further primary source contributions, future migration would pose an unacceptable risk.

7.0 HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENTS

The baseline HHRA and ERA were conducted by AECOM, a Mabbett team subcontractor, in support of the RI for the Blue Beach Disposal Area FUDS in North Kingstown, Rhode Island to evaluate potential human health and ecological effects of exposures to chemicals in soil, hydric soil, groundwater, porewater, sediment, and surface water in the on-Project and/or adjacent off-Project areas, and to determine whether Project-related chemicals in these areas pose a potential cancer risk or noncancer hazard above target levels to human health or the environment.

The Human Health and Ecological Risk Assessment Report is included as Appendix A to this RI report. Summaries of the HHRA and ERA findings are provided separately in this section. In summary, both risk assessments concluded that risks from constituents on the Project were within or below the USEPA target risk levels. A hypothetical future residential scenario was conservatively evaluated in the HHRA to represent a UU/UE scenario for informational purposes. This assessment identified naphthalene in groundwater as a potential risk driver for the potential future resident scenario (i.e., for drinking and showering). However, residential use is not a reasonably anticipated future use of the Site. There are currently no residents located on the Site, it is not zoned for residential use, and there is an ELUR preventing unrestricted residential use of the Site parcels.

The risk assessments were updated since the previous risk assessment conducted for the combined area consisted of the Blue Beach Disposal Area and Kiefer Park by GZA in 1997. The current risk assessments were specifically focused on assessing current exposure conditions on the Blue Beach Project area and for off-Project areas that might be affected by the Project. Specifically, the risk assessments were conducted using sample data collected in 2019 and that represent current on-Project conditions and did not use data from samples collected from beneath the cap on the Site. The risk assessments also evaluated off-Project conditions in Red Maple Swamp, the walking path, and along the Narragansett Bay beachfront.

7.1 Human Health Risk Assessment

The purpose of the HHRA was to evaluate whether exposure to Project-related COPCs pose a cancer risk and/or noncancer hazard to human health above USEPA target risk levels. The evaluation included performing a quantitative estimation of potential cancer risk and noncancer hazard to current and potential future human receptors that may be exposed to Project-related chemicals in environmental media within the on-Project Blue Beach area and off-Project areas (i.e., Off-Project Red Maple Swamp/tidal stream area and off-Project Narragansett Bay and Beachfront area), as applicable. The HHRA was conducted in accordance with CERCLA risk assessment guidance and the Project-specific Risk Assessment Work Plan provided as Appendix E of the SAP (Mabbett, 2019).

To evaluate potential risks to these receptors, the risk assessment is conducted using a series of steps in accordance with USEPA guidance. These steps are summarized as follows:

- Developing the types of exposures that may be encountered on the Site.
- Calculating the dose of constituents based on exposure routes.
- Estimating the exposure point concentrations of constituents for different areas of the Site.
- Compiling published toxicity information for comparison with the estimated exposures from the Site.
- Estimating risk from the Site, expressed as a noncancer hazard quotient or index (HQ or HI) and/or excess lifetime cancer risk (ELCR).

The full details of this process and the findings from each step are also detailed in Appendix A. A brief summary as it pertains to the risks calculated for the Site is provided below.

The HHRA evaluated potentially complete exposure pathways for human receptors identified based on current and reasonable future land-use scenarios in accordance with the CSM (Section 6.0). The HHRA quantitatively evaluated exposure to surface soil, subsurface soil, groundwater (shallow and deep), sediment, surface water, and soil vapor, as applicable, for a reasonable maximum exposure (RME) scenario. Based on the current and future land use, the following human receptors were evaluated in the HHRA:

- Current/Future Construction/Utility Worker
- Current/Future Outdoor Worker
- Current/Future Trespasser (adolescent)
- Current/Future Recreational User (adult/child)
- Future Indoor Worker

A hypothetical future residential scenario was conservatively evaluated in the HHRA to represent a UU/UE scenario for informational purposes. However, this is not a reasonably anticipated future use of the Site. There are currently no residents located on the Site, it is not zoned for residential use, and there is an ELUR preventing residential use on the Project area and an agreement with the current owner and RIDEM to use a soil vapor barrier for all of the buildings on the Site. Therefore, the additional human receptor class was added for UU/UE consideration:

- Future Resident (adult/child) exposed to On-Project groundwater for UU/UE evaluation only.

The HHRA evaluated the following exposure pathways, as applicable, for each receptor:

- Exposure to soil through incidental ingestion, dermal contact, and inhalation of fugitive dust and volatiles in outdoor air.
- Exposure to shallow groundwater through incidental ingestion, dermal contact, and inhalation of volatiles in an excavation trench.
- Exposure to hydric surface soil, sediment, and surface water in the off-Project Red Maple Swamp/tidal stream area through incidental ingestion and dermal contact.
- Exposure to soil vapor in the on-Project Blue Beach area via the vapor intrusion pathway.

Groundwater underlying the Site is not used for drinking water or other potable use and there is an ELUR recorded on the deed that prohibits potable use of groundwater from the on-Project Blue Beach area. However, on-Project groundwater was evaluated for a hypothetical future potable use scenario to represent a UU/UE scenario for informational purposes and, if needed, for the Feasibility Study.

The cumulative potential ELCR and noncancer HI for each exposure scenario were evaluated in comparison to USEPA's target risk range of 10^{-6} to 10^{-4} and target HI of 1 (per target organ). For each associated exposure scenario (i.e., area/receptor/medium) with a potential risk/HI above USEPA target levels, risk drivers were selected from those COPCs significantly contributing to an individual ELCR greater than 10^{-4} or target organ HI greater than 1 (at one significant figure), specifically, COPCs with an individual ELCR > 10^{-6} or HI > 1. If chemicals were identified as driving risk(s) above USEPA target levels, the risk drivers were selected as contaminants of concern (COCs) for the associated medium/receptor/exposure scenario.

A summary of the potential ELCR and HI results for each of the receptors evaluated in the HHRA is presented in Table 3-11 of Appendix A. In summary, the conclusions of the HHRA indicate the following:

The cumulative potential ELCRs do not exceed the USEPA target ELCR range of 10^{-6} to 10^{-4} and the total potential HIs per target endpoint do not exceed the USEPA target HI of 1 for the current/future construction worker, current/future outdoor worker, current/future trespasser, and future indoor worker in the on-Project Blue Beach area; or the current/future recreational user in the off-Project Red Maple Swamp/tidal stream area. Therefore, no COCs were identified for these receptors.

The only risks calculated as being above the USEPA target limits are for the hypothetical future residential exposure scenario in which on-Project groundwater is a source of potable water (e.g., drinking water and showering/bathing). While exiting ELURs prohibit residential use and potable groundwater use on-Project, residential exposures to on-Project groundwater was evaluated for UU/UE considerations only. Cumulative potential ELCR and total potential HIs per target endpoint exceed the USEPA target ELCR of 10^{-4} and USEPA's target HI of 1, respectively, for the hypothetical future residential scenario in the on-Project Blue Beach area. The following table provides a summary of the chemicals in groundwater that would pose an unacceptable level of risk if groundwater were used as a potable water source. The identified COCs, potential ELCRs, and HIs associated with the groundwater exposure scenarios for each COC are provided in Table 3-11 of Appendix A and summarized below:

Groundwater COCs	Potential ELCR	Potential HI
Inorganics		
Iron	N/A	4
Manganese	N/A	7
SVOCs		
2-Methylnaphthalene	N/A	2
Naphthalene	2×10^{-3}	20
VOCs		
TCE	6×10^{-5}	10
Total for Exposure Scenario	**2×10^{-3}**	**40**

N/A - Not applicable.

In addition, the EPC for lead in groundwater within the on-Project Blue Beach area (19 µg/L) is greater than the USEPA SDWA action level of 15 µg/L (USEPA, 2018a). Therefore, it was also identified as a groundwater COC for the potable water for the hypothetical future resident exposure scenario in this area.

7.2 Ecological Risk Assessment

The purpose of the ecological risk assessment (ERA) was to evaluate the potential adverse environmental effects of Project-related COPCs on ecological receptors and resources at or near the Project. The USEPA guidance for ecological risk includes an 8-step process that allows for multiple "off-ramps" to exit the process, if calculations indicate that risk levels are within acceptable levels and no additional evaluation is warranted. For the Blue Beach FUDS Project, the ERA included the first tier of the ecological risk process (i.e., Steps 1 and 2) as a screening level ERA (SLERA). For those constituents and concentrations in given media that were above the initial screening levels, the COPCs were further evaluated in the next step of the ERA process (referred to as Step 3a). As discussed further below, the more detailed evaluation of the data for the Blue Beach FUDS Project found that chemical constituents on the Site do not pose an unacceptable risk to ecological receptors.

The ERA evaluated the following potentially complete exposure pathways for terrestrial receptors in the on-Project Blue Beach exposure area:

- Terrestrial Invertebrates – exposed to surface soil through ingestion and direct contact.
- Terrestrial Plants – exposed to surface soil through root uptake.
- Birds and Mammals – exposed to surface soil through incidental ingestion and to food items which may have bioaccumulated Project-related COPCs.

The following exposure pathways were evaluated for the wetland portions of the off-Project Red Maple Swamp (i.e., tidal creek and marsh complex):

- Soil Invertebrates – exposed to hydric soil through ingestion and direct contact.
- Wetland Plants – exposed to hydric soil through root uptake.
- Birds and Mammals – exposed to surface soil, hydric soil, and sediment within the off-Project Red Maple Swamp/tidal stream area through incidental ingestion and to food items which may have bioaccumulated Project-related COPCs.

The following additional exposure pathways were evaluated for the aquatic portions of the Project found in the off-Project Red Maple Swamp/tidal stream area and off-Project Narragansett Bay and Beachfront area:

- Benthic Invertebrates – exposed to sediment and porewater through ingestion and direct contact.
- Aquatic Fish and Invertebrates – exposed to surface water through ingestion and direct contact.

In the initial screening process, these exposure pathways were evaluated through the comparison of surface soil, hydric soil, sediment, surface water, and porewater analytical data to media-specific ecological screening values (ESVs) and by using conservative food web modeling to assess potential risks to avian and mammalian receptors. Consistency with site-specific background conditions was also considered as part of the evaluation process of the findings from the initial screening steps, as part of the identification of COPCs in each media and exposure area. Therefore, following the USEPA guidance, additional evaluation using more Site-specific circumstances and less conservative assumptions, was warranted.

In the more Site-specific evaluation (Step 3a), the risk estimates for those COPCs retained following the initial screening process were recalculated using less conservative and more realistic assumptions including refined EPCs, ESVs, and TRVs. The more Site-specific evaluation used the same representative species and exposure pathways as the SLERA, but with refined, central tendency exposure (CTE) assumptions to more realistically estimate the potential risk to ecological receptors from COPCs that were detected above the conservative SLERA screening values.

The Step 3a evaluation also considered the results from field efforts conducted in 2020 to provide Site-specific data on the benthic community (macroinvertebrate community sampling) in the tidal stream and to evaluate the bioavailability and toxicity of sediments. Sediment samples were analyzed for acid volatile sulfides (AVS), simultaneously extracted metals (SEM), TOC, and a laboratory sediment toxicity test was conducted on samples collected from upstream portions of the tidal stream.

Nearly all of the HQs based on the refined ESVs were less than 1 indicating no need for further evaluation for the majority of the COPCs. No COPCs in surface water and pore water were identified based on comparisons to chronic and acute ESVs, low frequency of detection (FOD), and a discussion of the uncertainties associated with the ESVs and detected concentrations.

In the food web models for the on-Project Blue Beach area and the off-Project Red Maple Swamp/tidal stream area, all of the lowest-observed adverse effect level (LOAEL)-based HQs were less than 1. No-observed adverse effect level (NOAEL)-based HQs were greater than 1 for some COPCs, primarily for insectivorous receptors, with a maximum HQ of 3.8 for lead (American Robin) in the on-Project Blue Beach area. Given the conservative nature of the food web models (small birds and mammals were assumed to obtain diet only from the exposure areas) and the lack of LOAEL-based HQs above 1, the COPC concentrations in these two exposure areas do not present an unacceptable risk of adverse effects to wildlife populations.

Total PCBs in hydric soil and sediment in the off-Project Red Maple Swamp/tidal stream area were the only COPCs retained based on refined ESV screens. PCBs were further evaluated using equilibrium partitioning-based benchmarks identified by NOAA (2016) and indicate that PCBs are not expected to pose a risk to the benthic community. A sediment quality triad evaluation identified locations where at least one element of the triad was

impacted, but the triad evaluation and supplemental correlation evaluations did not support an indication of COPC-related benthic invertebrate community impacts.

Based on the Step 3a evaluation of surface soil, surface hydric soil, surface sediment, surface water, and pore water in the on-Project Blue Beach area, the off-Project Red Maple Swamp/tidal stream area, and the off-Project Narragansett Bay and Beachfront area, no COPCs were retained and no further evaluation is warranted for plants, soil invertebrates, benthic invertebrates/shellfish, fish, aquatic invertebrates, birds, or mammals in these exposure areas. No COCs were identified as posing ecological risk or warrant further evaluation for ecological risk under CERCLA.

7.3 Groundwater Protection

While the risk assessments concluded no unacceptable risks to current and foreseeable receptors at the Site, results of groundwater classified as GA were compared to RIDEM GA groundwater criteria to ensure the protectiveness of this groundwater resource in maintaining drinking water quality. Therefore, off-Project groundwater analytical results were compared to RIDEM GA groundwater criteria (which are comprised of USEPA MCLs and state-specific standards for MTBE and naphthalene) (RIDEM, 2009) (Table 5-12). A total of 18 off-Project groundwater samples (including one field duplicate sample) were collected in 2019. Groundwater criteria exceedances were not prevalent and only observed in a handful of samples for two VOCs (TCE and VC), two PAHs (benzo(a)pyrene and naphthalene), and one metal (lead).

TCE exceeded its MCL of 5 µg/L in samples collected from two monitoring wells, MW-106S (14 µg/L) and W98-1 (13 µg/L). The sample collected from MW-106D, the deeper paired well for MW-106S, contained a trace concentration of TCE, below the MCL. In addition, VC was detected above the MCL (2 µg/L) in the same sample collected from MW-106S (7.0 µg/L). Benzo(a)pyrene was detected above its MCL of 0.2 µg/L in one monitoring well, COE-2 (0.23 µg/L). Naphthalene does not have an MCL, but RIDEM has promulgated a state-specific standard for GA groundwater aquifers. Naphthalene was detected above the state-specific criteria for GA groundwater of 20 µg/L in samples collected from CDW-4 (26 µg/L) and WP-5 (34 µg/L). Naphthalene was also detected above the GA criteria in the primary sample collected from CDW-4 at an estimated (J-flag) 26 µg/L, but the field duplicate sample did not exceed the GA criteria. Lead was detected in samples of Off-Project groundwater above its MCL. While the total lead concentration (20.3 µg/L) from CDW-3 exceeded the MCL (15 µg/L), the dissolved phase lead result was below the detection limit, indicating the lead present in that sample was associated with suspended solids with a low mobility. Both the total and dissolved lead concentrations (451 and 56.1 µg/L, respectively) in the sample collected from COE-1 exceeded the MCL. These results suggest lead is mobile in the dissolved phase in the vicinity of COE-1, which is located on the western side of Red Maple Swamp. However, these lead impacts are not conclusively from the Blue Beach FUDS site as there were no lead impacts to groundwater identified at the adjacent sampling points (PZ-1, PZ-2, and W98-1) located within 20 feet of COE-1.

Even though off-Project Red Swamp groundwater is classified as GA indicating this groundwater resource is a known or presumed to be suitable for public or private drinking water use without treatment, there are currently no drinking wells present in this area and no foreseeable future plans to add a drinking water well. However, given the GA groundwater criteria exceedances that can potentially impact this groundwater resource, remedial alternatives will be developed and evaluated for off-Project groundwater.

8.0 SUMMARY AND CONCLUSIONS

The objective of the Former Blue Beach Disposal Area FUDS Comprehensive RI was to determine the nature and extent of DoD-related contamination at the Site, to evaluate the fate and transport of that contamination, and to quantify the potential human health and ecological risks associated with residual environmental contamination through an updated risk assessment.

The Site encompasses approximately 21.5 acres of land and is comprised of the Former Blue Beach Disposal Area FUDS (Project Area) and off-Project areas including a walking path, tidal stream, Red Maple Swamp, and Blue Beach. These recreational areas are depicted on the Site map provided on Figure 1-3. The Site does not include the Former Kiefer Park Tank Farm FUDS Project though data from this site was collected and reviewed.

Historical investigations have been performed on the Site since approximately 1984 and have included soil, hydric soil, groundwater, sediment, pore water, surface water, and soil gas sampling, as well as test pitting, geophysical surveys, engineering evaluations, and risk assessments.

The investigations conducted between 2011 to 2020 were completed by USACE in four tiered phases: the first phase was conducted in October-December 2011; the second phase in July-August 2014; the third phase in August-September 2015; and the fourth phase in 2019-2020. Each investigation was performed according to USACE-approved Work Plans (Watermark, 2011; Mabbett, 2014; Mabbett, 2015; Mabbett 2019). The specific methods used, and analytical data generated during these investigations is summarized in the 2011, 2014-2015, and 2019-2020 Trip Reports (Mabbett, 2012; Mabbett, 2016; Mabbett, 2020).

Study goals for the Comprehensive RI included the following:

- Assessment of the geophysical anomaly area (2011).
- Expansion of the monitoring well network and collection of additional groundwater, sediment, surface water, pore water, hydric soil, and surface and subsurface soil samples for analysis to better assess the nature and extent of contamination identified in previous investigations and address data gaps identified in the preliminary CSM (2011).
- Refinement of the horizontal and vertical extent of CVOCs in groundwater migrating south and west from the geophysical anomaly area, which is the presumed source of CVOCs in groundwater, by conducting a vertical groundwater profiling investigation upgradient and downgradient from the source area (2014).
- Repeating the 2011 investigation sampling effort at permanent groundwater monitoring wells, pore water sample locations, and co-located sediment and surface water locations. Collect Blue Beach intertidal beachfront sediment samples for analysis for constituents potentially migrating from groundwater to sediment (2014).
- Assessment of sediment, porewater, and surface water along the Narragansett Bay beachfront area adjacent to Blue Beach for constituents that may have migrated to these media from upgradient groundwater (2015).
- Assessment of upland soil, hydric soil, sediment, and groundwater (2019-2020).
- Performance of sediment toxicity testing and an invertebrate survey for the ecological risk assessment at on-Project and off-Project locations (2019-2020).
- Conducting a background sampling program was conducted to collect a representative data set for comparison with Site data to support the human health and ecological assessments and conclusions regarding naturally occurring or anthropogenic sources not associated with the Former Blue Beach Disposal area (2019-2020).

- Conducting a human health and ecological risk assessment for the Site and screening of off-Project GA groundwater for contamination in excess of state and federal standards.

Based on the horizontal and vertical extent of these chemicals within the Site, there appear to be at least two primary source areas present within the larger former Blue Beach Disposal Area: (1) the former PCB Removal Areas/former General Dynamics Salvage Yard/former Drum Storage Area on the eastern portion of the Project, where the majority of contaminants in soil have been removed and no longer act as a source area; and (2) the geophysical anomaly area on the western portion of the Project. Additionally, two areas at the Kiefer Park Tank Farm FUDS Project—the former tank farm area and the former interceptor trench area—appear to be the source of petroleum-related chemicals present at the Site.

COPCs for the Site were identified as metals, PCBs, SVOCs, CVOCs, and VOCs. Petroleum-related chemicals detected on and near the Site are attributed to releases from the Kiefer Park FUDS Project. PCBs were detected at trace levels in groundwater from two monitoring wells in 2008 (BMW-3 at 0.07 µg/L and OW-3 at 0.05 µg/L). Samples were also collected for PCB analysis from 38 groundwater monitoring wells during the 2019 investigation and PCBs were not detected in any of the samples. These data further confirm that current measures on the Site are effectively containing PCBs under the cap and under other Site improvements. In addition, much of the on-Property area has been improved with buildings and parking lots, further limiting the infiltration of precipitation, and reducing the potential for migration of contaminants from soil to groundwater. The most recent data discussed in Section 5.0 suggests that source control measures on the Property have been successful.

The second source area is on the Former Kiefer Park Tank Farm property to the north and upgradient of the Former Blue Beach Property and from the Red Maple Swamp. The Former Kiefer Park Tank Farm appears to be the primary source of petroleum-related constituents including naphthalene; 1,2,4-trimethylbenzene; benzene; ethylbenzene; toluene; and xylene. Similar to the Former Blue Beach Property, remediation measures on the Former Kiefer Park Tank Farm have been effective in mitigating sources from this area.

The data presented in this RI report (primarily from 2014 and 2019) indicates that the concentrations of COPCs in the secondary sources and pathways (Red Maple Swamp groundwater, soils, hydric soils, and sediment) are relatively low (concentrations do not pose a risk to human health or ecological receptors under current conditions) and groundwater impacts are limited to isolated areas of lead contamination. As current conditions do not pose an unacceptable risk, it is unlikely that, in the absence of further primary source contributions, future migration would pose an unacceptable risk.

In summary, the human health and ecological risk assessments concluded that risks from constituents on the Project were within or below the USEPA target risk levels with the exception of the potential future use of on-Project groundwater for residential purposes (i.e., for drinking and showering).

The only risks calculated as being above the USEPA target limits are for the hypothetical future residential exposure scenario in which on-Project groundwater is a source of potable water (e.g., drinking water and showering/bathing). Specifically, the concentrations of naphthalene in groundwater pose an unacceptable risk to the potential future resident if that resident used groundwater from the Project as the primary source of potable water. In addition, the EPC for lead in groundwater within the on-Project Blue Beach area (19 µg/L) is greater than the USEPA SDWA action level of 15 µg/L (USEPA, 2018a). Therefore, it was also identified as a groundwater COC for the potable water for the hypothetical future resident exposure scenario in this area.

Total PCBs in hydric soil and sediment in the off-Project Red Maple Swamp/tidal stream area were the only COPCs retained based on refined ESV screens. PCBs were further evaluated using equilibrium partitioning-based benchmarks identified by NOAA (2016) and indicate that PCBs are not expected to pose a risk to the benthic community. A sediment quality triad evaluation identified locations where at least one element of the triad was

impacted, but the triad evaluation and supplemental correlation evaluations did not support an indication of COPC-related benthic invertebrate community impacts.

Based on the evaluation of surface soil, surface hydric soil, surface sediment, surface water, and pore water in the on-Project Blue Beach area, the off-Project Red Maple Swamp/tidal stream area, and the off-Project Narragansett Bay and Beachfront area, no COPCs were retained, and no further evaluation is warranted for plants, soil invertebrates, benthic invertebrates/shellfish, fish, aquatic invertebrates, birds, or mammals in these exposure areas. No COCs were identified as posing ecological risk or warrant further evaluation for ecological risk under CERCLA.

The comprehensive RI performed by USACE between approximately 2011 and 2020 concluded that the human health and ecological risks from constituents on the Project are within or below the USEPA's target risk range, with the exception of the potential future use of groundwater (i.e., drinking water and showering/bathing) under a future residential exposure scenario. This scenario is not currently reasonably anticipated as a future use of the Site and an ELUR has been implemented as part of the groundwater remedy for the Former Kiefer Park Tank Farm FUDS that prohibits the use of groundwater as a potable supply.

While the risk assessments concluded no unacceptable risks to current and foreseeable receptors at the Site, groundwater samples collected from areas classified as GA were compared to RIDEM GA groundwater criteria to ensure the protectiveness of this groundwater resource in maintaining drinking water quality. Even though off-Project Red Swamp groundwater is classified as GA, indicating this groundwater resource is a known or presumed to be suitable for public or private drinking water use without treatment, there are currently no drinking water wells present in this area and no foreseeable future plans to add a drinking water well. However, given the GA groundwater criteria exceedances (TCE, VC, benzo[a]pyrene, naphthalene, and lead) that can potentially impact this groundwater resource, remedial alternatives will be developed and evaluated for off-Project groundwater.

Notes:
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
Screening values are USEPA Vapor Intrusion Screening Levels (VISL) for residential and industrial scenarios. See risk assessment for details.

GP2-TR2D 6-7	11/17/2011 13:45	TRICHLOROETHENE	5.8	µg/kg	940

Notes:
a: Sample depth interval suffix indicates depth below ground surface, in feet
b: ADR data validation confirmed that chemicals were detected at concentration reported without further qualification.
c: EPA RSL for Resident Soil with TR=10E-06 and THQ=1.0 (units correspond to those of the parameter)
d: Shaded values exceed EPA RSL for Resident Soil
e: Total chromium was reported by the laboratory. Results compared to regulatory criteria for chromium (III)
mg/kg: milligrams per kilogram
µg/kg: micrograms per kilogram
mg/l: milligrams per liter
N/A: Regulatory criteria not specified

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 1997)
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efro
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 1997)
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 19
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 19
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 19
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:

1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 19
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 19
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.

EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed.
J = Estimated value
Shaded:
> RIDEM Residential Direct Contact
>Human Health Screening Level
>Ecological Screening Level

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 19
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.

EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed.
J = Estimated value
Shaded:
> RIDEM Residential Direct Contact
>Human Health Screening Level
>Ecological Screening Level

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 1997)
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 199
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 199
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 1997)
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Soil Screening Levels (Eco-SSLs) (USEPA, 2005)
b) Oak Ridge National Laboratory terrestrial plant and invertebrate screening values (Efroymson, et al, 19
c) NOAA Screening Quick Reference Table values (Buchman, 2008)
d) USEPA Region 4 ecological screening values for soil (USEPA, 2018)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Region III BTAG sediment screening values (USEPA, 2006)
b) NOAA Screening Quick Reference Table values (Buchman, 2008)
See risk assessment for additional details.
***AVS/SEM analysis performed on samples collected on May 28, 2020.
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value

Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Region III BTAG sediment screening values (USEPA, 2006)
b) NOAA Screening Quick Reference Table values (Buchman, 2008)
See risk assessment for additional details.
***AVS/SEM analysis performed on samples collected on May 28, 2020.
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value

Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Region III BTAG sediment screening values (USEPA, 2006)
b) NOAA Screening Quick Reference Table values (Buchman, 2008)
See risk assessment for additional details.
***AVS/SEM analysis performed on samples collected on May 28, 2020.
--- = Sample not analyzed for this parameter
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Bold = Detected
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Region III BTAG sediment screening values (USEPA, 2006)
b) NOAA Screening Quick Reference Table values (Buchman, 2008)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Region III BTAG sediment screening values (USEPA, 2006)
b) NOAA Screening Quick Reference Table values (Buchman, 2008)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Region III BTAG sediment screening values (USEPA, 2006)
b) NOAA Screening Quick Reference Table values (Buchman, 2008)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA RSLs for Residential Soil.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA Region III BTAG sediment screening values (USEPA, 2006)
b) NOAA Screening Quick Reference Table values (Buchman, 2008)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Level
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level
Shaded = Exceeds RIDEM Residential Direct Exposure Criteria

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water
and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection
(LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds RSL or MCL

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds MCL or State Specifc Standard for GA Groundater

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds MCL or State Specifc Standard for GA Groundater

Notes:
1. Groundwater data compared to EPA RSLs for Tap Water and EPA Maximum Contaminant Levels (MCLs)
2. Groundwater data are not factored into the ecological risk assessment.
EN = Essential Nutrient
NT = Not Tested
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds MCL or State Specifc Standard for GA Groundater

Notes:
1. Porewater data not screened against human health risk-based criteria.
2. Ecological risk-based screening levels are selected from the following sources:
   a) USEPA chronic AWQC for aquatic life (EPA, 2020)
   b) EPA Region III BTAG surface water screening values (EPA, 2006)
   c) Secondary Chronic Values derived by the Oak Ridge National Laboratory (ORNL)
   See risk assessment for additional details.

--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Ecological Screening Limit

Notes:
1. Porewater data not screened against human health risk-based criteria.
2. Ecological risk-based screening levels are selected from the following source
a) USEPA chronic AWQC for aquatic life (EPA, 2020)
b) EPA Region III BTAG surface water screening values (EPA, 2006)
c) Secondary Chronic Values derived by the Oak Ridge National Laboratory (C
See risk assessment for additional details.
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Ecological Screening Limit

Notes:
1. Porewater data not screened against human health risk-based criteria.
2. Ecological risk-based screening levels are selected from the following source
   a) USEPA chronic AWQC for aquatic life (EPA, 2020)
   b) EPA Region III BTAG surface water screening values (EPA, 2006)
   c) Secondary Chronic Values derived by the Oak Ridge National Laboratory (C
   See risk assessment for additional details.
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Ecological Screening Limit

Notes:
1. Porewater data not screened against human health risk-based criteria.
2. Ecological risk-based screening levels are selected from the following sources:
   a) USEPA chronic AWQC for aquatic life (EPA, 2020)
   b) EPA Region III BTAG surface water screening values (EPA, 2006)
   c) Secondary Chronic Values derived by the Oak Ridge National Laboratory (ORNL)
   See risk assessment for additional details.
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of
Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Ecological Screening Limit

Notes:
1. Porewater data not screened against human health risk-based criteria.
2. Ecological risk-based screening levels are selected from the following source
   a) USEPA chronic AWQC for aquatic life (EPA, 2020)
   b) EPA Region III BTAG surface water screening values (EPA, 2006)
   c) Secondary Chronic Values derived by the Oak Ridge National Laboratory (
   See risk assessment for additional details.
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of
Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Ecological Screening Limit

Notes:
1. Human health risk-based screening levels are EPA National Recommended Ambient Water Quality Criteria (AWQC).
If no AWQC is available, the EPA RSL for tap water is used.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA chronic AWQC for aquatic life (EPA, 2020)
b) EPA Region III BTAG surface water screening values (EPA, 2006)
c) Secondary Chronic Values derived by the Oak Ridge National Laboratory (ORNL)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level

Notes:
1. Human health risk-based screening levels are EPA National Recommended Ambient Water Quality Criteria (AWQC).
If no AWQC is available, the EPA RSL for tap water is used.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA chronic AWQC for aquatic life (EPA, 2020)
b) EPA Region III BTAG surface water screening values (EPA, 2006)
c) Secondary Chronic Values derived by the Oak Ridge National Laboratory (ORNL)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit
Shaded = Exceeds Ecological Screening Level but not Human Health Screening Level

Notes:
1. Human health risk-based screening levels are EPA National Recommended Ambient Water Quality Criteria (AWQC).
If no AWQC is available, the EPA RSL for tap water is used.
See risk assessment for additional details and statistical analysis.
2. Ecological risk-based screening levels are selected from the following sources:
a) USEPA chronic AWQC for aquatic life (EPA, 2020)
b) EPA Region III BTAG surface water screening values (EPA, 2006)
c) Secondary Chronic Values derived by the Oak Ridge National Laboratory (ORNL)
See risk assessment for additional details.
EN = Essential Nutrient
--- = Sample not analyzed for this parameter
Bold = Detected
U = Not detected above the concentration listed, usually laboratory Limit of Detection (LOD) or the blank-corrected validated value
J = Estimated value
Shaded = Exceeds Human Health or Ecological Screening Limit

B-B Cross Section

Blue Beach FUDS

Figure No. 4-8C

Scale: NA

Drawn: MJH Approved: AMG

Projection: NA

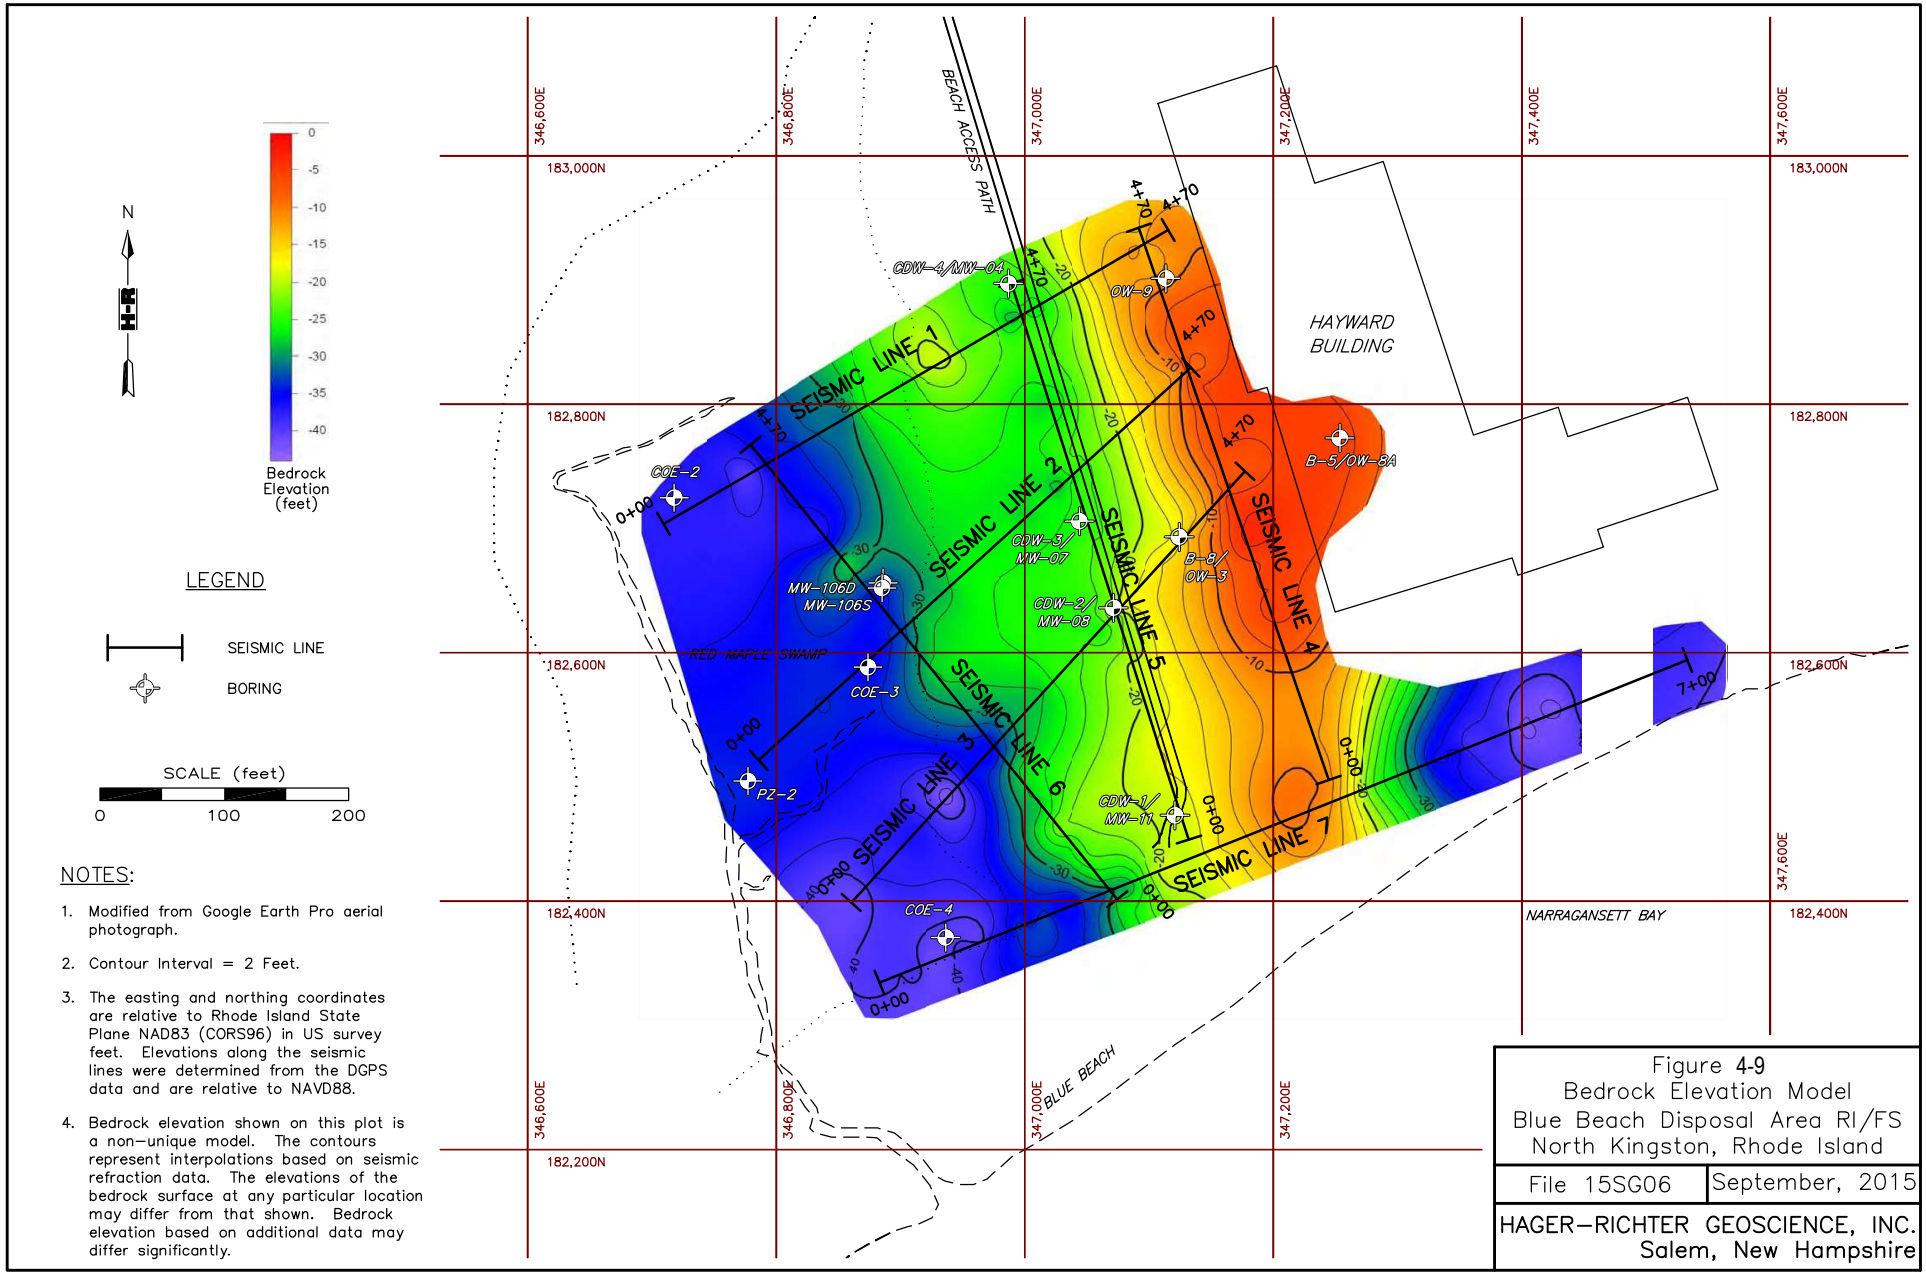
Date: 2/1/2024

Legend

- Bedrock
- SM—Silty Sand
- SW—Well Graded Sand
- SP — Poorly Graded Sand

NOTES:

- Depth to bedrock is assumed based on nearby borings not included in this cross section.
- Stratigraphy presented above in between wells is an approximation



NOTES:

1. Modified from Google Earth Pro aerial photograph.
2. Contour Interval = 2 Feet.
3. The easting and northing coordinates are relative to Rhode Island State Plane NAD83 (CORS96) in US survey feet. Elevations along the seismic lines were determined from the DGPS data and are relative to NAVD88.
4. Bedrock elevation shown on this plot is a non-unique model. The contours represent interpolations based on seismic refraction data. The elevations of the bedrock surface at any particular location may differ from that shown. Bedrock elevation based on additional data may differ significantly.

Former Blue Beach Disposal Area FUDS

SUMMARY OF BENZO(B)FLUORANTHENE DETECTED IN OFF-PROJECT SURFACE HYDRIC SOIL

North Kingstown, Rhode Island

NOTES

- = Sample result does not exceed a screening level.
- = Sample result exceeds at least one screening level.

Analytical results in units of µg/kg.

Surface soil samples originate from 0 to 1 foot bgs.

Table of Contents

1. Introduction 1
1.1 Project Background and Setting 1
1.2 Report Organization 2
2. Data Selection and Evaluation 3
2.1 Summary of Analytical Data Evaluated in the Risk Assessments 3
2.1.1 Soil 3
2.1.2 Hydric Soil 4
2.1.3 Groundwater 4
2.1.4 Porewater 5
2.1.5 Sediment 5
2.1.6 Surface Water 5
2.1.7 Soil Vapor 6
2.2 Data Treatment 6
2.2.1 Total PAH and PCB Summations 6
2.2.2 Treatment of Duplicate Discrete Samples 8
2.2.3 Analyses via Multiple Methods 8
2.2.4 Summary Statistics 8
2.2.4.1 Discrete Samples 8
2.2.4.2 ISM Samples 8
2.3 Background Evaluation 9
3. Human Health Risk Assessment 12
3.1 Data Evaluation/Hazard Identification 12
3.1.1 Selection of Chemicals of Potential Concern 12
3.1.1.1 Frequency of Detection and Essential Nutrients 13
3.1.1.2 Comparison to Human-Health Screening Levels 13
3.1.1.3 Surrogate Screening Levels 14
3.1.1.4 Comparison to Background Levels 14
3.1.2 COPC Selection Results 15
3.2 Exposure Assessment 17
3.2.1 Human Health Conceptual Site Model 17
3.2.2 Current/Future Use Scenarios 19
3.2.3 Future Use Scenarios 19
3.2.4 Calculation of Dose 20
3.2.5 Exposure Point Concentrations 21
3.2.5.1 Soil 21
3.2.5.2 Hydric Soil 21
3.2.5.3 Groundwater 21
3.2.5.4 Sediment 22
3.2.5.5 Surface Water 22
3.2.5.6 Soil Vapor 22
3.2.5.7 Outdoor Air (Fugitive Dust and Volatiles), Shower Air, and Trench Air 22
3.3 Toxicity Assessment 23
3.3.1 Toxicity Information for Noncarcinogenic Effects 23
3.3.2 Toxicity Information for Carcinogenic Effects 24
3.3.3 Adjustment of Toxicity Factors 24
3.3.4 Chemical-Specific Information 25

3.4 Risk Characterization....26
3.5 Estimation of Potential Risk and Hazard....26
3.5.1 Description of Estimated Potential Risks and Hazards....28
3.5.2 Uncertainty Discussion....32
3.5.2.1 Hazard Identification....32
3.5.2.2 Exposure Assessment....33
3.5.2.3 Toxicity Assessment....34
3.5.2.4 Risk Characterization....34
4. Ecological Risk Assessment....36
4.1 Organization of the ERA....36
4.2 Screening Level Problem Formulation....37
4.2.1 Ecological Setting....37
4.2.2 Selection of Specific Ecological Receptors and Receptor Pathways....38
4.2.3 Selection of Assessment Endpoints and Measures of Effect....38
4.2.4 Ecological Conceptual Site Model....40
4.3 Screening Level Risk Analysis....40
4.3.1 Data Evaluation and Identification of COPCs....40
4.3.2 Ecological Effects Assessment....41
4.3.3 Ecological Exposure Assessment....42

1. Introduction

A baseline human health risk assessment (HHRA) and ecological risk assessment (ERA) have been conducted in support of the Comprehensive Remedial Investigation (RI) for the Former Blue Beach Disposal Area Formerly Used Defense Site (FUDS) in North Kingstown, Rhode Island (the Project). The HHRA and ERA were performed by AECOM on behalf of Mabbett & Associates, Inc. (Mabbett) for the United States Army Corps of Engineers (USACE), New England District (CENAE), in accordance with the Updated Risk Assessment Work Plan (RAWP) included as Appendix E to the Sampling and Analysis Plan (SAP) for the Comprehensive Remedial Investigation for the Former Blue Beach Disposal Area FUDS (Mabbett, 2019).

The primary objectives of the HHRA and ERA are to evaluate the potential risk/hazard to human and ecological receptors associated with exposure to chemicals detected in soil, hydric soil, groundwater, porewater, sediment, surface water, and soil vapor that are attributable to past operations at the Former Blue Beach Disposal Area FUDS. The HHRA and ERA were performed in accordance with the United States Environmental Protection Agency (USEPA) Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and USACE risk assessment guidance, as available/applicable.

1.1 Project Background and Setting

The Project is located in the southern portion of the Quonset Business Park (formerly the Quonset Point Naval Air Station [NAS]) in the town of North Kingstown, Rhode Island approximately 20 miles south of Providence, Rhode Island. The Quonset Business Park is managed by the Quonset Development Corporation (QDC), a quasi-public agency overseen by the Rhode Island Economic Development Corporation. **Figure 1-1** is a Site Location map that shows the current footprint of the Site as well as surrounding areas.

The Project area encompasses approximately 12.5 acres consisting of relatively flat, developed land consisting of five real parcels. The western portion of the Project area is currently owned by Hayward Industrials, Inc., and operated by Goldline Properties, LLC, which has its headquarters and manufacturing facility within the Project area. The eastern portion of the Project area is owned by Falvey Realty, LLC, which operates the Falvey Cargo Company within the Project area. The Project area is bordered to the north by the former Kiefer Park Tank Farm (Kiefer Park) which is currently undeveloped property, to the south by beach front (Blue Beach) and Narragansett Bay, to the east by an industrial park, and to the west by a paved walking path that extends from Circuit Drive to Blue Beach, and a wetland, salt marsh and an associated tidal stream on the other side of the path referred to as the Red Maple Swamp/tidal stream.

The Project property was formerly used as a salvage yard for the storage and disposal of vehicle parts, machinery, construction debris, drummed materials, and miscellaneous wastes during its operation by Quonset Point NAS from 1940 to 1974. The property was acquired by the Department of Defense (DoD) and used until its deactivation in 1974 by the Department of the Navy. It was then conveyed to the Rhode Island Port Authority in 1978 for redevelopment.

Various investigation and remediation activities have been performed at the Project beginning in the early 1980s. Historic investigations have overlapped with investigations at Kiefer Park, adjacent to the Project to the north. A baseline risk assessment was conducted in 1997 for the combined area consisting of the Blue Beach Disposal Area and Kiefer Park (GZA, 1997). Since the time the risk assessment was prepared by GZA, additional investigation has been performed to fill data gaps, including the collection of data for various media present on the Project and off-Project areas. The RI report provides further details on the past investigations conducted on and in the vicinity of the Project.

Following preliminary assessment of data obtained during field investigation work performed through 2015, it was determined that additional data collection was needed to fill the following data gaps in order to perform a CERCLA-compliant risk assessment.

- Conduct further sampling and analysis of polychlorinated biphenyls (PCBs) (Aroclors), polycyclic aromatic hydrocarbons (PAHs), and metals in on-Project Blue Beach area soils to obtain an appropriate soil dataset that reflects current soil conditions; i.e., soils not removed by previously conducted excavations or buried under a USEPA-approved cap.

- Collect additional soil data in the on-Project Blue Beach area, soil, hydric soil and sediment data in the off-Project Red Maple Swamp/tidal marsh area, and sediment data in the off-Project beach front area to obtain a large enough datasets for calculation of media/area/chemical-specific exposure point concentrations (EPCs) equal to the 95 percent (%) upper confidence limits (UCLs), rather than the maximum detected concentrations.
- Collect an appropriate media-specific background dataset to enable a statistical comparison of Site-specific concentrations to those that represent naturally occurring or local anthropogenic background sources to distinguish and focus recommendations for remedial action on Site-related impacts only.

A more detailed description of the Site background and the complete set of RI study goals is provided in the RI report.

1.2 Report Organization

This risk assessment report is organized into the following sections:

- Section 1.0: Introduction
- Section 2.0: Analytical Data Summary
- Section 3.0: Human Health Risk Assessment
- Section 4.0: Ecological Risk Assessment
- Section 5.0: Summary and Conclusions
- Section 6.0: References

2. Data Selection and Evaluation

This section summarizes the analytical data collected as part of the 2019-2020 RI field program in addition to data collected from previous investigations selected for evaluation in the HHRA and/or ERA. Environmental data evaluated in the risk assessments include soil, hydric soil, groundwater, porewater, sediment, surface water, and soil vapor collected within the Project and/or adjacent off-Project areas defined below. Available data selected for evaluation in the risk assessments were grouped into one of the following exposure areas presented on **Figure 2-1**:

- On-Project Blue Beach area – within the Former Blue Beach Disposal Area FUDS (e.g., within the jurisdictional Blue Beach FUDS boundary)
- Off-Project Red Maple Swamp/tidal stream area – within the tidal marsh referred to as “Red Maple Swamp” and the adjacent public walking path from Circuit Drive to Blue Beach
- Off-Project Narragansett Bay and Beachfront area – within the Narragansett Bay and Beachfront

The media and areas evaluated in the risk assessments are summarized below:

Media **	On-Project Blue Beach	Off-Project Red Maple Swamp/Tidal Stream	Off-Project Narragansett Bay and Beachfront
Soil	X	X	
Hydric soil		X	
Groundwater	X		
Porewater		X	X
Sediment		X	X
Surface Water		X	X
Soil Vapor	X		
X – Indicates analytical data evaluated for the associated media/area. ** Macroinvertebrate community survey data and sediment toxicity test data were also incorporated into the ERA to further evaluate the exposure of benthic invertebrates to sediment.			

2.1 Summary of Analytical Data Evaluated in the Risk Assessments

A brief description of the environmental data evaluated in the risk assessments is provided below by media. Summary tables of samples and analytical data evaluated in the HHRA are presented in **Attachment A**. Sample location figures are presented in the main body of the RI report.

2.1.1 Soil

Discrete soil samples were collected in the on-Project Blue Beach and off-Project Red Maple Swamp/tidal stream areas during multiple sampling events conducted between 1987 and 2019 from various depth intervals between the ground surface and 16 feet (ft) below ground surface (bgs). Most of the soil samples from the off-Project Red Maple Swamp/tidal stream area were collected from along the walking path. Soil samples were analyzed for target analyte list (TAL) metals, PCB Aroclors, pesticides, semi-volatile organic compounds (SVOCs), volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), and total organic carbon (TOC), although not all samples were analyzed for all analytes. Potential impacts due to petroleum products are assessed using the relevant VOC and SVOC data for individual chemicals. Therefore, TPH results were not evaluated in the risk assessments.

Soil samples collected during previous investigations considered not to be representative of current conditions or representative of excavated or inaccessible soils were excluded from evaluation in the HHRA and ERA in accordance with the RAWP provided in the SAP (Mabbett, 2019). These data include soil samples collected over 20 years ago (i.e., 1987 through 1994) and those located under the USEPA-approved cap. The exclusion of these data resulted in the exclusion of all discrete soil data for pesticides and PCB Aroclors (i.e., soil samples located beneath a USEPA-

approved cap and/or collected over 20 years ago) in the on-Project Blue Beach area. There is no evidence of bulk storage or releases of pesticides or off-label pesticide use at the Site, therefore, pesticides are not considered Project-related and were not further assessed.

Soil samples were collected during the 2019 sampling event via the incremental sampling methodology (ISM) within three sampling units (SUs) within the on-Project Blue Beach area and analyzed for PCB Aroclors. Within each of the SUs (referred to as BG-1, BG-5, and the upland soil sampling area [UPS]), triplicate ISM soil samples were collected from a 0 to 1 ft bgs and 1 to 3 ft bgs interval.

Soil samples were grouped into two different depth intervals for evaluation in the risk assessments, as applicable. Surface soil was defined as soil collected at a depth within 0 to 1 ft bgs. Subsurface soil was defined as soil collected at a depth greater than (>)1 ft bgs. Two soil samples were collected from a depth interval that overlaps both the surface and subsurface soil depth intervals (i.e., 0-4 and 0-5 ft bgs). These samples were treated as subsurface soil in the risk assessments. Consistent with CERCLA risk assessment practice (USEPA, 1989), soils deeper than 15 ft bgs were not included in the risk assessments because receptors are not considered to contact these deeper soils. The one exception to this is one soil sample collected from 14.25 to 15.5 ft bgs, which was also included as subsurface soil.

A list of soil samples and a summary of the analytical soil data evaluated in the risk assessments are presented in **Attachment A, Tables A-1a through A-1c**.

2.1.2 Hydric Soil

Hydric soil samples were collected from the off-Project Red Maple Swamp/tidal stream area during sampling events performed in 1994, 2011, and 2019 from 0 to 1 ft bgs and 1 to 2 ft bgs. Hydric soil samples were analyzed for inorganics, PCB Aroclors, pesticides, SVOCs, VOCs, and TOC, although not all samples were analyzed for all analytes. Hydric soil data collected during previous investigations considered not to be representative of current conditions were excluded from evaluation in the HHRA and ERA in accordance with the RAWP provided in the SAP (Mabbett, 2019). These data include hydric soil samples collected over 20 years ago (i.e., 1994). The exclusion of these data resulted in the exclusion of all pesticide data. There is no evidence of bulk storage or releases of pesticides or off-label pesticide use at the Site, therefore, pesticides are not considered Project-related and are not further assessed.

Hydric soil data were grouped into two different depth intervals for evaluation in the risk assessments, as applicable. Surface hydric soil was defined as hydric soil collected from 0 to 1 ft bgs. Subsurface hydric soil was defined as hydric soil collected from 1-2 ft bgs. Redevelopment activities are not anticipated to occur in this area; therefore, hydric subsurface soil is not likely to be available for exposure by human and ecological receptors. Therefore, hydric subsurface soil was not evaluated in the ERA. Hydric subsurface soil was evaluated in the HHRA through the chemical of potential concern (COPC) selection and EPC calculation steps for informational purposes only, as further discussed in Section 3.

A list of hydric soil samples and a summary of the analytical hydric soil data evaluated in the risk assessments are presented in **Attachment A, Tables A-2a and A-2b**.

2.1.3 Groundwater

Groundwater samples were collected from the on-Project Blue Beach, off-Project Red Maple Swamp/tidal stream, and off-Project Narragansett Bay and Beachfront areas during multiple sampling events conducted between 2008 and 2019. Groundwater samples were analyzed for metals, PCBs, pesticides, SVOCs, VOCs, and TPH, although not all samples were analyzed for all analytes. Potential impacts due to petroleum products are assessed using the relevant VOC and SVOC data for individual chemicals. Therefore, TPH results were not evaluated in the risk assessments.

Groundwater data collected from the off-Project areas were not evaluated in the HHRA because there are no complete exposure pathways to groundwater in these areas. The off-Project Red Maple Swamp/tidal stream area is a wetland/salt marsh/creek and is therefore highly unlikely to be redeveloped under a future use scenario, and the land owner (QDC) is currently in the process of recording an Environmental Land Use Restriction (ELUR) on the parcel deed to prohibit the use of groundwater as a potable water source without treatment. As a result, water supply wells

are not likely to be constructed in this area and construction/utility work is also not anticipated to occur. Samples from groundwater wells in this area were used to provide data for consideration in the RI to update the conceptual site model (CSM) and refine groundwater flow patterns. Groundwater samples from the off-Project Narragansett Bay and Beachfront area were collected in 2014 to provide information for use in determining whether collection of sediment and surface water samples within the off-Project Narragansett Bay was appropriate. Based on these groundwater data, sediment and surface water samples were collected in the off-Project Narraganset Bay and Beachfront area for evaluation in the risk assessments. Construction/utility work is not anticipated to occur along the beach/shoreline, and recreational receptors present on the beach were evaluated in the HHRA for potential contact with surface water in Narragansett Bay.

The ERA does not use groundwater data given there are no complete exposure pathways to ecological receptors.

In accordance with the RAWP provided in the SAP (Mabbett, 2019), unfiltered (total) groundwater results from the most recently available groundwater sampling events, conducted in 2014 and 2019, were evaluated in the HHRA. Groundwater data were summarized in two ways for evaluation in the HHRA, as applicable: (1) groundwater collected from all depths, and (2) shallow groundwater, defined as groundwater samples collected less than or equal to 15 ft bgs.

A list of groundwater samples and a summary of the analytical groundwater data evaluated in the HHRA are presented in **Attachment A, Tables A-3a and A-3b**.

2.1.4 Porewater

Porewater samples (unfiltered) were collected in the off-Project Red Maple Swamp/tidal stream and off-Project Narraganset Bay and Beachfront areas during multiple sampling events conducted between 2008 and 2015. Porewater samples were analyzed for inorganics, PCBs, pesticides, SVOCs, and VOCs, although not all samples were analyzed for all analytes. Porewater data are evaluated in the ERA but are not utilized in the HHRA because there are no complete human exposure pathways.

A list of porewater samples and a summary of the analytical porewater data evaluated in the ERA are presented in **Attachment A, Tables A-4a through A-4c**.

2.1.5 Sediment

Sediment samples were collected in the off-Project Red Maple Swamp/tidal stream and off-Project Narraganset Bay and Beachfront areas during multiple sampling events conducted between 1994 and 2020. Sediment samples were analyzed for inorganics, PCBs, pesticides, SVOCs, VOCs, TPH, and TOC although not all samples were analyzed for all analytes. Tidal creek sediments were also collected in 2020 for simultaneously extracted metals (SEM), acid volatile sulfides (AVS) and toxicity testing to support the ERA. Potential impacts due to petroleum products are assessed using the relevant VOC and SVOC data for individual chemicals. Therefore, TPH results were not evaluated in the risk assessments.

Sediment data collected during previous investigations considered not to be representative of current conditions were excluded from evaluation in the HHRA and ERA in accordance with the RAWP provided in the SAP (Mabbett, 2019). These data include sediment samples collected over 20 years ago (i.e., 1994 to 1995). The exclusion of these data resulted in the exclusion of all sediment data for pesticides. There is no evidence of bulk storage or releases of pesticides or off-label pesticide use at the Site, therefore, pesticides are not considered Project-related and are not further assessed. Sampling depths for sediment used in the risk assessments were 0 to 0.5 ft bgs in the off-Project Red Maple Swamp/tidal stream area and 0 to 0.5 ft bgs and 0 to 1 ft bgs in the off-Project Narraganset Bay and Beachfront area.

A list of sediment samples and a summary of the analytical sediment data evaluated in the risk assessments are presented in **Attachment A, Tables A-5a through A-5c**.

2.1.6 Surface Water

Surface water samples were collected in the off-Project Red Maple Swamp/tidal stream area in 2011 and 2014 and in the Narragansett Bay within the off-Project Narraganset Bay and Beachfront area in 2015. Surface water samples were analyzed for unfiltered (total) and filtered (dissolved) inorganics, PCBs, and VOCs, although not all samples

were analyzed for all analytes. The HHRA utilizes only the total inorganic surface water data, while the ERA utilizes both the total and dissolved inorganic data.

A list of surface water samples and a summary of the analytical surface water data evaluated in the risk assessments are presented in **Attachment A, Tables A-6a through A-6c.**

2.1.7 Soil Vapor

Soil vapor samples were collected in the on-Project Blue Beach area in 1992 and 2006 and analyzed for VOCs. Soil vapor results from samples collected from the 2006 sample event were selected for evaluation in the HHRA as being more representative of current conditions on the Project. Soil vapor results from the 1992 sampling event were not quantitatively evaluated in the HHRA because they were collected over 20 years ago and are not considered representative of current conditions.

A list of soil vapor samples and a summary of the analytical soil vapor data evaluated in the HHRA are presented in **Attachment A, Tables A-7a and A-7b**.

2.2 Data Treatment

Analytical soil, hydric soil, groundwater, porewater, sediment, surface water, and soil vapor data were validated and qualified prior to use in the risk assessments. Data evaluation and validation included a comparison of the analytical results for Site and background samples to results for corresponding blank (laboratory, field, equipment, and trip) samples. No analytical results were rejected ("R" qualified) by the evaluation. Multiple results in soil, hydric soil, groundwater, porewater, sediment, and surface water were qualified as estimated ("J" qualified). In addition, analytical results for aluminum in one background hydric soil sample, copper and manganese in 11 background sediment samples, and mercury analyzed by SEM methods in 10 sediment samples were qualified with a "B", indicating that the analyte was detected in the laboratory method blank analyzed concurrently with the sample. SEM and AVS results were not validated prior to evaluation in the risk assessments. Results with "J" or "B" qualifiers were used in the risk assessments without modification. If the value was flagged with "U" or "UJ," the result was considered a non-detect value.

For each medium/exposure area, analytical data were compiled into summary statistics for evaluation in the HHRA and ERA. Summary statistics were calculated following data treatment, as described in this section.

2.2.1 Total PAH and PCB Summations

Groups of chemicals including PAHs, low molecular weight (LMW) PAHs, high molecular weight (HMW) PAHs, PCB Aroclors, and xylenes (i.e., o-, m-, and p-xylenes) were totaled per sample prior to calculating summary statistics. These totals were calculated as the sum of individual compound concentrations; treatment of non-detects is discussed below. Total PAH sums were used only in the ERA; the HHRA evaluated PAHs as individual compounds. Ecological benchmarks are generally based on the PAH sums, and USEPA Region 4 guidance (USEPA, 2018a) specifies the use of benchmarks based on PAH sums for soil and sediment. Total PCB Aroclors and xylenes sums are used in both the HHRA and the ERA.

The PAH compounds were grouped into LMW and HMW PAH totals as follows:

PAH Compound	CAS	Molecular Weight Group
Benzo(a)pyrene	50-32-8	High
Benzo(g,h,i)perylene	191-24-2	High
Pyrene	129-00-0	High
Dibenzo(a,h)anthracene	53-70-3	High
Benzo(b)fluoranthene	205-99-2	High
Fluoranthene	206-44-0	High
Benzo(k)fluoranthene	207-08-9	High
Chrysene	218-01-9	High
Benzo(a)anthracene	56-55-3	High

PAH Compound	CAS	Molecular Weight Group
Indeno(1,2,3-cd)pyrene	193-39-5	High
Naphthalene *	91-20-3	Low
Anthracene	120-12-7	Low
Acenaphthene	83-32-9	Low
Phenanthrene	85-01-8	Low
Fluorene	86-73-7	Low
2-Methylnaphthalene	91-57-6	Low
Acenaphthylene	208-96-8	Low
1-Methylnaphthalene	90-12-0	Low

* Naphthalene results reported for the SVOC method were used in the total LMW PAH calculations.

Total PCB Aroclors were calculated as the sum of individual Aroclor compounds as follows:

PCB Aroclor	CAS
Aroclor 1260	11096-82-5
Aroclor 1254	11097-69-1
Aroclor 1242	53469-21-9
Aroclor 1221	11104-28-2
Aroclor 1232	11141-16-5
Aroclor 1248	12672-29-6
Aroclor 1016	12674-11-2
Aroclor 1262 *	37324-23-5
Aroclor 1268 *	11100-14-4

* Analysis of these PCB Aroclors were included in only one sampling event, as further discussed below.

All PCB datasets included the analysis of seven PCB Aroclors (the first 7 listed in the above table). The PCB datasets from the November 2011 sampling event, including hydric soil, porewater, sediment, and surface water samples in the off-Project Red Maple Swamp/tidal marsh area, also included analysis of Aroclor 1262 and Aroclor 1268, however, neither of these Aroclors was detected in any of the samples analyzed in any media. Therefore, Aroclor 1262 and Aroclor 1268 were not included in the PCB Aroclor analyses in following sampling events.

For data sets that include non-detect results for individual PAH or PCB Aroclors, the level of detection (LOD) was used to represent the non-detect result and the sum of concentrations was calculated using the Kaplan-Meier (KM) method, which is a non-parametric statistical method that does not require assumptions of normality (Kaplan and Meier, 1958). The KM method is recommended in USEPA ProUCL software (Version 5.1.002; USEPA, 2016) for calculating the 95% UCL on the arithmetic mean concentration for data sets with one or more censored or non-detect results (USEPA, 2015a). In the application of summing a group of related compounds such as PAHs and PCBs, the KM mean was estimated for sample datasets that included non-detects and this KM mean was then multiplied by the number of compounds (mean × n) to compute the PAH or PCB sum for that sample.

The KM mean was calculated in R Software package that implements ProUCL's KM approach (Millard SP, 2013). At least two detected individual compounds are required for the calculation of the KM mean. If a PAH or PCB dataset included non-detect results but had at least two detected individual compounds with distinct concentration results, the KM mean was estimated and rounded to the fourth decimal place.

To safeguard against a potentially biased-high estimate of the KM mean, a simple summation was calculated (i.e., sum of detected concentrations and LODs for non-detect results) to establish an upper bound of the total concentration value. If the KM summation resulted in a total concentration greater than the simple sum of detected concentrations and LODs, the simple sum was used instead.

In cases of datasets with less than two detected individual compounds, a simple sum was calculated (i.e., sum of detected concentrations and LODs for non-detected results). Simple sums were calculated for all xylene totals and a few PAH totals that had less than two detected individual compounds.

2.2.2 Treatment of Duplicate Discrete Samples

For discrete sample locations in which a field duplicate sample was also collected (e.g. parent sample and corresponding field duplicate), the combined sample results for each chemical/medium/area/depth interval combination was processed for use in the calculation of summary statistics. Parent and field duplicates were resolved as follows: 1) where both the parent sample and the duplicate are not detected, the lower of the LODs was used, 2) where both the parent sample and the duplicate are detected, the average of the detected results was used, and 3) where one of the pair is reported as not detected and the other is detected, the detected concentration was used.

2.2.3 Analyses via Multiple Methods

In some samples, naphthalene was analyzed using different methods in the same samples (e.g., SVOC and VOC methods). Naphthalene results from both SVOC and VOC methods were summarized and evaluated separately for consideration in the risk assessments. Naphthalene is an LMW PAH and was therefore included in the total LMW PAH sum calculations derived for each sample, as discussed in Section 2.2.1. Naphthalene results reported for the SVOC method were used in the total LMW PAH calculations. The total LMW PAH values are considered only in the ERA. In general, in cases where a sample evaluated in the ERA had naphthalene results from both SVOC and VOC methods (e.g., a subset of surface soil, surface hydric soil, and surface sediment samples), the SVOC result was higher. Therefore, the use of the SVOC result in the total LMW PAH calculation is not expected to underestimate associated ecological risks.

2.2.4 Summary Statistics

For each chemical detected at least once within an area/media/depth interval (i.e., surface soil, subsurface soil, etc.), the summary statistics include the minimum and maximum detected concentrations, location of maximum detected concentration, frequency of detection (FOD), and the range of detection limits calculated in accordance with USEPA Risk Assessment Guidance for Superfund (RAGS; USEPA, 1989). Additional summary statistics, including the 95% UCL concentration and the mean concentration were compiled as applicable. The UCL and mean concentrations were calculated using different methods for discrete and ISM samples, as described below.

2.2.4.1 Discrete Samples

USEPA ProUCL software (Version 5.1.002; USEPA, 2016) was used to calculate the ProUCL-recommended 95% UCL and the KM Mean concentration, as applicable for use in the evaluation of COPCs in the HHRA and/or ERA, as described in Sections 3 and 4, respectively. Where a sufficient sample size or FOD was not available for ProUCL to calculate a reliable statistic, in which case the program provided a warning or other message indicating a UCL is not recommended, the maximum detected concentration was utilized for evaluation in the HHRA and ERA, as indicated in Sections 3 and 4, respectively. Similarly, where a KM mean was not calculated by ProUCL (i.e., datasets with 100% detected results), the mean of the detected results was used. The ProUCL inputs and outputs associated with the HHRA and ERA are presented separately in **Attachment B**.

2.2.4.2 ISM Samples

Results for PCBs from triplicate ISM soil samples collected from each of the three SUs within the on-Project Blue Beach area were used to calculate a 95% UCL concentration per depth interval (i.e., surface soil and subsurface soil) for evaluation in the HHRA and/or ERA. The SU-specific 95% UCL concentrations were calculated based on triplicate ISM samples within each SU. The SU-specific 95% UCLs were treated as individual results for calculation of the FOD and the maximum detected concentration used in the preliminary COPC screening steps of the HHRA and ERA, as discussed in Sections 3 and 4, respectively. The SU-specific 95% UCLs were also used to calculate a weighted mean UCL concentration for the on-Project Blue Beach area, by weighting the SU-specific UCLs based on the size (i.e., surface area) of the SU. This additional refinement was conducted to address uncertainty associated with the variability in the triplicate sample results and to ensure that a conservative estimate of a mean concentration representative of the on-Project Blue Beach exposure area was obtained, without inappropriately biasing the exposure point concentration toward a specific SU.

Due to the nature of the ISM sampling which results in a smaller sample size per SU than what is recommended for the appropriate use of USEPA's ProUCL Software (USEPA, 2016), the ISM calculator provided in the Interstate Technology Regulatory Council ISM guidance (ITRC, 2012) was used to calculate the SU-specific 95% UCLs. The ISM calculator is designed to calculate UCLs for data sets with few samples based on both the Chebyshev and Student's t methods (ITRC, 2012). If the coefficient of variation (CV), calculated as the standard deviation divided by the arithmetic mean concentration, is greater than 35% (indicating high variability), the Chebychev UCL is

recommended. If the CV is less than 35% (indicating low variability), the Student's t UCL is recommended (ITRC, 2012). The CVs associated with all of the on-Project Blue Beach ISM soil data sets were less than 35%, therefore, the Student's t UCL was the selected UCL for all data sets. UCLs calculated based on small sample sizes may be greater than the maximum detected concentration, which was the case for this project. Consistent with ISM guidance (ITRC, 2012), the UCL was used, even if greater than the maximum detected concentration.

The SU-specific 95% UCL calculations performed using the ITRC ISM Calculator and the weighted mean UCLs for the on-Project Blue Beach exposure area are provided in **Attachment C**.

2.3 Background Evaluation

Representative soil, hydric soil, and sediment background chemistry data (discrete samples) for metals and PAHs were collected for comparison to Site-specific data within the risk assessments. A list of the soil, hydric soil, and sediment background samples and the associated analytical data summary tables are presented by media in **Attachment A.**

Representative background soil, hydric soil, and sediment were collected in May 2020 at Rome Point State Park in North Kingstown, Rhode Island, and in the upstream portion of the off-Project Red Maple Swamp/tidal stream area (between Circuit Drive and outfall 025). Both areas are deviations from background sampling locations identified in the RAWP provided in the SAP (Mabbett, 2019), as described in the Draft Trip Report for the Comprehensive Remedial Investigation Former Blue Beach Disposal Area FUDS (Mabbett, 2020), because permission was not granted for access to previously identified background areas. Rome Point State Park is located on Narragansett Bay with similar shoreline features to the former Blue Beach Disposal Area but has not been impacted by past military operations. The portion of the tidal stream where the background sediment samples were collected is upgradient and outside of the Site-related influence.

The available background data were compiled and compared with Site-specific data to distinguish Site-related impacts from non-Site-related background conditions (naturally occurring or anthropogenic). The background evaluation consisted of a tiered process and was conducted as part of the COPC selection process to focus the HHRA and ERA on Site-related COPCs, in accordance with the Tri-Service Position Paper on Background Levels in Risk Assessment (USACE, 2011), as follows:

- The background datasets were evaluated for the presence of outliers using the default outlier test (Dixon's Test) in USEPA's ProUCL software (USEPA, 2016) prior to conducting the following tiers of background evaluation. These statistical tests can identify "extreme" values in the background datasets; however, extreme values were not identified as outliers unless additional justification was evident. Datasets with background samples identified as extreme values were further evaluated by conducting outlier tests with data transformations. If a sample was identified as an extreme value and the same sample was identified for other COPCs in the same chemical group, the value was removed from the dataset prior to the background threshold values (BTV) calculation, the two-sample hypothesis test, and the geochemical analysis.
- Derivation of BTVs - Medium-specific BTVs were derived for chemicals identified as preliminary COPCs in the HHRA and/or ERA. The processes for selecting preliminary COPCs for human health and ecological receptors are described in detail in Sections 3 (HHRA) and 4 (ERA), respectively.
- Hypothesis testing - For each medium and chemical for which preliminary COPCs were detected at concentrations above BTVs, hypothesis testing for centrality was conducted to compare the mean background concentration with Site-related concentrations.
- Geochemical analysis - For metals identified as preliminary COPCs that are not eliminated based on a comparison to BTVs or hypothesis testing, a geochemical analysis was conducted to distinguish whether metals concentrations are either present due to Site/anthropogenic activities or are naturally occurring. The premise of conducting a geochemical evaluation is to identify metals concentrations that are originally derived from minerals (rocks) that, when exposed, break down and result in the release of metals. The metals will form new minerals (secondary minerals) via new processes, including absorption and precipitation. The primary metals that adsorb to other metals are aluminum (Al), iron (Fe), and manganese (Mn) (i.e., Al as mostly clays, Fe and Mn as primarily oxyhydroxides). If the metals detected at the Site are naturally occurring, a relationship can be observed via regression. A regression graph is utilized, plotting the concentrations of major/reference metals (Al, Fe, and Mn) on the x-axis against other metals on the y-axis. If the metals form a good regression (line) from the

lower left corner to upper right corner of the graph, then these metals are most likely to be naturally occurring. If there is not a good regression, their presence is most likely is due to Site or other anthropogenic activities.

For media/chemicals for which requirements for conducting a statistical evaluation are not met (e.g., Site or background dataset consist of mainly non-detects), a qualitative/graphical comparison (using box plots or other plots, as appropriate) was performed.

The results of the background evaluation were used in the HHRA and ERA as discussed in Sections 3 and 4, respectively. Chemicals identified as being detected at concentrations consistent with background (i.e., non-Site related COPCs) were not be further quantitatively evaluated in the HHRA and ERA.

The background evaluation is provided in **Attachment D** and overall results are summarized below.

Outlier values were identified for three samples: a surface soil sample, a hydric surface soil sample, and a hydric subsurface soil sample, and extreme values determined to be outliers for these samples were removed from the datasets prior to BTV calculation, two-sample hypothesis test, and the geochemical analysis.

Media	COPCs with Outlier Values Removed from Datasets
Surface soil (SB-412)	Anthracene, benzo(b)fluoranthene, chrysene, dibenzo(a,h)anthracene, pyrene, total HMW PAHs, and total PAHs
Hydric surface soil (SSH-313)	Arsenic, chromium, cobalt, copper, iron, and manganese
Hydric subsurface soil (SSH-313)	Arsenic, cobalt, and iron

BTVs were calculated for preliminary COPCs and compared to Site concentrations in the risk assessments. Any preliminary COPC for which Site concentrations are less than the BTVs were eliminated from the risk assessments. These comparisons are discussed separately within the HHRA (Section 3) and the ERA (Section 4).

A two-sample hypothesis test was conducted for each COPC retained following the comparison of BTVs to Site concentrations in the risk assessments. The two-sample hypothesis test compared the central tendency (i.e., the mean or median) of the Site and background datasets and identify the COPCs for which Site and background concentrations are consistent. The following table presents the COPCs for which the central tendency (i.e., median or mean concentrations) of Site datasets are less than or equal to background datasets and were not retained for further evaluation in the risk assessments. COPCs were eliminated for all exposure media and areas with the exception of hydric subsurface soil for which no COPCs were eliminated based on the two-sample hypothesis test results.

Media	COPCs Not Retained Based on Two-Sample Hypothesis Tests
Surface Soil	**On-Project Blue Beach Area**: chromium, cobalt, manganese, mercury, nickel, silver, anthracene, benzo(a)pyrene, total HMW PAHs, total PAHs; **Off-Project Red Maple Swamp / Tidal Stream Area:** chromium, lead, zinc, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, chrysene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, pyrene, total HMW PAHs, total PAHs.
Subsurface Soil	**On-Project Blue Beach Area:** arsenic, copper, lead, manganese
Sediment	**Off-Project Red Maple Swamp / Tidal Stream Area:** aluminum, arsenic, barium, beryllium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, silver, thallium, vanadium, and fluorene; **Off-Project Narragansett Bay / Beachfront Area:** aluminum, arsenic.
Hydric Surface Soil	**Off-Project Red Maple Swamp / Tidal Stream Area:** manganese, anthracene, benzo(a)anthracene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, pyrene, total HMW PAHs

The last step in the background evaluation was the geochemical evaluation, which was performed for metals retained as COPCs based on the results of the two-sample hypothesis tests which concluded Site concentrations were greater

than background. Correlations between the reference elements and COPCs were examined using scatterplots and pairwise correlations. Significant, positive correlations between reference elements and COPCs in background and Site indicated the COPC is naturally occurring and eliminated from the HHRA and ERA. The following COPCs were eliminated from further evaluation in the risk assessments on the basis of the geochemical evaluation:

Media	**COPCs Not Retained Based on Two-Sample Hypothesis Tests**
Sediment	**Off-Project Red Maple Swamp / Tidal Stream Area:** cadmium and zinc
Hydric Surface Soil	**Off-Project Red Maple Swamp / Tidal Stream Area:** aluminum, chromium, cobalt, iron, manganese, vanadium, and zinc
Hydric Subsurface Soil	**Off-Project Red Maple Swamp / Tidal Stream Area:** arsenic, cobalt, iron, and vanadium

3. Human Health Risk Assessment

The HHRA was conducted to evaluate whether exposure to COPCs attributable to past operations at the former Blue Beach Disposal Area may pose a risk and/or hazard to human health above USEPA target levels. The evaluation included performing a quantitative estimation of potential cancer risk and noncancer hazard to current and potential future human receptors that may come into contact with Site-related chemicals in soil, hydric soil, groundwater, sediment, surface water, and soil vapor within the on-Project Blue Beach area and off-Project areas (i.e., Off-Project Red Maple Swamp/tidal stream area and off-Project Narragansett Bay and Beachfront area), as applicable. **Table 3-1** presents a summary of the exposure areas, human receptors, and current and potential future exposure routes qualitatively and/or quantitatively evaluated in the HHRA. The HHRA was conducted in accordance with USEPA CERCLA risk assessment guidance (USEPA, 1989, 2004, 2005a, and 2009).

The HHRA was conducted in accordance with the RAWP provided in the SAP (Mabbett, 2019) with certain updates to reflect the most currently available USEPA HHRA guidance. USEPA's four step HHRA paradigm (USEPA, 1989) was followed to conduct the HHRA, as follows:

- Data Evaluation and Hazard Identification
- Exposure Assessment
- Toxicity Assessment
- Risk Characterization

Each of the tiers of evaluation is discussed in further detail in the following subsections.

Tables are numbered based on the Risk Assessment Guidance for Superfund (RAGS) Part D (USEPA 2001) numbering system, as noted in the following table. Table numbers also include the report section number before the RAGS Part D table number, and a final number where multiple tables are included (e.g., the Table 2s are numbered Table 3-2-1 to 3-2-10, as there are 10 of them).

Table #	RAGS Part D Table Title
Table 1	Selection of Exposure Pathways (HHRA)
Table 2	Occurrence, Distribution, and Selection of Chemicals of Potential Concern
Table 3	Exposure Point Concentration Selection
Table 4	Values Used for Daily Intake Calculations
Table 5	Non-Cancer Toxicity Data
Table 6	Cancer Toxicity Data
Table 7	Calculation of Chemical Cancer Risks and Non-Cancer Hazards
Table 9	Summary of Receptor Risks and Hazards for COPCs
Table 10	Risk Summary

Note: RAGS Part D Table 8 (Calculation of Radiation Cancer Risks) is not applicable to this HHRA.

3.1 Data Evaluation/Hazard Identification

The data evaluation and hazard identification step involve identification and summarization of Site data appropriate for use in the HHRA, and the selection of COPCs for quantitative evaluation in the HHRA. Analytical data was grouped for evaluation in the HHRA, as discussed in Section 2.1.

3.1.1 Selection of Chemicals of Potential Concern

COPCs are a subset of the complete list of chemicals detected in Project media that are carried through the quantitative risk assessment process. The HHRA COPC selection process may consider low FOD, low toxicity and low concentration, consistency with Site-specific background, essential nutrient status, and whether the chemical is

likely to be present due to laboratory contamination. For this HHRA, Site-related COPCs were established per exposure area, medium, and depth interval (as appropriate) as described in the following sub-sections.

3.1.1.1 Frequency of Detection and Essential Nutrients

Essential nutrients, including magnesium, calcium, potassium, and sodium were not selected as COPCs for further evaluation in the HHRA, consistent with USEPA guidance (USEPA, 1989). Chemicals were not eliminated as COPCs on the basis of low FOD alone. However, a discussion of COPCs with a low FOD is provided in the risk characterization.

3.1.1.2 Comparison to Human-Health Screening Levels

Preliminary COPCs were identified based on a comparison of the maximum detected concentrations of each chemical detected in discrete samples per media/area/depth interval (as applicable) to human health screening levels (or regulatory values as available). For PCBs analyzed from ISM soil samples, the SU-specific 95% were used for the preliminary COPC evaluation because they are greater than the maximum detected concentrations, as discussed in Section 2.2.4.2. Chemicals detected at concentrations above the screening levels were identified as preliminary COPCs for further evaluation in comparison with background, as discussed in the following section. Chemicals either not detected in a particular medium or detected at concentrations below the screening levels and regulatory values were not identified as COPCs for the associated medium/area and were not evaluated further in the HHRA. For chemicals lacking a screening level, a conservative surrogate chemical was identified, if available, and its screening level selected for use in the COPC selection. A chemical was eliminated as a COPC if there are no associated toxicity values available with which quantitative evaluation in the HHRA may be performed, an appropriate surrogate cannot be identified, and the investigation provides no other evidence of an apparent source of unacceptable risk.

Screening levels used to select preliminary human health COPCs are discussed by media below.

Soil and Hydric Soil

The USEPA Regional Screening Levels (RSLs) (USEPA, 2020a) based on a target ELCR of 1×10^{-6} and a target hazard quotient (HQ) of 0.1 were used in the HHRA to select COPCs in soil and hydric soil. The RSLs based on a target HQ of 0.1 were used to account for potential cumulative effects of multiple constituents on the same target organ. The residential soil RSLs were used in the selection of preliminary COPCs for evaluation of all receptors. The residential soil RSLs are based on USEPA's default residential exposure frequency of 350 days/year and exposure duration of 26 years. Use of the residential soil RSLs is conservative for non-residential scenarios because the exposure frequency and duration associated with non-residential exposure scenarios are less than those for a residential scenario.

The industrial soil RSLs were used for comparative purposes only and were not used in the selection of preliminary COPCs. The industrial soil RSLs are based on the default 250 days/year exposure frequency and 25-year default exposure duration for workers.

A comparison to screening levels protective of the soil to groundwater pathway was not included in this HHRA. Analytical groundwater data are available and were evaluated directly.

Tables 3-2.1 and 3-2.2 present the preliminary COPC selection for surface soil and subsurface soil, respectively. **Tables 3-2.3 and 3-2.4** present the preliminary COPC selection for hydric surface soil and hydric subsurface soil, respectively.

Groundwater

As discussed in Section 2.1.3, groundwater data were summarized in two ways for evaluation in the HHRA, (1) groundwater collected from all depths, and (2) shallow groundwater, defined as groundwater samples collected less than or equal to 15 ft bgs. The following screening levels were used for both groundwater datasets:

- USEPA tap water RSLs (USEPA, 2020a) based on a target ELCR of 1×10^{-6} and a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals on the same target organ).
- USEPA Maximum Contaminant Levels (MCLs) (USEPA, 2018b).

Chemicals detected at a concentration greater than the RSL or MCL were selected as preliminary groundwater COPCs. These levels are protective of a residential drinking water exposure scenario. Therefore, use of these

screening levels is conservative for selecting COPCs for non-drinking water exposure scenarios (such as incidental ingestion by a construction worker). **Tables 3-2.5 and 3-2.6** present the preliminary COPC selection for groundwater and shallow groundwater, respectively.

Shallow groundwater data were also evaluated in comparison to USEPA Vapor Intrusion Screening Levels (VISLs) for groundwater based on a target ELCR of 1×10^{-6} and a target HQ of 0.1 (USEPA, 2020b) as a preliminary screening evaluation of the potential vapor intrusion pathway. However, soil vapor data were the primary dataset used for selection of COPCs for evaluation of the potential vapor intrusion pathway. VISLs associated with a residential and industrial worker exposure scenario were used for comparison. **Table 3-2.7** presents the comparison of shallow groundwater data to VISLs.

Sediment

Published human health screening levels are not available for sediment. Therefore, residential soil RSLs were used for selecting preliminary COPCs in sediment. The use of residential soil RSLs for evaluation of sediment is very conservative due to the lower exposure frequency for sediment as compared to soil. **Table 3-2.8** presents the preliminary COPC selection for sediment.

Surface Water

The following surface water screening levels were used in the HHRA:

- USEPA National Recommended Ambient Water Quality Criteria (AWQC) for human health consumption of water and organisms (USEPA, 2020c).
- USEPA tap water RSLs based on a target ELCR of 1×10^{-6} and a target HQ of 0.1 (USEPA, 2020a). The tap water RSLs are protective of a residential drinking water exposure scenario. Therefore, use of these screening levels is overly conservative for selecting surface water COPCs.

Chemicals detected at a concentration greater than the USEPA AWQC (or RSL if an AWQC is not available) were selected as preliminary surface water COPCs. **Table 3-2.9** presents the preliminary COPC selection for surface water.

Soil Vapor

The USEPA VISLs for soil vapor based on a target ELCR of 1×10^{-6} and a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals on the same target organ) (USEPA, 2020b) were used to select soil vapor COPCs for further evaluation of the potential vapor intrusion pathway. The residential VISLs were used in the selection of preliminary soil vapor COPCs for evaluation of all receptors. The residential VISLs are based on USEPA's default residential exposure frequency of 350 days per year and exposure duration of 26 years. Use of the residential VISLs is conservative for a non-residential scenario because the exposure frequency and duration associated with a non-residential exposure scenario is less than that for a residential scenario.

The industrial VISLs were used for comparative purposes only. The industrial VISLs are based on a USEPA default exposure frequency of 250 days per year and exposure duration of 25 years for an indoor worker scenario. **Table 3-2.10** presents the preliminary COPC selection for soil vapor.

3.1.1.3 Surrogate Screening Levels

For certain analytes lacking a chemical-specific screening level, a conservative surrogate chemical was selected and its screening level was used in the preliminary COPC selection. Specific instances where surrogate assignments were made are identified in footnotes in **Tables 3-2.1 through Table 3-2.10**.

3.1.1.4 Comparison to Background Levels

Preliminary COPCs identified in soil, hydric soil and sediment based on the comparison to human health screening levels were further evaluated in conjunction with background data, as available. The background evaluation was conducted as described in Section 2.3. Chemicals within a medium/area/depth interval that are (1) not detected at a concentration above the associated BTV, (2) for which the hypothesis testing for centrality concludes that Site concentrations are consistent with background, or (3) the geochemical analysis concludes that Site concentrations are consistent with background, were not identified as Site-related COPCs and were excluded from further quantitative evaluation in the HHRA. Preliminary COPCs that were not identified as being consistent with background were identified as Site-related COPCs and were further quantitatively evaluated in the HHRA.

Attachment D presents the background evaluation, including outlier evaluation, derivation of BTVs, hypothesis testing and geochemical analysis. The comparison of the surface soil, subsurface soil, hydric surface soil, hydric subsurface soil, and sediment datasets to the associated BTVs is provided in the preliminary COPC selection tables; **Tables 3-2.1, 3-2.2, 3-2.3, 3-2.4, and 3-2.8**, respectively.

3.1.2 COPC Selection Results

Table 3-2.11 summarizes the preliminary COPCs identified per media/depth interval/area based on the comparison of the maximum detected concentration (or maximum SU-specific 95% UCL concentration for ISM soil samples) to human health screening levels. For soil, hydric soil, and sediment COPCs with an associated medium-specific dataset, it also summarizes the results of each tier of background evaluation and whether the preliminary COPC was retained or excluded from being a Site-related COPC based on the associated tier. **Table 3.2.11** presents whether each preliminary COPC was retained as a Site-related COPC for further evaluation in the HHRA.

A summary of the Site-related COPCs identified for further evaluation in the HHRA are indicated with an “X” in the following tables provided by medium and depth interval (as applicable):

Soil				
Exposure Point	CAS Number	COPC	Surface Soil	Subsurface Soil
On-Project Blue Beach Area		**Inorganics**		
	7440-36-0	Antimony	X	X
	7440-43-9	Cadmium	X	X
		PCBs		
	Tot-PCB-ARO	Total PCB Aroclors	X	X
		SVOCs		
	53-70-3	Dibenzo(a,h)Anthracene	X	
		VOCs		
	95-63-6	1,2,4-Trimethylbenzene		X
	100-41-4	Ethylbenzene		X
	Tot-Xylenes	Total Xylenes		X
	79-01-6	Trichloroethylene		X

CAS – Chemical Abstracts Service.

*Naphthalene was identified as a COPC based on results from SVOC and VOC analytical methods.

No Site-related COPCs were identified in the Off-Project Narragansett Bay and Beachfront area; therefore, this area was not further quantitatively evaluated in the HHRA.

3.2 Exposure Assessment

The purpose of the exposure assessment is the quantification of the extent, frequency, and duration of actual or potential exposure to COPCs by pathways relevant to the on-Project and off-Project exposure areas and activities of the potential receptors. As part of the exposure assessment, current and potential future exposure pathways were determined through the identified populations which may potentially be exposed to COPCs identified within the following exposure areas:

- On-Project Blue Beach area – within the Former Blue Beach Disposal Area FUDS
- Off-Project Red Maple Swamp/tidal stream area – within the tidal marsh referred to as “Red Maple Swamp” and the adjacent public walking path from Circuit Drive to Blue Beach

An exposure pathway describes the course a chemical follows while moving through environmental media to the receptor. An exposure pathway may consist of a mechanism of release of chemicals to an environmental medium (e.g., soil), an exposure route (e.g., ingestion), and a receptor (e.g., construction worker). An exposure pathway is considered complete when contact by a receptor with impacted media may occur under current site conditions or in the future. USEPA (1989, 1991) guidance requires that plausible exposures under both current and future land use scenarios be evaluated in an HHRA. A summary of the exposure areas, human receptors, and current and potential future exposure routes qualitatively and/or quantitatively evaluated in the HHRA is presented on **Table 3-1**. No Site-related sediment or surface water COPCs were identified in the Off-Project Narragansett Bay and Beachfront area; therefore, this area was not further quantitatively evaluated in the HHRA.

3.2.1 Human Health Conceptual Site Model

The Quonset Business Park Master Land Use and Development Plan, adopted October 2008, identifies the Site as being located in an area designated for light industrial use. The majority of the Project area is currently used for industrial/manufacturing purposes. The Project area is bordered to the north by the former Kiefer Park Tank Farm,

which is currently undeveloped property. South of the Project area is Blue Beach bordering the Narragansett Bay. The beach is currently used recreationally. A paved walking path runs along the west side of the Project area extending from Circuit Drive to Blue Beach (Narragansett Bay Beachfront). The walking path is bordered by trees and vegetation. To the west of the walking path is a salt marsh and tidal creek, referred to as Red Maple Swamp, which is accessible by humans. Surface water in this area is very shallow; therefore, potential exposure may occur via a limited wading scenario. To the west of the off-Project Red Maple Swamp/tidal stream area is a residential area.

There are currently no residential receptors within the on-Project Blue Beach area and residential use is not a reasonably anticipated future use of the Site. The area is not zoned for residential use, and an ELUR barring residential use of the parcel has been recorded. Groundwater within the on-Project Blue Beach area is classified by the Rhode Island Department of Environmental Management (RIDEM) as 'GB', may not be suitable for drinking without treatment. Based on its proximity to Narragansett Bay and wetlands, groundwater is likely to be brackish, and the extraction of groundwater to serve as a water source (or to treat) would likely draw additional saline water into the system and would, therefore, not be implementable. Additionally, an ELUR recorded on the deed prohibits potable use of groundwater from the parcel. However, the HHRA conservatively evaluated a future unlimited use/unrestricted exposure (UU/UE) scenario for informational purposes and for use in the forthcoming Feasibility Study (FS), if needed. In the unlikely event that the Project area is converted to residential use in the future, it is not reasonable to expect that the residents would use groundwater as a potable water source. A remedial response will not necessarily be taken based on the results of the future UU/UE scenario given it is not a reasonably anticipated future use for the Site, per the DoD Defense Environmental Restoration Program (DERP) Management Manual (DoD, 2012), which states "The DoD Component shall consider current and reasonably anticipated future land uses in risk assessments. The DoD Component does not have to assume that the reasonably anticipated future land use is residential."

The buildings currently located within the on-Project Blue Beach area are used for industrial/manufacturing purposes and have vapor barriers installed. Therefore, the vapor intrusion pathway is considered incomplete under a current use scenario. Additionally, Hayward Pool Products, which is currently located on the on-Project Blue Beach area, has previously submitted a written statement to RIDEM that any future buildings constructed on its parcels would include a vapor barrier to prevent vapor intrusion. However, the HHRA performed a screening level evaluation of the potential vapor intrusion pathway for a future on-Project Blue Beach indoor worker to provide information for determining whether a vapor intrusion mitigation system is recommended for future buildings constructed on the on-Project Blue Beach. A screening level vapor intrusion evaluation was also assessed for a hypothetical future on-Project Blue Beach residential scenario as part of the UU/UE scenario evaluation.

Although there are no known plans for redevelopment on the on-Project Blue Beach area, it is conservatively assumed that limited construction or utility-related activities may occur in this area.

Groundwater in the off-Project Red Maple Swamp is classified by RIDEM as 'GA', known or presumed to be suitable for drinking water use without treatment. However, this area is a salt marsh and is therefore highly unlikely to be redeveloped under a future use scenario. Additionally, QDC (the parcel owner) is currently in the process of recording an ELUR on the deed that will restrict groundwater use for potable purposes. As a result, water supply wells are not likely to be constructed and construction/utility work is also not considered to occur in this area. Therefore, there are no complete exposure pathways in which humans are likely to contact groundwater in this area. The off-Project residential area located to the west of the off-Project Red Maple Swamp/tidal marsh area is currently on a municipal water supply. Groundwater flow patterns indicate that migration of on-Project groundwater to the off-Project Residential area is unlikely. Therefore, there are no complete exposure pathways associated with an off-Project Resident.

The reasonably anticipated current and future receptors and exposure pathways evaluated in the HHRA based on current and potential future land use are discussed in the following sections. The quantitative exposure assumptions used to evaluate these receptors in the HHRA were selected to represent a reasonable maximum exposure (RME) scenario in accordance with USEPA guidance (USEPA, 1989, 2002a, 2004, 2011 and 2014a) and utilizing professional judgement. **Tables 3-4.1 through 3-4.8** present the medium-specific exposure assumptions per receptor and exposure route.

3.2.2 Current/Future Use Scenarios

The HHRA addresses current and future potential exposure scenarios. The current scenario timeframe represents exposure to existing Site conditions (i.e., no land redevelopment). With the exception of the construction/utility worker scenario, which assumes intrusive soil work occurs, the current/future use scenarios only involve exposure to surface soil. For the non-intrusive soil scenarios, subsurface soil (greater than 1 ft bgs) would not be disturbed unless future land redevelopment occurs. The future evaluation for these scenarios, including exposure to subsurface soil, is discussed in Section 3.2.3.

Current/Future Construction/Utility Worker - A current/future construction/utility worker was evaluated in the HHRA for the following exposure pathways within the on-Project Blue Beach area:

- Exposure to surface and subsurface soil through incidental ingestion, dermal contact and inhalation of airborne particles and volatiles in outdoor air; and
- Exposure to shallow groundwater via incidental ingestion, dermal contact, and inhalation of volatiles from an excavation trench.

The construction/utility worker is assumed to be involved in a construction project 40 days per year for 1 year. It is conservatively assumed for purposes of the HHRA that a construction/utility worker may be exposed to on-Project soil and groundwater for 10 hours per day.

Current/Future Outdoor Worker - A current/future outdoor worker was evaluated in the HHRA for exposure to surface soil in the on-Project Blue Beach area through incidental ingestion and dermal contact and inhalation of airborne particles and volatiles in outdoor air. The outdoor worker is assumed to be a full-time worker and utilizes USEPA-recommended default exposure inputs.

Current/Future Trespasser – An adolescent trespasser (age 7 to <16 years) was evaluated in the HHRA for exposure to surface soil in the on-Project Blue Beach area through incidental ingestion, dermal contact; and inhalation of airborne particles and volatiles in outdoor air. It was assumed, based on professional judgment, that trespassers may contact soil within the on-Project Blue Beach area for 26 days per year (i.e., one day per week for the warmer 6 months of the year).

Current/Future Recreational User – A recreational user (adult/child) was evaluated in the HHRA for the following exposure pathways within the off-Project Red Maple Swamp/tidal stream area:

- Exposure to surface soil through incidental ingestion, dermal contact, and inhalation of airborne particles and volatiles in outdoor air; and
- Exposure to hydric surface soil, sediment, and surface water through incidental ingestion and dermal contact under a limited wading scenario.

No Site-related COPCs were identified in the off-Project Narragansett Bay and Beachfront area. Therefore, this area is not further evaluated in the HHRA.

3.2.3 Future Use Scenarios

The future use scenarios include those exposure scenarios that are not currently applicable, but that may reasonably occur in the future. This scenario also conservatively assumes that exposure to subsurface soil may occur for current/future receptors under a hypothetical future land use scenario in which subsurface soils are brought to the surface and made available for contact.

Future Outdoor Worker - A future outdoor worker was evaluated in the HHRA for exposure to subsurface soil in the on-Project Blue Beach area through incidental ingestion, dermal contact, and inhalation of airborne particles and volatiles in outdoor air. The outdoor worker is assumed to be a full-time worker and utilizes USEPA-recommended default exposure inputs.

Future Trespasser – An adolescent trespasser (age 7 to <16 years) was evaluated in the HHRA for exposure to subsurface soil in the on-Project Blue Beach area through incidental ingestion, dermal contact, and inhalation of airborne particles and volatiles in outdoor air. It was assumed, based on professional judgment, that trespassers may

contact soil within the on-Project Blue Beach area for 26 days per year (i.e., one day per week for the warmer 6 months of the year).

Future Recreational User – A recreational user (adult/child) was evaluated in the HHRA for the following exposure pathways within the off-Project Red Maple Swamp/tidal stream area:

- Exposure to subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles and volatiles in outdoor air; and
- Exposure to hydric surface soil, sediment, and surface water through incidental ingestion and dermal contact under a limited wading scenario. Redevelopment activities are not considered to occur in this area; therefore, hydric subsurface soil is not likely to be available for exposure by recreational users. Hydric subsurface soil was evaluated in the HHRA through the COPC selection and EPC calculation steps for informational purposes only.

It was assumed, based on professional judgment, that recreational users may contact soil, hydric soil, sediment, and surface water within the off-Project Red Maple Swamp/tidal stream area for 26 days per year (i.e., one day per week for the warmer 6 months of the year) and that exposure to surface water occurs for 1 hour per day. USEPA-recommended default inputs for a residential adult/child soil exposure scenario were used for the majority of the remaining exposure parameters. The sediment/hydric soil ingestion rate was assumed to be 10% of the USEPA-recommended default soil ingestion rate for a residential scenario.

No Site-related COPCs were identified in the off-Project Narragansett Bay and Beachfront area. Therefore, this area is not further evaluated in the HHRA.

Future Indoor Worker – A future indoor worker was evaluated in the HHRA for exposure to soil vapor in the on-Project Blue Beach area from inhalation of volatiles in indoor air via the vapor intrusion pathway under a future use scenario in which additional industrial buildings would be constructed in the on-Project Blue Beach area without a vapor mitigation system (i.e., vapor barrier). This scenario is not a likely future use scenario because Haywood Pool Products, which is currently located on the Project area, has previously submitted a written statement to RIDEM that any future buildings constructed on its parcels would include a vapor barrier to prevent vapor intrusion. However, this scenario was evaluated in the HHRA for informational purposes.

Hypothetical Future Resident (Adult/Child) – A hypothetical future resident (adult/child) was conservatively evaluated in the HHRA to represent a UU/UE scenario. Although this is not a reasonably anticipated future use of the Site, it was evaluated for informational purposes only. A hypothetical future resident was evaluated for the following exposure pathways in the on-Project Blue Beach area:

- Exposure to surface and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) and volatiles in outdoor air;
- Inhalation of volatiles in soil vapor via the vapor intrusion pathway; and
- Exposure to groundwater via ingestion of drinking water, and dermal contact and inhalation of volatiles during bathing/showering.

The hypothetical future residential scenario was evaluated using USEPA-recommended default exposure inputs.

3.2.4 Calculation of Dose

The purpose of the exposure assessment is estimate the magnitude, frequency, duration, and routes of current and reasonably anticipated future human exposure to COPCs associated with the Site. USEPA guidance documents used in this exposure assessment include the RAGS, Part A (USEPA, 1989); Exposure Factors Handbook (USEPA, 2011); Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites (USEPA, 2002a); RAGS Part E (Supplemental Guidance for Dermal Risk Assessment) (USEPA, 2004); and Supplemental Guidance: Update of Standard Default Exposure Factors (USEPA, 2014a).

Equations are presented for the calculation of chronic daily intake values for the ingestion, dermal contact, and inhalation pathways of exposure. The equations are used for calculating a lifetime average daily dose (LADD) (oral/dermal) or lifetime average daily exposure (LADE) (inhalation) relevant to cancer risk (i.e., cancer intake) or for calculating an average daily dose (ADD) (oral/dermal) or average daily exposure (ADE) (inhalation) relevant to

noncancer hazard (i.e., noncancer intake). The medium-specific equations used for the calculation of carcinogenic and noncarcinogenic intakes of the COPCs are presented in **Tables 3-4.1 through 3-4.8**, along with the RME parameters used for each receptor evaluated in the HHRA, as discussed in Section 3.2.3. Absorption factors and other parameters used in the calculation of dermal dose were obtained from USEPA guidance and are presented in **Attachment E-1**.

3.2.5 Exposure Point Concentrations

To evaluate the magnitude of potential human exposures, the concentration of each COPC in each exposure medium/exposure area is estimated. The estimate of this exposure point concentration is referred to as an EPC. EPCs for evaluation of the RME scenario for each of the COPCs identified within a medium/exposure area are described below.

In accordance with USEPA guidance (USEPA, 1989; 2002b), EPCs for evaluation of COPCs in the HHRA were set to equal the 95% UCL on the arithmetic mean concentration. The maximum detected concentration was used as the EPC when (1) the 95% UCL for a COPC exceeded the maximum detected concentration because of small sample sizes or high data set variability; or (2) where a sufficient sample size or FOD was not available for ProUCL to calculate a reliable statistic, in which case it provided a warning or other message indicating a UCL is not recommended. Maximum detected concentrations were not substituted for UCLs greater than the maximum detect for ISM datasets (PCBs only).

3.2.5.1 Soil

Soil EPCs were calculated differently for discrete and ISM datasets. The EPCs for Total PCB Aroclors in surface and subsurface soil within the on-Project Blue Beach area (ISM soil datasets) are equal to the weighted mean UCL concentration of the SU-specific 95% UCLs based on SU size (acreage), calculated as described in Section 2.2.4.2. Soil EPCs for all other COPCs associated with discrete sample datasets are equal to the 95% UCL concentration, calculated as described in Section 2.2.4.1, or the maximum detected concentration if an appropriate 95% UCL was not calculated by ProUCL due to one of the scenarios previously described.

In the off-Project Maple Swamp/tidal stream area, Total PCB Aroclors and benzo(a)pyrene were detected at a low FOD in surface soil and subsurface soil, respectively. Therefore, 95% UCLs could not be calculated. In these cases, the maximum detected concentrations were conservatively used as the EPCs. Naphthalene was identified as a subsurface soil COPC in the off-Project Red Maple Swamp/tidal stream area based on results from both SVOC and VOC analytical methods. Naphthalene results were summarized separately based on both the SVOC and VOC method results throughout the COPC selection process and the development of EPCs. The higher of the EPCs (i.e., the EPC calculated from the results from the VOC method) is the selected EPC for further evaluation of naphthalene in subsurface soil in the off-Project Red Maple Swamp/tidal stream area.

The complete set of EPCs for surface soil and subsurface soil within the on-Project Blue Beach area and off-Project Red Maple Swamp/tidal stream area are presented in **Tables 3-3.1 and 3-3.2**, respectively.

3.2.5.2 Hydric Soil

Hydric soil EPCs are equal to the 95% UCL concentration, calculated as described in Section 2.2.4.1, for COPCs except for PCBs. Total PCB Aroclors were detected at a low FOD in subsurface hydric soil. Therefore, a 95% UCL could not be calculated. The EPC for Total PCB Aroclors in subsurface hydric soil in the off-Project Red Maple Swamp/tidal stream area is conservatively equal to the maximum detected concentration. The complete set of EPCs for surface hydric soil and subsurface hydric soil within the off-Project Red Maple Swamp/tidal stream area are presented in **Tables 3-3.3 and 3-3.4**, respectively.

3.2.5.3 Groundwater

COPCs were identified within the on-Project Blue Beach area for further evaluation of groundwater under a hypothetical future residential exposure scenario in which groundwater would be used as a source of drinking water or for showering/bathing. COPCs were also identified in shallow groundwater within the on-Project Blue Beach area for further evaluation of a current/future construction/utility worker exposure scenario. Groundwater data for COPCs were reviewed to identify samples within the core of the plume for use in deriving EPCs, consistent with USEPA guidance (USEPA, 2014b). No distinct groundwater plumes were identified, and the areas of higher concentration varied by COPC. However, two wells (MW-101S and MW-103) did not have any detections of groundwater COPCs at concentrations greater than the associated screening levels (described in Section 3.1.1.2). Therefore, these wells

were excluded from the EPC calculations for groundwater and shallow groundwater to avoid the potential for these lower concentrations outside of the area of higher concentrations to bias the groundwater EPCs low.

EPCs for both the groundwater and shallow groundwater datasets are equal to the 95% UCL concentration, calculated as described in Section 2.2.4.1, or the maximum detected concentration if an appropriate 95% UCL was not calculated by ProUCL due to one of the scenarios previously described. The EPC was equal to the maximum detected concentration for multiple COPCs within the groundwater and shallow groundwater datasets due to a low FOD. Naphthalene was identified as a groundwater COPC in the on-Project Blue Beach area based on results analyzed by SVOC and VOC methods. As with soil, the higher of the EPCs for naphthalene (in this case, the EPC presented for the SVOC method) is the selected EPC for further evaluation of naphthalene in groundwater in the on-Project Blue Beach area.

Lead was identified as a COPC in groundwater. The EPC for lead is equal to the arithmetic mean concentration (i.e., rather than the 95% UCL on the arithmetic mean) in accordance with USEPA guidance (USEPA, 2003a and 2007).

The complete set of EPCs for groundwater and shallow groundwater within the on-Project Blue Beach area are presented in **Tables 3-3.5 and 3-3.7**, respectively.

3.2.5.4 Sediment

One sediment COPC was identified in the off-Project Red Maple Swamp/tidal stream area. The sediment EPC is equal to the 95% UCL concentration, calculated as described in Section 2.2.4.1. The EPC for sediment within the off-Project Red Maple Swamp/tidal stream area is presented in **Table 3-3.9**.

3.2.5.5 Surface Water

Two surface water COPCs were identified in the off-Project Red Maple Swamp/tidal stream area. Both COPCs were only detected in 1 out of 10 samples in the dataset. Therefore, the surface water EPCs for both COPCs are conservatively equal to the maximum detected concentration due to the low FOD. The EPCs for surface water within the off-Project Red Maple Swamp/tidal stream area are presented in **Table 3-3.10**.

3.2.5.6 Soil Vapor

Three soil vapor COPCs were identified in the on-Project Blue Beach area. These COPCs were detected in one of the six samples in the dataset. The soil vapor EPCs are conservatively equal to the maximum detected concentration. The EPCs for soil vapor within the on-Project Blue Beach area are presented in **Table 3-3.11**.

3.2.5.7 Outdoor Air (Fugitive Dust and Volatiles), Shower Air, and Trench Air

EPCs for COPCs in outdoor air (fugitive dust and volatiles), shower air, and trench air were estimated as discussed in this section.

Fugitive Dust and Volatiles in Outdoor Air

For the soil COPCs, the concentration in fugitive dust originating from soil was estimated by combining the surface soil or subsurface soil EPC (as applicable) with a particulate emission factor (PEF). The USEPA-recommended default PEF of 1.36×10^9 m^3/kg for a non-excavation scenario (USEPA, 2002a) was used for evaluation of the outdoor worker, trespasser, recreational user, and hypothetical future residential exposure scenarios. The USEPA-recommended default PEF of 7.74×10^5 m^3/kg for unpaved road traffic as part of an excavation scenario (USEPA, 2002a) was used for evaluation of the construction/utility worker exposure scenario. Fugitive dust EPCs are not presented separately, as the PEF is applied to the soil EPC in the risk calculation spreadsheets (**Tables 3-7.1 through 3.7.7**).

For the volatile soil COPCs, the concentration of volatiles in outdoor air originating from soil was estimated by combining the surface soil or subsurface soil EPC (as applicable) with a receptor/area-specific volatilization factor (VF) calculated in accordance with USEPA guidance (2002a). The VF calculations are included in **Attachment E-2**.

Shower Air

For evaluation of the bathing/showering pathway, concentrations of volatiles in the shower were modeled using the Foster and Chrostowski (1987) shower model. The shower model was used to estimate the concentrations in shower air resulting from a unit groundwater concentration (1 microgram per liter [µg/L]). The shower air concentrations estimated based on the unit groundwater concentration were then multiplied by the chemical-specific groundwater

EPCs in **Table 3-3.5** to estimate the shower air EPCs. The shower model used to estimate shower air EPCs is presented in **Attachment E-3**. Shower air EPCs are presented in **Table 3-3.6**.

Trench Air

Excavation trench air concentrations of COPCs resulting from volatilization from groundwater infiltrating an excavation trench were modeled by the use of the method recommended by USEPA (1994) for predicting volatilization from standing water. The trench model was used to estimate the concentrations in trench air resulting from a unit groundwater concentration (1 µg/L). The trench air concentrations estimated based on a unit groundwater concentration were then multiplied by the chemical-specific shallow groundwater EPCs in **Table 3-3.7** to estimate the concentrations of volatile COPCs in outdoor air within an excavation trench. The trench model used to estimate trench air EPCs is presented in **Attachment E-4**. Trench air EPCs are presented in **Table 3-3.8**.

Vapor Intrusion Pathway

Soil vapor EPCs for COPCs identified within the on-Project Blue Beach area (presented in **Table 3-3.11)** were further evaluated using USEPA's VISL Calculator (USEPA, 2020b). The VISL Calculator utilizes USEPA's default soil vapor to indoor air attenuation factor of 0.03 (USEPA, 2015b) to provide a conservative estimate of the indoor air concentration that may be present in an overlying building under a scenario in which the vapor intrusion pathway is complete (i.e., no vapor barrier). The VISL Calculator then estimates the potential ELCR and noncancer HQ associated with the modeled indoor air concentration. The VISL Calculator outputs for the on-Project Blue Beach area future indoor worker and hypothetical future residential exposure scenarios are presented in **Attachment E-5**.

3.3 Toxicity Assessment

The purpose of the toxicity or dose-response assessment is to identify the types of adverse health effects a chemical may potentially cause, and to define the relationship between the dose of a chemical and the likelihood or magnitude of an adverse effect (response) (USEPA, 1989). The USEPA's guidance regarding the hierarchy of sources of human health dose-response values in risk assessment was used (USEPA, 2003b; 2018b) and is presented below:

- Tier 1: USEPA's Integrated Risk Information System (IRIS) (USEPA, 2020d);
- Tier 2: Provisional Peer-Reviewed Toxicity Values (PPRTVs) obtained from USEPA via the USEPA National Center for Environmental Assessment (NCEA) in Cincinnati, Ohio (USEPA, 2020e);
- Tier 3: Other sources of dose-response values include, California EPA's Office of Environmental Health and Hazard Assessment (OEHHA) Toxicity Criteria Database (CalEPA, 2020f), Minimal Risk Levels (MRLs) published by the Agency for Toxic Substances and Disease Registry (ATSDR, 2020), and the Health Effects Assessment Summary Tables (HEAST) (USEPA, 1997a).

Where published dose-response values were not available for a chemical, dose-response values based on surrogate chemicals (i.e., chemicals with structural similarities) were identified. The chosen surrogate is referenced in the summary table(s) of dose-response values (**Tables 3-5.1 to 3-5.2 and Tables 3-6.1 to 3-6.2**).

3.3.1 Toxicity Information for Noncarcinogenic Effects

Systemic toxic effects other than cancer can be associated with exposures to chemicals. Reference doses (RfDs) for oral exposures, and reference concentrations (RfCs) for inhalation exposures, are the toxicity values that are used to evaluate the potential of developing noncarcinogenic effects because of exposure to chemicals. RfDs and RfCs were developed based on the premise that there are protective mechanisms that must be overcome before an appreciable risk of adverse health effects is manifested during a defined exposure period. It is assumed that there is a threshold dose that must be exceeded before adverse effects can occur.

Chemicals classified as carcinogens may also produce other systemic effects. These chemicals were also evaluated for potential noncarcinogenic toxic effects and were included in the determination of chronic toxicity HQs, which characterize noncancer hazards. Carcinogenic effects, however, are usually manifested at levels that are significantly lower than those associated with systemic toxic effects; thus, cancer is usually the predominant adverse effect for chemicals that may elicit carcinogenic and noncarcinogenic responses.

Table 3-5.1 summarizes the oral noncarcinogenic toxicity values (i.e., RfDs) and the corresponding critical effects for the COPCs identified. **Table 3-5.2** summarizes the inhalation noncarcinogenic toxicity values (i.e., RfCs) and the corresponding critical effects for the COPCs.

Tables 3-5.1 and 3-5.2 contain both chronic and subchronic toxicity values. Subchronic toxicity values are applicable to the construction/utility worker scenario where exposures are expected to occur over a brief (i.e., 1 year) duration. Chronic toxicity values are applicable to the other receptors whose exposures are expected to occur over a longer interval of time. Subchronic toxicity values are not generally found in IRIS. If published subchronic toxicity factors are not available from Tier 2 or 3 sources, subchronic toxicity values were derived from chronic toxicity values. According to USEPA guidance (USEPA 1989), if a chronic toxicity value has been developed based on subchronic data, a subchronic toxicity value may be calculated by removal of the uncertainty factor used to extrapolate from subchronic to chronic exposures (typically a factor of 10). If subchronic toxicity values are not available and the chronic toxicity value is derived from chronic data, the chronic toxicity value is adopted as the subchronic toxicity value.

3.3.2 Toxicity Information for Carcinogenic Effects

The potential for human carcinogenic effects is evaluated based on the chemical-specific CSFs and unit risk factors (URFs) values along with the weight-of-evidence classification (categories A through E) of the USEPA (USEPA, 1989). The CSF and URF values are the toxicity values that quantitatively define the dose-response relationship of a known or suspected carcinogen. The CSF and URF values are a mathematical extrapolation of the slope of the dose-response curve from high doses administered to animals (or the exposures observed in human epidemiological studies) to the doses estimated for exposure in the environment. The USEPA has developed CSFs and URFs for chemicals classified as carcinogens based on the premise that there is no threshold (i.e., there is no level of exposure below which there is no risk of a carcinogenic effect).

USEPA's Guidelines for Carcinogen Risk Assessment (USEPA 2005a) classifies human carcinogenic potential as "known/likely," "cannot be determined," and "not likely" to replace the weight of evidence categories A through E. The guidelines also acknowledge that the mode of action of a carcinogen may involve both threshold and non-threshold mechanisms.

Table 3-6.1 summarizes the oral carcinogenic toxicity values (i.e., CSFs) and the corresponding weight-of-evidence classifications. **Table 3-6.2** summarizes the inhalation carcinogenic toxicity values (URFs).

The quantitative evaluation of potential risks for carcinogens with a mutagenic mode of action (i.e., carcinogenic PAHs and trichloroethene) followed USEPA guidance for early life exposure to carcinogens (USEPA, 2005a). Specifically, the quantification of cancer risks for child receptor involves the use of age-dependent adjustment factors (ADAFs). An ADAF of 10 was used for childhood exposures occurring from birth to 2 years of age, an ADAF of 3 was used for exposures occurring between the ages of 2 and 16 years, and an ADAF of 1 was used for adult exposures (USEPA, 2005), including the worker receptors, recreational adult, and residential adult.

Vinyl chloride also acts via a mutagenic model of action. However, the CSFs for vinyl chloride account for mutagenic effects, therefore, application of the ADAFs is not necessary for evaluation of mutagenic mode of action for vinyl chloride. The methodology for evaluating mutagenic mode of action is further discussed in Section 3.5.

3.3.3 Adjustment of Toxicity Factors

No RfDs or CSFs are available for evaluating dermal exposure. Therefore, carcinogenic risk and noncarcinogenic hazard associated with dermal exposure may be evaluated using an oral CSF or RfD adjusted such that the toxicity value is appropriate for the dermal pathway. As detailed by USEPA (2004), for purposes of evaluating dermal exposure, it is generally necessary to adjust an oral toxicity factor (i.e., RfD or CSF) from an administered (i.e., applied) dose to an absorbed (i.e., internal) dose. Because the toxicity values for the COPCs are expressed as oral doses (i.e., applied or intake-based), it is necessary to adjust both the RfDs and CSFs for these substances in estimating exposure on an absorbed-dose basis when assessing dermal exposure.

The oral RfDs and oral CSFs for each COPC were modified according to the following equations (USEPA, 2004) for use in assessing dermal exposure:

$$RfD_{ABS} = RfD_o \times ABS_{GI}$$

$$SF_{ABS} = SF_o / ABS_{GI}$$

Where:

RfD_{ABS} = Absorbed RfD (i.e., adjusted dermal RfD) (milligram per kilogram per day [mg/kg-day])

RfD_o = Oral RfD (mg/kg-day)

ABS_{GI} = Fraction of chemical absorbed in gastrointestinal tract (dimensionless) in critical toxicity study. Absolute oral bioavailability factor for each chemical (i.e., oral to dermal adjustment factor)

SF_{ABS} = Absorbed slope factor (i.e., adjusted dermal slope factor)

SF_o = Oral slope factor $(mg/kg\text{-}day)^{-1}$

Table 3-5.1 and Table 3-6.1 present the oral to dermal adjustment factors used to adjust the oral toxicity criteria for the COPCs evaluated in the dermal exposure pathways. Absorption factors and other parameters used in the calculation of dermal dose were obtained from USEPA guidance and are presented in **Attachment E-1**.

3.3.4 Chemical-Specific Information

The following chemical-specific approaches were followed in the HHRA:

Arsenic

Arsenic was identified as a COPC in subsurface soil and hydric surface soil within the off-Project Red Maple Swamp/tidal stream area and in groundwater and shallow groundwater in the on-Project Blue Beach area. To assess the oral bioavailability of arsenic in soil, a relative bioavailability factor of 0.6 (i.e., 60%) has been applied to the ingestion risk calculations. Because the oral RfD and CSF for arsenic are based on drinking water studies and the oral absorption of arsenic from water has been shown to be higher than the absorption of arsenic from a solid matrix, the relative bioavailability factor has been developed as an upper-bound estimate of the oral absorption efficiency of soil-borne arsenic (USEPA, 2012). The relative bioavailability factor is not applicable to the dermal route of exposure. However, because hydric soil is a soil-like matrix, the soil arsenic relative bioavailability factor has also been used for arsenic in hydric soil. The evaluation of incidental ingestion of soil associated with other COPCs utilizes a relative bioavailability factor of 1 (i.e., 100%).

Chromium

Many metals can exist in different oxidation states; for some metals, the oxidation state can have different toxicities. This is the case for chromium. Chromium exists in two common oxidation states: trivalent chromium (chromium-3, Cr[III], or Cr+3), and hexavalent chromium (chromium-6, Cr[VI], or Cr+6). Trivalent chromium is essentially nontoxic as evidenced by its residential soil RSL of 120,000 mg/kg (USEPA, 2020a). It can be bought over-the-counter as a supplement and is included in most vitamins. USEPA has classified hexavalent is a human carcinogen by the inhalation route of exposure (USEPA, 2020d).

Chromium is most commonly present in the environment in the trivalent state because typical conditions in the environment favor the reduction of chromium from the hexavalent to the trivalent state. Hexavalent chromium in soil is expected to be reduced to trivalent chromium by organic matter, and is facilitated by low pH (ATSDR, 2012). In addition, if hexavalent chromium is ingested, it is rapidly converted to the trivalent form after entering the stomach. Therefore, hexavalent chromium is not considered by USEPA to pose a cancer risk via the ingestion route of exposure (USEPA, 2020f).

There is no evidence to suggest that hexavalent chromium is present at the Site. Therefore, in the absence of soil screening levels for total chromium, soil screening levels for trivalent chromium were used. The only medium in which total chromium was identified as a COPC is groundwater, based on the maximum detected concentration being

greater than the associated MCL. However, the maximum detected concentration of total chromium in groundwater did not exceed the tapwater RSL for trivalent chromium.

In the absence of published toxicity values for total chromium, toxicity values for trivalent chromium were used to assess chromium in the HHRA.

Lead

Lead was identified as a COPC in groundwater. Uncertainties in the dose-response relationship between exposure to lead and biological effects make it unclear whether the noncarcinogenic effects of lead exhibit a threshold response. Therefore, a published RfD for lead is not available. Although USEPA has classified lead as a B2 (probable human) carcinogen, no CSF has been developed. Therefore, potential exposures to lead cannot be evaluated using the traditional methods of risk assessment. Lead in groundwater was evaluated in comparison to the Safe Drinking Water Act (SDWA) action level of 15 µg/L, presented on the USEPA MCL table (USEPA, 2018b).

Total PCB Aroclors

Cancer toxicity values for Total PCBs (high risk and persistence) recommended in USEPA's IRIS database (2020d) were used for evaluation of Total PCBs. The oral RfD for PCB Aroclor 1254 (USEPA, 2020d) was used to evaluate noncarcinogenic oral/dermal pathways.

Carcinogenic PAHs

The CSF and IUR for benzo(a)pyrene, along with the appropriate relative potency factors (USEPA, 1993a), have been used to evaluate the potency of the individual carcinogenic PAHs (benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene. Only benzo(a)pyrene has an oral RfD and an inhalation RfC. Consistent with the USEPA RSL table (USEPA, 2020a), RPFs are not used to develop RfDs and RfCs for the remaining carcinogenic PAHs.

Trichloroethene

USEPA (2020d) characterizes trichloroethene as carcinogenic to humans based on human epidemiological studies on kidney and liver tumors and non-Hodgkin's lymphoma. Trichloroethene acts by a mutagenic mode of action for the induction of kidney tumors. Thus, USEPA has published separate CSFs and URFs associated with each of these target endpoints. Therefore, ADAFs are applied for the evaluation of the mutagenic mode of action associated with the induction of kidney tumors using the CSFs and URFs associated with this endpoint. ADAFs are not applied to the CSFs and URFs associated with the non-Hodgkin's lymphoma endpoint.

3.4 Risk Characterization

Risk characterization combines estimates of exposure with toxicity data to develop estimates of the probability that an adverse effect will occur under the specified conditions of exposure. The risk characterization was divided into three phases: (1) risk estimation, (2) risk description, and (3) uncertainty analysis.

Risk estimation is undertaken by combining the toxicity factors and exposure assessment equations to calculate estimates of potential risks. Noncarcinogenic risks are reported as a pathway-specific hazard index (HI), which is the sum of individual COPC HQs for that pathway. Estimates of carcinogenic risks are reported as ELCRs. Current practice considers carcinogenic risks to be additive when assessing exposure to a mixture of hazardous substances. Risk description entails several discussions, including the relative contributions of individual exposure pathways to the total potential risk for each medium. The significance of the risk estimates is relative to risk management criteria set forth in USEPA policy. The uncertainty analysis describes and quantifies, where possible, the impact of data uncertainty and variability, exposure assumptions, and toxicity values on estimates of potential risk.

3.5 Estimation of Potential Risk and Hazard

Noncancer hazard is estimated by means of a HQ. To calculate noncarcinogenic HQs, the ADDs or ADEs, calculated as described in Section 3.2.4 were divided by the RfDs or RfCs as follows:

- Oral/dermal: HQ = ADD (mg/kg-day) ÷ RfD (mg/kg-day)
- Inhalation: HQ = ADE (mg/m^3) ÷ RfC (mg/m^3)

The sum of this ratio for all chemicals within an exposure point and pathway that have the same target organ or type of toxicity is termed the pathway HI. The HI is useful as a reference point for gauging potential effects of environmental exposures to complex mixtures but cannot be equated to a probability or effect level. In general, HIs that are less than 1 are not of regulatory concern; however, a HI of greater than 1 does not automatically indicate that an adverse effect will occur and should not automatically be interpreted as posing an unacceptable risk to the exposed population. Both USEPA and RIDEM use a target HI per target organ of 1 (USEPA 1991; RIDEM, 2019) as the acceptable HI.

The total pathway HI for each exposure point was calculated by summing the HQs for COPCs that have similar systemic effects. Total HIs for each receptor by medium were calculated by summing the total HIs across pathways within the media (e.g., summing dermal and ingestion soil risk estimates). As a first approximation, all COPCs are assumed to have additive effects. Total HIs, assuming additivity of effects, are presented per media and exposure pathway in **Tables 3-7.1 through 3-7.7**. In cases where the total HI, assuming additivity of effects, for a receptor exceeded 1, only COPCs that have similar systemic effects (i.e., target organs) were summed for each pathway and medium. Total HIs, assuming additivity of effects, exceeded 1 only for the hypothetical future residential scenario. Total HIs per target organ for the hypothetical future residential scenario are presented in **Tables 3-9.9 and 3-9.10**.

The potential cancer risk for each receptor is estimated for each medium by means of an ELCR. USEPA (1991) states that where the cumulative incremental current or future potential ELCR to an individual is less than 10^{-4}, action generally is not warranted unless there are adverse environmental impacts. RIDEM uses a target cumulative ELCR of 1×10^{-5} (RIDEM, 2019) to define acceptable risk.

To calculate the ELCR, the chemical- and pathway-specific LADDs calculated as described in Section 3.2.4 were multiplied by CSFs or URFs as follows:

- Oral/Dermal: ELCR = LADD (mg/kg-day) x CSF $(mg/kg\text{-}day)^{-1}$
- Inhalation ELCR = LADE (milligram per cubic meter [mg/m^3]) x URF (microgram per cubic meter [$\mu g/mg^3$])$^{-1}$ x 1,000 µg/mg

The resulting value represents the incremental upper-bound probability that an individual could develop cancer over his or her lifetime due to exposure to potential carcinogens under the conditions specified in the exposure scenario. For example, carcinogenic risk levels of 10^{-6} and 10^{-4} represent an incremental chance of one-in-one-million and one-in-ten-thousand, respectively, that an individual could contract cancer over a lifetime.

The potential cancer risk for each pathway (e.g., the soil ingestion pathway) was calculated by summing the potential risks from each COPC at each exposure point within the pathway, and receptor risks for each medium were calculated by summing ELCRs for each pathway within the medium (e.g., the soil incidental ingestion and dermal contact pathways). Pathway ELCRs are calculated in **Tables 3-7.1 through 3-7.7**. Total potential ELCRs are presented per area, media and exposure pathway in **Tables 3-9.1 through 3-9.10**.

Carcinogenic PAHs, TCE, and vinyl chloride were selected as COPCs in one or more media. These chemicals have been determined by USEPA to produce tumors through a mutagenic mode of action. USEPA has developed CSFs and URFs for vinyl chloride specific to life-stage. The quantification of potential cancer risks PAHs and TCE followed USEPA guidance entitled *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (USEPA, 2005a). The quantification of potential cancer risks for the adolescent trespasser, recreational user and hypothetical resident uses ADAFs for each of the chemicals identified as COPCs with mutagenic modes of action. Specifically, an ADAF of 10 was used for exposures occurring to children from birth to 2 years of age and an ADAF of 3 was used for exposures occurring between the ages of 2 and 16 years. The following general equation demonstrates how ADAFs are incorporated into the oral/dermal and inhalation risk calculations:

$$Risk_{oral/dermal} = \text{Exposure dose (mg/kg-day)} \times CSF\ (mg/kg\text{-}day)^{-1} \times ADAF$$

$$Risk_{inhalation} = \text{Exposure concentration } (\mu g/m^3) \times IUR\ (\mu g/m^3)^{-1} \times ADAF$$

In this HHRA, the residential and recreational user exposure scenarios include evaluation of a child and adult. The child age range consists of a young child, ages 0 to less than 6 years old. For the residential and recreational child receptors, a combined age-weighted ADAF of 5.3 was calculated as shown below:

Combined, age-weighted ADAF representative of a child (0 to <6 years) =

$$ADAF_{0-<2\ years}\ (10) \times (2\ years/6\ years) + ADAF_{2-<6\ years}\ (3) \times (4\ years/6\ years) = 5.3.$$

The above ADAF is applied in the calculation of risk in **Tables 3-7.4 through 3-7.7**. Application of the combined age-weighted ADAFs to the exposure dose/concentration associated with the entire age range (i.e., 0 to <6 years) is mathematically equivalent to the application of the individual ADAFs of 10 and 3 to the exposure dose/concentrations for the associated individual age ranges of 0 to <2 years and 2 to <6 years, respectively.

Table 3-11 provides a summary of the total potential ELCRs and noncarcinogenic HIs for each of the receptors evaluated. Total potential ELCRs and target organic-specific HIs above USEPA target levels are identified in bold font. **Table 3-11** also lists the chemicals identified as risk drivers for each exposure scenario in which the total potential ELCR or total potential HI are above USEPA target levels (i.e., total ELCR > 10^{-4}, and total HI > 1 per target endpoint). For each associated exposure scenario (i.e., area/receptor/medium) with a potential risk/HI above USEPA target levels, risk drivers were selected from those COPCs significantly contributing to an individual ELCR > 10^{-4} or target organ HI > 1 (at one significant figure), specifically, COPCs with an individual ELCR > 10^{-6} or HI > 1. Summary tables showing the total receptor ELCRs and HIs for risk drivers only are presented in **Table 3-10.1**. These risk drivers are selected as chemicals of concern (COCs) in the associated medium for the associated receptor/exposure scenario.

3.5.1 Description of Estimated Potential Risks and Hazards

This subsection summarizes the human health risks potentially associated with exposures to COPCs in environmental media (surface soil, subsurface soil, hydric surface soil, groundwater, shallow groundwater, sediment, surface water, and soil vapor) in the on-Project and off-Project areas, as applicable. Individual chemical-specific noncarcinogenic risks are expressed as HIs and carcinogenic risks are expressed as probabilities of developing cancer (i.e., ELCRs). Noncarcinogenic hazards and carcinogenic risks were calculated for RME scenarios. The RME represents the reasonable maximum exposure and potential risk a receptor may receive from an exposure point.

For the recreational and residential receptors, child and adult ELCRs have been summed to present the total potential ELCR for the receptor within each exposure area. However, because the child is the most sensitive receptor for the estimation of noncarcinogenic risks, only the child receptor HIs were presented for these receptors.

Table 3-11 provides a summary of the total potential ELCR and total potential noncarcinogenic HI and risk drivers by area, receptor, and media.

Current/Future Construction/Utility Worker

A current/future construction/utility worker scenario was evaluated for exposure within the on-Project Blue Beach area to COPCs in surface and subsurface soil through incidental ingestion, dermal contact, and inhalation of fugitive dust and volatiles in outdoor air; incidental ingestion and dermal contact with shallow groundwater, and inhalation of volatiles in the air of an excavation trench (trench air). The estimated potential ELCRs and noncancer HIs for a current/future construction worker are provided for each exposure medium in **Table 3-7.1**. The total potential RME ELCRs and HIs for a current/future construction/utility scenario are presented for surface soil, shallow groundwater, and trench air in **Table 3-9.1** and for subsurface soil, shallow groundwater, and trench air in **Table 3-9.2**.

The total potential ELCRs and noncancer HIs associated with the current/future construction/utility worker scenario are summarized below:

- The cumulative potential ELCR and total potential HI associated with exposure to surface soil, shallow groundwater, and trench air within the on-Project Blue Beach area under a current/future scenario are 1×10^{-6} and 0.5, respectively.

- The cumulative potential ELCR and total potential HI associated with exposure to subsurface soil, shallow groundwater, and trench air within the on-Project Blue Beach area under a current/future scenario are 1×10^{-6} and 0.5, respectively.

Further evaluation of total potential HI per target organ was not performed because the total potential HI for the combined endpoints did not exceed 1. The cumulative potential ELCRs and total potential HIs associated with the construction/utility worker exposure scenario in the on-Project Blue Beach area do not exceed USEPA's ELCR risk range of 10^{-6} to 10^{-4} or USEPA's target HI of 1. These ELCR/HI results also do not exceed RIDEM's target cumulative risk level of 1×10^{-5} and target HI of 1. Therefore, no risk drivers or COCs were selected for this receptor.

Current/Future and Future Outdoor Worker

An outdoor worker scenario was evaluated for exposure within the on-Project Blue Beach area to COPCs in soil through incidental ingestion, dermal contact, and inhalation of fugitive dust and volatiles in outdoor air. The current/future land use scenario included the evaluation of surface soil, and the future land use scenario included the evaluation of subsurface soil, assuming under a hypothetical future land use scenario subsurface soils may be brought to the surface and made available for contact. The estimated potential ELCRs and noncancer HIs for an outdoor worker scenario are provided by exposure medium in **Tables 3-7.1**. The total potential RME ELCRs and HIs are presented for a current/future outdoor worker scenario in **Table 3-9.3** and for a future outdoor worker scenario in **Table 3-9.4**.

The total potential ELCRs and noncancer HIs associated with the outdoor worker scenarios area are summarized below:

- The cumulative potential ELCR and total potential HI associated with exposure to surface soil within the on-Project Blue Beach area under a current/future scenario are 4×10^{-7} and 0.02, respectively.
- The cumulative potential ELCR and total potential HI associated with exposure to subsurface soil within the on-Project Blue Beach area under a future scenario are 1×10^{-6} and 0.1, respectively.

Further evaluation of total potential HI per target organ was not performed because the total potential HI for the combined endpoints did not exceed 1. The cumulative potential ELCRs and total potential HIs associated with the current/future and future outdoor worker exposure scenarios in the on-Project Blue Beach area do not exceed USEPA's ELCR risk range of 10^{-6} to 10^{-4} or USEPA's target HI of 1. These ELCR/HI results also do no exceed RIDEM's target cumulative risk level of 1×10^{-5} and target HI of 1. Therefore, no risk drivers or COCs were selected for this receptor.

Current/Future Trespasser

An adolescent trespasser scenario was evaluated for exposure to COPCs in soil from the on-Project Blue Beach area through incidental ingestion, dermal contact, and inhalation of fugitive dust and volatiles in outdoor air. The current/future land use scenario included the evaluation of surface soil, and the future land use scenario included the evaluation of subsurface soil, assuming under a hypothetical future land use scenario, that subsurface soils may be brought to the surface and would be available for contact. The estimated potential ELCRs and noncancer HIs for an adolescent trespasser scenario are provided for each exposure medium in **Tables 3-7.3**. The total potential RME ELCRs and HIs are presented for a current/future adolescent trespasser scenario in **Table 3-9.5** and for a future adolescent trespasser scenario in **Table 3-9.6**.

The total potential ELCRs and noncancer HIs associated with the adolescent trespasser scenarios area are summarized below:

- The cumulative potential ELCR and total potential HI associated with exposure to surface soil within the on-Project Blue Beach area under a current/future scenario are 2×10^{-8} and 0.004, respectively.
- The cumulative potential ELCR and total potential HI associated with exposure to subsurface soil within the on-Project Blue Beach area under a future scenario are 3×10^{-8} and 0.008, respectively.

Further evaluation of total potential HI per target organ was not performed because the total potential HI for the combined endpoints did not exceed 1. The cumulative potential ELCRs and total potential HIs associated with the

current/future and future adolescent trespasser exposure scenario in the on-Project Blue Beach area do not exceed USEPA's ELCR risk range of 10^{-6} to 10^{-4} or USEPA's target HI of 1. These ELCR/HI results also do no exceed RIDEM's target cumulative risk level of 1×10^{-5} and target HI of 1. Therefore, no risk drivers or COCs were selected for this receptor.

Current/Future Recreational User

A recreational user (adult/child) scenario was evaluated for exposure within the off-Project Red Maple Swamp/tidal stream area to COPCs in soil through incidental ingestion, dermal contact, and inhalation of fugitive dust and volatiles in outdoor air, in hydric surface soil and sediment through incidental ingestion and dermal contact, and in surface water through dermal contact under a limited wading scenario. The current/future land use scenario included the evaluation of surface soil, and the future land use scenario included the evaluation of subsurface soil, conservatively assuming under a hypothetical future land use scenario that subsurface soils within the walking path may be brought to the surface and made available for contact. The estimated potential ELCRs and noncancer HIs for a recreational user scenario are provided for each exposure medium in **Table 3-7.4** (adult) and **Table 3-7.5** (child). The total potential RME ELCRs and HIs are presented for a current/future recreational user scenario in **Table 3-9.7** and for a future adolescent trespasser scenario in **Table 3-9.8**.

The total potential ELCRs and noncancer HIs associated with the recreational user scenarios area are summarized below:

- The cumulative potential ELCR and total potential HI associated with exposure to surface soil, hydric surface soil, sediment, and surface water within the off-Project Red Maple Swamp/tidal stream area under a current/future scenario are 1×10^{-6} and 0.05, respectively.
- The cumulative potential ELCR and total potential HI associated with exposure to subsurface soil, hydric surface soil, sediment, and surface water within the off-Project Red Maple Swamp/tidal stream area under a future scenario are 2×10^{-6} and 0.06, respectively.

Further evaluation of total potential HI per target organ was not performed because the total potential HI for the combined endpoints did not exceed 1. The cumulative potential ELCRs and total potential HIs associated with the current/future and future recreational user (adult/child) scenarios in the off-Project Red Maple Swamp/tidal stream area do not exceed USEPA's ELCR risk range of 10^{-6} to 10^{-4} or USEPA's target HI of 1. These ELCR/HI results also do not exceed RIDEM's target cumulative risk level of 1×10^{-5} and target HI of 1. Therefore, no risk drivers or COCs were selected for this receptor.

Hypothetical Future Resident

A hypothetical future (adult/child) scenario was evaluated for exposure within the on-Project Blue Beach area to COPCs in soil through incidental ingestion, dermal contact, and inhalation of fugitive dust and volatiles in outdoor air, and in groundwater through ingestion as drinking water and dermal contact and inhalation of volatiles while bathing/showering. The estimated potential ELCRs and noncancer HIs for a hypothetical future residential scenario are provided for each exposure medium in **Table 3-7.6** (adult) and **Table 3-7.7** (child). The total potential RME ELCRs and HIs for a hypothetical future residential scenario are presented for surface soil, groundwater, and shower air in **Table 3-9.9** and for subsurface soil, groundwater, and shower air in **Table 3-9.10**.

The total potential ELCRs and noncancer HIs associated with the hypothetical future residential scenario area are summarized below:

- The cumulative potential ELCR and total potential HI (for combined target endpoints) associated with exposure to surface soil, groundwater, and shower air within the on-Project Blue Beach area under a hypothetical future scenario in which groundwater is used as a source of drinking water and other potable use are 2×10^{-3} and 50, respectively. Further evaluation of total potential HI per target organ was performed. Target organ HIs ranged from 0.001 to 30.
- The cumulative potential ELCR and total potential HI (for combined target endpoints) associated with exposure to subsurface soil, groundwater, and shower air within the on-Project Blue Beach area under a hypothetical future scenario in which groundwater is used as a source of drinking water and other potable use are 2×10^{-3} and

0.5, respectively. Further evaluation of total potential HI per target organ was performed. Target organ HIs ranged from 0.001 to 30.

The cumulative potential ELCRs and total potential HIs associated with a hypothetical future residential (adult/child) exposure scenario for the on-Project Blue Beach area exceed USEPA's ELCR risk range of 10^{-6} to 10^{-4} and the USEPA target HI of 1. The hypothetical future resident ELCR/HI results also exceed RIDEM's target cumulative risk level of 1×10^{-5} and target HI of 1. The primary source of risk to the hypothetical future resident is from the groundwater pathways. The potential risk associated with surface soil of $2x10^{-6}$ and the noncancer HI of 0.3 are within the USEPA ELCR risk range of 10^{-6} to 10^{-4} and the USEPA target HI of 1.

The EPC for lead in groundwater within the on-Project Blue Beach area (19 µg/L) is greater than the USEPA SDWA action level of 15 µg/L, presented on the USEPA MCL table (USEPA, 2018b).

The following table provides a summary of the COPCs identified as COCs in groundwater for a hypothetical future residential exposure scenario in which groundwater is a source of potable water and exposure may occur based on the ingestion of groundwater as drinking water and/or dermal contact and inhalation while showering/bathing exposure pathways. The potential ELCR's and HIs associated with the groundwater exposure scenarios for each COC are also provided in the table.

Groundwater COCs	Potential ELCR	Potential HI
Inorganics		
Arsenic	6×10^{-5}	0.5
Iron	N/A	4
Lead	N/A	N/A
Manganese	N/A	7
SVOCs		
1-Methylnaphthalene	8×10^{-5}	0.1
2-Methylnaphthalene	N/A	2
Benzo(a)Pyrene	4×10^{-6}	0.02
Naphthalene	2×10^{-3}	20
VOCs		
TCE	6×10^{-5}	10
Vinyl Chloride	4×10^{-5}	0.04

N/A - Not applicable.

Soil vapor COPCs in the on-Project Blue Beach area were further evaluated using the USEPA VISL Calculator (USEPA, 2020b) (presented in **Attachment E-5**) to assess the potential risk/hazard associated with the vapor intrusion pathway under a hypothetical future residential use scenario in which residences would be constructed on the Project without a vapor mitigation system (i.e., vapor barrier). This scenario is not a likely future use scenario because the area is not zoned for residential use and an ELUR barring residential use of the parcel has been recorded. However, this scenario was evaluated in the HHRA for informational purposes under a UU/UE scenario. The total potential ELCR and total HI associated with residential exposure to soil vapor COPCs via the vapor intrusion pathway are 5×10^{-5} and 0.3, respectively. These results do not exceed USEPA's ELCR risk range of 10^{-6} to 10^{-4} or USEPA's target HI of 1.

Indoor Worker

Soil vapor COPCs in the on-Project Blue Beach area were evaluated using the USEPA VISL Calculator (USEPA, 2020b) (presented in **Attachment E-5**) to assess the potential risk/hazard associated with the vapor intrusion pathway under a future use scenario in which industrial buildings would be constructed in the on-Project Blue Beach area without a vapor mitigation system (i.e., vapor barrier). This scenario is not a likely future use scenario because Haywood Pool Products, which is currently located on the Project area, previously submitted a written statement to RIDEM that any future buildings constructed on their parcels would include a vapor barrier to prevent vapor intrusion. However, this scenario was evaluated in the HHRA for informational purposes. The total potential ELCR and total HI

associated with an indoor worker exposure to soil vapor COPCs via the vapor intrusion pathway are 5×10^{-6} and 0.07, respectively. These results do not exceed USEPA's ELCR risk range of 10^{-6} to 10^{-4} or USEPA's target HI of 1.

3.5.2 Uncertainty Discussion

For each step of the HHRA process, assumptions must be made due to a lack of absolute scientific knowledge. Some of the assumptions are supported by considerable scientific evidence, and others have less empirical background. Each assumption introduces some degree of uncertainty into the HHRA process. Regulatory HHRA methodology requires that conservative assumptions be made in each step of the HHRA process to ensure that public health is protected. Therefore, when all of the assumptions are combined (i.e., in the final numerical potential risk estimates), it is much more likely that risks are overestimated rather than underestimated.

The assumptions that introduce the greatest amount of uncertainty in this HHRA are discussed in this section. These are discussed in qualitative terms, given the conservative nature of the assumptions, the measured concentrations of constituents on the Site, and the identified current and future uses of the Site.

3.5.2.1 Hazard Identification

In general, the field sampling targeted areas with the potential to have been impacted by historical Project-related activities. This type of sampling is expected to bias results high given human receptors are not only present in these areas, but also in areas that are less impacted. ISM sampling was conducted for PCB Aroclors in soil within the on-Project Blue Beach area. This sampling approach is expected to provide a more accurate estimate of PCB Aroclors concentrations across the on-Project Blue Beach area than the discrete sampling conducted for other chemicals.

The chemicals detected in media on and in the vicinity of the Project were screened against conservative risk-based screening levels. Chemicals detected at concentrations greater than screening levels were selected as preliminary COPCs for further evaluation in comparison with the background dataset to select COPCs for quantitative evaluation in the HHRA. A subset of chemicals detected at a site is generally selected for quantitative analysis for several reasons. Some chemicals may be present at concentrations that can be assumed, with reasonable assurance, not to pose a risk to human health. A review of the results of HHRA demonstrate that in most cases risks are attributable only to one or a few chemicals, and that most of the chemicals quantitatively evaluated do not contribute significantly to total risk estimates (USEPA, 1993b). The screening process is conducted to identify the COPCs that contribute the greatest to potential risk. The screening process used in this HHRA is conservative. Additional conservatism was added by use of screening levels based on a target HQ of 0.1. Although the excluded chemicals may pose a level of risk, that risk would contribute negligibly to the total Project risk. Therefore, not evaluating the excluded chemicals does not measurably affect the numerical estimates of hazard or risk and will not affect remedial decision-making for the Project.

Environmental sample collection and laboratory analyses are intended to be representative of the location and media sampled. However, each step in the process includes the potential to lose representativeness and introduce bias. The values reported by the laboratory may not accurately represent the EPC for a given media and receptor. The magnitude of analytical error is usually small compared to other sources of uncertainty, although the relative uncertainty increases for results that are near the LOD. The reported concentrations of chemicals detected below the Limit of Quantitation (LOQ) but above the method detection limit (i.e., J-flagged data) are imprecise and are thus estimated concentrations. However, to minimize underestimation of Project concentrations, J-flagged data were included in the HHRA. Inclusion of these data in development of EPCs generally returns conservative exposure concentration and resulting risk estimates. In addition, non-detects for area-specific COPCs were included in the EPC calculation for that area at the full LOD and ProUCL calculates EPCs using various methods (i.e., KM) to estimate concentrations below the LOD. Inclusion of these data in the HHRA may provide an over-estimate or under-estimate of exposure and potential risk. The direction of the uncertainty is unknown and depends on the proportion of the J-qualified values and the magnitude to the LOQ relative to the decision limit.

The HHRA quantitatively evaluated the total (unfiltered) groundwater data for inorganic analytes. However, it is recognized that dissolved (filtered) groundwater data may better represent potential exposure to groundwater via the dermal contact exposure pathway for inorganics. Therefore, use of the total (unfiltered) groundwater data in the HHRA may over-estimate potential risk/hazard associated with inorganic COPCs. However, the potential ELCR/HI associated with the inorganic COCs (arsenic, iron, lead, and manganese) is a small fraction of the total potential ELCR/HI estimated for the hypothetical future resident groundwater exposure. Therefore, use of dissolved (filtered) groundwater data for inorganic COCs, which is expected to be lower than the total (unfiltered) results, would

negligibly change the total potential ELCR and total potential HI associated with a hypothetical future residential exposure to groundwater and would not change the conclusions of the HHRA.

3.5.2.2 Exposure Assessment

When estimating human doses (i.e., intakes) from potential exposure to various media containing COPCs, several assumptions are made. Uncertainty may exist, for example, in assumptions for the rates of ingestion, frequency and duration of exposure, and bioavailability of the chemicals in the environmental medium. When limited information is available as a basis for these assumptions, conservative (i.e., health-protective) estimates of potential exposure were made.

Exposure Assumptions

The intent of this HHRA was to evaluate “reasonable” exposure scenarios. However, the HHRA also evaluated several hypothetical exposure scenarios that are not likely to exist. For example, there are currently no residential receptors within the on-Project Blue Beach area; it is not zoned for residential use, and an ELUR barring residential use of the parcel has been recorded on the deed. Groundwater within the on-Project Blue Beach area is classified by RIDEM as ‘GB’, not suitable for drinking without treatment. Additionally, an ELUR recorded on the deed prohibits potable use of groundwater from the parcel. However, as a conservative measure, the on-Project Blue Beach area was evaluated for hypothetical future residential exposure scenarios to represent a UU/UE scenario.

The exposure inputs used to describe the extent, frequency, and duration of exposure are associated with some uncertainty. Actual risks for some individuals within an exposed population may vary from those predicted depending on the actual exposure durations, intake rates (e.g., soil ingestion rates), and body weights. The exposure assumptions were selected to produce a reasonable upper-bound estimate of exposure in accordance with USEPA guidelines. Therefore, exposures and estimated potential risks for the evaluated receptors are likely to be representative of reasonable upper-bound exposures.

Bioavailability

Bioavailability is the measure of the degree to which a chemical may be systemically absorbed following exposure. Oral bioavailability is a measure of the degree to which a chemical may be systemically absorbed following ingestion, and dermal bioavailability is a measure of the degree to which a chemical may absorb through the skin and into the blood stream. Some chemicals are absorbed almost completely (100% bioavailability) when ingested in pure form. Other chemicals may pass through the body largely unabsorbed. The amount of absorption that occurs is chemical and situation specific and is not always understood. To account for these uncertainties, USEPA’s default assumptions regarding absorption are conservative, and intended to apply to most sites and exposure conditions.

The HHRA was conducted using USEPA default soil/hydric sediment/sediment absorption factors for dermal exposure (USEPA, 2004) and an assumption of 100% relative oral absorption for all COPCs with the exception of arsenic. USEPA’s relative bioavailability factor of 0.6 was used for arsenic (USEPA, 2012). These estimates are uncertain and may result in either an overestimation or underestimation of risk.

Exposure Point Concentrations

EPCs used to estimate potential risk/HI associated with exposure to soil, hydric soil, groundwater, shallow groundwater, sediment, and surface water (based on discrete sampling datasets) in the HHRA were equal to the 95% UCL, unless the UCL was greater than the maximum detected concentration or an insufficient sample size or FOD was available for calculation of a UCL. In these cases, the EPC was set equal to the maximum detected concentration. The use of the maximum detected concentration to estimate potential risk/HI associated with COPCs with a low FOD may result in an over-estimation of potential risk/HI.

For the evaluation of Total PCB Aroclors in soil from ISM samples, a weighted mean UCL concentration of the SU-specific 95% UCLs based on SU size (acreage) was developed and used as EPC. This additional refinement was conducted to address uncertainty associated with the variability in the triplicate sample results and to ensure that a conservative estimate of a mean concentration representative of the on-Project Blue Beach exposure area was obtained, without inappropriately biasing the exposure point concentration toward a specific SU.

3.5.2.3 Toxicity Assessment

Uncertainty is associated with the toxicity values and toxicity information available to assess potential adverse effects. One of the major contributors to uncertainty is the accuracy of the toxicity values used. A cancer potency value is a mathematical extrapolation of the slope of the dose-response curve from high doses administered to animals (or the exposures observed in epidemiological studies) to the low doses commonly experienced in the environment. The USEPA has developed potency values for COPCs classified as carcinogens, based on the premise that there is no threshold (i.e., there is no level of exposure below which there is no risk of a carcinogenic effect). USEPA's Guidelines for Carcinogen Risk Assessment (USEPA, 2005a) acknowledges that the mode of action of a carcinogen may involve both threshold and non-threshold mechanisms. To the extent that the approach used to develop the potency estimate is incorrect, the extrapolated risks may be overestimations or underestimations. However, in the derivation of toxicity values, conservative assumptions are employed. Therefore, toxicity values tend to be biased toward overestimating potential risk.

For dermal exposure pathways, the absence of dermal toxicity criteria necessitated the derivation from oral toxicity data. To calculate potential risk estimates for the dermal pathway, gastrointestinal absorption efficiency factors that reflect the toxicity study conditions were used to modify the oral toxicity criteria. For the chemicals with gastrointestinal absorption efficiencies greater than 50%, 100% gastrointestinal absorption was used, in accordance with USEPA (2004). The potential risk estimates for the dermal pathways may be overestimated or underestimated depending on how closely these values reflect the difference between the oral and dermal routes. Chronic toxicity values, developed based on continuous lifetime exposures, were used for the evaluation of discontinuous, less-than-lifetime exposures (e.g., recreational user). Therefore, total receptor risk estimates may be overestimated with the degree of overestimation dependent on the degree of deviation from a continuous lifetime exposure scenario.

Total chromium was evaluated as trivalent chromium in this HHRA. Chromium is most commonly present in the environment in the trivalent state because typical conditions in the environment favor the reduction of chromium from the hexavalent to the trivalent state. Hexavalent chromium in soil is expected to be reduced to trivalent chromium by organic matter, which is facilitated by low pH (ATSDR, 2012). In addition, if hexavalent chromium is ingested, it is rapidly converted to the trivalent form after entering the stomach, and is therefore not considered by USEPA to pose a cancer risk via the ingestion route of exposure (USEPA, 2020f). Although the evaluation of total chromium as trivalent chromium introduces some level of uncertainty to the assessment, there is no evidence to suggest that hexavalent chromium is present at the Site.

Cancer toxicity values for total PCBs (high risk and persistence) recommended in USEPA's IRIS database (2020d) were used for evaluation of total PCBs. A published noncancer toxicity value (RfD) is not available for total PCBs. Therefore, the oral RfD for Aroclor 1254 (USEPA, 2020d) was used to evaluate noncarcinogenic oral/dermal pathways associated with exposure to total PCB Aroclors. There are uncertainties associated with using Aroclor 1254 as a surrogate for Total PCBs. Since the PCB composition at a site may differ from the PCB composition for which the noncancer RfD for Aroclor 1254 is based, producing different toxicological responses, uncertainty is introduced by using this as a surrogate RfD.

3.5.2.4 Risk Characterization

The potential risk of adverse human health effects is characterized based on estimated potential exposures and potential dose-response relationships. Three areas of uncertainty are introduced in this phase of the HHRA: the evaluation of potential exposure to multiple chemicals, the combination of upper-bound exposure estimates with upper-bound toxicity estimates, and the risk to sensitive populations.

Once potential exposure to and potential risk from each COPC are estimated, the total upper-bound potential risk is determined by combining the estimated potential health risk from each of the COPCs. Potential carcinogenic effects are added unless evidence exists indicating that the COPCs interact synergistically (a combined effect that is greater than a simple addition of potential individual effects) or antagonistically (a combined effect that is less than a simple addition of potential individual effects) with each other. For noncarcinogenic effects, USEPA guidance indicates that HQs should only be summed to an HI for COPCs that have the same or similar toxic endpoints (USEPA, 1989). The toxic endpoint is defined as the most sensitive noncarcinogenic health effect used to derive the RfD/RfC or other suitable toxicity value (USEPA, 1989). For screening purposes in this HHRA, the HIs were calculated by summing the HQs for all COPCs, regardless of target endpoint, as a first approximation of noncarcinogenic risk. Target organ-specific HIs were calculated only for those scenarios in which the total HI based on the combined target endpoints

were greater than 1 (i.e., the hypothetical future resident scenario). The total potential HIs presented based on the combined target endpoints provide an over-estimation of potential HI.

Based on USEPA guidance, the goal of an HHRA is to estimate an upper-bound, but reasonable, potential exposure and ELCR/HI. Most of the assumptions about exposure and toxicity used in this evaluation are representative of statistical upper-bounds or even maximum levels for each parameter. The result of combining several such upper-bound assumptions is that the final estimate of potential exposure or potential ELCR/HI is conservative and likely overestimates rather than underestimates the potential ELCR/HI associated with a receptor's exposure to Project media.

4. Ecological Risk Assessment

The Ecological Risk Assessment (ERA) was conducted to evaluate the potential for adverse environmental effects due to exposures to chemicals in soil, hydric soil, porewater, sediment, and surface water within the Project and/or adjacent off-Project areas, and to determine whether chemicals in these areas pose an unacceptable risk to the environment.

The ERA was conducted in accordance with USEPA guidelines for ecological risk assessment under CERCLA (USEPA, 1997b) and is based on the following key guidance documents:

- Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessment, Interim Final. (USEPA, 1997b);
- Guidelines for Ecological Risk Assessment (USEPA, 1998);
- The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments (USEPA, 2001); and
- A Guide to Screening Level Ecological Risk Assessment (Tri-Services Environmental Risk Assessment Work Group [TSERAWG], 2008).

The ERA includes a screening level ERA (SLERA), which is considered the first tier of the ecological risk process (i.e., Steps 1 and 2 of the USEPA eight-step process for ERA [USEPA, 1997b]). Conducting a SLERA is consistent with a tiered approach to ecological risk assessment recommended by USEPA (1997b, 1998, and 2001). Conducting assessments in a tiered, step-wise manner allows the risk assessor and risk manager to maximize the use of available Project information and sampling data, and provides the opportunity to reduce the uncertainties inherent in the ecological risk assessment process through the use of focused supplemental data collection to fill key data gaps identified in the previous tier of the assessment, if necessary.

The SLERA is designed as a conservative assessment (e.g., maximum media concentrations, conservative benchmarks) to avoid eliminating a COPC that may pose a risk to sensitive ecological receptors. At the end of Step 2 of the SLERA, a scientific/management decision point (SMDP) is reached when a conclusion can be made that either (1) the available data indicate the potential for ecological risk and further investigation is warranted, (2) the available data indicate either no or low potential for ecological risk and no further work is warranted, or (3) there are data gaps that must be addressed before the presence or absence of risk can be concluded (e.g., additional sampling or analysis). SMDPs occur at several key points in the eight-step process and are used by the risk assessor and risk manager to determine if the process should continue, and if enough data have been evaluated to determine the outcome of the ERA.

In cases where the SLERA indicates sufficient potential ecological risk, further ecological risk assessment may be warranted in a second-tier analysis referred to as the baseline ERA (BERA) (i.e., Steps 3 through 8 of the USEPA eight-step process).

This ERA includes a SLERA performed according to USEPA's eight-step ERA process (USEPA, 1997) in which COPCs identified in Steps 1 and 2 are retained for further investigation for specific receptors/pathways. The list of COPCs was refined consistent with the initial stage of a BERA, referred to as Step 3a, to reduce uncertainty in the SLERA Step 1 and 2 conclusions and to refine the SMDP recommendations by applying more realistic exposure assumptions. The results of the SLERA and BERA Step 3a COPC refinement are provided in this document.

4.1 Organization of the ERA

This ERA is organized into three major sections, as suggested by USEPA's Framework for Ecological Risk Assessment (USEPA, 1992); these sections are Problem Formulation (Section 4.2), Risk Analysis (Section 4.3), and Risk Characterization (Section 4.4). The SLERA conclusions and SMDP are provided in Section 4.5 and the Step 3a refinement of COPCS is presented in Section 4.6. An overview of each of these sections is provided below:

- Screening Level Problem Formulation - This section describes the environmental setting and chemicals at the Site, including Site history, types of waste found at the Site, chemical fate and transport, potential receptors and

potentially complete exposure pathways. Assessment endpoints and measurement endpoints are defined. The final product of the Screening Level Problem Formulation is the ecological CSM which defines potential exposure pathways at the Site.

- Screening Level Risk Analysis – During the risk analysis phase, data are evaluated to identify COPCs and characterize potential ecological exposures and effects.
- Screening Level Risk Characterization - During risk characterization, exposure and stressor response profiles are integrated through risk estimation. Risk characterization also includes a summary of uncertainties, strengths, and weaknesses associated with the risk assessment.
- SLERA Conclusions - This section presents a summary of the SLERA and provides recommendations for the SMDP.
- Step 3 COPC Refinement – This section further evaluates the COPCs identified in the screening level process by considering alternate EPCs and ESVs and evaluating additional data related to the bioavailability of COPCs in sediment.

The risk assessment process is frequently iterative, and new information brought forth during the exposure estimate, for instance, may lead to a review of the problem formulation phase, or additional data collection and analysis.

4.2 Screening Level Problem Formulation

Problem formulation is the initial systematic planning phase of the ecological risk assessment process. It provides the basis for the approach and methodology to be used as well as defining the specific scope and objectives of the risk evaluation. This section describes the physical setting and ecological habitats found in the vicinity of the Project. This section also summarizes the potentially complete exposure pathways and relevant ecological receptors, develops the CSM, and identifies the ecological screening values used to evaluate the analytical data.

4.2.1 Ecological Setting

The Blue Beach Disposal Site, located in North Kingstown, Rhode Island (Washington County), is a 13-acre property. The northern portion of the Property is used as a salvage/material storage yard and the southern portion of the Project is in commercial/industrial use. It is bordered by industrial land uses and roadways to the north, east and west sides. Also, on the west side of the Project is the Red Maple Swamp into which a drainage channel flows from the north. Narragansett Bay borders the Project to the south. The drainage channel is connected to the bay, particularly at high tides, forming a tidal stream. There is a concrete seawall located along most of the southern boundary of the Project.

The focus of the SLERA is on three exposure areas of the Project defined in Section 2.0 (**Figure 2-2**), as follows:

- On-Project Blue Beach – the area within the jurisdictional Blue Beach FUDS boundary
- Off-Project Red Maple Swamp/tidal stream area– the area within the Red Maple Swamp including the associated tidal stream, “Red Maple Swamp”, and the walking path from Circuit Drive to Blue Beach
- Off-Project Narragansett Bay and Beachfront area

A Site visit was conducted by AECOM in August 2011 and photographs taken during this visit are presented in **Attachment F**. Maintained lawn areas are present around the building to the west before transitioning to forested habitat and the Red Maple Swamp and to the south before transitioning to a mix of grasses and shrubs along the beach front (**Figure 4-1** presents the forest and wetland resources of the off-Project Red Maple Swamp area).

The turf area of the on-Project Blue Beach area is approximately 3.5 acres in size including a small area (approximately 0.5 acres) to the north of the parking lot area and south of Circuit Drive and a larger area to the west and south of the buildings (approximately 3 acres).Surrounding land uses include commercial to the north and east. The Blue Beach Walking Path runs north to south from Circuit Drive to the beachfront in between the on-Project Blue Beach area and the off-Project Red Maple Swamp/tidal stream area. The presence of this walking path may diminish the habitat value of the beach for shorebirds such as red knot (*Calidris canutus*), a Federally-listed (Threatened) sandpiper species, due to the presence of recreational beach use.

The Red Maple Swamp includes an open area of estuary grasses and low shrubs (approximately 4 acres) with a tidally-influenced stream surrounded by a forest (approximately 3 acres) on three sides and the shoreline of Narragansett Bay to the south. Dominant species of the open wetland habitat include *Phragmites australis* (a non-native, invasive species), *Spartina alterniflora*, and *S. patens* and in the forested area and red maple (*Acer rubrum*) along the forested fringes where freshwater discharge is expected. The open wetland area continues to the west/southwest of the Red Maple Swamp area. The Red Maple Swamp is bordered to the north and west by residential properties. To the north of the open wetland area is a commercial property and a drainage retention pond borders (to the west) the forested section closest to Circuit Drive.

Due to the current industrial and commercial land uses and maintenance (e.g., mowing) of the on-Project Blue Beach area, this upland area likely provides limited ecological habitat functions. The presence of mammals and birds are likely limited due to the lack of habitat diversity and structure such as shrubs and trees. The habitat quality of the off-Project Red Maple Swamp/tidal stream area appears to be in better condition with areas of open water, a tidally-influenced stream channel, and forested swamp habitats present. This area likely provides beneficial ecological functions to aquatic and semi-aquatic animals including amphibians, fish, and semi-aquatic birds and mammals. The beachfront habitat provides limited ecological function due to stone bank revetments; however, areas of “natural” beachfront are also present. As a result, this area also provides some ecological functions to aquatic and semi-aquatic mammals as well as shorebirds.

4.2.2 Selection of Specific Ecological Receptors and Receptor Pathways

Ecological receptors are the components of ecosystems (i.e., species or sensitive habitats) that are or may be adversely affected by a chemical, physical, or biological stressor. Receptors can be any part of an ecological system, including species, populations, communities, and the ecosystem itself. The SLERA is focused on the pathways for which the potential for chemical exposures are the highest and most likely to occur and for which there are adequate data pertaining to the receptors, exposure pathways, and toxicity for completion of risk analyses.

Exposure pathways for several groups of ecological receptors were identified as potentially relevant. Each exposure pathway includes a potential source of a chemical, an environmental medium (e.g., surface soil, sediment, surface water, porewater), and a potential exposure route to an ecological receptor. Incomplete routes of exposure were not evaluated in the SLERA. This approach is used to focus the risk evaluation on exposure pathways that are considered potentially complete and for which there are adequate data pertaining to the receptors, exposure, and toxicity for completion of the risk analysis.

Exposure pathways for several groups of ecological receptors were identified as potentially relevant. In addition, the SLERA evaluated:

- Soil invertebrates and terrestrial plants directly exposed to surface soil in the on-Project Blue Beach area.
- Birds and small mammals exposed through incidental ingestion of surface soil and/or by ingestion of prey items impacted by surface soil in in the on-Project Blue Beach area.
- Benthic invertebrates/shellfish exposed to surface sediment and/or porewater associated with the tidal stream in the off-Project Red Maple Swamp/tidal stream area and the off-Project Narragansett Bay and Beachfront area;
- Fish and aquatic invertebrates exposed to surface water associated with the tidal stream in the off-Project Red Maple Swamp/tidal marsh and the off-Project Narragansett Bay and Beachfront area;
- Soil invertebrates and plants exposed to soil and hydric soil in the off-Project Red Maple Swamp/tidal stream area; and
- Birds and mammals exposed through incidental ingestion of surface soil, hydric soil, sediment, and/or by ingestion of prey items impacted by surface soil, hydric soil, and/or sediment in the off-Project Red Maple Swamp/tidal stream area.

4.2.3 Selection of Assessment Endpoints and Measures of Effect

Assessment endpoints are formal expressions of the actual environmental value to be protected (USEPA, 1998). They usually describe potential adverse effects to long-term persistence, abundance, or reproduction of populations of key species or key habitats. Measures of effect (i.e., measurement endpoints) are quantifiable ecological

characteristics related to the assessment endpoint. Measurement endpoints are often stressor-specific and are used to evaluate the assessment endpoint with respect to potential ecological risks. The endpoints evaluated in this SLERA are presented below.

Assessment Endpoint	Measurement Endpoint(s)
On-Project Blue Beach Area	
Sustainability (survival, growth, reproduction) of local populations of soil invertebrates and plants exposed to surface soils associated with the on-Project Blue Beach area.	Comparison of surface soil concentrations from the On-Project Blue Beach area against soil screening benchmarks that are protective of soil invertebrates and plants.
Sustainability (survival, growth, reproduction) of local populations of small mammals and birds exposed to surface soils and food items associated with the on-Project Blue Beach area.	Comparison of calculated total daily dose (TDD) for avian and mammalian receptors from exposure to chemicals in soil and/or ingestion of prey items to chemical-specific toxicity reference values (TRVs). Doses above the TRVs are considered indicative of a potential for ecological risks.
Off-Project Red Maple Swamp/Tidal Stream Area	
Sustainability (survival, growth, reproduction) of local populations of soil invertebrates and plants exposed to soil and hydric soil associated with the off-Project Red Maple Swamp/tidal stream area.	Comparison of surface soil and surface hydric soil concentrations from the off-Project Red Maple Swamp/tidal stream area against soil screening benchmarks that are protective of soil invertebrates and plants.
Sustainability (survival, growth, reproduction) of local populations of small mammals and birds exposed to soil, hydric soil, and sediment associated with the off-Project Red Maple Swamp/tidal stream area.	Comparison of calculated TDD for avian and mammalian receptors from exposure to chemicals in soil, hydric soil, sediment and/or ingestion of prey items to chemical-specific TRVs. Doses above the TRVs are considered indicative of a potential for ecological risks.
Sustainability (survival, growth, reproduction) of local populations of benthic invertebrates/shellfish exposed to sediment associated with the tidal stream in the off-Project Red Maple Swamp/tidal stream area.	Comparison of surface sediment concentrations from the tidal stream in the off-Project Red Maple Swamp/tidal stream area against benthic invertebrate-based sediment screening benchmarks identified in the literature.
	Comparison of surface water and porewater concentrations from the tidal stream in the off-Project Red Maple Swamp/tidal stream area, against aquatic life-based surface water screening benchmarks identified in the literature.
Sustainability (survival, growth, reproduction) of local populations of fish and aquatic invertebrates exposed to surface water associated with the tidal stream in the off-Project Red Maple Swamp/tidal stream area.	Comparison of surface water concentrations from the tidal stream in the off-Project Red Maple Swamp/tidal stream area against aquatic life-based surface water screening benchmarks identified in the literature.
Off-Project Narragansett Bay and Beachfront Area	
Sustainability (survival, growth, reproduction) of local populations of benthic invertebrates/shellfish exposed to sediment associated with the tidal stream in the off-Project Narragansett Bay and Beachfront area.	Comparison of surface sediment concentrations from the off-Project Narragansett Bay and Beachfront area against benthic invertebrate-based sediment screening benchmarks identified in the literature.
	Comparison of surface water and porewater concentrations from the off-Project Narragansett Bay and Beachfront area against aquatic life-based surface water screening benchmarks identified in the literature.
Sustainability (survival, growth, reproduction) of local populations of fish and aquatic invertebrates exposed to surface water associated with the off-Project Narragansett Bay.	Comparison of surface water concentrations and porewater from the off-Project Narragansett Bay against aquatic life-based surface water screening benchmarks identified in the literature.

4.2.4 Ecological Conceptual Site Model

The end product of the problem formulation step is the development of the ecological CSM. The ecological CSM summarizes the current knowledge of the Project and ecological resources potentially at risk. The ecological CSM is a set of working hypotheses regarding how ecological receptors at the Project may be exposed to chemicals.

The ecological CSM is included as **Figure 4-2**. The CSM displays the exposure pathways through which groups of ecological receptors may be exposed to COPCs in each environmental medium at the Project. The objective of the CSM is to identify the ecologically important exposure and migration pathways, and to specify exposure scenarios evaluated in the SLERA.

Sources of chemicals of potential concern at the Project are considered to be related to historical activities. Past operations may have resulted in direct releases of chemicals to soil based on its former use as a salvage yard for the storage and disposal of vehicle parts, machinery, construction debris, drummed materials, and miscellaneous wastes. Chemicals in soil may have migrated downward into subsurface soil and ultimately to groundwater. Dissolved chemicals in groundwater may have discharged to downgradient to the tidal streams and to Narragansett Bay.

Based on available information, the media of interest for the SLERA were:

- Surface soil (0-1 ft bgs);
- Surface hydric soil (0-1 ft bgs);
- Surface sediment (0-0.5 ft bgs);
- Surface water; and
- Porewater.

As described in Section 4.2.2, potentially exposed receptor communities include soil invertebrates, plants, benthic invertebrates/shellfish, fish and aquatic invertebrates, small mammals and birds. The assessment and measurement endpoints described in Section 4.2.3 address each ecological receptor/pathway scenario identified in **Figure 4-2**.

4.3 Screening Level Risk Analysis

The risk analysis phase of the SLERA is based on the CSM developed in problem formulation and addresses the characterization of potential ecological exposure and corresponding effects. The ecological exposure assessment involves the identification of potential exposure pathways and an evaluation of the magnitude of exposure to ecological receptors. The ecological effects assessment describes the potential adverse effects to ecological receptors from exposure to COPCs in environmental media.

4.3.1 Data Evaluation and Identification of COPCs

Analytical data were grouped for evaluation in the SLERA, as discussed in Section 2.1. Consistent with the HHRA COPC selection process, COPCs were selected for the SLERA based on a comparison of the maximum detected concentrations of each chemical detected in discrete samples per media/area/depth interval (as applicable) to ecological screening values (ESVs). For PCBs analyzed from ISM surface soil samples collected from the on-Project Blue Beach area, the highest of the SU-specific 95% UCLs (as described in Section 2.2.4.2 and shown in **Attachment C**) was used in the SLERA instead of the maximum detected concentration (the 95% UCL is higher than the maximum detected concentration of the ISM samples). The ESVs are included in **Tables 4-1 through 4-3** and were identified based on conservative endpoints and sensitive ecological effects data and they were used for a preliminary screening of surface soil, surface water and sediment concentrations.

Chemicals detected at concentrations above the ESVs were identified as preliminary COPCs for further evaluation in comparison with background, as discussed in Section 2.3. The COPC selection process may consider low FOD, low toxicity and low concentration, consistency with Site-specific background, essential nutrient status, and whether the chemical is likely to be present due to laboratory contamination. Essential nutrients, including magnesium, calcium, potassium, and sodium were not retained as COPCs for further evaluation in the SLERA, consistent with USEPA guidance (USEPA, 1989). A chemical was not retained as a COPC if it was consistent with background based on the BTV comparison, two-sample hypothesis test comparisons, qualitative/graphical background comparisons, or the geochemical analysis.

4.3.2 Ecological Effects Assessment

Receptor- and media-specific ESVs were selected to identify ecological COPCs and evaluate the potential for ecological risks from the Project. These ESVs were used to conduct a preliminary screening of Project constituent concentrations to determine if there is a need to conduct further analyses or investigations at the Project.

Literature-derived soil ESVs are presented in **Table 4-1** and were selected to evaluate potential impacts to soil invertebrates and plants exposed to soil and hydric soil using the following hierarchy:

- Ecological Soil Screening Levels (Eco-SSLs) for plants and invertebrates developed according to USEPA guidance (USEPA, 2005b);
- Oak Ridge National Laboratory (ORNL) terrestrial plant and invertebrate (earthworm) screening values (Efroymson, et al., 1997a, 1997b). Values for soil microorganisms and microbial processes (Efroymson et al., 1997b) were selected in cases when earthworm based values are not available;
- Dutch Intervention Values and Target Values (RIVM, 1994, 1995, 2000) as cited in Buchman (2008).
- USEPA Region 4 soil screening levels (USEPA, 2018a); and
- USEPA Region 5 Ecological Screening Levels for soil (USEPA, 2003c).

The Eco-SSLs for birds and mammals were used to evaluate potential risks to higher trophic-level wildlife receptors exposed to surface soil chemicals. If wildlife Eco-SSLs were not available, wildlife-based values available from USEPA Region 4 (USEPA, 2018a) or Region 5 (USEPA, 2003c) were identified if available. The lowest of the ESVs for plants, invertebrates, and wildlife were used to select COPCs.

Sediment analytical chemistry analysis results were compared to low effect risk-based sediment ESVs presented in **Table 4-2**. Sources for sediment screening values were considered in this order:

- USEPA Region III Biological Technical Assistance Group (BTAG) freshwater and marine sediment screening values (USEPA, 2006a,b);
- National Oceanic and Atmospheric Administration (NOAA) Screening Quick Reference Table (Buchman, 2008)

Marine sediment values were identified, when available, for the off-Project Narragansett Bay and Beachfront area. If marine values were not available, then freshwater screening values were selected from the above hierarchy. For the off-Project Red Maple Swamp/tidal stream area, the lower of available freshwater and marine ESVs were selected.

Surface water and porewater analytical chemistry analysis results were compared to risk-based surface water ESVs presented in **Table 4-3**. Sources for surface water ESVs were considered in this order:

- Chronic federal Ambient Water Quality Criteria (AWQC) for aquatic life (USEPA, 2020);
- USEPA Region III BTAG surface water screening values (USEPA, 2006c,d); and
- Secondary Chronic Values derived by the Oak Ridge National Laboratory (ORNL) (Suter and Tsao, 1996).

Marine surface water ESVs were selected preferentially for the off-Project Narragansett Bay and Beachfront area. If marine values were not available, then freshwater screening values were selected from the above hierarchy. For the off-Project Red Maple Swamp/tidal stream area, the lower of available freshwater and marine ESVs were selected to account for the estuarine nature of the system. Hardness-dependent freshwater surface water screening values were adjusted to the average hardness of 183 mg/L as $CaCO_3$ measured in Red Maple Swamp surface water.

Risks to mammals and birds from exposure to chemicals in surface soil and hydric soil/sediment were evaluated using food web models to estimate the TDD which was compared to TRVs representing acceptable daily doses in mg/kg-day. Detected chemicals were evaluated using a food web model if the chemical is identified as an ‘important bioaccumulative compound’ by USEPA (USEPA, 2000).

TRVs incorporated into the quantitative evaluation of potential ecological risks to wildlife were obtained from the following sources: TRVs derived according to USEPA guidance (USEPA, 2005) during the development of Eco-SSLs, ORNL publication Toxicological Benchmarks for Wildlife: 1996 Revision (Sample et al,. 1996), and the LANL EcoRisk Database (LANL, 2017). When TRVs were not derived in these documents, the literature was reviewed for relevant

data and TRVs were derived using the methodology of ORNL (Sample et al., 1996). TRVs used in the SLERA are based on No Observed Adverse Effect Levels (NOAELs).

4.3.3 Ecological Exposure Assessment

The second step of the SLERA is the screening level exposure estimate and risk calculation in which risks are estimated by comparing maximum detected concentrations with associated ESVs. Maximum detected concentrations were identified by exposure area and medium.

Tables 4-4 through 4-11 identify detected chemical and provide ESV comparisons, as well as the results of relevant background comparisons (i.e., comparisons to BTVs, two-sample hypothesis test comparisons, geochemical analysis).

For the food web model, exposure assumptions (e.g., body weights, relative consumption of food items, foraging range, exposure duration, etc.) for wildlife species were obtained from the USEPA's Wildlife Exposure Factors Handbook (USEPA, 1993c). Allometric equations (Nagy, 2001) were used to estimate food ingestion rates. Separate screening level food web models were conducted for the on-Project Blue Beach area (surface soil) and the off-Project Red Maple Swamp/tidal stream area (combined data set of surface soil, hydric soil, and sediment data).

Wildlife receptors evaluated in the food web model include:

- American robin - insectivore foraging in the on-Project Blue Beach area;
- Marsh wren - insectivore foraging in the off-Project Red Maple Swamp/tidal stream area;
- Bobwhite quail - herbivore foraging in the on-Project Blue Beach area;
- Raccoon – omnivore foraging in the on-Project Blue Beach area and in the off-Project Red Maple Swamp/tidal stream area;
- Meadow vole - herbivore foraging in the on-Project Blue Beach area and in the off-Project Red Maple Swamp/tidal stream area; and
- Short-tailed shrew - insectivore foraging in the on-Project Blue Beach area and in the off-Project Red Maple Swamp/tidal stream area.

Chemical concentrations in food items were calculated using bioaccumulation factors (BAFs) and other uptake factors from published sources or regression equations from the USEPA Eco-SSL Guidance (USEPA, 2007b) and other literature sources (e.g., Bechtel Jacobs, 1998a,b). The USEPA's Biota-Sediment Accumulation Factor (BSAF) database was used as a primary source to identify sediment-to-invertebrate uptake factors for organic chemicals. Soil-based uptake factors were used for sediment/hydric soil when sediment uptake factors were not available.

The on-Project Blue Beach area food web model (**Attachment G-1**) evaluated the potential for risks to birds and mammals due to exposure to bioaccumulative chemicals detected in surface soil. With the exception of Total PCBs, the maximum detected surface soil concentrations were considered in this model. As described in Section 4.3.1, the highest SU-specific 95% UCL was used in the SLERA instead of the maximum detected concentration for PCBs collected via ISM (the 95% UCL is higher than the maximum detected concentration of the ISM samples).

The food web model for the off-Project Red Maple Swamp/tidal stream area (**Attachment G-2**) considered the potential for wildlife exposures to surface soil associated with the walking path, hydric soil associated with the Red Maple Swamp, and sediment associated with the tidal stream. The maximum detected concentrations of bioaccumulative chemicals detected in these three media were considered in this model.

The results of the on-Project and off-Project food web models are summarized in **Tables 4-12 and 4-13**, respectively.

4.3.4 SLERA Risk Calculations

HQs were calculated for each COPC in each medium (i.e., surface soil, hydric soil, surface sediment, surface water, porewater) by dividing the maximum detected concentration (or 95% UCL for Total PCB data collected via ISM) by the relevant ESV using the following formula:

$$HQ = \text{Maximum detected concentration} / ESV$$

For higher trophic level wildlife receptors (i.e., birds and mammals evaluated in the food web models), the risk estimate is also based on the HQ, defined as the ingested dose divided by the species-specific TRV:

$$HQ = TDD/TRV$$

Analytes which exceed their respective screening benchmarks (i.e., HQs > 1) and analytes without screening benchmarks were retained as preliminary COPCs. Essential nutrients (calcium, magnesium, potassium, and sodium) were not retained as COPCs. Preliminary COPCs were evaluated as described in Section 2.3 to determine whether concentrations in exposure areas are consistent with background. Preliminary COPCs were retained as final COPCs if they are not consistent with background.

4.4 Screening Level Risk Characterization

Risk characterization provides a quantitative evaluation of the potential for adverse ecological impacts due to COPCs in an area of concern. The results of the environmental risk analysis are used to quantify the potential adverse environmental effects, or to determine whether a conclusion of no significant risk can be reached for each assessment endpoint evaluated. This ecological risk characterization summarizes the results of the risk analysis phase of work and provides an interpretation of the ecological significance findings. Aspects of ecological significance that have been considered to help place the Project into a broader ecological context include the nature and magnitude of effects.

The presence of COPCs in environmental media at concentrations which exceed ecological screening values does not necessarily constitute ecological risk. For instance, certain COPCs may not be absorbed into an organism's system following ingestion or may not be absorbed through direct contact due to the chemical form of the COPCs. The decision concerning the necessity for further evaluation requires the weighing of such factors as the frequency, magnitude, and pattern of these exceedances. These factors were considered in the uncertainty analysis described in Section 4.4.4.

4.4.1 On-Project Blue Beach Area Risk Characterization

Table 4-4 identifies the COPCs in soil selected based on ESV comparisons for the on-Project Blue Beach area surface soils. The table below identifies the preliminary surface soil COPCs identified based on a maximum detected concentration above the lowest soil ESV identified in **Table 4-1** or a lack of an ESV. Shading in the table below identifies the COPCs retained after the background comparisons and the HQs calculated from the maximum detected concentration are provided for these COPCs.

On-Project Blue Beach Surface Soil COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**
Aluminum	BTV	NCOPC
Antimony	**--**	**11.6**
Cadmium	**--**	**33.3**
Chromium	Hypothesis testing	NCOPC
Cobalt	Hypothesis testing	NCOPC
Copper	**--**	**4.1**
Iron	BTV	NCOPC
Lead	**--**	**34.8**
Manganese	Hypothesis testing	NCOPC
Mercury	Hypothesis testing	NCOPC
Nickel	Hypothesis testing	NCOPC
Silver	Hypothesis testing	NCOPC
Vanadium	BTV	NCOPC
Zinc	**--**	**9.2**
Total PCB Aroclors	**NE**	**24.0**
Anthracene	Hypothesis testing	NCOPC
Dibenzo(a,h)anthracene	[a]	NCOPC
Total HMW PAHs	Hypothesis testing	NCOPC

On-Project Blue Beach Surface Soil COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**
Benzoic acid	**NE**	**500**
Bis-(2-Ethylhexyl)-Phthalate	**NE**	**43.0**
Acetone	**NE**	**9.8**

Notes:
Shading identifies COPCs retained after background comparisons.
Maximum HQ = Maximum detected concentration / COPC selection ESV.
NCOPC – Not a COPC.
NE – Not evaluated in background comparisons because they were not part of background study.
[a] Although dibenzo(a,h)anthracene was initially retained based on the ESV and background comparisons, it was not retained as a COPC. Due to the additive toxicity of PAHs, PAHs were only retained as COPCs based on the Total HMW or LMW PAH evaluations. Total HMW PAHs were not retained in this evaluation based on the two-sample hypothesis conclusion that Site is less than or equal to background. Total LMW PAHs were not retained in this evaluation because the maximum detected concentration is less than the ESV. Therefore, PAHs were not further evaluated in on-Project Blue Beach area surface soil.

HQs calculated based on the maximum concentration detected for each of the COPCs retained in the on-Project Blue Beach area surface soil ranged from 4.1 for copper to 500 for benzoic acid (based on a single detected concentration in 26 samples). Given that COPCs were selected based on the lowest of the ESVs for plants, invertebrates, and wildlife, and that the HQs were calculated from the highest concentration of analyte detected, except for PCBs which were calculated from the higher 95% UCL, these HQs represent a conservative estimate of potential risks.

Table 4-12 identifies the food web COPCs identified based on the on-Project Blue Beach screening level food web model. The food web model evaluated maximum detected surface soil concentrations for bioaccumulative chemicals (USEPA, 2000), which included selected metals, Total HMW and LMW PAHs, and Total PCBs. Wildlife receptors evaluated in the food web model included two herbivores (bobwhite quail and meadow vole), two insectivores (American robin and short-tailed shrew), and one omnivore (raccoon).

COPCs were retained for further food web evaluations if NOAEL-based HQs were above 1 and the COPC was not consistent with background. Arsenic and selenium were eliminated as food web COPCs based on comparisons to BTVs and chromium, mercury, nickel, silver, and Total HMW PAHs were eliminated based on hypothesis testing. HQs for Total LMW PAHs were less than one. The table below summarizes the HQs above 1 for the wildlife receptors and the retained food web COPCs.

On-Project Blue Beach Food Web COPCs with HQs > 1			
Food Web COPC	**American Robin**	**Raccoon**	**Short-tailed Shrew**
Cadmium	**6.1**	**1.3**	**10.1**
Copper	**2.5**	HQ < 1	**1.4**
Lead	**11.1**	HQ < 1	**2.8**
Zinc	**1.5**	HQ < 1	**1.1**
Total PCB Aroclors	**2.7**	HQ < 1	**6.1**

Notes:
Shading identifies HQs > 1 for food web COPCs retained after background comparisons.
No HQs above 1 were identified for the herbivores (bobwhite quail and meadow vole).

HQs for the on-Project Blue Beach area food web COPCs were highest for the insectivores and ranged up to 11.1 for the American robin for lead and 10.1 for short-tailed shrew for cadmium.

4.4.2 Off-Project Red Maple Swamp/Tidal Stream Area Risk Characterization

4.4.2.1 Surface Soil

Table 4-5 identifies the soil COPCs selected based on ESV comparisons for the surface soil associated with the walking path in the off-Project Red Maple Swamp/tidal stream area. The table below identifies the preliminary surface soil COPCs identified based on a maximum detected concentration above the lowest soil ESV identified in **Table 4-1** or a lack of an ESV. Shading in the table below identifies the COPCs retained after the background comparisons and maximum HQs are provided for these COPCs.

Off-Project Red Maple Swamp/Tidal Stream Surface Soil COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**
Aluminum	BTV	NCOPC
Chromium	Hypothesis testing	NCOPC
Cobalt	BTV	NCOPC
Iron	BTV	NCOPC
Lead	Hypothesis testing	NCOPC
Mercury	BTV	NCOPC
Vanadium	BTV	NCOPC
Zinc	Hypothesis testing	NCOPC
Aroclor 1260	[a]	NCOPC
Total PCB Aroclors	**NE**	**12.5**
Anthracene	Hypothesis testing	NCOPC
Benzo(a)anthracene	Hypothesis testing	NCOPC
Benzo(a)pyrene	Hypothesis testing	NCOPC
Benzo(b)fluoranthene	Hypothesis testing	NCOPC
Benzo(g,h,i)perylene	Hypothesis testing	NCOPC
Chrysene	Hypothesis testing	NCOPC
Dibenzo(a,h)anthracene	Hypothesis testing	NCOPC
Indeno(1,2,3-cd)pyrene	Hypothesis testing	NCOPC
Pyrene	Hypothesis testing	NCOPC
Total HMW PAHs	Hypothesis testing	NCOPC

Notes:
Shading identifies COPCs retained after background comparisons.
Maximum HQ = Maximum detected concentration / COPC selection ESV.
NCOPC – Not a COPC.
NE – Not evaluated in background comparisons because they were not part of background study.
[a] Although Aroclor 1260 was initially retained based on the ESV comparisons, it was not retained as a COPC. Due to the additive toxicity of PCBs, PCBs were only retained as COPCs based on the Total PCB evaluation. Total PCBs were retained as a COPC so the evaluation of Total PCBs captures potential impacts associated with Aroclor 1260.

Total PCBs were the only surface soil COPC identified in **Table 4-5**. The HQ of 12.5 was based on the comparison to the conservative Dutch ESV presented by Buchman (2008).

4.4.2.2 Surface Hydric Soil

Table 4-6 identifies the hydric soil COPCs selected based on ESV comparisons for the surface hydric soil associated with off-Project Red Maple Swamp. The table below identifies the preliminary surface hydric soil COPCs identified based on a maximum detected concentration above the lowest soil ESV identified in **Table 4-1** or a lack of an ESV. Shading in the table below identifies the COPCs retained after the background comparisons and the HQs calculated from the maximum concentrations (and 95% UCL for PCBs) are provided for these COPCs.

Off-Project Red Maple Swamp/Tidal Stream Surface Hydric Soil COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**
Aluminum	Geochemical analysis	NCOPC
Antimony	**--**	**4.3**
Cadmium	**--**	**6.6**
Chromium	Geochemical analysis	NCOPC
Cobalt	Geochemical analysis	NCOPC
Copper	**--**	**1.6**
Iron	Geochemical analysis	NCOPC
Lead	**--**	**25.2**
Mercury	**--**	**16.2**
Selenium	**--**	**9.4**
Thallium	**--**	**1.2**
Vanadium	Geochemical analysis	NCOPC

Off-Project Red Maple Swamp/Tidal Stream Surface Hydric Soil COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**
Zinc	Geochemical analysis	NCOPC
Aroclor 1260	[a]	NCOPC
Total PCB Aroclors	**NE**	**115**
1-Methylnaphthalene	[b]	NCOPC
2-Methylnaphthalene	[b]	NCOPC
Anthracene	Hypothesis testing	NCOPC
Benzo(a)anthracene	Hypothesis testing	NCOPC
Benzo(a)pyrene	[b]	NCOPC
Benzo(b)fluoranthene	[b]	NCOPC
Benzo(g,h,i)perylene	Hypothesis testing	NCOPC
Benzo(k)fluoranthene	Hypothesis testing	NCOPC
Chrysene	Hypothesis testing	NCOPC
Dibenzo(a,h)anthracene	[b]	NCOPC
Indeno(1,2,3-cd)pyrene	[b]	NCOPC
Naphthalene	[b]	NCOPC
Pyrene	Hypothesis testing	NCOPC
Total HMW PAHs	Hypothesis testing	NCOPC
2,4-Dichlorophenol	**NE**	**180**
Acetone	**NE**	**107**
Carbon Disulfide	**NE**	**3.7**
Toluene	**NE**	**7.2**

Notes:
Shading identifies COPCs retained after background comparisons.
Maximum HQ = Maximum detected concentration / COPC selection ESV.
NCOPC – Not a COPC.
NE – Not evaluated in background comparisons because they were not part of background study.
[a] Although Aroclor 1260 was initially retained based on the ESV comparisons, it was not retained as a COPC. Due to the additive toxicity of PCBs, PCBs were only retained as COPCs based on the Total PCB evaluation. Total PCBs were retained as a COPC so the evaluation of Total PCBs captures potential impacts associated with Aroclor 1260.
[b] Individual PAHs were not retained as COPCs. Due to the additive toxicity of PAHs, PAHs were only retained as COPCs based on the Total HMW or LMW PAH evaluations. Total HMW PAHs were not retained in this evaluation based on the two-sample hypothesis conclusion that Site is less than or equal to background. Total LMW PAHs were not retained in this evaluation because the maximum detected concentration is less than the ESV. Therefore, PAHs were not retained for further evaluation in hydric soil.

HQs for the COPCs retained in the off-Project Red Maple Swamp area surface hydric soil ranged from 1.2 for thallium to 180 for 2,4-dichloropenol. Given that COPCs were selected based on the lowest of the ESVs for plants, invertebrates, and wildlife, and were calculated from the highest concentrations detected, these HQs represent a conservative estimate of potential risks.

4.4.2.3 Surface Sediment

Table 4-7 identifies the sediment COPCs selected based on ESV comparisons for the surface sediment associated with the tidal stream in the Off-Project Red Maple Swamp/tidal stream area. Samples were collected between outfall 025 and Narragansett Bay. Preliminary surface sediment COPCs are identified in the table below based on a maximum detected concentration above the sediment ESV for COPC selections (as shown in **Table 4-2**) or a lack of an ESV. Shading in the table identifies the COPCs retained after the background comparisons and maximum HQs are provided for these COPCs.

Off-Project Red Maple Swamp/Tidal Stream Surface Sediment COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**
Aluminum	Hypothesis testing	NCOPC
Arsenic	Hypothesis testing	NCOPC
Barium	Hypothesis testing	NCOPC
Beryllium	Hypothesis testing	NCOPC

Off-Project Red Maple Swamp/Tidal Stream Surface Sediment COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**
Cadmium	Geochemical analysis	NCOPC
Chromium	Hypothesis testing	NCOPC
Cobalt	Hypothesis testing	NCOPC
Copper	Hypothesis testing	NCOPC
Iron	Hypothesis testing	NCOPC
Lead	Hypothesis testing	NCOPC
Manganese	Hypothesis testing	NCOPC
Mercury	Hypothesis testing	NCOPC
Nickel	Hypothesis testing	NCOPC
Selenium	Hypothesis testing	NCOPC
Silver	Hypothesis testing	NCOPC
Thallium	Hypothesis testing	NCOPC
Vanadium	Hypothesis testing	NCOPC
Zinc	Geochemical evaluation	NCOPC
Aroclor 1260	[a]	NCOPC
Total PCB Aroclors	**NE**	**37.5**
1-Methylnaphthalene	[b]	NCOPC
2-Methylnaphthalene	[b]	NCOPC
Acenaphthene	BTV	NCOPC
Acenaphthylene	[b]	NCOPC
Anthracene	BTV	NCOPC
Benzo(a)anthracene	BTV	NCOPC
Benzo(a)pyrene	BTV	NCOPC
Benzo(b)fluoranthene	BTV	NCOPC
Benzo(g,h,i)perylene	BTV	NCOPC
Benzo(k)fluoranthene	BTV	NCOPC
Chrysene	BTV	NCOPC
Dibenzo(a,h)anthracene	BTV	NCOPC
Fluoranthene	BTV	NCOPC
Fluorene	Hypothesis testing	NCOPC
Indeno(1,2,3-cd)pyrene	BTV	NCOPC
Naphthalene [c]	[b]	NCOPC
Phenanthrene	BTV	NCOPC
Pyrene	BTV	NCOPC
Total High MW PAHs	BTV	NCOPC
Total Low MW PAHs	BTV	NCOPC
Total PAHs	BTV	NCOPC
Bis(2-ethylhexyl)phthalate	**NE**	**12.2**
Carbazole	BTV	NCOPC
2-Butanone (MEK)	**NE**	**NC**
Acetone	**NE**	**NC**
Carbon Disulfide	**NE**	**15.7**

Notes:
Shading identifies COPCs retained after background comparisons.
Maximum HQ = Maximum detected concentration / COPC selection ESV.
NCOPC – Not a COPC.
NC – Not Calculated (no ESV available).
NE – Not evaluated in background comparisons because they were not part of background study.
[a] Although Aroclor 1260 was initially retained based on the ESV comparisons, it was not retained as a COPC. Due to the additive toxicity of PCBs, PCBs were only retained as COPCs based on the Total PCB evaluation. Total PCBs were retained as a COPC so the evaluation of Total PCBs captures potential impacts associated with Aroclor 1260.
[b] Individual PAHs were not retained as COPCs. Due to the additive toxicity of PAHs, PAHs were only retained as COPCs based on the Total HMW or LMW PAH evaluations. Total HMW PAHs, Total LMW PAHs, and Total PAHs were not retained in this evaluation because the maximum detected concentrations were less than their respective

Off-Project Red Maple Swamp/Tidal Stream Surface Sediment COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**

BTVs. Therefore, PAHs were not retained for further evaluation in sediment in the off-Project Red Maple Swamp/tidal stream area..
[c] Naphthalene was analyzed using both SVOC and VOC methods. Naphthalene was retained as a COPC based on the SVOC results, but not based on the VOC results.

HQs for the COPCs retained in the off-Project Red Maple Swamp area surface sediment ranged from 12.2 for bis(2-ethylhexyl)phthalate to 69 for Total PCBs. Sediment ESVs were not identified for 2-butanone and acetone so these chemicals were retained as COPCs, but HQs could not be calculated.

4.4.2.4 Surface Water and Porewater

Table 4-9 and 4-10 identify the surface water and porewater COPCs, respectively, for the off-Project Red Maple Swamp/tidal stream area. These COPCs were selected by comparing maximum surface water and porewater concentrations against surface water ESVs (as shown in **Table 4-3**). Background comparisons were not used to evaluate surface water or porewater COPCs. The table below identifies the surface water and porewater COPCs and provides the maximum HQs for these COPCs.

Off-Project Red Maple Swamp/Tidal Stream Surface Water and Porewater COPC Selection		
Medium	**COPC**	**Maximum HQ for Retained COPC**
Surface Water	**Barium - dissolved**	**4.1**
	Barium - total	**3.4**
	Carbon disulfide	**2.8**
Porewater	**Barium - dissolved**	**17.0**
	Lead - dissolved	**4.1**
	Barium – total	**16.8**
	Silver – total	**2.2**
	Carbon Disulfide	**1.2**
	Toluene	**1.4**

Notes:
Shading identifies COPCs retained after ESV comparisons.
Maximum HQ = Maximum detected concentration / COPC selection ESV.

In surface water and porewater, barium was detected in all samples in the off-Project Red Maple Swamp/tidal stream area and resulted in the highest HQs. The remaining COPCs were detected in fewer samples (FODs ranged from 4% to 26%).

4.4.2.5 Wildlife Exposures

Table 4-13 identifies the food web COPCs identified based on the off-Project Red Maple Swamp/tidal stream area screening level food web model (**Attachment G-2**). The food web model evaluated the maximum detected concentrations from the following off-Project datasets: surface soil from the off-Project Red Maple Swamp walking path, hydric surface soil from the off-Project Red Maple Swamp, and surface sediment from the off-Project tidal stream.

The off-Project food web considered the same set of bioaccumulative chemicals and followed the same general approach as the on-Project food web model described in Section 4.4.1. Wildlife receptors evaluated in the food web model included one herbivore (meadow vole), two insectivores (marsh wren and short-tailed shrew), and one omnivore (raccoon).

COPCs were retained for further food web evaluations if NOAEL-based HQs were above 1 and the COPC was not consistent with background for all three media. Chromium, zinc, and Total LMW PAHs were consistent with background based on a combination of comparisons to BTVs, hypothesis testing, and geochemical evaluations across the three media. All HQs for arsenic, cadmium, silver, and Total LMW PAHs were less than one. The table below summarizes the HQs above 1 for the wildlife receptors and the retained food web COPCs.

Off-Project Red Maple Swamp/Tidal Stream Food Web COPCs with HQs > 1				
Food Web COPC	**Marsh Wren**	**Meadow Vole**	**Raccoon**	**Short-tailed Shrew**
Copper	**7.8**	HQ < 1	HQ < 1	**2.7**
Lead	**7.7**	HQ < 1	HQ < 1	**1.3**
Mercury	**13.9**	1.4	0.25	**1.3**
Nickel	0.66	HQ < 1	HQ < 1	**1.3**
Selenium	**5.7**	**6.3**	**1.1**	**5.6**
Total PCB Aroclors	**3.7**	HQ < 1	HQ < 1	**1.8**
Notes: Shading identifies HQs > 1 for food web COPCs retained after background comparisons.				

4.4.3 Off-Project Narragansett Bay and Beachfront Area

4.4.3.1 Surface Sediment

Table 4-8 identifies the sediment COPCs selected based on ESV comparisons for the surface sediment collected from the off-Project Narragansett Bay and Beachfront area. The table below identifies the preliminary surface sediment COPCs identified based on a maximum detected concentration above the sediment ESV for COPC selections (as shown in **Table 4-2**), or the chemicals lacked ESVs. Shading in the table identifies the COPCs retained after the background comparisons and maximum HQs are provided for these COPCs.

Off-Project Narragansett Bay and Beachfront Surface Sediment COPC Selection		
Preliminary COPC	**Eliminated as a COPC Based On -**	**Maximum HQ for Retained COPC**
Aluminum	Hypothesis testing	NCOPC
Thallium	BTV	NCOPC
Total PCB Aroclors	**--**	**2.1**
Carbon Disulfide	**--**	**13.4**

Notes:
Shading identifies COPCs retained after background comparisons.
Maximum HQ = Maximum detected concentration / COPC selection ESV.
NCOPC – Not a COPC.

The maximum detected concentrations of total PCBs and carbon disulfide are greater than the benthic invertebrate ESVs with HQs of 2.1 and 13.4, respectively. PCBs were detected in each of the ten sediment samples with similar concentrations (ranging from 0.070 to 0.083 mg/kg). Carbon disulfide was detected in just over half of the sediment samples and all but one detected concentration exceeded the freshwater sediment ESV (a marine ESV was not identified).

4.4.3.2 Surface Water and Porewater

Table 4-11 identifies the porewater COPCs for the off-Project Narragansett Bay and Beachfront area. Surface water samples were collected from this exposure area in 2015 and analyzed for metals and VOCs; and none of these analytes were detected. The porewater COPCs were selected by comparing the maximum porewater concentrations with surface water ESVs (as shown in **Table 4-3**). Background comparisons were not used to evaluate porewater COPCs because porewater was not included in the background study. The table below identifies the porewater COPCs and provides the maximum HQs for these COPCs.

Off-Project Narragansett Bay and Beachfront Porewater COPC Selection		
Medium	**COPC**	**Maximum HQ for Retained COPC**
Porewater	**Barium – dissolved**	**7.3**
	Barium – total	**8.5**
	Lead – total	**3.7**

Notes:
Shading identifies COPCs retained after ESV comparisons.
Maximum HQ = Maximum detected concentration / COPC selection ESV.

Barium and lead were identified as COPCs in porewater but were detected relatively infrequently (FODs ranged from 5% to 10%). Barium resulted in the highest HQs when compared to the freshwater ESV (a marine ESV was not identified).

4.4.4 Uncertainty Analysis

Ecological risk assessment results depend primarily on the weight of evidence supporting particular conclusions, and each line of evidence is subject to varying degrees of uncertainty. Due to the complexity of ecosystems and the associated mechanisms that cause ecological stress, uncertainty in environmental risk characterization is inevitable. Uncertainty stems from a number of sources, including but not limited to the following:

- Sampling and statistical variability, and the use of point estimates for variables rather than distributions;
- Limitations of toxicity testing;
- Difficulty of extrapolating from laboratory data to field data;
- Uncertainties in evaluating environmental responses to mixtures of chemicals;
- Assumptions underlying the use of fate and transport models; and
- A range of conditions for which models or HQs are applicable.

Additional sources of uncertainty associated with this ecological risk characterization are described below. In general, the assumptions made in multiple points in the SLERA tend to err on the side of overestimating risks. The cumulative impact of multiple conservative assumptions is more likely to overestimate than underestimate potential risks to ecological receptors.

In general, the sampling design targeted areas with the potential to have been impacted by historical Project-related activities. However, portions of these areas may not represent preferred ecological habitats or areas likely to be frequented by ecological receptors. This is particularly true in the vicinity of the buildings and parking lots in the on-Project area and the walking path of the off-Project Red Maple Swamp/tidal stream area, which may be unattractive to some wildlife receptors. Therefore, ecological exposures to some samples may be limited or receptors may prefer to forage in other areas. This type of sampling is expected to bias results high.

ISM sampling for PCBs is expected to provide a more accurate estimate of potential PCB exposures across the on-Project Blue Beach area than the discrete sampling conducted for other chemicals. As indicated above, the discrete sampling was often biased towards areas expected to have been impacted by historical Project-related activities, which tends to overestimate actual exposures of ecological receptors to COPCs over an area.

4.4.4.1 Uncertainties in the Ecological Toxicity Assessment

The risk screening is based on the assumption that the detected chemicals are 100% bioavailable and that the most sensitive life stages of each environmental receptor are present. The screening values are conservative and often based on toxicity tests performed with sensitive test organisms. These factors are likely to overestimate the actual risk to receptors at the Project.

Similarly, bioavailability in prey items is likely overestimated because the food web models assumed that the COPCs consumed by wildlife receptors were present in a form that was 100% bioavailable (100% of the COPC is assimilated by the organism after ingestion). However, this is unlikely.

It is recognized that laboratory data that are used for generating screening or protective criteria may not have been obtained under conditions that accurately represent the complexities of potential exposures in the field. Laboratory-based ecological screening values are typically derived under conditions that favor high bioavailability (e.g., using sediment with low pH and organic matter [USEPA, 2005c] or using soluble chemical forms [lead acetate] to conduct tests). Therefore, the weathered chemical present at the Site, is likely to be in a less soluble form than that used in the laboratory study. In such circumstances, risk is overestimated.

Conservative assumptions are incorporated into the derivation of the ESVs. For example, the Eco-SSLs for wildlife assume that the diet of the receptor is obtained solely from impacted soil and food items. However, these receptors are also likely to feed in un-impacted areas such that overall dietary exposure would be much lower (i.e., diet incorporates exposure to areas within and outside of the Project with lower soil concentrations of COPCs) so the

wildlife Eco-SSLs may be overly conservative. Similarly, the diet assumptions used to derive some of the Eco-SSLs, for insectivores in particular, may be overly conservative because it is assumed that the avian and mammalian insectivores have an exclusive diet of earthworms when in reality insectivore diets can include insects and mammals. Furthermore, Eco-SSLs are derived to be protective of the conservative end of the exposure and effects species distribution for the four groups of ecological receptors (i.e., plants, soil invertebrates, birds, and mammals).

Toxicological studies on which screening values are based deal with a single chemical. Effects resulting from a simultaneous exposure to multiple chemicals are usually not addressed in those studies. The community-level screening values and wildlife TRVs used do not generally account for possible synergistic, antagonistic, or additive effects of COPC mixtures in environmental media. These factors may result in an underestimate or overestimate of potential risk. Assessing potential risks due to exposures to chemical mixtures is challenging as chemicals within the mixture may not be equally bioavailable and may not act on the receptor with the same toxic mechanisms.

Community-level ESVs are not available for all of the chemicals that were analyzed in surface soil, surface water, and sediment. Therefore, the potential risks from these chemicals were not estimated for inclusion in the risk assessment and the total risk may be underestimated. These chemicals were carried forward as COPCs; however, the lack of ESVs contributes to the uncertainty associated with this risk assessment.

For the purposes of screening hydric soil data, terrestrial soil ESVs were used to compare with the maximum detected hydric soil concentrations. However, the soil ESVs were developed based on the exposures of soil invertebrates and plants and it is uncertain if they are applicable to hydric soil conditions, e.g., seasonal or tidal flooding. Therefore, it is unknown if the use of the soil ESVs over- or underestimates risks for the hydric soil pathway.

For some inorganic chemicals in surface water, ESVs are calculated based on the hardness of the water. Hardness data was available for the off-Project Red Maple Swamp/tidal stream area surface water data but not for the porewater data. The average hardness value for surface water (183 mg/kg) was used to adjust the porewater ESVs. It is unknown if this is an over or under estimation of hardness in pore water.

4.4.4.2 Uncertainties in Exposure Modeling

Exposure modeling includes multiple assumptions that add uncertainty to each step of the process. The first step in estimating uptake or intake of COPCs by representative species is determining the EPC of COPCs. The EPC is used to estimate the chemical exposure of an individual using the Site as a foraging area. This step depends on several assumptions that create uncertainty. In accordance with USEPA guidance (1997), the maximum concentrations of COPCs measured in each media and exposure area (with the exception of PCBs in soil from the on-Project Blue Beach area as discussed in Section 4.31.) were selected to represent the maximum exposure for screening purposes. This is more conservative than using the average or 95% UCL COPC concentrations and will tend to overestimate exposure and thus overestimate risk.

Other sources of uncertainty associated with the EPC include chemical bioavailability and mobility. Extraction methods used to determine chemical concentrations in soil and sediment are rigorous and destructive; chemicals are often sorbed to soil or sediment particles such that they may not be available to ecological receptors under environmental conditions.

The use of BAFs in exposure modeling, rather than Site-specific tissue data, also represents a source of uncertainty. The physical characteristics of the soil or sediment in the study that were used to derive the BAFs, may not match the Site soil characteristics. The potential for variation between species of plants, earthworms, and benthic invertebrates is not accounted for, and the similarity of test species to species on-Site is not accounted for by the use of a BAF. Furthermore, the use of surrogate chemicals or default values was required when BAFs were unavailable for a some COPCs. BAFs are available only for a subset of chemicals, so a default BAF of 1 was used as a surrogate when appropriate chemical surrogates were not available (e.g., invertebrate concentration equal to soil concentration). However, BAFs are available for most chemicals known to bioaccumulate.

Species-specific exposure factors are another source of uncertainty. The exposure models used to predict uptake of COPCs by animals via various pathways depend on factors such as body weight, daily food and water intake, and the percentage of soil, plant, and prey material constituting the food intake. These values are all point estimates and each are associated with uncertainty.

The SLERA evaluates the most likely pathways for the COPCs associated with the Project. In addition to the pathways that were evaluated, other lower exposure pathways were not included in this evaluation and this adds an additional uncertainty that has the potential to underestimate risks. Exposure pathways that were not considered include plant absorption of air chemicals, inhalation of contaminated dust by animals, and dermal absorption of chemicals from soil by animals other than soil invertebrates. These routes could contribute to the overall exposure of representative species to chemicals in soil and sediment. These pathways are expected to have a minimum contribution toward exposure compared to the pathways chosen for quantitative evaluation. This small possibility of underestimating risks is not of a magnitude that it would offset the otherwise conservative assumptions made in the exposure modeling.

4.4.4.3 Uncertainty in the Hazard Quotient Method

The use of HQs for the assessment of risk presents some level of uncertainty. Primarily, calculation of an HQ is based on exposure modeling and development of criteria or screening values, two exercises that have uncertainty in and of themselves. Although the endpoints measured in most toxicological studies used to generate the screening values are the same (development/growth/ reproduction/survival), the effects of simultaneous exposure to multiple constituents may be, for example, synergistic or antagonistic (i.e., not necessarily additive). Thus, HQs for specific chemical, receptor, and pathway combinations were not calculated at this screening level. This contributes to uncertainty in the calculated HQs for the pathway and, consequently, the HQ for the receptor from all pathways.

4.4.4.4 Uncertainties Associated with Background and Geochemical Evaluations

Because of the natural variation of metals present in soils and sediment from different geological areas, local populations of plants and animals have adapted over time to local soil conditions. Although the risk assessment may identify a metal in soil as a potential risk to local receptors, if the maximum detected concentration of the metal is within the normal background range for the local soil, it is assumed that the metal does not present an unacceptable risk to local ecological receptors. “Normal” varies from place to place, depending on the kinds of rocks or other parent materials that occur in the area from which the soil is derived.

A background evaluation and a geochemical evaluation were included in this SLERA to estimate normal concentrations and focus the risk evaluation on COPCs that may be related to historical DoD activities associated with the on-Project area. The purpose of these evaluations was to avoid overestimating Site-related risks by eliminating chemicals that are present based on natural conditions or non-DoD anthropogenic sources (e.g., PAHs from atmospheric deposition or road runoff). This approach focuses the risk calculations on Site-related risks that a receptor may be exposed to on-Site.

The background datasets considered in **Attachment D** represent concentrations of metals, PAHs, and other SVOCs from un-impacted areas. Metals may be naturally occurring and derived from local geological formations. PAHs may also be naturally occurring (e.g., from forest fires), but PAHs and other organic constituents may also present in the environment due to anthropogenic sources related to incomplete combustion of organic materials (e.g., oil, coal, wood) or spills. The available background samples may not represent the full spread of conditions observed within the on-Project and off-Project exposure areas (e.g., pH, TOC, and hardness), so some uncertainties are associated with the background evaluation. Therefore, the geochemical evaluation was included to further evaluate metals relative to naturally occurring conditions. The interpretation of these evaluations, particularly the geochemical correlations, is somewhat subjective but is typically based on multiple lines of evidence to avoid excluding a chemical that is truly Site-related.

4.5 SLERA Conclusions

The USEPA guidance for the SLERA (USEPA 1997) allows for the following possible decisions:

- There is adequate information to conclude that ecological risks are negligible and, therefore, remediation is not needed based on ecological risk.
- The information is not adequate to make a decision at this point, and the ecological risk assessment will continue to Step 3.
- Information indicates a potential for adverse ecological effects, and a more thorough assessment is warranted.

A number of chemicals in surface soil, surface hydric soil, sediment, surface water, and porewater have HQs greater than or equal to 1, indicating a potential for adverse effects to representative species from exposure to these media. Based on this evaluation, the SMDP is to continue the ERA into Step 3.

Table 4-14 summarizes the COPCs retained in each exposure area and media based on the ESV comparisons or the food web models. These COPCs are retained for further evaluation in Step 3a, the first step of the BERA.

4.6 Step 3a COPC Refinement

The results of the SLERA were summarized in Section 4.5 and included Steps 1 and 2 of the eight-step USEPA ERA approach (USEPA 1997). The BERA follows a subsequent multi-step process (Steps 3 through 8) to evaluate ecological risks and to determine whether Site remediation is warranted from an ecological perspective. The BERA process includes decision criteria for exiting from, or proceeding with, the ERA process at multiple points, including in Step 3.

The purpose of Step 3a is to reevaluate COPCs that were retained in the SLERA for further evaluation, and to identify and eliminate from further consideration those COPCs that were retained because of the use of conservative exposure scenarios.

In Step 3a, the SLERA risk estimates were recalculated using less conservative but more realistic assumptions. Step 3a uses the same representative species and exposure pathways, but with refined, central tendency exposure assumptions to more realistically estimate the potential risk to ecological receptors from COPCs that were carried through the conservative SLERA screening process.

The list of COPCs identified in the SLERA was refined using these calculated risk estimates to remove COPCs from further consideration. The Step 3a questions that help refine the SLERA included the following:

- Do any of the COPCs identified in the SLERA occur infrequently at any of the sites (i.e., in less than 5% of the samples)? If so, the exposure of representative species may be overestimated.
- Are high concentrations and risks widespread across the site or limited to discrete locations? (magnitude and extent of contamination and risk)
- Could the COPC be in a chemical form that is less hazardous? (bioavailability of the COPC)
- Do more realistic exposure assumptions reduce potential risk to an acceptable level?

The evaluation presented in this section presents a refinement of the COPCs based on the following factors:

- Evaluation of COPCs with low FOD (≤5%) and sufficient data from acceptable site characterization (at least 20 samples).
- Evaluation of more representative EPCs;
- Evaluation of alternative ESVs for the community-level ecological receptor evaluations (e.g., soil invertebrate community, plant community, benthic invertebrate community, surface water community);
- Evaluation of more representative exposure assumptions for wildlife receptors evaluated in the food web models; and
- Evaluation of alternative TRVs for wildlife receptors evaluated in the food web models.

After the reevaluation/refinement, the decision criteria for Step 3a included:

- If the reevaluation of the conservative exposure assumptions used in the SLERA supports an acceptable risk determination for all COPCs, then a no further action designation was warranted, and the site exits the ERA process.
- If the reevaluation of the conservative exposure assumptions does not support an acceptable risk, the BERA process continues to Step 3b or remediation.

Similar to the SLERA process, Step 3a utilizes existing data with additional information obtained primarily from a literature search. Additionally, Step 3a employs the same dose models and risk characterization methods as those used in the SLERA, with changes to the values of some input parameters.

To further refine estimates of risk for the benthic invertebrate community in the tidal stream of the off-Project Red Maple Swamp/tidal stream, additional field efforts included collection of data to assess the bioavailability of divalent metals (i.e., simultaneously extracted metals [SEM], acid volatile sulfides [AVS], and total organic carbon [TOC] data), sediment toxicity testing, and macroinvertebrate community sampling.

4.6.1 Step 3a Refinement Approach

Those chemicals that were detected in surface soil, surface hydric soil, sediment, surface water, and porewater and that had HQ values of 1 or greater for terrestrial ecological receptors, benthic organisms, aquatic life, or wildlife, and were not consistent with or below background conditions or not eliminated based on the geochemical evaluation, were retained for further evaluation in Step 3a of the BERA (see **Table 4-14**).

The EPCs considered in the SLERA were the maximum detected concentration in the relevant media datasets; this approach is conservative, particularly for mobile receptors. In Step 3a, the average exposure is estimated as the 95% UCL of the mean, which conservatively represents the RME expected for ecological resources. For the discrete datasets, the selected EPC for Step 3a is the lesser of the 95% UCL or the maximum concentration. UCLs were calculated using USEPA's ProUCL Version 5.1 software (USEPA 2016). Supporting documentation for the UCLs is provided in **Attachment B**.

The EPCs for Total PCBs in surface soil within the on-Project Blue Beach area (the ISM soil dataset) are equal to the weighted mean UCL concentration of the SU-specific 95% UCLs based on SU size (acreage), calculated as described in Section 2.2.4.2. and provided in **Attachment C**.

Alternative ESVs used to refine the COPCs were obtained from several sources, including compilations of screening values used by other USEPA regions and the LANL database (LANL, 2017). These alternative ESVs represent concentrations above which adverse effects to ecological receptors are more likely to occur (e.g., probable effect levels for sediment, LANL low effect screening levels for plants and soil invertebrates).

Multiple conservative assumptions were considered in determining the potential exposure of wildlife receptors to the COPCs in the screening level food web model. These included use of the maximum detected concentrations, NOAEL-based TRVs, and conservative assumptions about wildlife exposure parameters (e.g., exposure duration [ED], area use factor [AUF]). Therefore, the refinement of the wildlife COPCs considered more realistic values for these food web inputs.

Typically, the ED considers potential seasonal limitations for exposure such as migration of organisms out of the region. For this Step 3a refinement step, it was assumed that the food web receptors could forage all year round and no reduction in exposure due to seasonal migration was used.

For the AUFs, the potential size of the available habitat relative to the expected normal spatial range of species foraging and nesting activities was considered. For some receptors (e.g., raccoon), the size of the exposure areas is small with regard to the potential home ranges (USEPA, 1993c). Therefore, the amount of time spent within the exposure areas may be only a small proportion of the animal's expected range. AUFs were estimated using home ranges identified for each receptor from USEPA guidance and estimates of the acreage of the on-Project and off-Project exposure areas. When the home range was smaller than the exposure area the AUF remained at 1. For more far ranging receptors, the AUF was less than 1 so that the exposure estimate only reflected the amount of the diet likely to be obtained from within the exposure area.

The TRVs considered in the screening level food web models were based on NOAELs. However, evaluation against a NOAEL-based TRV only identifies levels below which no effect has been seen. It is also useful to consider the chemical concentration at which adverse effects start to manifest (i.e., LOAEL-based TRV). These two approaches are considered to constitute the lower bound (i.e., conservative screening level assumptions and NOAEL-based TRVs) and upper bound (i.e., more realistic assumptions, LOAEL-based TRVs) of the TRV range (USEPA, 1997). The difference in the risk estimates based on the different toxicity-based TRV endpoints may be evaluated to allow

further interpretation of the risk results. Therefore, the refined food web models considered TRVs based on both NOAELs and LOAELs.

4.6.2 Step 3a Risk Calculations

The Step 3a risk calculations for direct contact exposures included comparisons of the maximum EPCs (i.e., the lower of the maximum detected concentration or the 95% UCL) against both the screening level ESVs (identified in **Tables 4-1 through 4-3**) and the alternative effect-based screening levels. This approach is similar to the refined food web models which include both NOAEL- and LOAEL-based TRVs. The Step 3a risk calculations are summarized in the following sub-sections by media and exposure type.

Soil EPCs were calculated differently for discrete and ISM datasets. The EPCs for Total PCB Aroclors in surface and subsurface soil within the on-Project Blue Beach area (ISM soil datasets) are equal to the weighted mean UCL concentration of the SU-specific 95% UCLs based on SU size (acreage), calculated as described in Section 2.2.4.2. Soil EPCs for all other COPCs associated with discrete sample datasets are equal to the 95% UCL concentration, calculated as described in Section 2.2.4.1, or the maximum detected concentration if an appropriate 95% UCL was not calculated by ProUCL due to one of the scenarios previously described.

4.6.2.1 Surface Soil Direct Contact

Potential impacts to the terrestrial plant and invertebrate communities were evaluated in Step 3a by comparing maximum surface soil EPCs against plant- and invertebrate-based ESVs (**Table 4-15**).

In the on-Project Blue Beach area, the maximum EPC for bis(2-ethylhexyl)phthalate exceeded the screening level ESV for plants, but was well below the refined ESV for plants. No other EPCs exceeded the plant ESVs. For soil invertebrates, the maximum EPCs for zinc, total PCBs, benzoic acid, bis(2-ethylhexyl)phthalate, and acetone exceeded the screening level ESVs for invertebrates, but, with the exception of benzoic acid, were well below the refined ESVs for invertebrates. The soil invertebrate HQ was 2.5 for benzoic acid; however, this was based on a single detected concentration out of 26 samples. All of the nondetect values (detection limits) are below the refined ESV for soil invertebrates. This COPC is eliminated based on a low FOD (<5% detected and greater than 20 samples).

In the off-Project Red Maple Swamp/tidal stream area, Total PCBs were the only COPC retained for surface soil associated with the walking path. The maximum surface soil EPC was below the screening level ESV for plants, and above the screening level ESV for soil invertebrates (based on a Dutch Target Value reported by Buchman [2008]). An alternative soil invertebrate ESV was not identified for PCBs so a benthic invertebrate ESV was used to further evaluate potential invertebrate risks. The maximum surface soil EPC for Total PCBs was below the refined ESV for invertebrates.

These results indicate that risks to terrestrial plants and soil invertebrates are not expected due to direct exposure to COPCs in surface soil and no further evaluation of this pathway is warranted.

4.6.2.2 Surface Hydric Soil Direct Contact

Potential impacts to the wetland plant and invertebrate communities were evaluated in Step 3a by comparing maximum surface hydric soil EPCs against plant- and invertebrate-based ESVs (**Table 4-16**).

In the off-Project Red Maple Swamp/tidal stream area, the maximum EPCs for lead, selenium, and 2,4-dichlorophenol exceeded the screening level ESVs for plants but were below the refined ESVs. The maximum EPCs for mercury, Total PCBs, 2,4-dichlorophenol, acetone, carbon disulfide, and toluene exceeded the screening level ESVs for invertebrates, and, with the exception of total PCBs, were below the refined ESVs for invertebrates. Due to the lack of a soil invertebrate-based ESV for Total PCBs, a benthic invertebrate ESV was used to evaluate potential invertebrate risks. The maximum hydric soil EPC exceeded the benthic invertebrate ESV used in the refined screen.

These results indicate that, with the exception of Total PCBs, risks to wetland plants and invertebrates are not expected due to direct exposure to COPCs in surface hydric soil. Only Total PCBs in surface hydric soil warrant further evaluation (see Section 4.6.3).

4.6.2.3 Sediment Direct Contact

Potential impacts to the benthic invertebrate communities were evaluated in Step 3a by comparing maximum surface sediment EPCs against benthic invertebrate community-based ESVs (**Table 4-17**).

In the off-Project Red Maple Swamp/tidal stream area, the maximum EPCs for Total PCBs, bis(2-ethylhexyl)phthalate, and carbon disulfide exceeded the screening level ESVs but, with the exception of Total PCBs, were below the refined ESVs. Screening level ESVs were not available for 2-butanone and acetone, but the maximum EPCs for these COPCS were below the refined ESVs.

In the off-Project Narragansett Bay and Beachfront Area, the maximum EPCs for Total PCBs and carbon disulfide exceeded the screening level ESVs but were below the refined ESVs.

These results indicate that, with the exception of Total PCBs in sediment associated with the tidal stream, risks to benthic invertebrates are not expected due to direct exposure to COPCs in sediment.

Additional field efforts were conducted to further assess the potential for risks to benthic invertebrates within the tidal stream. This additional sampling focused on ten sampling locations within the tidal stream: five located between Circuit Drive and outfall 025 (background/reference sediment samples) and five located between outfall 025 and Narragansett Bay (referred to as Site samples for the purpose of the additional assessment in the tidal stream).

SEM, AVS, and TOC were measured in ten samples collected in May 2020 to evaluate potential divalent metals bioavailability. USEPA (2005) guidance on metals bioavailability evaluates possible binding of metals by both AVS and organic matter. Therefore, data were evaluated on a sample-by-sample basis using the following scale to evaluate whether the organic carbon binding phase (represented as fraction organic carbon or foc), in conjunction with the AVS, is affecting the bioavailability of divalent metals in sediments:

- If the $(\sum SEM\text{-}AVS)/f_{oc}$ excess exceeds 3,000 µmol/gram of organic carbon (g_{oc}), the sediments are presumed to be "likely to be toxic";
- If the (∑SEM-AVS)/foc excess is between 130 and 3,000 $\mu mol/g_{oc}$, predictions of effects are uncertain; and
- If the $(\sum SEM\text{-}AVS)/f_{oc}$ excess is less than 130 $\mu mol/g_{oc}$, the sediments are presumed to "not likely" be toxic.

As indicated in **Table 4-18**, all ten of the samples were found “not likely to be toxic.” These results indicate that divalent metals are not expected to be bioavailable and, therefore, are not toxic to benthic invertebrates present in the tidal stream.

Table 4-19 summarizes the results of 28-day sediment toxicity tests conducted with an amphipod (*Leptocheirus plumulosus*). Toxicity tests were conducted under specified laboratory conditions using bulk sediment samples collected in May 2020 and the associated laboratory toxicity report is provided in **Attachment H**. Standardized statistical tests were conducted to identify significant differences in survival, growth, biomass, or reproduction between individual off-Project tidal stream samples and the upstream background/reference locations, and between individual stream and laboratory control samples. The individual paired statistics were performed by the laboratory using Comprehensive Environmental Toxicity Information System (CETIS), version 1.9.6.3 software and program exports are included in **Attachment H**.

Data sets were evaluated to determine normality of distribution and homogeneity of sample variance. Data sets were subsequently evaluated using the appropriate parametric or non-parametric Analysis of Variance (ANOVA) statistic. If outliers were found in the data set, then the analysis was conducted both with and without the outlier included in the data set. Pair-wise comparisons were made using the appropriate statistical evaluation. Statistical difference was evaluated at $\alpha = 0.05$. A statistical difference between an individual off-Project tidal stream sample and an individual background/reference sample is not necessarily indicative of an off-Project tidal stream sample that is different from background conditions as a whole.

As indicated in **Table 4-19**, samples collected from SED-333 and SED-337 were not statistically different from the laboratory control or the upstream background/reference samples. The sample collected from SED-335 showed statistical differences from the laboratory control and/or a sub-set of the upstream background/reference samples for all tested endpoints. The samples collected from SED-331 and SED-339 showed statistical differences from the laboratory control and/or a sub-set of the upstream background/reference samples for growth and reproduction endpoints but not for survival.

Macroinvertebrate samples were collected from these ten stream locations in May 2020 and samples were processed in the laboratory and invertebrates were identified to the lowest practical level (generally genus or species) and

enumerated by taxon. **Attachment I** provides the individual invertebrate counts and associated metrics from each sample. The community metrics are summarized in **Table 4-20** and include total richness (number of taxa), total density (number of specimens), Shannon Diversity Index (a measure of biological diversity), and the Hilsenhoff Biotic Index (HBI; a measure of pollution tolerance). In general, the metrics were variable both upstream from and downstream from outfall 025 with no clear spatial pattern.

Additional characterization of the potential for risks to the benthic invertebrate community off-Project tidal stream are provided in Section 4.6.3.

4.6.2.4 Surface Water Direct Contact

Potential impacts to aquatic life were evaluated in Step 3a by comparing maximum surface water EPCs against aquatic life-based ESVs (**Table 4-21**).

In the off-Project Red Maple Swamp/tidal stream area, the maximum surface water EPCs for barium (dissolved and total) and carbon disulfide exceeded the screening level aquatic life ESVs (based on chronic exposures) but were below the refined ESVs (based on acute exposures). It is recognized that the use of an acute screening value for evaluating surface water may underestimate chronic exposures, so the basis of the screening levels ESVs was also re-considered.

The surface water screening level ESV for barium is a USEPA Region 3 freshwater screening benchmark for dissolved barium (4 ug/L). This ESV is a Tier II secondary chronic value (SCV) presented by Suter and Tsao (1996) and is based on 16% reproductive impairment at 5,800 ug/L in a 21-day test on *Daphnia magna* (detected concentrations of barium in aqueous samples were below this level). Tier II values are based on a smaller data set than is required to develop a state water quality standard or AWQC and uncertainty factors are applied to the available data to derive the SCV.

Recent Dutch guidance (RIVM, 2020) suggested a chronic freshwater screening level for barium of 624 ug/L based on data for algae, invertebrates and fish. The Dutch guidance could not derive a marine screening level based on a lack of studies. Only a single reliable marine study was identified which reported a chronic no observed effect concentration (NOEC) of 100 ug/L dissolved barium for embryonic development of Californian mussels. Detected concentrations of barium were below this level. Therefore, the risks predicted based on the screening level (chronic) ESV for barium appear to be overestimated.

The screening level ESV for carbon disulfide in surface water (0.92 ug/L) is also a USEPA Region 3 freshwater screening benchmarks based on a Tier II SCV presented by Suter and Tsao (1996). The lowest chronic values (LCV) for daphnids and fish were estimated at reported as 244 ug/L and over 9,500 ug/L (Suter and Tsao, 1996). As stated above for barium, the SCV is derived by applying uncertainty factors to the available data. The surface water ESV is 265 times lower than the lowest LCV reported for daphnids. The single detection of carbon disulfide in surface water from off-Project Red Maple Swamp/tidal stream area is well below the LCV for daphnids. Therefore, the risks predicted based on the screening level (chronic) ESV for carbon disulfide appear to be overestimated.

These results indicate that chronic (and acute) risks to aquatic life are not expected due to direct exposure to COPCs in surface water and no further evaluation of this pathway is warranted.

4.6.2.5 Porewater Direct Contact

Benthic invertebrates present within the sediment may be exposed to porewater concentrations of COPCs. Therefore, in addition to considering sediment exposures, potential impacts to benthic invertebrates was evaluated in Step 3a by comparing maximum porewater EPCs against aquatic life-based ESVs (**Table 4-22**).

In the off-Project Red Maple Swamp/tidal stream area, the maximum porewater EPCs for barium (dissolved and total), lead (dissolved), silver (total) and toluene exceeded the screening level aquatic life ESVs (based on chronic exposures) but were below the refined ESVs (based on acute exposures). Toluene was also eliminated based on a low FOD (<5% detects and at least 20 samples).

In the off-Project Narragansett Bay and Beachfront Area, the maximum porewater EPCs for barium (dissolved and total), and lead (total), exceeded the screening level aquatic life ESVs (based on chronic exposures) and were below the refined ESVs (based on acute exposures).

It is recognized that the use of an acute screening value for evaluating porewater may underestimate chronic exposures, so the basis of the screening levels ESVs and the range and frequency of porewater detections were considered.

As described above, the barium ESV (4 ug/L) is based on a Tier II SCV. All of the porewater concentrations of barium in both exposure areas are below the proposed Dutch freshwater chronic value of 624 ug/L and the chronic marine NOEC of 100 ug/L (RIVM, 2020). Therefore, porewater risks predicted based on the screening level (chronic) ESV for barium appear to be overestimated.

The screening level lead ESVs were based on the freshwater and marine AWQCs (4.8 and 5.6 ug/L, respectively). Lead was detected infrequently in both exposure areas. In the off-Project Red Maple Swamp/tidal stream area the only detected concentration of dissolved lead (19.6 ug/L) was collected from location PW-3-2014 (collected at a depth of 2.7-3 ft in 2014); however, lead was not detected in porewater at this location (PW-103, collected at a shallower depth of 0.75 to 1 ft) in 2011. There are also some uncertainties associated with the dissolved lead detection since total lead was not detected at a detection limit of 2 ug/L at the same location and sampling event. In the off-Project Narragansett Bay and Beachfront Area, lead was analyzed in total and dissolved phase in 10 samples. Total recoverable lead was detected at two locations in 2015 (PW-OFF-7 and PW-OFF-9) and both concentrations (17.8 and 20.8 ug/L, respectively) are higher than the marine screening level ESV of 5.6 ug/L. Locations PW-OFF-7 and PW-OFF-9 coincide with the end of the recreation trail on the beach.

The screening level silver ESV (0.23 ug/L) for off-Project Red Maple Swamp/tidal stream area was based on the USEPA Region 3 marine surface water screening value. Silver was detected in only one out of 10 samples at location PW-104 in 2011 and this concentration (0.51 ug/L) exceeds the screening level ESV.

All of the porewater samples were collected from depths of 0.75 to 3 ft below the sediment surface which is likely representative of groundwater flow and may overestimate porewater exposures for benthic receptors exposed to more shallow sediment horizons. It is likely that these porewater samples overestimate actual exposures to COPCs in more shallow horizons that incorporate dilution with surface water.

Lead and silver were detected infrequently in the dissolved and total recoverable samples collected from each of the exposure areas. In addition, lead and silver were not retained as COPCs in sediment or surface water in these exposure areas. Therefore, it is expected that chronic risks due to porewater exposure are overestimated based on the evaluation of the detected porewater concentrations.

These results indicate that chronic (and acute) risks to benthic invertebrates are not expected due to direct exposure to COPCs in porewater and no further evaluation of this pathway is warranted.

4.6.2.6 On-Project Food Web Exposures

Based on the results of the screening level food web model, the refined food web model for the on-Project Blue Beach area evaluated the potential for risks to the American robin, raccoon, and short-tailed shrew using the maximum surface soil EPC. **Table 4-23** summarizes the HQs based on the NOAEL- and LOAEL-based TRVs and calculations are provided in **Attachment G-3**.

All HQs for the raccoon and all LOAEL-based HQs for the American robin and short-tailed shrew were less than 1. The NOAEL-based HQs above 1 are summarized below:

- American robin – cadmium (HQ = 1.6), lead (HQ = 3.8), and Total PCBs (HQ = 1.7)
- Short-tailed shrew – cadmium (HQ = 2.6) and Total PCBs (HQ = 1.5)

The refined food web model assumed that the robin and shrew obtained all of their diet from soil invertebrates on-Project Blue Beach area and the invertebrate ingestion component (rather than incidental soil ingestion) dominates the calculated doses for these receptors. The raccoon has a much larger home range and was assumed to forage outside of the exposure area. However, all of the HQs for the raccoon would still be below 1 if it was assumed that the raccoon only foraged within the exposure area (AUF of 1).

4.6.2.7 Off-Project Food Web Exposures

Based on the results of the screening level food web model, the refined food web model for the off-Project Red Maple swamp/tidal stream area evaluated the potential for risks to the marsh wren, meadow vole, raccoon, and short-tailed

shrew using the maximum EPC based on the surface soil, hydric soil, and sediment datasets from this exposure area. **Table 4-24** summarizes the HQs based on the NOAEL- and LOAEL-based TRVs and calculations are provided in **Attachment G-4**.

All HQs for the raccoon and all LOAEL-based HQs for the marsh wren, meadow vole, raccoon, and short-tailed shrew were less than 1. The NOAEL-based HQs above 1 are summarized below:

- Marsh wren – copper (HQ = 2.5), lead (HQ = 1.2), mercury (4.5), selenium (1.4), and Total PCBs (HQ = 1.3)
- Meadow vole – selenium (HQ = 1.3)
- Short-tailed shrew – selenium (HQ = 1.3) and Total PCBs (HQ = 1.6)

The refined food web model assumed that the marsh wren, meadow vole, and shrew obtained all of their diet from food items present within the off-Project Red Maple swamp/tidal stream area. It was assumed that the wren and shrew would consume only wetland invertebrates and the vole would feed only on wetland plants. The raccoon has a much larger home range and was assumed to forage outside of the exposure area. However, all of the HQs for the raccoon would still be below 1 if it was assumed that the raccoon only foraged within the exposure area (AUF of 1).

4.6.3 Step 3a Uncertainty Analysis

Many of the uncertainties described in Section 4.4.4 also apply to the refined evaluation. Although some conservative assumptions from the SLERA were reduced in the refinement step (e.g., use of alternate EPCs, LOAEL-based TRVs), the general ERA approach is still more likely to over-estimate rather than under-estimate ecological risks.

AUFs less than 1 were used for the raccoon in the Step 3a food web models to refine the conservative risks in the SLERA which assumed a receptor only feeds within an exposure area. The remaining receptors considered in the Step 3a food web models (e.g., robin, marsh wren, meadow vole, shrew) have smaller home ranges and AUFs remained at 1. In these cases, it is assumed that if an animal has a home range that is smaller than the exposure area, there will be one or more individuals inhabiting the exposure area and deriving 100% of its resources from the exposure area. This is a significant uncertainty, and likely to overestimate risk because actual home ranges vary considerably in space and time depending on the actual available resources (including shelter and water) provided by the exposure area. It is unlikely that an individual mobile receptor will be present wholly within the exposure area throughout its lifecycle. In addition, for receptors with home ranges similar in size to the exposure area, no more than one or a few individuals would be expected to occupy the area. This overestimates population level risk, as most members of the local population are not affected by the exposure area. This is particularly true for the on-Project Blue Beach area which encompasses approximately 3.2 acres of open space around active buildings.

Plants and, to a lesser degree, soil, sediment, and aquatic invertebrates are more bound to a single location as they lack mobility and can occur in large numbers and densities over small areas. For this reason, there is less overestimation of risk, although the actual adverse effects would be expected to be highly localized to actual locations with elevated concentrations.

Samples for SEM, AVS, and TOC, sediment toxicity testing, and macroinvertebrate community metrics were collected from within the off-Project tidal stream to further assess the potential for risks to benthic invertebrates. Initially, sediment chemistry samples (e.g., metals, SVOCs, PCBs, etc.) and sediment toxicity testing samples were collected in the fall of 2019. The toxicity test did not meet test acceptability criteria so new samples for toxicity testing were collected in May 2020 from the same locations sampled in 2019. The May 2020 field event also included SEM, AVS, and TOC sampling and macroinvertebrate community sampling. While the sediment chemistry, toxicity testing, and macroinvertebrate community samples are co-located in space (i.e., from the same locations), the sediment chemistry samples were collected more than six months earlier than the toxicity testing and macroinvertebrate community samples. This results in some level of uncertainty associated with the evaluation of these data to identify COPC-related impacts.

An upgradient tidal stream was not accessible for background/reference sampling for the toxicity testing and macroinvertebrate community, so the most upstream portion of the stream located between Circuit Drive and outfall 025 was treated as the upstream background/reference area for the interpretation of the toxicity testing and macroinvertebrate community results. This portion of the stream is upgradient of historical DoD sources and captures

contributions from road runoff and other sources than could discharge into the tidal stream. The conditions in the upper portion of the stream at the time of the macroinvertebrate sampling were much drier than in the downstream portions of the stream that are subject to more tidal influence. In some cases, invertebrate samples in the background/reference area were collected by passing sediment through the kicknet rather than by passing the kicknet through the water. These differences in habitat may result in some differences in the macroinvertebrate community between the areas.

4.6.4 Step 3a Risk Characterization

The Step 3a risk evaluation assessed COPCs and exposure pathways that were carried through the initial conservative screening process. In the Step 3a refinement process, risk calculations were analyzed and interpreted to determine the likelihood of adverse environmental effects, and to determine whether a conclusion of no significant risk can be reached for each assessment endpoint evaluated. The ecological risk characterization summarizes the results of the risk calculations and provides an interpretation of the ecologically significant findings.

Aspects of ecological significance that may be considered to help place sites into a broader ecological context include the nature and magnitude of effects, spatial and temporal patterns of effects, results of the background/reference site analyses, and potential for recovery once a stressor has been removed.

Risk characterization incorporates all available data for the COPCs and pathways. For each assessment endpoint, the risk characterization includes a risk estimate (i.e., the HQ), determination of ecological significance and risk acceptability, and evaluation of the uncertainties.

Two exit criteria were used in selecting a risk management decision for the Site following the completion of Step 3a. These criteria are:

- No further evaluation and no remediation from an ecological perspective are warranted because the Site does not pose unacceptable risk, or
- The Site poses potentially unacceptable ecological risks and the BERA process continues to Step 3b or remediation.

If the characterization results support a “no further evaluation and no remediation” decision, the Site exits the ERA process. The sub-sections below present the risk characterization for the three exposure areas evaluated in Step 3a.

4.6.4.1 On-Project Blue Beach Area Risk Characterization

The assessment endpoints selected for the on-Project Blue Beach Area included the sustainability of local populations of soil invertebrates, plants, birds, and mammals (Section 4.2.3).

Table 4-15 presents the comparison of surface soil EPCs from the on-Project Blue Beach area with soil screening benchmarks protective of soil invertebrates and plants. All COPCs were eliminated based on either low FOD or HQs below 1. Based on this evaluation, no COPCs were retained and no further evaluation is warranted for soil invertebrates or plants in this exposure area.

Table 4-23 summarizes the HQs based on the NOAEL- and LOAEL-based TRVs used in the refined food web model. NOAEL-based HQs were above 1 for the insectivorous American robin (cadmium, lead, Total PCBs) and short-tailed shrew (cadmium and Total PCBs). This food web model assumed that these receptors obtained all of their diet only from earthworms within this exposure area with no off-Site foraging or migration in the winter months. These assumptions are likely to overestimate risks for receptors with may consume a more varied diet and forage elsewhere given that much of the on-Project area includes open areas around buildings that may not be attractive for foraging. None of the LOAEL-based HQs were above 1.

Given the conservative nature of the food web model and the lack of LOAEL-based HQs above 1, the surface soil of the on-Project Blue Beach area does not present an unacceptable risk of adverse effects to wildlife populations. Based on this evaluation, no COPCs were retained and no further evaluation is warranted for birds and mammals in this exposure area.

4.6.4.2 Off-Project Red Maple Swamp/Tidal Stream Area Risk Characterization

The assessment endpoints selected for the off-Project Red Maple Swamp/tidal stream area included the sustainability of local populations of soil invertebrates, plants, benthic invertebrates/shellfish, fish aquatic

invertebrates, birds, and mammals (Section 4.2.3). This exposure area includes surface soil associated with the walking path, hydric soil associated with the Red Maple Swamp, and sediment, surface water, and porewater associated with the tidal stream.

Table 4-15 presented the comparison of surface soil EPCs from the off-Project Red Maple Swamp/tidal stream area against soil screening benchmarks protective of soil invertebrates and plants. The only surface soil COPC identified (Total PCBs) was eliminated based on HQs below 1. **Table 4-16** presented the comparison of surface hydric soil EPCs from the off-Project Red Maple Swamp/tidal stream area against the same soil screening benchmarks. In this comparison, all of the COPCs, except Total PCBs, were eliminated based on either low FOD or HQs below 1. The hydric soil EPC did not exceed the refined plant ESV but did exceed the refined invertebrate ESV based on sediment invertebrates (refined soil-based ESVs were not identified for invertebrates). Based on this evaluation, only Total PCBs in hydric soil warrant further evaluation for potential impacts to invertebrates. Further evaluation of Total PCBs in hydric soil is provided in Section 4.6.4.2.1.

Potential risks to benthic invertebrates were assessed by evaluated COPC concentrations in surface sediment and porewater and through the evaluation of sediment toxicity testing and macroinvertebrate community metrics. The refined surface sediment comparison provided in **Table 4-17** identified only a single COPC with an HQ above 1 when probable effects-based ESVs were considered. Based on this evaluation, Total PCBs in surface sediment warrant further evaluation for potential impacts to invertebrates. The sediment toxicity testing and macroinvertebrate community metrics summarized in **Tables 4-19 and 4-20**, respectively, show some potential for adverse impacts on the benthic community within the tidal stream; however, the source of potential impacts is not identified. Further evaluation of Total PCBs in sediment and further evaluation of the sediment toxicity testing and macroinvertebrate community metrics are provided in Sections 4.6.4.2.1 and 4.6.4.2.2.

The refined porewater evaluation presented in **Table 4-22** identified HQs above 1 when chronic ESVs were considered but not when acute ESVs were considered. As discussed in Section 4.6.2.5, there are some uncertainties associated with the chronic ESVs (more recent barium screening values (RIVM, 2020) are higher than the chronic ESV used in **Table 4-22**), the infrequent detections of the COPCs, and the depth at which porewater was collected (likely to be below the depth where most invertebrates are found). Therefore, it is expected that chronic risks due to porewater exposure are overestimated based on the evaluation of the detected porewater concentrations. Based on this evaluation, no porewater COPCs are retained and no further evaluation is warranted for benthic invertebrates exposed to porewater in this exposure area. It is noted that PCBs were analyzed for and not detected in porewater.

Potential risks to fish and aquatic invertebrates were assessed by evaluated COPC concentrations in surface water. The refined surface water comparison provided in **Table 4-21** identified HQs above 1 when chronic ESVs were considered but not when acute ESVs were considered. As described in Section 4.6.2.4, there are some uncertainties associated with the chronic ESVs (more recent barium screening values are higher than the value used in **Table 4-21**, the carbon disulfide ESV may be overly conservative). Therefore, it is expected that chronic risks to fish and aquatic invertebrates due to surface water exposure are overestimated based on the evaluation of the detected surface water concentrations. Based on this evaluation, no surface water COPCs are retained and no further evaluation is warranted for fish and aquatic invertebrates exposed to surface water in this exposure area.

Table 4-24 summarizes the HQs based on the NOAEL- and LOAEL-based TRVs used in the refined food web model. NOAEL-based HQs were above 1 for the insectivorous marsh wren (copper, lead, selenium, and Total PCBs) and short-tailed shrew (selenium and Total PCBs) and for the herbivorous meadow vole (selenium). This food web model assumed that these receptors obtained all of their diet only from earthworms or plants within this exposure area with no off-Site foraging or migration in the winter months. These assumptions are likely to overestimate risks for receptors which may consume a more varied diet and forage elsewhere. None of the LOAEL-based HQs were above 1.

Given the conservative nature of the food web model and the lack of LOAEL-based HQs above 1, the exposure media within the off-Project Red Maple Swamp/tidal stream area (surface soil, hydric soil, sediment) do not present an unacceptable risk of adverse effects to wildlife populations. Based on this evaluation, no COPCs are retained and no further evaluation is warranted for birds and mammals in this exposure area.

As summarized above, the only COPCs warranting further evaluation in this exposure area are Total PCBs in hydric soil and Total PCBs in sediment from the tidal stream. Additional evaluation of the sediment toxicity testing and macroinvertebrate community metrics from the tidal stream are provided in the following sub-sections.

4.6.4.2.1 Additional Characterization of PCBs in Hydric Soil and Tidal Stream Sediment

Total PCBs were retained as COPCs for invertebrates in hydric soil and tidal stream sediment based on comparisons to refined sediment ESVs. The probable effect-based sediment ESVs were based on freshwater probable effect concentrations (PECs; MacDonald, et al., 2000) and marine effects-range medians (ERMs; Buchman, 2008).

Table 4-25 presents a sample-by-sample comparison of the sediment and hydric soil concentrations relative to these refined ESVs. In general, PCB concentrations in the sediment are lower than in hydric soil and multiple individual samples exceed the PEC and/or ERM.

Recent work by National Oceanic and Atmospheric Administration (NOAA) on PCB toxicity to benthic invertebrates suggests that the bulk sediment-based screening values may be overly conservative. NOAA (2016) demonstrates that the use of a dose-response curve, rather than point estimates, may be more appropriate to quantify the benthic community risks due to PCBs. NOAA (2016) and Finkelstein et al. (2017) present dose response curves for Aroclor 1254 (as a surrogate for total PCBs) based on equilibrium partitioning (EqP) to estimate % injury to benthic invertebrates. A 10% injury to the benthic community was associated with 50.43 mg PCBs/kg organic carbon (OC) and 20% injury was associated with 89 mg PCBs/kg OC (see Table 5 in Finkelstein et al. [2017]).

In **Table 4-25**, the 10% injury concentration was adjusted to reflect the sample-specific TOC of the sediment and hydric soil samples (or the media-specific average when sample-specific TOC data were not available) and these sample-specific benchmarks were used to further evaluate the available PCB data. TOC concentrations ranged from 0.3% up to 44% and the associated 10% injury benchmarks ranged from 0.15 mg/kg to 22.2 mg/kg. Only the Total PCB concentration in the sample with the lowest TOC (SED 5 from 2011) exceeded the 10% injury benchmark. In the remaining samples, adverse impacts on the benthic community would not be expected. SED-335 was collected in 2019 from the same portion of the tidal stream where SED 5 was sampled in 2011 and the TOC level in the SED-335 was much higher (19%) than in SED 5.The average TOC level in the stream sediments was 9.3% so the SED 5 TOC level was unusually low and may not be representative of typical stream conditions.

The sediment and hydric soil results were also generally below sediment quality benchmarks reported by Fuchsman et al. (2006) and normalized to 1% TOC. These screening values were 2.1 mg/kg for Aroclor 1242, 4.9 mg/kg for Aroclor 1248, and 15 mg/kg for Aroclor 1254 (NOAA, 2016). Although screening values were not derived for Aroclor 1260 (the dominant Aroclor in sediment and hydric soil), based on the upward trend of screening values for the other Aroclors, a comparison against Aroclor 1254-based benchmarks is considered adequately protective. All of the sediment and hydric soil PCB results were below the Aroclor 1254 benchmark of 15 mg/kg at 1% TOC.

These results indicate that the risks to benthic receptors are overestimated by the screening level and refined ESVs considered in the SLERA and Step 3a and that risks to the benthic community in the hydric soil of the Red Maple Swamp and the sediment of the tidal stream due to exposure to PCBs are not expected above the USEPA's risk range.

Based on the review of the literature-based screening values, and the nature and extent of the exceedances, it is concluded that the benthic receptors in the off-Project Red Maple Swamp/tidal stream area are not at unacceptable risk due to exposure to PCBs. Alternate screening values identified by NOAA (2016) show that the bulk sediment based ESVs such as the PEC and ERM overestimate risks. When TOC is considered, PCB levels in sediment and hydric soil are below thresholds associated with significant risks to the benthic community.

4.6.4.2.2 Additional Characterization of Biological Sampling in the Tidal Stream

As described in Section 4.6.2.3, sediment toxicity testing and macroinvertebrate community sampling were conducted in May 2020 and the results are summarized in **Tables 4-19 and 4-20**, respectively. Statistical comparisons of toxicity testing endpoints identified differences between some individual off-Project tidal stream samples and individual background/reference samples or laboratory control results. Results for macroinvertebrates community metrics varied with no identified spatial pattern.

A series of statistical correlations were conducted using co-located toxicity testing results, macroinvertebrate community survey results, and sediment chemistry to evaluate the relationships between stressors (e.g., chemicals in sediment) and adverse impact on the biological community. **Attachment J-1** provides a brief summary of the approach and the findings with exports from the statistical software. Parameters selected for the correlation analysis included TOC, % fines (silt + clay), the (∑SEM-AVS)/foc, HQs based on the probable effect ESVs for HMW PAHs and LMW PAHs, freshwater PEC-Quotients (PEC-Qs), and marine ERM-Quotients (ERM-Qs). PEC-Qs and ERM-Qs

were calculated for metals (as the mean PEC-Q or ERM-Q for metals with PECs and ERMs), Total PAHs, and Total PCBs.

The average of the mean PEC-Q for metals, the PEC-Q for Total PAHs, and the PEC-Q for Total PCBs was also included as a value representing metals and organic stressors (referred to as Mean of Total PAHs, Total PCBs, and Mean Metals PEC-Qs). A similar mean ERM-Q was also derived for metals, PAHs, and PCBs (referred to as Mean of Total PAHs, Total PCBs, and Mean Metals ERM-Qs).

A total of five endpoints from the toxicity tests, four macroinvertebrate community metrics, and 17 chemical and physical parameters were subject to a correlation test (Spearman's Rho) to assess if biological responses were related to sediment chemistry or physical data. As summarized in **Attachment J-1 Table 1**, no statistically significant ($p<0.05$) correlations were identified between the chemical or physical stressors and the biological responses. These results indicate an overall lack of correlation between invertebrate toxicity endpoints or macroinvertebrate metrics and chemical concentrations in sediment.

As an additional approach for characterizing potential risks to the benthic invertebrate community, a sediment quality triad evaluation (**Attachment J-2**) was conducted to determine if off-Project Red Maple Swamp/tidal stream sample results for sediment chemistry, toxicity testing, and biological community surveys are impacted compared to upstream reference/background conditions. A reference envelope approach was used for this evaluation to incorporate the spatial and temporal variation observed in the upstream background samples (Hunt et al., 2001). The sediment chemistry and biological results for the five samples located in the upstream background/reference area between Circuit Drive and outfall 025 were used to determine the reference envelope values.

Reference envelope values were derived as lower or upper limits for sediment chemistry, toxicity testing endpoints, and community survey metrics to represent reference conditions. The sediment quality triad approach identified by Chapman (1992) was used to evaluate the potential for sediment COPC-related impacts on the biological community. The sediment quality triad evaluation considered the following endpoints:

- Sediment chemistry – Mean of Total PAHs, Total PCBs, and Mean Metals PEC-Qs and Mean of Total PAHs, Total PCBs, and Mean Metals ERM-Qs as measures of potential adverse impacts based on freshwater and marine benchmarks, respectively
- Sediment Toxicity – Mean Biomass and Reproduction (as Mean Juveniles per Surviving Amphipod) as sensitive measures of impacts in the toxicity tests (these endpoints showed the most frequent individual statistical differences in **Table 4-19**)
- Benthic Macroinvertebrate Community – Total Richness, Total Density, and HBI as measures of diversity and pollution tolerance.

The findings for each element of the triad were interpreted based on a matrix provided by Chapman (1992) and are provided in **Table 4-26**. Based on the categories identified by Chapman (1992) and comparisons to reference envelope values, the sediment quality triad evaluation indicates that:

- None of the samples showed adverse impacts for all three elements of the triad.
- SED-333 did not show adverse impacts relative to the reference envelope values for any of the triad components which, according to Chapman (1992), provides "strong evidence that there is no pollution induced degradation."
- The remaining four samples showed an impact relative to the reference envelope values for at least one element of the triad but did not support an indication of COPC-related benthic invertebrate community impacts.
  - SED-331 and SED-335 showed impacts to the sediment chemistry and toxicity portions of the triad but not to the macroinvertebrate community.
  - SED-339 showed impacts to the toxicity portion of the triad (based on reproduction only) but not to sediment chemistry or macroinvertebrate community.
  - SED-337 showed impacts to the macroinvertebrate community portion of the triad (based on HBI only) but not to sediment chemistry or toxicity.

According to Chapman (1992), the findings for SED-331 and SED-335 suggest that "toxic chemicals are stressing the system." As indicated in **Table 4-17**, Total PCBs were the only COPC retained in the Step 3a refined screening for

tidal stream sediments. A review of Total PCB concentrations in **Table 4-25**, shows that PCBs were not detected in the SED-331 sample and the Total PCB concentration for SED-335 was 1.5 mg/kg (above the PEC and ERM, but well below the sample-specific 10% benthic injury benchmark). In addition, PCBs were analyzed for and not detected in total or dissolved phase porewater collected from five sediment locations in and near the tidal stream in 2011 (data presented in **Attachment A**). These results suggest that PCBs are not likely to be the cause of impacts at these locations (or other locations in the stream).

A review of the PEC-Q and ERM-Qs calculated in **Attachment J-1** show that the quotients based on metals and Total PAHs for these two samples were less than 1, suggesting that these chemicals are not likely to result in adverse impacts to the benthic community. In addition, the SEM, AVS, TOC analysis presented in **Table 4-18** indicated that the divalent metals were not likely to be bioavailable. These two samples did have among the highest TOC levels in the stream, 44% for SED-331 and 19% for SED-335, which suggests samples were collected from depositional areas. Although the sediment quality triad indicated the potential for COPC-related impacts, primarily related to PCBs, the PCB evaluation provided in **Table 4-25** and the lack of statistical correlations between biological responses and PCBs (or other chemical stressors) suggests that observed impacts are not related to Project-related chemicals.

4.6.4.3 Off-Project Narragansett Bay and Beachfront Area Risk Characterization

The assessment endpoints selected for the off-Project Narragansett Bay and Beachfront Area included the sustainability of local populations of benthic invertebrates/shellfish, fish, and aquatic invertebrates (Section 4.2.3).

No surface water COPCs for fish and aquatic invertebrates were identified for this exposure area. Potential risks to benthic invertebrates were assessed by evaluated COPC concentrations in surface sediment and porewater. The refined surface sediment comparison provided in **Table 4-17** did not identify COPCs with HQs above 1 when probable effects-based ESVs were considered.

The refined porewater evaluation presented in **Table 4-22** identified HQs above 1 when chronic ESVs were considered but not when acute ESVs were considered. As discussed in Section 4.6.2.5, there are some uncertainties associated with the chronic ESVs (more recent barium screening values are higher than the value used in **Table 4-22**), the infrequent detections of the COPCs, and the depth at which porewater was collected (likely to be below the depth where most invertebrates are found). Therefore, it is expected that chronic risks due to porewater exposure are overestimated based on the evaluation of the detected porewater concentrations.

Based on the evaluation of surface water (all non-detect), surface sediment, and porewater, no COPCs are retained and no further evaluation is warranted for benthic invertebrates/shellfish, fish, and aquatic invertebrates in this exposure area.

4.6.5 Step 3a Summary and Conclusions

The purpose of Step 3a was to reevaluate those COPCs that were retained in the initial screening process because of the use of overly conservative exposure scenarios. This reevaluation considered alternate EPCs based on the 95% UCL, rather than the maximum detected concentration, refined ESVs and TRVs based on a literature search and applicability to the Project, sediment toxicity testing and macroinvertebrate surveys from the tidal stream, and a discussion of the conservatism and uncertainties associated with several of the direct contact screening values.

Table 4-27 identifies the preliminary COPCs retained from the SLERA and re-evaluated in Step 3a and summarizes the FODs, maximum EPCs and HQs calculated in refined ESV comparisons and food web models. The findings are briefly summarized below:

- **On-Project Blue Beach Area** – No surface soil COPCs were retained based on the refined ESV screening; all COPCs were eliminated based on low FOD or HQs below 1. In the food web model, no HQs above 1 were calculated using the LOAEL-based TRV. The American robin and short-tailed shrew had HQs ranging up to 3.8 using the NOAEL-based TRVs and assuming that all food was obtained from the exposure area. Given the conservative nature of the food web model and the lack of LOAEL-based HQs above 1, the surface soil of the on-Project Blue Beach area does not present an unacceptable risk of adverse effects to wildlife populations.
    - Based on the evaluation of surface soil in the on-Project Blue Beach area, no COPCs are retained and no further evaluation is warranted for plants, soil invertebrates, birds or mammals in this exposure area.

- **Off-Project Red Maple Swamp/Tidal Stream Area** – Total PCBs in hydric soil and sediment were the only COPCs retained based on refined ESV screens. PCBs were further evaluated using EqP-based benchmarks identified by NOAA (2016) which indicate PCBs are not expected to pose an unacceptable risk to the benthic community. A sediment quality triad evaluation identified locations where at least one element of the triad was impacted, but the triad evaluation and supplemental correlation evaluations did not support an indication of COPC-related benthic invertebrate community impacts. COPCs in surface water and porewater were eliminated based on comparisons to chronic and acute ESVs, low FOD, and the uncertainties associated with the ESVs and detected concentrations.

  In the food web model, no HQs above 1 were calculated using the LOAEL-based TRV. The marsh wren, meadow vole, and short-tailed shrew had HQs ranging up to 4.5 using the NOAEL-based TRVs and assuming that all food was obtained from the exposure area. Given the conservative nature of the food web model and the lack of LOAEL-based HQs above 1, the exposure media within the off-Project Red Maple Swamp/tidal stream area (surface soil, hydric soil, sediment) do not present an unacceptable risk of adverse effects to wildlife populations.

  – Based on the evaluation of surface soil, surface hydric soil, surface sediment, surface water, and porewater in the off-Project Red Maple Swamp/tidal stream area, no COPCs are retained and no further evaluation is warranted for plants, soil invertebrates, benthic invertebrates/shellfish, fish, aquatic invertebrates, birds or mammals in this exposure area.

- **Off-Project Narragansett Bay and Beachfront Area** - No surface sediment COPCs were retained based on the refined ESV screening; all COPCs were eliminated based on HQs below 1. COPCs were not identified for surface water in the SLERA based on a lack of detected chemicals. COPCs in porewater were eliminated based on comparisons to chronic and acute ESVs, low FOD, and a discussion of the uncertainties associated with the ESVs and detected concentrations.

  – Based on the evaluation of surface sediment, surface water, and porewater in the off-Project Narragansett Bay and Beachfront area, no COPCs are retained and no further evaluation is warranted for benthic invertebrates/shellfish, fish, or aquatic invertebrates in this exposure area.

Based on the results of the Step 3a evaluation, no COCs were identified for further ecological risk evaluation under CERCLA.

5. Summary and Conclusions

The baseline HHRA and ERA were conducted in support of the RI for the Blue Beach Disposal Area FUDS in North Kingstown, Rhode Island to evaluate potential human health and ecological effects of exposures to chemicals in soil, hydric soil, groundwater, porewater, sediment, and surface water in the Project and/or adjacent off-Project areas, and to determine whether Project-related chemicals in these areas pose a potential cancer risk or noncancer hazard above target levels to human health or the environment. Summaries of the HHRA and ERA are provided separately in this section.

5.1 Human Health Risk Assessment

The purpose of the HHRA is to evaluate whether exposure to Project-related COPCs pose a cancer risk and/or noncancer hazard to human health above USEPA target risk levels. The evaluation included performing a quantitative estimation of potential cancer risk and noncancer hazard to current and potential future human receptors that may come into contact with Site-related chemicals in environmental media within the on-Project Blue Beach area and off-Project areas (i.e., Off-Project Red Maple Swamp/tidal stream area and off-Project Narragansett Bay and Beachfront area), as applicable. The HHRA was conducted in accordance with CERCLA risk assessment guidance and the Project-specific RAWP provided in the SAP (Mabbett, 2019).

The HHRA evaluated potentially complete exposure pathways for human receptors identified based on current and reasonable future land-use scenarios in accordance with the Site CSM. The HHRA quantitatively evaluated exposure to surface soil, subsurface soil groundwater (all depths), shallow groundwater, sediment, surface water, and soil vapor, as applicable, for an RME scenario. Based on the current and future land use, the following human receptors were evaluated in the HHRA:

- Current/Future Construction/Utility Worker
- Current/Future Outdoor Worker
- Current/Future Trespasser (adolescent)
- Current/Future Recreational User (adult/child)
- Future Indoor Worker

The HHRA evaluated the following exposure pathways, as applicable for each receptor:

- exposure to soil through incidental ingestion, dermal contact, and inhalation of fugitive dust and volatiles in outdoor air;
- exposure to shallow groundwater through incidental ingestion, dermal contact, and inhalation of volatiles in an excavation trench;
- exposure to hydric surface soil, sediment, and surface water in the off-Project Red Maple Swamp/tidal stream area through incidental ingestion and dermal contact; and
- exposure to soil vapor in the on-Project Blue Beach area via the vapor intrusion pathway.

A hypothetical future residential scenario, including use of groundwater as a source of potable water, was also conservatively evaluated in the HHRA to represent a UU/UE scenario for informational purposes and for use in a forthcoming FS, if needed. However, residential use is not a reasonably anticipated future use of the Site. There are currently no residents located on the Project area and it is not zoned for residential use. In the unlikely event that the Project area is converted to residential use in the future, it is not reasonable to expect that the residents would use groundwater as a potable water source. Groundwater underlying the Site is not used for drinking water or other potable use and there is an ELUR recorded on the deed that prohibits potable use of groundwater from the on-Project Blue Beach area. Additionally, based on its proximity to Narragansett Bay and wetlands, groundwater is likely to be brackish, and the extraction of groundwater to serve as a water source (or to treat) would likely draw additional saline water into the system and would, therefore, not be implementable.

The cumulative potential ELCR and noncancer HI for each exposure scenario were evaluated in comparison to USEPA's target risk range of 10^{-6} to 10^{-4} and target HI of 1 (per target organ). For each associated exposure scenario (i.e., area/receptor/medium) with a potential risk/HI above USEPA target levels, risk drivers were selected from those COPCs significantly contributing to an individual ELCR > 10^{-4} or target organ HI > 1 (at one significant figure), specifically, COPCs with an individual ELCR > 10^{-6} or HI > 1. These risk drivers are selected as COCs for the associated medium/receptor/exposure scenario.

A summary of the potential ELCR and HI results for each of the receptors evaluated in the HHRA is presented in **Table 3-11**. In summary, the conclusions of the HHRA indicate that the cumulative potential ELCRs do not exceed USEPA's target ELCR range of 10^{-6} to 10^{-4} and the total potential HIs per target endpoint do not exceed USEPA's target HI of 1 for the current/future construction worker, current/future outdoor worker, current/future trespasser, and future indoor worker in the on-Project Blue Beach area; or the current/future recreational user in the off-Project Red Maple Swamp/tidal stream area. Therefore, no COCs were identified for these receptors.

5.2 Ecological Risk Assessment

The purpose of the ERA is to evaluate the potential adverse environmental effects of Project-related COPCs on ecological receptors and resources at or near the Project. The ERA included a screening level ERA (SLERA), which is considered the first tier of the ecological risk process (i.e., Steps 1 and 2) and, in cases where the SLERA indicated sufficient potential ecological risk, the COPCs were further evaluated in a sub-tier of the BERA (referred to as Step 3a).

The ERA evaluated the following potentially complete exposure pathways for terrestrial receptors in the on-Project Blue Beach exposure area:

- Terrestrial Invertebrates – exposed to surface soil through ingestion and direct contact;
- Terrestrial Plants – exposed to surface soil through root uptake; and
- Birds and Mammals – exposed to surface soil through incidental ingestion and to food items which may have bioaccumulated Project-related COPCs.

The following exposure pathways were evaluated for the wetland portions of the off-Project Red Maple Swamp/tidal stream area:

- Soil Invertebrates – exposed to hydric soil through ingestion and direct contact;
- Wetland Plants – exposed to hydric soil through root uptake; and
- Birds and Mammals – exposed to surface soil, hydric soil, and sediment within the off-Project Red Maple Swamp/tidal stream area through incidental ingestion and to food items which may have bioaccumulated Project-related COPCs.

The following additional exposure pathways were evaluated for the aquatic portions of the Project found in the off-Project Red Maple Swamp/tidal stream area and off-Project Narragansett Bay and Beachfront area:

- Benthic Invertebrates – exposed to sediment and porewater through ingestion and direct contact; and
- Aquatic Fish and Invertebrates – exposed to surface water through ingestion and direct contact.

These exposure pathways were evaluated through the comparison of surface soil, hydric soil, sediment, surface water, and porewater analytical data to media-specific ESV and through conservative food web modeling to avian and mammalian receptors. Consistency with background conditions was also considered as part of the COPC selection process. As indicated in **Table 4-14**, the SLERA identified COPCs in all media and exposure areas. Therefore, the SLERA SMDP indicated that additional evaluation was warranted in Step 3a, the first step of the BERA.

The purpose of Step 3a is to reevaluate COPCs that were retained in the SLERA for further evaluation, and to identify and eliminate from further consideration those COPCs that were retained because of the use of conservative exposure scenarios. In Step 3a, the SLERA risk estimates were recalculated using less conservative but more realistic assumptions including refined EPCs, ESVs, and TRVs. Step 3a uses the same representative species and exposure pathways, but with refined, central tendency exposure assumptions to more realistically estimate the

potential risk to ecological receptors from COPCs that failed the conservative SLERA screening process. Additional field efforts conducted to support the evaluation of the benthic community in the tidal stream (i.e., SEM, AVS, TOC, sediment toxicity testing, macroinvertebrate community sampling) were also considered.

As summarized in **Table 4-27**, nearly all of the HQs based on the refined ESVs were less than 1 indicating no need for further evaluation for the majority of the COPCs. COPCs in surface water and porewater were eliminated based on comparisons to chronic and acute ESVs, low FOD, and a discussion of the uncertainties associated with the ESVs and detected concentrations.

In the food web models for the on-Project Blue Beach area and the off-Project Red Maple Swamp/tidal stream area, all of the LOAEL-based HQs were less than 1. NOAEL-based HQs were greater than 1 for some COPCs, primarily for insectivorous receptors, with a maximum HQ of 3.8 for lead (American Robin) in the on-Project Blue Beach area. Given the conservative nature of the food web models (small birds and mammals were assumed to obtain diet only from the exposure areas) and the lack of LOAEL-based HQs above 1, the COPC concentrations in these two exposure areas do not present an unacceptable risk of adverse effects to wildlife populations.

Total PCBs in hydric soil and sediment in the off-Project Red Maple Swamp/tidal stream area were the only COPCs retained based on refined ESV screens. PCBs were further evaluated using EqP-based benchmarks identified by NOAA (2016) which indicate PCBs are not expected to pose a risk to the benthic community. A sediment quality triad evaluation identified locations where at least one element of the triad was impacted, but the triad evaluation and supplemental correlation evaluations did not support an indication of COPC-related benthic invertebrate community impacts.

Based on the Step 3a evaluation of surface soil, surface hydric soil, surface sediment, surface water, and porewater in the on-Project Blue Beach area, the off-Project Red Maple Swamp/tidal stream area, and the off-Project Narragansett Bay and Beachfront area, no COPCs are retained and no further evaluation is warranted for plants, soil invertebrates, benthic invertebrates/shellfish, fish, aquatic invertebrates, birds or mammals in these exposure areas. No COCs were identified for further evaluation under CERCLA.

				Trespasser	Adolescent (ages 7-<16)	Ingestion	Quant	Trespassers may access the area and incidentally ingest subsurface soil under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
						Dermal	Quant	Trespassers may access the area and come into contact with subsurface soil under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
				Hypothetical Resident	Adult	Ingestion	Quant	Residents may incidentally ingest soil under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
						Dermal	Quant	Residents may come into contact with soil under a hypothetical future scenario in which the ELUR is removed and area is redeveloped for residential use.
					Child	Ingestion	Quant	Residents may incidentally ingest soil under a hypothetical future scenario in which the area is redeveloped for residential use.
						Dermal	Quant	Residents may come into contact with soil under a hypothetical future scenario in which the area is redeveloped for residential use.
			Off-Project Red Maple Swamp/Tidal Stream Area (Walking Path) (c)	Recreational User	Adult	Ingestion	Quant	Recreational users may incidentally ingest subsurface soil along the walking path under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
						Dermal	Quant	Recreational users may come into contact with subsurface soil along the walking path under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
					Child	Ingestion	Quant	Recreational users may incidentally ingest subsurface soil along the walking path under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
						Dermal	Quant	Recreational users may come into contact with subsurface soil along the walking path under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
		Fugitive Dust/Particulates and Volatiles Originating from Subsurface Soil (1 - 15 feet) (a)	On-Project Blue Beach Area	Outdoor Worker	Adult	Inhalation	Quant	The site is located in an area designated for light industrial use; Outdoor workers may inhale airborne particulates/fugitive dust and volatiles originating from subsurface soil while performing work outdoors under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
				Trespasser	Adolescent (ages 7-<16)	Inhalation	Quant	Trespassers may access the area and inhale airborne particulates/fugitive dust and volatiles originating from subsurface soil under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
				Hypothetical Resident	Adult	Inhalation	Quant	Residents may inhale airborne particulates/fugitive dust and volatiles originating from soil under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
					Child	Inhalation	Quant	Residents may inhale airborne particulates/fugitive dust and volatiles originating from soil under a hypothetical future scenario in which the area is redeveloped for residential use.
			Off-Project Red Maple Swamp/Tidal Stream Area (Walking Path) (c)	Recreational User	Adult	Inhalation	Quant	Recreational users may inhale airborne particulates/fugitive dust and volatiles originating from subsurface soil along the walking path under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.
					Child	Inhalation	Quant	Recreational users may inhale airborne particulates/fugitive dust and volatiles originating from subsurface soil along the walking path under a potential future scenario in which it is brought to the surface as a result of redevelopment activities.

TABLE 3-1
SELECTION OF EXPOSURE PATHWAYS
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Future	Hydric Soil	Subsurface Hydric Soil (1 - 2 feet)	Off-Project Red Maple Swamp/Tidal Stream Area	Recreational User	Adult	Ingestion	Quant	Redevelopment activities are not considered to occur in this area; therefore, hydric subsurface soil is not likely to be available for exposure. However, hydric subsurface soil was evaluated through the COPC selection and EPC calculation steps of the HHRA.
						Dermal	Quant	Redevelopment activities are not considered to occur in this area; therefore, hydric subsurface soil is not likely to be available for exposure. However, hydric subsurface soil was evaluated through the COPC selection and EPC calculation steps of the HHRA.
					Child	Ingestion	Quant	Redevelopment activities are not considered to occur in this area; therefore, hydric subsurface soil is not likely to be available for exposure. However, hydric subsurface soil was evaluated through the COPC selection and EPC calculation steps of the HHRA.
						Dermal	Quant	Redevelopment activities are not considered to occur in this area; therefore, hydric subsurface soil is not likely to be available for exposure. However, hydric subsurface soil was evaluated through the COPC selection and EPC calculation steps of the HHRA.
	Groundwater	Shallow Groundwater (b)	On-Project Blue Beach Area	Construction/Utility Worker	Adult	Ingestion	Quant	Construction and/or utility activities may occur, leading to incidental ingestion of shallow groundwater.
						Dermal	Quant	Construction and/or utility activities may occur, leading to direct contact with shallow groundwater.
		Trench Air				Inhalation	Quant	Construction and/or utility activities may occur, leading to inhalation of volatiles originating from shallow groundwater that accumulates in an excavation trench.
		Groundwater	On-Project Blue Beach Area	Hypothetical Resident	Adult	Ingestion	Quant	Residents may ingest groundwater as drinking water under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
						Dermal	Quant	Residents may come into contact with groundwater used for bathing/showering under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
					Child	Ingestion	Quant	Residents may ingest groundwater as drinking water under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
						Dermal	Quant	Residents may come into contact with groundwater used for bathing/showering under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
		Shower Air	On-Project Blue Beach Area	Hypothetical Resident	Adult	Inhalation	Quant	Residents may inhale volatiles originating from groundwater used for bathing/showering under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
					Child	Inhalation	Quant	Residents may inhale volatiles originating from groundwater used for bathing/showering under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
	Soil Vapor	Indoor Air	On-Project Blue Beach Area	Hypothetical Resident	Adult	Inhalation	Quant	Residents may inhale volatiles in indoor air originating from soil vapor, via the vapor intrusion pathway, under a hypothetical future scenario in which the ELUR is removed and the area is redeveloped for residential use.
					Child	Inhalation	Quant	
				Indoor Worker	Adult	Inhalation	Quant	Current buildings have vapor barriers installed making the vapor intrusion pathway incomplete under a current scenario. Future indoor workers may inhale volatiles in indoor air originating from soil vapor, via the vapor intrusion pathway, under a hypothetical future scenario in which new commercial/industrial buildings are constructed without vapor intrusion mitigation systems.

Notes:
ELUR - Environmental land-use restriction; An ELUR prohibiting residential use and potable use of groundwater within the on-Project Blue Beach Area has been recorded. However, this scenario is being evaluated to represent a unlimited use/unrestricted exposure (UU/UE) scenario for informational purposes. See further discussion in the report text.
None - Exposure scenario is considered incomplete or insignificant and is not quantitatively evaluated in the human health risk assessment.
Quant - Exposures quantitatively evaluated in the human health risk assessment.
(a) This soil depth interval includes one soil sample collected from a depth of 14.25 to 15.5 feet below ground surface.
(b) Shallow groundwater is defined in this Human Health Risk Assessment as the top 15 feet below ground surface. However, three samples with a sampling interval of less than 15 feet to 16 feet below ground surface were also included as being representative of shallow groundwater.
(c) This scenario includes two soil samples in the Red Maple Swamp/tidal stream area to the west of the walking path.

TABLE 3-2.1
OCCURRENCE, DISTRIBUTION AND SELECTION OF PRELIMINARY CHEMICALS OF POTENTIAL CONCERN - SURFACE SOIL
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future
Medium:	Soil
Exposure Medium:	Surface Soil (0 - 1 foot)

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Residential RSL (NC/C) (4)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	Preliminary COPC Flag (Y/N) (5)	Rationale for Selection or Deletion (6)	Background Value (7)	Exceed BTV? (Y/N)	Industrial RSL (NC/C) (8)	Exceed Industrial RSL? (Y/N)

Notes:

Refer to Attachment A for analytical data tables and summary of samples within each area.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

BTV = Background Threshold Value.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential nutrient.

ft = Feet.

L = Lead screening levels developed by USEPA using blood-lead modeling based on target blood lead concentration of 5 micrograms per deciliter (ug/dL).

mg/kg = Milligrams per kilogram.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

RSL = Regional Screening Level.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags. J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
Total PCB results for the on-Project Blue Beach area are associated with soil samples collected from three sampling units (SUs) using an incremental sampling methodology (ISM). Summary statistics were calculated following resolution of triplicate ISM samples per SU with the SU-specific concentration equal to the 95 percent upper confidence limit (UCL) concentration (95% UCL) (calculated using the ISM calculator). The SU-specific 95% UCL, which is higher than the SU-specific maximum detected concentration, is selected as a conservative concentration for purposes of COPC selection.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) Screening levels are equal to the USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2020).
The following surrogates were used for chemicals without available screening levels or with multiple forms:
The value for cadmium in the diet was used for cadmium.
The value for trivalent chromium was used for chromium.
The value for manganese non-diet was used for manganese.
The value for mercuric chloride was used for mercury.
The value for Aroclor-1254 was used for total PCBs.
The value for acenaphthene was used for acenaphthylene.
The value for pyrene was used for benzo(g,h,i)perylene and phenanthrene.
The value for isopropylbenzene (cumene) was used for 4-isopropyltoluene.

(5) Preliminary COPCs are selected as chemicals detected at concentrations greater than residential soil RSLs.

(6) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

(7) Equal to the Background Threshold Value (BTV) calculated for chemicals identified as preliminary COPCs within the associated medium and exposure point (area), as described in the report text.

(8) A comparison to the USEPA industrial soil RSLs (based on a target risk level of 1E-6 and target hazard quotient of 0.1) (May 2020) is also provided for informational purposes. Surrogates for chemicals without available industrial soil RSLs are consistent with those described in footnote (5). Industrial soil RSLs are not utilized for COPC selection..

Notes:

Refer to Attachment A for analytical data tables and summary of samples within each area. *This soil depth interval includes one soil sample collected from a depth of 14.25 to 15.5 feet below ground surface.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

BTV = Background Threshold Value.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential nutrient.

ft = Feet.

L = Lead screening levels developed by USEPA using blood-lead modeling based on target blood lead concentration of 5 micrograms per deciliter (ug/dL).

mg/kg = Milligrams per kilogram.

TABLE 3-2.2
OCCURRENCE, DISTRIBUTION AND SELECTION OF PRELIMINARY CHEMICALS OF POTENTIAL CONCERN - SUBSURFACE SOIL
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe: Current/Future
Medium: Soil
Exposure Medium: Subsurface Soil (1 - 15 feet) *

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Residential RSL (NC/C) (4)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	Preliminary COPC Flag (Y/N) (5)	Rationale for Selection or Deletion (6)	Background Value (7)	Exceed BTV? (Y/N)	Industrial RSL (NC/C) (8)	Exceed Industrial RSL? (Y/N)

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

RSL = Regional Screening Level.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags. J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.
Total PCB results for the on-Project Blue Beach area are associated with soil samples collected from three sampling units (SUs) using an incremental sampling methodology (ISM). Summary statistics were calculated following resolution of triplicate ISM samples per SU with the SU-specific concentration equal to the 95 percent upper confidence limit (UCL) concentration (95% UCL) (calculated using the ISM calculator). The SU-specific 95% UCL, which is higher than the SU-specific maximum detected concentration, is selected as a conservative concentration for purposes of COPC selection.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) Screening levels are equal to the USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2020).
The following surrogates were used for chemicals without available screening levels or with multiple forms:
The value for cadmium in the diet was used for cadmium.
The value for trivalent chromium was used for chromium.
The value for manganese non-diet was used for manganese.
The value for mercuric chloride was used for mercury.
The value for Aroclor-1254 was used for total PCBs.
The value for pyrene was used for benzo(g,h,i)perylene and phenanthrene.
The value for isopropylbenzene (cumene) was used for 4-isopropyltoluene.

(5) Preliminary COPCs are selected as chemicals detected at concentrations greater than residential soil RSLs.

(6) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

(7) Equal to the Background Threshold Value (BTV) calculated for chemicals identified as preliminary COPCs within the associated medium and exposure point (area), as described in the report text.

(8) A comparison to the USEPA industrial soil RSLs (based on a target risk level of 1E-6 and target hazard quotient of 0.1) (May 2020) is also provided for informational purposes. Surrogates for chemicals without available industrial soil RSLs are consistent with those described in footnote (5). Industrial soil RSLs are not utilized for COPC selection..

TABLE 3-2.3
OCCURRENCE, DISTRIBUTION AND SELECTION OF PRELIMINARY CHEMICALS OF POTENTIAL CONCERN - SURFACE HYDRIC SOIL
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future
Medium:	Hydric Soil
Exposure Medium:	Surface Hydric Soil (0 - 1 feet)

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Residential RSL (NC/C) (4)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	Preliminary COPC Flag (Y/N) (5)	Rationale for Selection or Deletion (6)	Background Value (7)	Exceed BTV? (Y/N)

Notes:

Refer to Attachment A for analytical data tables and summary of samples.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

BTV = Background Threshold Value.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential nutrient.

ft = Feet.

L = Lead screening levels developed by USEPA using blood-lead modeling based on target blood lead concentration of 5 micrograms per deciliter (ug/dL).

mg/kg = Milligrams per kilogram.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags. J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) Screening levels are equal to the USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2020).

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in the diet was used for cadmium.

The value for trivalent chromium was used for chromium.

The value for manganese non-diet was used for manganese.

The value for mercuric chloride was used for mercury.

The value for Aroclor-1254 was used for total PCBs.

The value for acenaphthene was used for acenaphthylene.

The value for pyrene was used for benzo(g,h,i)perylene and phenanthrene.

(5) Preliminary COPCs are selected as chemicals detected at concentrations greater than residential soil RSLs.

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

(7) Equal to the Background Threshold Value (BTV) calculated for chemicals identified as preliminary COPCs within the associated medium and exposure point (area), as described in the report text.

TABLE 3-2.5
OCCURRENCE, DISTRIBUTION AND SELECTION OF PRELIMINARY CHEMICALS OF POTENTIAL CONCERN - GROUNDWATEF
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Future
Medium:	Groundwater
Exposure Medium:	Groundwater

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Background Value (4)	Screening Toxicity Value (NC/C) (5)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	Preliminary COPC Flag (Y/N) (6)	Rationale for Selection or Deletion (7)

Notes:

Refer to Attachment A for analytical data tables and summary of samples.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential nutrient.

MCL = USEPA Maximum Contaminant Level (http://www.epa.gov/safewater/contaminants/index.html, accessed September 2020).

ug/L = Micrograms per liter.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) A background dataset is not available for groundwater.

(5) Screening levels are equal to the USEPA Regional Screening Level (RSL) for tapwater based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2020).

Value for lead is the Safe Drinking Water Act (SDWA) action level, presented on the USEPA MCL table.

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in water was used for cadmium.

The value for trivalent chromium was used for chromium.

The value for manganese non-diet was used for manganese.

The value for mercuric chloride was used for mercury.

The value for pyrene was used for benzo(g,h,i)perylene and phenanthrene.

The value for isopropylbenzene (cumene) was used for 4-isopropyltoluene.

(6) Chemicals detected at concentrations greater than either the screening toxicity level or ARAR are selected as preliminary COPCs.

(7) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

TABLE 3-2.6
OCCURRENCE, DISTRIBUTION AND SELECTION OF PRELIMINARY CHEMICALS OF POTENTIAL CONCERN - SHALLOW GROUNDWATER
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Future
Medium:	Groundwater
Exposure Medium:	Shallow Groundwater

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Background Value (4)	Screening Toxicity Value (NC/C) (5)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	Preliminary COPC Flag (Y/N)	Rationale for Selection or Deletion (6)

Notes:

Refer to Attachment A for analytical data tables and summary of samples.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential nutrient.

MCL = USEPA Maximum Contaminant Level (http://www.epa.gov/safewater/contaminants/index.html, accessed September 2020).

ug/L = Micrograms per liter.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) A background dataset is not available for groundwater.

(5) Screening levels are equal to the USEPA Regional Screening Level (RSL) for tapwater based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2020).

Value for lead is the Safe Drinking Water Act (SDWA) action level, presented on the USEPA MCL table.

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in water was used for cadmium.

The value for trivalent chromium was used for chromium.

The value for manganese non-diet was used for manganese.

The value for mercuric chloride was used for mercury.

The value for pyrene was used for benzo(g,h,i)perylene and phenanthrene.

The value for isopropylbenzene (cumene) was used for 4-isopropyltoluene.

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

TABLE 3-2.7
OCCURRENCE, DISTRIBUTION AND SCREENING EVALUATION FOR THE SHALLOW GROUNDWATER TO INDOOR AIR (VAPOR INTRUSION) PATHWAY
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe	Future
Medium:	Groundwater
Exposure Medium:	Shallow Groundwater (Vapor Intrusion to Indoor Air)

Exposure Point	CAS Number	Chemicals	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Background Value (4)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	Residential VISL (NC/C) (5)	Exceed Residential VISL? (Y/N)	Industrial VISL (NC/C) (5)	Exceed Industrial VISL? (Y/N)

Notes:

Refer to Attachment A for analytical data tables and summary of samples.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

ug/L = Micrograms per liter.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VISL = Vapor Intrusion Screening Level.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) A background dataset is not available for groundwater.

(5) Groundwater screening levels were obtained from the USEPA Vapor Intrusion Screening Level (VISL) calculator (May 2020) for a residential and industrial scenario based on a target risk of 1E-6 for carcinogens and a target hazard of 0.1 for noncarcinogens. Only chemicals detected in shallow groundwater that are indicated as being sufficiently volatile by the USEPA VISL calculator are included.

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for elemental mercury was used for mercury.

The value for 1,1-dichloroethene was used for cis-1,2-dichloroethene.

The value for isopropylbenzene (cumene) was used for 4-isopropyltoluene.

TABLE 3-2.8
OCCURRENCE, DISTRIBUTION AND SELECTION OF PRELIMINARY CHEMICALS OF POTENTIAL CONCERN - SEDIMENT
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future
Medium:	Sediment
Exposure Medium:	Sediment

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Screening Toxicity Value (NC/C) (4)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	Preliminary COPC Flag (Y/N)	Rationale for Selection or Deletion (5)	Background Value (6)	Exceed BTV? (Y/N)

Notes:

Refer to Attachment A for analytical data tables and summary of samples within each area.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

BTV = Background Threshold Value.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential Nutrient.

L = Lead screening levels developed by USEPA using blood-lead modeling based on target blood lead concentration of 5 micrograms per deciliter (ug/dL). Soil screening level was conservatively used for sediment.

mg/kg = Milligrams per kilogram.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) Screening levels are equal to the USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1E-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2020).

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in the diet was used for cadmium.

The value for trivalent chromium was used for chromium.

The value for manganese non-diet was used for manganese.

The value for mercuric chloride was used for mercury.

The value for Aroclor-1254 was used for total PCBs.

The value for acenaphthene was used for acenaphthylene.

The value for fluorene was used for carbazole.

The value for pyrene was used for benzo(g,h,i)perylene and phenanthrene.

(5) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

(6) Equal to the Background Threshold Value (BTV) calculated for chemicals identified as preliminary COPCs within the associated medium and exposure point (area), as described in the report text.

Notes:

Refer to Attachment A for analytical data tables and summary of samples within each area.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

AWQC = USEPA National Recommended Ambient Water Quality Criteria (https://www.epa.gov/wqc/national-recommended-water-quality-criteria-human-health-criteria-table, accessed September 2020). Value for Human Health for the consumption of water and organisms.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

ug/L = Micrograms per liter.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) A background dataset is not available for surface water.

(5) Screening levels are equal to the USEPA Regional Screening Level for Tapwater. May 2020. Values based on a target risk level of 1E-6 and a target hazard quotient of 0.1 to account for cumulative effects on the same target organ.

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in water was used for cadmium.

The value for trivalent chromium was used for chromium.

Value for lead is the Safe Drinking Water Act (SDWA) action level, as presented on the USEPA Maximum Contaminant Level (MCL) Table (https://www.epa.gov/ground-water-and-drinking-water/national-primary-drinking-water-regulations, accessed September 2020).

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

(7) Value for 1,2,4-trichlorobenzene used as a surrogate for 1,2,3-trichlorobenzene.

TABLE 3-2.10
OCCURRENCE, DISTRIBUTION AND SELECTION OF PRELIMINARY CHEMICALS OF POTENTIAL CONCERN - SOIL VAPOF
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe Future
Medium: Soil Vapor
Exposure Medium: Soil Vapor

Exposure Point	CAS Number	Chemicals	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Background Value (4)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	Residential VISL (NC/C) (5)	Preliminary COPC Flag (Y/N)	Rationale for Selection or Deletion (6)	Industrial VISL (NC/C) (5)	Exceed Industrial VISL? (Y/N) (7)

Notes:

Refer to Attachment A for analytical data tables and summary of samples.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

ug/m^3 = Micrograms per cubic meter.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

USEPA = United States Environmental Protection Agency.

VISL = Vapor Intrusion Screening Level.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) A background dataset is not available for soil vapor.

(5) Soil vapor screening levels were obtained from the USEPA Vapor Intrusion Screening Level (VISL) calculator (May 2020) for a residential scenario based on a target risk of 1E-6 for carcinogens and a target hazard of 0.1 for noncarcinogens.

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for toluene was used for 4-ethyl toluene.

The value for 1,1-dichloroethene was used for cis-1,2-dichloroethene and trans-1,2-dichloroethene.

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); No Available Screening Level (NSL)

(7) A comparison to the USEPA VISLs for an industrial scenario (based on a target risk level of 1E-6 and target hazard quotient of 0.1) (May 2020) is also provided for informational purposes. Surrogates for chemicals without available industrial soil RSLs are consistent with those described in footnote (5). Industrial VISLs are not utilized for COPC selection..

TABLE 3-2.11
SELECTION OF CHEMICALS OF POTENTIAL CONCERN
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Exposure Media	Exposure Point	CAS Number	Preliminary COPCs (1)	Background Evaluation Results (2)			Final Site-Related COPC? (4)
				BTV Comparison (3)	Hypothesis Test	Geochemical Analysis	

Notes:

-- = Associated background evaluation step not performed because a background dataset is not available for the associated media/analyte, because the associated COPC was eliminated in a previous tier of background evaluation, or because the associated test (i.e., geochemical analysis) is not available for the analyte (i.e., non-metals).

BTV = Background Threshold Value.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

N = No.

N/A = Not Available/Applicable.

NCOPC = Chemical identified as being present at concentrations less than or consistent with background, and is therefore, considered not to be a site-related COPC.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

VOCs = Volatile organic compounds.

Y = Yes.

(1) Preliminary COPCs selected based on comparison to human health screening levels (performed in Tables 2.1 through 2.10) were further evaluated in conjunction with background data, as available.

(2) BTVs, hypothesis testing and geochemical analysis are presented in Attachment D.

(3) The comparisons of the maximum detected concentration for each area/medium/depth interval to the medium-specific BTVs is provided for surface soil, subsurface soil, hydric surface soil, hydric subsurface soil, and sediment in the preliminary COPC selection tables; Tables 2.1, 2.2, 2.3, 2.4, and 2.8, respectively.

(4) Preliminary COPCs for which an appropriate background dataset is not available or which were not identified as being consistent with background (in the associated area/medium/depth interval) are selected as site-related COPCs for further evaluation in the human health risk assessment.

(5) Analyte was either not detected or not detected at a high enough frequency in the background samples to calculate a BTV.

(6) Analyte was not detected at a high enough frequency in the site dataset to perform the hypothesis test.

								Value	Units	Statistic (4)	Rationale (5)

Notes:
% = percent.
CAS = Chemical Abstracts Service.
COPC = Chemical of potential concern.
EPC = Exposure point concentration
ISM = Incremental Sampling Methodology
ITRC ISM calculator = Interstate Technology & Regulatory Council Incremental Sampling Methodology Calculator. 2012. (https://www.itrcweb.org/GuidanceDocuments/ISM-1_2012_with_Clarifications.pd
mg/kg = Milligrams per kilogram.
N/A = Not Available/Applicable.
PCBs = Polychlorinated biphenyls
SU = Sampling unit.
SVOCs = Semivolatile organic compounds.
UCL = Upper confidence limit.
USEPA = United States Environmental Protection Agency

(1) Arithmetic means were calculated as follows:
Total PCB results for the on-Project Blue Beach area are associated with ISM soil samples collected from three SUs. The value is equal to the arithmetic mean concentration of the SU-specific 95% UCLs calculated using the ITRC ISM calculator (presented in Attachment C).
For all other COPCs, where there is at least one non-detect, the value is equal to the Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software referenced in footnote (2). For datasets in which there are 100% detected results, a KM mean can not be calculated, and the mean of the detected results is used.

(2) UCLs were calculated as follows:
Total PCB results for the on-Project Blue Beach area are associated with ISM soil samples collected from three SUs. The value is equal to the weighted mean concentration of the SU-specific UCLs based on SU size (acreage). SU-specific UCLs are equal to the 95% UCL (calculated using the ITRC ISM calculator, presented in Attachment C).
For all other COPCs, UCL calculations were performed using USEPA's ProUCL software version 5.1.002. For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed.
NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; N/A = Not applicable; NC = Not calculated.

(3) Equal to the maximum detected concentration.
Total PCB results for the on-Project Blue Beach area are associated with ISM soil samples collected from three SUs. The value is equal to the maximum concentration of the SU-specific 95% UCLs calculated using the ITRC ISM calculator (presented in Attachment C).

(4) Refer to ProUCL output in Attachment B for the selected UCL and the ProUCL Version 5.1 User Guide (USEPA, 2015) for further information regarding each method.
Maximum Concentration = Maximum detected concentration.

(5) The UCL suggested by ProUCL is used, unless otherwise noted.
(a) For total PCB results for the on-Project Blue Beach area, the weighted mean UCL concentration [described in footnote (2)] is usec
(b) Maximum detected concentration used as the EPC due to the low number of detections

								Value	Units	Statistic (4)	Rationale (5)

Notes:

*This soil depth interval includes one soil sample collected from a depth of 14.25 to 15.5 feet below ground surface

% = percent.

CAS = Chemical Abstracts Service.

EPC = Exposure point concentration

ISM = Incremental Sampling Methodology

ITRC ISM calculator = Interstate Technology & Regulatory Council Incremental Sampling Methodology Calculator. 2012. (https://www.itrcweb.org/GuidanceDocuments/ISM-1_2012_with_Clarifications.pd

mg/kg = Milligrams per kilogram.

PCBs = Polychlorinated biphenyls

SU = Sampling unit.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

USEPA = United States Environmental Protection Agency

VOCs = Volatile organic compounds.

(1) Arithmetic means were calculated as follows:

Total PCB results for the on-Project Blue Beach area are associated with ISM soil samples collected from three SUs. The value is equal to the arithmetic mean concentration of the SU-specific 95% UCLs calculated using the ITRC ISM calculator (presented in Attachment C).

For all other COPCs, where there is at least one non-detect, the value is equal to the Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software referenced in footnote (2). For datasets in which there are 100% detected results, a KM mean can not be calculated, and the mean of the detected results is used.

(2) UCLs were calculated as follows:

Total PCB results for the on-Project Blue Beach area are associated with ISM soil samples collected from three SUs. The value is equal to the weighted mean concentration of the SU-specific UCLs based on SU size (acreage). SU-specific UCLs are equal to the 95% UCL (calculated using the ITRC ISM calculator, presented in Attachment C).

For all other COPCs, UCL calculations were performed using USEPA's ProUCL software version 5.1.002. For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed.

NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; N/A = Not applicable; NC = Not calculated.

(3) Equal to the maximum detected concentration.

Total PCB results for the on-Project Blue Beach area are associated with ISM soil samples collected from three SUs. The value is equal to the maximum concentration of the SU-specific 95% UCLs calculated using the ITRC ISM calculator (presented in Attachment C).

J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Refer to ProUCL output in Attachment B for the selected UCL and the ProUCL Version 5.1 User Guide (USEPA, 2015) for further information regarding each method.

Maximum Concentration = Maximum detected concentration.

(5) The UCL suggested by ProUCL is used, unless otherwise noted.

(a) For total PCB results for the on-Project Blue Beach area, the weighted mean UCL concentration [described in footnote (2)] is used.

(b) Maximum detected concentration used for EPC. ProUCL does not provide a recommended UCL due to the low number of detections.

(c) Naphthalene was analyzed via both SVOC and VOC methods. The higher of the EPCs (i.e., the EPC presented for the VOC method) is the selected EPC for further evaluation of naphthalene in subsurface soil within the off-Project Red Maple Swamp / tidal stream area in the risk assessment.

TABLE 3-3.5

EXPOSURE POINT CONCENTRATION SUMMARY

REASONABLE MAXIMUM EXPOSURE

HUMAN HEALTH RISK ASSESSMENT

BLUE BEACH DISPOSAL AREA

NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Future
Medium:	Groundwater
Exposure Medium:	Groundwater

Exposure Point (6)	Chemical of Potential Concern	CAS Number	Units	Detection Frequency	Arithmetic Mean (1)	UCL (Distribution) (2)	Maximum Concentration (Qualifier) (3)	Exposure Point Concentration			
								Value	Units	Statistic (4)	Rationale (5)

Notes:

% = percent.

CAS = Chemical Abstracts Service.

COPC = Chemical of potential concern.

EPC = Exposure point concentration.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

ug/L = Micrograms per liter.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) For datasets where there is more than one detected result and at least one non-detect result, the value is equal to the Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software referenced in footnote (2). For datasets with 100% detected results or only one detected result, a KM mean cannot be calculated; the value presented is the mean of the detected results or the detected result, respectively.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.002. For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed.
NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; N/A = Not applicable; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Refer to ProUCL output in Attachment B for the selected UCL and the ProUCL Version 5.1 User Guide (USEPA, 2015) for further information regarding each method.
Maximum Concentration = Maximum detected concentration.

(5) The UCL suggested by ProUCL is used, unless otherwise noted.
(a) Maximum detected concentration used for EPC due to low number of detections. ProUCL-calculated UCL is provided, but is not recommended for use.
(b) ProUCL recommends two UCLs. The higher of two recommended UCLs is selected for use.
(c) ProUCL recommends two UCLs; one of which is greater than the maximum detected concentration. Therefore, the recommended UCL that is less than the maximum detected concentration is selected as the EPC.
(d) The mean concentration is selected as the EPC for lead, in accordance with USEPA guidance, as discussed in the risk assessment report text.
(e) 95% UCL exceeds maximum detected concentration. Therefore, the maximum concentration is used for the EPC.
(f) Maximum detected concentration used for EPC due to the low number of detections. UCL not calculated by ProUCL.
(g) Naphthalene was analyzed via both SVOC and VOC methods. The higher of the EPCs (i.e., the EPC presented for the SVOC method) is the selected EPC for further evaluation of naphthalene in groundwater within the on-Project Blue Beach area in the risk assessment.

(6) Groundwater results from wells MW-101S and MW-103 were removed from the groundwater dataset used to calculate EPCs. Groundwater concentrations in these wells are not detected above screening levels and are not considered to be within the area of higher groundwater concentrations.

TABLE 3-3.6

EXPOSURE POINT CONCENTRATION SUMMARY

REASONABLE MAXIMUM EXPOSURE

HUMAN HEALTH RISK ASSESSMENT

BLUE BEACH DISPOSAL AREA

NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Future
Medium:	Groundwater
Exposure Medium:	Shower Air

Exposure Point (5)	Chemical of Potential Concern	CAS Number	Units	Detection Frequency	Arithmetic Mean (1)	UCL (Distribution) (2)	Maximum Concentration (Qualifier) (3)	Exposure Point Concentration			
								Value	Units	Statistic (4)	Rationale

Notes:

% = percent.

CAS = Chemical Abstracts Service.

COPC = Chemical of potential concern.

EPC = Exposure point concentration.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

ug/L = Micrograms per liter.

ug/m^3 = Micrograms per cubic meter.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) For datasets where there is more than one detected result and at least one non-detect result, the value is equal to the Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software referenced in footnote (2). For datasets with 100% detected results or only one detected result, a KM mean cannot be calculated; the value presented is the mean of the detected results or the detected result, respectively.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.002. For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; N/A = Not applicable; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) The shower air EPCs were estimated based on the groundwater EPC (presented in Table 3.5.RME) using the Foster and Chrostowski (1987) shower model (presented in Attachment E-3), as discussed in the HHRA text.

(5) Naphthalene was analyzed via both SVOC and VOC methods. The higher of the EPCs (i.e., the EPC presented for the SVOC method) is the selected EPC for further evaluation of naphthalene in the risk assessment.

TABLE 3-3.7

EXPOSURE POINT CONCENTRATION SUMMARY

REASONABLE MAXIMUM EXPOSURE

HUMAN HEALTH RISK ASSESSMENT

BLUE BEACH DISPOSAL AREA

NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Future
Medium:	Groundwater
Exposure Medium:	Shallow Groundwater

Exposure Point (6)	Chemical of Potential Concern	CAS Number	Units	Detection Frequency	Arithmetic Mean (1)	UCL (Distribution) (2)	Maximum Concentration (Qualifier) (3)	Exposure Point Concentration			
								Value	Units	Statistic (4)	Rationale (5)

Notes:

% = percent.

CAS = Chemical Abstracts Service.

COPC = Chemical of potential concern.

EPC = Exposure point concentration.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

ug/L = Micrograms per liter.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) For datasets where there is more than one detected result and at least one non-detect result, the value is equal to the Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software referenced in footnote (2). For datasets with 100% detected results or only one detected result, a KM mean cannot be calculated; the value presented is the mean of the detected results or the detected result, respectively.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.002. For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed.
NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; N/A = Not applicable; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Refer to ProUCL output in Attachment B for the selected UCL and the ProUCL Version 5.1 User Guide (USEPA, 2015) for further information regarding each method.
Maximum Concentration = Maximum detected concentration.

(5) The UCL suggested by ProUCL is used, unless otherwise noted.
(a) Maximum detected concentration used for EPC due to low number of detections. ProUCL-calculated UCL is provided, but is not recommended for use.
(b) ProUCL recommends two UCLs. The higher of two recommended UCLs is selected for use.
(c) ProUCL recommends two UCLs; one of which is greater than the maximum detected concentration. Therefore, the recommended UCL that is less than the maximum detected concentration is selected as the EPC.
(d) ProUCL recommended UCL exceeds the maximum detected concentration. Therefore, the maximum concentration is used for the EPC.
(e) Maximum detected concentration used for EPC due to the low number of detections. UCL not calculated by ProUCL.

(6) Groundwater results from wells MW-101S and MW-103 were removed from the groundwater dataset used to calculate EPCs. Groundwater concentrations in these wells are not detected above screening levels and are not considered to be within the area of higher groundwater concentrations.

Notes:

CAS = Chemical Abstracts Service.

COPC = Chemical of potential concern.

EPC = Exposure point concentration.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

ug/L = Micrograms per liter.

ug/m³ = Micrograms per cubic meter.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) For datasets where there is more than one detected result, the value is equal to the Kaplan-Meier (KM) mean calculated using USEPA's ProUCL software referenced in footnote (2). For datasets with only one detected result, a KM mean cannot be calculated; the value presented is the detected result.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.002. For data sets with multiple detection limits for non-detects, the use of the Kaplan Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed.
NP = Non-parametric; N = Normal; LN = Lognormal; G = Gamma; N/A = Not applicable; NC = Not calculated.
The UCL recommended by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.

(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Trench air EPCs were estimated based on the shallow groundwater EPCs (presented in Table 3.7.RME) using an attenuation factor calculated in a trench air model (presented in Attachment E-4), as discussed in the HHRA report text.

TABLE 3-4.1

VALUES USED FOR DAILY INTAKE CALCULATIONS - SURFACE SOIL AND SUBSURFACE SOIL

REASONABLE MAXIMUM EXPOSURE

HUMAN HEALTH RISK ASSESSMENT

BLUE BEACH DISPOSAL AREA

NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future; Future
Medium:	Soil
Exposure Medium:	Surface soil; Subsurface Soil

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

< = Less than.

USEPA = United States Environmental Protection Agency.

(1) Professional judgment; conservatively assumes 100 percent of soil ingested is from the Site.

(2) Default value for adult resident.

(3) Assumes access to soils in the area may occur 1 day per week for 26 weeks (6 months) of the year, based on professional judgment.

(4) Exposure duration reflects age-range of 7 to <16 years.

(5) Weighted average body weight for adolescent ages 6 to 16 years old.

(6) Professional judgement; assumes one event per day.

(7) Default value for adult resident; assumes an adult recreational user accesses the area for 20 years.

(8) Default value for child resident; assumes a child recreational user accesses the area for 6 years.

(9) Default value for child resident.

(10) Represents the weighted mean surface area for males and females ages 21+, including head, hands, and forearms (USEPA, 2011; Table 7-2).

(11) Represents the arithmetic mean of weighted average of body-specific (hands, forearms, and face) mean adherence factors for adult commercial/industrial activities (USEPA, 2011; Table 7-20).

(12) Represents the weighted mean surface area for male and female adults, including head, hands, forearms, and lower legs (USEPA, 2011; Table 7-2).

(13) Represents the geometric mean (50th percentile) of weighted average body-specific (hands, forearms, lower legs and face) adherence factors for gardeners (USEPA, 2004; Exhibit C-2).

(14) Represents the weighted mean surface area for males and females ages 0 to <6 years old, including head, hands, forearms, lower legs, and feet (USEPA, 2011; Table 7-2).

(15) Represents the geometric mean (50th percentile) of weighted average body-specific (hands, forearms, lower legs and face) adherence factors for children playing (wet soil) (USEPA, 2004; Exhibit C-2).

(16) Represents the weighted mean surface area for males and females ages 6 to <16 years old, including hands, forearms, lower legs, and head (USEPA, 2011; Table 7-2).

(17) Construction/utility activities are assumed to occur for 40 days over the course of a 1 year period (for RME scenario), based on professional judgment.

(18) Represents the geometric mean (50th percentile) of weighted average body-specific (face, forearms, and hands) adherence factors for construction workers (USEPA, 2004; Exhibit C-2).

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(kg/mg)] = (IR x EF x ED x CF x FI))/(BW x AT) [CS and RBA are factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(kg/mg)] = (SA x AF x EV x EF x ED x CF)/(BW x AT) [CS and ABS are factored into the risk calculation in Table 7s]

Outdoor Worker:	Cancer Ingestion Intake =	3.06E-07	Cancer Dermal Intake =	1.29E-06
Outdoor Worker:	Noncancer Ingestion Intake =	8.56E-07	Noncancer Dermal Intake =	3.62E-06
Resident - Adult:	Cancer Ingestion Intake =	3.42E-07	Cancer Dermal Intake =	1.45E-06
Resident - Adult:	Noncancer Ingestion Intake =	1.20E-06	Noncancer Dermal Intake =	5.06E-06
Resident - Child:	Cancer Ingestion Intake =	1.10E-06	Cancer Dermal Intake =	2.60E-06
Resident - Child:	Noncancer Ingestion Intake =	1.28E-05	Noncancer Dermal Intake =	3.03E-05
Trespasser:	Cancer Ingestion Intake =	2.08E-08	Cancer Dermal Intake =	5.28E-08
Trespasser:	Noncancer Ingestion Intake =	1.62E-07	Noncancer Dermal Intake =	4.11E-07
Recreational User - Adult:	Cancer Ingestion Intake =	2.54E-08	Cancer Dermal Intake =	1.07E-07
Recreational User - Adult:	Noncancer Ingestion Intake =	8.90E-08	Noncancer Dermal Intake =	3.76E-07
Recreational User - Child:	Cancer Ingestion Intake =	8.14E-08	Cancer Dermal Intake =	1.93E-07
Recreational User - Child:	Noncancer Ingestion Intake =	9.50E-07	Noncancer Dermal Intake =	2.25E-06
Construction/Utility Worker:	Cancer Ingestion Intake =	6.46E-09	Cancer Dermal Intake =	2.07E-08
Construction/Utility Worker:	Noncancer Ingestion Intake =	4.52E-07	Noncancer Dermal Intake =	1.45E-06

Cancer risk from ingestion = Soil concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Soil concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Soil concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Soil concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

				ATc	Averaging Time - cancer	25,550	days	USEPA, 1989	
				ATnc	Averaging Time - noncancer	365	days	USEPA, 1989	

Notes:

< = Less than.

USEPA = United States Environmental Protection Agency.

(1) Assumes a trespasser accesses the area for 2 hours per event. Equals the mean time spent outdoors for ages 6 to 16 years (USEPA, 2004, Table 16-1).

(2) Assumes access to soils in the area may occur 1 day per week for 26 weeks (6 months) of the year, based on professional judgment.

(3) Exposure duration reflects age-range of 7 to <16 years.

(4) Assumes recreational users may be exposed to fugitive dust while wading in the off-Project Red Maple Swamp/tidal stream once per day, based on professional judgment.

(5) Default value for adult resident; assumes an adult recreational user accesses the area for 20 years.

(6) Default value for child resident; assumes a child recreational user accesses the area for 6 years.

(7) Conservatively assumes a 10-hour work day, based on professional judgement.

(8) Construction/utility activities are assumed to occur for 40 days over the course of a 1 year period (for RME scenario), based on professional judgment.

(9) Default particulate emission factor for a non-excavation scenario (Equation B-8; USEPA, 2002).

(10) Default subchronic particulate emission factor for unpaved road traffic (Equation E-18; USEPA, 2002).

HUMAN HEALTH RISK ASSESSMENT

BLUE BEACH DISPOSAL AREA

NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future; Future
Medium:	Sediment; Hydric Soil
Exposure Medium:	Sediment; Hydric Soil

Exposure Route	Receptor Population	Receptor Age	Exposure Point(s)	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

< = Less than.

USEPA = United States Environmental Protection Agency.

(1) Assumes the incidental ingestion rate for sediment/hydric soil is 10 percent of the soil ingestion rate recommended by USEPA (2014).

(2) Assumes access to sediment/hydric soil in the area may occur 1 day per week for 26 weeks (6 months) of the year, based on professional judgment.

(3) Professional judgment; conservatively assumes 100 percent of sediment/hydric soil ingested is from the associated area.

(4) Represents the geometric mean weighted value for children playing in wet soil (USEPA, 2004; Exhibit 3-3). Equal to the USEPA default surface area for contact with soil by a residential child (USEPA, 2014).

(5) Represents the geometric mean weighted value for residential gardeners (USEPA, 2004; Exhibit 3-3). Equal to the USEPA default soil adherence factor for a residential adult (USEPA, 2014).

(6) Professional judgment; assumes one event per day.

(7) Represents the weighted mean surface area for male and female adults, including head, hands, forearms, and lower legs (USEPA, 2011; Table 7-2).

(8) Represents the weighted mean surface area for males and females ages 0 to <6 years old, including head, hands, forearms, lower legs, and feet (USEPA, 2011; Table 7-2). Equal to the USEPA default surface area for contact with soil by a residential child (USEPA, 2014).

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(kg/mg)] = (IR x EF x ED x CF x FI))/(BW x AT) [CS and RBA are factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(kg/mg)] = (SA x AF x EV x EF x ED x CF)/(BW x AT) [CS and ABS are factored into the risk calculation in Table 7s]

Recreational User - Adult:	Cancer Ingestion Intake =	2.54E-09	Cancer Dermal Intake =	1.07E-07
Recreational User - Adult:	Noncancer Ingestion Intake =	8.90E-09	Noncancer Dermal Intake =	3.76E-07
Recreational User - Child:	Cancer Ingestion Intake =	8.14E-09	Cancer Dermal Intake =	1.93E-07
Recreational User - Child:	Noncancer Ingestion Intake =	9.50E-08	Noncancer Dermal Intake =	2.25E-06

Cancer risk from ingestion = Sediment concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Sediment concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Sediment concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Sediment concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

VALUES USED FOR DAILY INTAKE CALCULATIONS - SURFACE WATER

REASONABLE MAXIMUM EXPOSURE

HUMAN HEALTH RISK ASSESSMENT

BLUE BEACH DISPOSAL AREA

NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe:	Current/Future
Medium:	Surface Water
Exposure Medium:	Surface Water

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

N/A = Not applicable.

USEPA = United States Environmental Protection Agency.

(1) Assumes contact with surface water for 1 hour on each day exposure occurs.

(2) Assumes access to surface water in the area may occur 1 day per week for 26 weeks (6 months) of the year, based on professional judgment.

(3) The body surface area assumed to contact surface water during wading activities is assumed to be the same as is recommended for soil (USEPA, 2014).

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(L/ug)]= (IR x EF x ED x CF)/(BW x AT) [CW is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(L/ug)(event/cm)]= (SA x EV x EF x ED x CF1 x CF2)/(BW x AT) [DA (including CW, PC, and ET) is factored into the risk calculation in Table 7s]

Recreational User - Adult (Wading):	Cancer Ingestion Intake =	N/A	Cancer Dermal Intake =	1.53E-06
Recreational User - Adult (Wading):	Noncancer Ingestion Intake =	N/A	Noncancer Dermal Intake =	5.37E-06
Recreational User - Child (Wading):	Cancer Ingestion Intake =	N/A	Cancer Dermal Intake =	9.66E-07
Recreational User - Child (Wading):	Noncancer Ingestion Intake =	N/A	Noncancer Dermal Intake =	1.13E-05

Cancer risk from ingestion = Surface water concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Surface water concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Surface water concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Surface water concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

Notes:

ATSDR = Agency for Toxic Substances and Disease Registry
CAS = Chemical Abstracts Service.
HEAST = Health Effects Assessment Summary Tables.
IRIS = Integrated Risk Information System.
mg/kg-day = Milligrams per kilogram per day.
N/A = Not Applicable/Not Available.
PCBs = Polychlorinated biphenyls.
PPRTV = Provisional Peer Reviewed Toxicity Values.
RfD = Reference Dose.
RSL = Regional Screening Level.
SVOCs = Semi-volatile organic compounds.
USEPA = United States Environmental Protection Agency.
VOCs = Volatile organic compounds.

TABLE 3-5.1
NON-CANCER TOXICITY DATA -- ORAL/DERMAL
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Chemical of Potential Concern (1)	CAS Number	Chronic/ Subchronic (2)	Oral RfD		Oral Absorption Efficiency for Dermal (3)	Absorbed RfD for Dermal (5)		Primary Target Organ(s)	Combined Uncertainty/Modifying Factors	RfD:Target Organ(s)	
			Value	Units		Value	Units			Source(s)	Date(s) (6) (MM/YYYY)

(1) The following surrogates were used for chemicals without toxicity values or multiple forms:

RfD for cadmium in water used for evaluation of cadmium in groundwater; RfD for cadmium in food/diet used for evaluation of cadmium in soil.

RfD for chromium III, insoluble salts used.

RfD for manganese, non-diet used.

When assessing exposure to manganese in soil or drinking water, IRIS recommends applying a modifying factor of 3 to the oral RfD of 0.14 mg/kg-day. The USEPA Regional Screening Level (RSL) User's Guide (2020) also indicates that the average dietary manganese content (in the United States) of the diet (5 mg/day) be subtracted from the critical dose of 10 mg/day when assessing exposure to non-dietary manganese. Therefore, the RfD is (10 mg/day - 5 mg/day)/ Modifying Factor (3) = 1.67 mg/day / 70 kg = 0.024 mg/kg-day.

RfD for thallium is based on thallium soluble salts. No PPRTVs were developed for thallium in the PPRTV document (USEPA, 2012) due to database deficiencies.

Appendix A of the PPRTV document indicates that it is inappropriate to derive provisional chronic or subchronic RfDs for thallium, but that information is available which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors as a screening value. The use of this screening provisional value is highly uncertain but is the value used in the USEPA RSL Tables (USEPA, 2020).

RfD for vanadium is derived from the IRIS oral RfD for Vanadium Pentoxide by factoring out the molecular weight (MW) of the oxide ion. Vanadium Pentoxide (V205) has a molecular weight of 181.88. The two atoms of Vanadium contribute 56% of the MW. Vanadium Pentoxide's oral RfD of 9E-03 mg/kg-day multiplied by 56% gives a Vanadium oral RfD of 5.04E-03 mg/kg-day.

RfD for Aroclor 1254 used for Total PCB Aroclors.

(2) Published value where available. Where not available, when the chronic RfD is based on a subchronic study, a subchronic RfD has been developed by the elimination of the uncertainty factor for subchronic to chronic adjustment. If no subchronic data are available, the chronic RfD has been adopted as the subchronic RfD.

(a) Subchronic data not available. Chronic RfD has therefore been adopted as the subchronic value.

(3) Oral Absorption Efficiencies from Exhibit 4-1 (USEPA, 2004. Risk Assessment Guidance for Superfund, Part E).

(4) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral reference dose is necessary (USEPA, 2001).

(5) Calculated as: (oral RfD) x (oral to dermal adjustment factor).

(6) Reflects the date associated with the source of the toxicity information. For online databases, including IRIS and PPRTV, the date reflects the date on which the information was obtained from the online source.

HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Chemical of Potential Concern	CAS Number	Chronic/ Subchronic (1)	Inhalation RfC		Primary Target Organ(s)	Combined Uncertainty/Modifying Factors	RfC : Target Organ(s)	
			Value	Units			Source(s)	Date(s) (2) (MM/YYYY)

Notes:

ATSDR = Agency for Toxic Substances and Disease Registry.

CalEPA = California Environmental Protection Agency, Office of Environmental Health Hazard Assessment.

CAS = Chemical Abstracts Service.

HEAST = Health Effects Assessment Summary Tables.

IRIS = Integrated Risk Information System.

PCBs = Polychlorinated biphenyls.

PPRTV = Provisional Peer Reviewed Toxicity Value.

N/A = Not Applicable/Not Available.

RfC = Reference concentration.

RfD = Reference dose.

SVOCs = Semi-volatile organic compounds.

ug/m^3 = Micrograms per cubic meter.

VOCs = Volatile organic compounds.

(1) Published value where available. Where not available, when the chronic RfC is based on a subchronic study, a subchronic RfC has been developed by the elimination of the uncertainty factor for subchronic to chronic adjustment. If no subchronic data are available, the chronic RfC has been adopted as the subchronic RfC.

(a) Subchronic data not available. Chronic RfC has therefore been adopted as the subchronic value.

(2) Reflects the date associated with the source of the toxicity information. For online databases, including IRIS, CalEPA, and PPRTV, the date reflects the date on which the information was obtained from the online source.

(3) Intermediate Minimal Risk Level (MRL), presented in units of parts per million (ppm), converted to RfC.

Notes:

CAS = Chemical Abstracts Service.

CSF = Cancer slope factor.

IRIS = Integrated Risk Information System.

mg/kg-day = Milligrams per kilogram per day.

N/A = Not Applicable/Not Available.

NHL = Non-Hodgkin's lymphoma.

PCBs = Polychlorinated biphenyls.

SVOCs = Semi-volatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

USEPA Group:

A - Human carcinogen

B1 - Probable human carcinogen - indicates that limited human data are available

B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans

C - Possible human carcinogen

D - Not classifiable as a human carcinogen (by the oral route)

(1) The following surrogates were used for chemicals without toxicity values or multiple forms:

CSF for PCBs used for Aroclor-1254. The Reasonable Maximum Exposure (RME) slope factor presented represents the upper-bound slope factor for high risk and persistence situations.

CSF for benzo(a)pyrene, along with the appropriate relative potency factor (USEPA, 1993), used for the other carcinogenic polycyclic aromatic hydrocarbons (PAHs).

IRIS provides a range of CSF for benzene of 1.5E-02 to 5.5E-02 $(mg/kg-day)^{-1}$. IRIS states that each value within this range has equal scientific plausibility. The high end of the range is used to be conservative.

(2) Oral Absorption Efficiencies from Exhibit 4-1 (USEPA, 2004. Risk Assessment Guidance for Superfund, Part E).

(3) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral slope factor is necessary (USEPA, 2004. Risk Assessment Guidance for Superfund, Part E. Final. Exhibit 4-1).

(4) Calculated as: (oral slope factor) / (oral to dermal adjustment factor)

(5) Reflects the date associated with the source of the toxicity information. For online databases, including IRIS, the date reflects the date on which the information was obtained from the online source.

(6) CSF of 4.6E-02 per mg/kg-day was evaluated separately based on the CSF specific to kidney effects, evaluated for mutagenic mode of action, and non-Hodgkin's lymphoma (NHL) and liver, evaluated for non-mutagenic carcinogenic effects.

(7) Value for continuous lifetime exposure from birth used for evaluation of the residential exposure scenarios.

(8) Value for continuous lifetime exposure during adulthood used for evaluation of the worker exposure scenarios.

(9) The CSFs for vinyl chloride account for mutagenic effects, therefore, application of the age-dependent adjustment factors (ADAFs) is not necessary for evaluation of mutagenic mode of action.

TABLE 3-6.2
CANCER TOXICITY DATA -- INHALATION
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Chemical of Potential Concern (1)	CAS Number	Unit Risk		Weight of Evidence/ Cancer Guideline Description	Unit Risk : Inhalation CSF	
		Value	Units		Source(s)	Date(s) (2) (MM/YYYY)

Notes:

CAS = Chemical Abstracts Service.

CalEPA = California Environmental Protection Agency. Office of Environmental Health Hazard Assessment (OEHHA).

CSF = Cancer slope factor.

IRIS = Integrated Risk Information System.

N/A = Not Applicable/Not Available.

NHL = Non-Hodgkin's lymphoma.

PCBs = Polychlorinated biphenyls.

PPRTV = Provisional Peer Reviewed Toxicity Values.

SVOCs = Semi-volatile organic compounds.

ug/m^3 = Micrograms per cubic meter.

URF = Unit risk factor.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

USEPA Group:

A - Human carcinogen

B1 - Probable human carcinogen = indicates that limited human data are available

B2 - Probable human carcinogen = indicates sufficient evidence in animals and inadequate or no evidence in humans

C - Possible human carcinogen

D - Not classifiable as a human carcinogen

(1) The following surrogates were used for chemicals without toxicity values or multiple forms:
URF for benzo(a)pyrene, along with the appropriate relative potency factor (USEPA, 1993), used for the other carcinogenic polycyclic aromatic hydrocarbons (PAHs).
IRIS provides a range of URF for benzene of 2.2E-6 (ug/m3)-1 to 7.8E-6 (ug/m3)-1. IRIS states that each value within this range has equal scientific plausibility. The high end of the range is used to be conservative.

(2) Reflects the date associated with the source of the toxicity information. For online databases, including IRIS, CalEPA, and PPRTV, the date reflects the date on which obtained from the online source.

(3) Consistent with the IRIS file for PCBs, for inhalation of dust containing PCBs, the high risk and persistence slope factors are used. The Reasonable Maximum Exposure (RME) URF presented represents the upper-bound slope factor.
The URF was converted from the slope factors as follows: Upper-bound URF: [2 (milligram per kilogram [mg/kg]-day) $^{-1}$ x (20 cubic meter [m^3]/day / 70 kilogram) x 1 milligram / 1000 microgram] =0.00057 (ug/m^3)$^{-1}$

(4) URF of 4.1E-06 (ug/m^3)$^{-1}$ was evaluated separately based on the URF specific to kidney effects, evaluated for mutagenic mode of action, and non-Hodgkin's lymphoma (NHL) and liver, evaluated for non-mutagenic carcinogenic effects.

(5) Value for continuous lifetime exposure from birth used for evaluation of the residential/recreational exposure scenarios.

(6) Value for continuous lifetime exposure during adulthood used for evaluation of the worker exposure scenarios.

Total Receptor Risk/Hazard												(2)					(2)

Notes:
ADAF = Age-dependent adjustment factor.
CSF = Cancer slope factor.
EPC = Exposure point concentration.
IUR = Inhalation unit risk factor.
N/A = Not applicable.
NHL = Non-Hodgkin's lymphoma.
PCBs = Polychlorinated biphenyls.
RfC = Inhalation reference concentration.
RfD = Oral reference dose.
RME = Reasonable Maximum Exposure.
SVOCs = Semivolatile organic compounds.
VOCs = Volatile organic compounds.
(1) ADAF is used for chemicals with a mutagenic mode of action for carcinogenesis. The cancer risk is adjusted by multiplying the calculated risk by the ADAF.
(2) Presented on corresponding summary of risk/hazard table.

TABLE 3-7.2
CALCULATION OF CHEMICAL CANCER RISKS AND NON-CANCER HAZARDS - OUTDOOR WORKER
REASONABLE MAXIMUM EXPOSURE
HUMAN HEALTH RISK ASSESSMENT
BLUE BEACH DISPOSAL AREA
NORTH KINGSTOWN, RHODE ISLAND

Scenario Timeframe: Current/Future; Future
Receptor Population: Outdoor Worker
Receptor Age: Adult

							Cancer Risk Calculations						Noncancer Hazard Calculations				
					EPC		Intake/Exposure Concentration		CSF or IUR				Intake/Exposure Concentration		RfD or RfC		
Medium	Exposure Medium	Exposure Point	Exposure Route	Chemical of Potential Concern	Value	Units	Value	Units	Value	Units	ADAF (1)	Cancer Risk	Value	Units	Value	Units	Hazard Quotient

Notes:
ADAF = Age-dependent adjustment factor.
CSF = Cancer slope factor.
EPC = Exposure point concentration.
IUR = Inhalation unit risk factor.
N/A = Not applicable.
NHL = Non-Hodgkin's lymphoma.
PCBs = Polychlorinated biphenyls.
RfC = Inhalation reference concentration.
RfD = Oral reference dose.
RME = Reasonable Maximum Exposure.
SVOCs = Semivolatile organic compounds.
VOCs = Volatile organic compounds.
(1) ADAF is used for chemicals with a mutagenic mode of action for carcinogenesis. The cancer risk is adjusted by multiplying the calculated risk by the ADAF.
(2) Presented on corresponding summary of risk/hazard table.
