Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Notes
-- = Not Evaluated
C = Combined Primary/Field Duplicate Sample
CASRN = Chemical Abstracts Service Registry Number
EPA = Environmental Protection Agency
LOD = Limit of Detection
mg/kg = millgram per kilogram
N/A = Not Applicable
N = Primary Sample
ND = Non-Detect or Not Detected
RSL = Regional Screening Level
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

SL Sources
EPA Residential Soil RSL, November 2022 - Target Cancer Risk = 1E-06, Target Hazard Quotient = 0.1.

Notes
-- = Not Evaluated
C = Combined Primary/Field Duplicate Sample
CASRN = Chemical Abstracts Service Registry Number
EPA = Environmental Protection Agency
LOD = Limit of Detection
mg/kg = millgram per kilogram
N/A = Not Applicable
N = Primary Sample
ND = Non-Detect or Not Detected
RSL = Regional Screening Level
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.

Notes
-- = Not Evaluated
C = Combined Primary/Field Duplicate Sample
CASRN = Chemical Abstracts Service Registry Number
EPA = Environmental Protection Agency
LOD = Limit of Detection
mg/kg = millgram per kilogram
N/A = Not Applicable
N = Primary Sample
ND = Non-Detect or Not Detected
RSL = Regional Screening Level
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.

SL Sources
EPA Residential Soil RSL, November 2022 - Target Cancer Risk = 1E-06, Target Hazard Quotient = 0.1.

LOD = Limit of Detection
mg/kg = millgram per kilogram
N/A = Not Applicable
N = Primary Sample
ND = Non-Detect or Not Detected
RSL = Regional Screening Level
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.

Notes
-- = Not Evaluated
C = Combined Primary/Field Duplicate Sample
CASRN = Chemical Abstracts Service Registry Number
EPA = Environmental Protection Agency
LOD = Limit of Detection
mg/kg = millgram per kilogram
N/A = Not Applicable
N = Primary Sample
ND = Non-Detect or Not Detected
RSL = Regional Screening Level
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.

SL Sources
EPA Residential Soil RSL, November 2022 - Target Cancer Risk = 1E-06, Target Hazard Quotient = 0.1.

Notes
-- = Not Evaluated
C = Combined Primary/Field Duplicate Sample
CASRN = Chemical Abstracts Service Registry Number
EPA = Environmental Protection Agency
LOD = Limit of Detection
mg/kg = millgram per kilogram
N/A = Not Applicable
N = Primary Sample
ND = Non-Detect or Not Detected
RSL = Regional Screening Level
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend
ND — Not detected at the LOD
Detect — Detected result
Detect — Detected result > SL

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD.
However, the associated numerical value is approximate.

Notes:
% = Percent
ARAR = Applicable or Relevant and Appropriate Requirement
CASRN = Chemical Abstracts Service Registry Number
COPC = Chemical of Potential Concern
ft bgs = feet below gound surface
J = Estimated Concentration (+/- indicates a positive/negative bias)
LOD = Limit of Detection
LOQ = Limit of Quantitation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency
(1) Summary statistics were only evaluated for chemicals with at least two distinct detects.
(2) Site data screened against:
R-RSL = EPA Residential Soil Regional Screening Level, November 2022 - Target Cancer Risk = 1E-06, Target Hazard Quotient = 0.1. (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables)
(3) An asterisk,'*', indicates surrogate toxicity information was used to derive a screening level (see Tables 5-10 through 5-15).

Notes:
% = Percent
ARAR = Applicable or Relevant and Appropriate Requirement
CASRN = Chemical Abstracts Service Registry Number
COPC = Chemical of Potential Concern
ft bgs = feet below gound surface
J = Estimated Concentration (+/- indicates a positive/negative bias)
LOD = Limit of Detection
LOQ = Limit of Quantitation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency
(1) Summary statistics were only evaluated for chemicals with at least two distinct detects.
(2) Site data screened against:
R-RSL = EPA Residential Soil Regional Screening Level, November 2022 - Target Cancer Risk = 1E-06, Target Hazard Quotient = 0.1. (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables)
(3) An asterisk,'*', indicates surrogate toxicity information was used to derive a screening level (see Tables 5-10 through 5-15).

Table J.4-5
Human Health Screening Summary – Area of Concern 3, Total Soil (0 - 5 ft bgs)
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

Scenario Timeframe: Current and Future
Medium: Soil
Exposure Medium: Soil
Exposure Point: Total Soil (0 - 5 ft bgs)

Notes:
% = Percent
ARAR = Applicable or Relevant and Appropriate Requirement
CASRN = Chemical Abstracts Service Registry Number
COPC = Chemical of Potential Concern
ft bgs = feet below gound surface
J = Estimated Concentration (+/- indicates a positive/negative bias)
LOD = Limit of Detection
LOQ = Limit of Quantitation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency
(1) Summary statistics were only evaluated for chemicals with at least two distinct detects.
(2) Site data screened against:
R-RSL = EPA Residential Soil Regional Screening Level, November 2022 - Target Cancer Risk = 1E-06, Target Hazard Quotient = 0.1. (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables)
(3) An asterisk,'*', indicates surrogate toxicity information was used to derive a screening level (see Tables 5-10 through 5-15).

Table J.4-11
Human Health Screening Summary – Area of Concern 5 (Coal Aggregate Bins), Total Soil (0 - 10 ft bgs)
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

Scenario Timeframe: Current and Future
Medium: Soil
Exposure Medium: Soil
Exposure Point: Total Soil (0 - 10 ft bgs)

Notes:
% = Percent
ARAR = Applicable or Relevant and Appropriate Requirement
CASRN = Chemical Abstracts Service Registry Number
COPC = Chemical of Potential Concern
ft bgs = feet below gound surface
J = Estimated Concentration (+/- indicates a positive/negative bias)
LOD = Limit of Detection
LOQ = Limit of Quantitation
MDC = Maximum Detected Concentration
mg/kg = milligram per kilogram
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency
(1) Summary statistics were only evaluated for chemicals with at least two distinct detects.
(2) Site data screened against:
R-RSL = EPA Residential Soil Regional Screening Level, November 2022 - Target Cancer Risk = 1E-06, Target Hazard Quotient = 0.1. (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables)
(3) An asterisk,'*', indicates surrogate toxicity information was used to derive a screening level (see Tables 5-10 through 5-15).

Table J.4-14
Human Health Screening Summary – Area of Concern 5 (Coal Storage Area), Total Soil (0 - 10 ft bgs)
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

Scenario Timeframe: Current and Future
Medium: Soil
Exposure Medium: Soil
Exposure Point: Total Soil (0 - 10 ft bgs)

# 1.0 INTRODUCTION

The objectives of this Ecological Resource Receptor Inventory are to provide a brief description of habitat conditions at each area of concern (AOC) involved in the Phase 1 ecological risk screening process, a list of potential receptors observed or expected (based on habitat association) at each AOC, and discussion of species and habitats of special concern located within or near the AOCs of interest. This information will be used to determine appropriate receptors or receptor groups that will be considered for evaluation in the Phase 1 ecological screening process and if needed, the subsequent Screening Level Ecological Risk Assessment (SLERA). Information about ecological receptors and habitat conditions was collected from a variety of sources including:

- *Three Rivers Wildlife Management Plan* [New York State Department of Environmental Conservation (NYSDEC), 2018a];
- New York Natural Heritage Database (NYNHD) (NYNHD, 2022), the United States Fish and Wildlife Service (USFWS) Information for Planning and Consultation (IPaC) (USFWS, 2022a);
- USFWS National Wetland Inventory database search (USFWS, 2022b);
- *Wetland Delineation and Vernal Pool Survey* (Bluestone, 2020);
- Correspondence with Ms. Bonnie Parton (wildlife biologist – Three Rivers Wildlife Management Area) (NYSDEC, 2022a); and
- Numerous field observations at each AOC.

If required, a SLERA will be conducted to evaluate risks to ecological receptors resulting from exposure to site-related contaminants present in soil and, if suggested by the phased groundwater assessment, surface water, pore water, and sediment. This evaluation will be guided by historical information, but only analytical data to be collected as part of the current remedial investigation (RI) will be used to assess potential ecological risk. A SLERA will be based on reasonable, protective assumptions about the potential for ecological receptors to be exposed to, and to be adversely affected by, contaminants of potential ecological concern (COPECs) in the various media affected by the site. At the completion of the SLERA, the Project Development Team (PDT) will review the results and determine if a Baseline Ecological Risk Assessment (BERA) is warranted and what additional data collection activities are suitable.

# 2.0 ECOLOGICAL SETTING

The ecological risk screening will focus on terrestrial habitat types within AOC 1 (Ammonium Picrate Area), AOC 4 (Bunker Area), AOC 5 (Former Power Plant Area). These three areas were the primary AOCs of ecological concern as determined by the PDT, however, AOC 3 (Former Landfill) which is located under an existing parking lot will also be assessed. Due to the limited area and low-quality ecological habitat at AOC 3, surface soils will not be considered an ecological exposure medium. As part of the Phase 1 Risk Screening process groundwater information collected at each AOC will be evaluated to determine if the potential exists for groundwater discharge into nearby wetlands. If groundwater discharge is considered possible, the Phase 1 Screening will identify associated data gaps that may include a recommendation to collect pore water, surface water, and sediment samples and these data will be incorporated into future ecological risk evaluations.

A brief description of habitats and potential ecological receptors is provided in the following sections. When available, the flora and fauna information provided is based on species that have been observed in and around the Site or that are expected to occur in this region or local habitat based on available species distribution data. Lists of protected species and habitats of concern in the vicinity of New York Ordnance Works (NYOW) AOCs is also provided. The potential receptors identified below are meant only to represent species broadly typical of this habitat type. These species may not necessarily occur within any AOC because of regional and local factors that affect species distribution. Sources of information used to provide descriptions of the ecological setting include:

- Notes from site visits by PDT members, field sampling events and wetland/vernal pool associated site visits;
- New York Natural Heritage Database Search for the Town of Lysander – New York Nature Explorer (NYNHD, 2022);
- *Habitat Management Plan for the Three Rivers Wildlife Management Area* (WMA) 2018-2027 (NYSDEC, 2018a);
- *New England Wildlife: Habitat, Natural History, and Distribution* (DeGraff and Yamasaki, 2001);
- *Three Rivers Bird Conservation Area* (NYSDEC, 2018b);
- US Fish and Wildlife National Wetlands Inventory (USFWS, 2022b);
- *Wetland Delineation and Vernal Pool Survey Report* (Bluestone, 2020); and
- Communications with Ms. Bonnie Parton, wildlife biologist, NYSDEC (NYSDEC, 2022a).

## 2.1 AOC-SPECIFIC HABITAT DESCRIPTIONS

The following discussion provides a description of terrestrial and wetland habitat conditions observed during site visits, wetland habitats within or near AOCs 1, 3, 4 and 5 as identified in the National Wetlands Inventory Database (USFWS, 2022b) and the Wetland Delineation and Vernal Pool Survey (Bluestone, 2020) and additional wildlife and habitats of concern identified in the New York Natural Heritage Database for the town of Lysander (NYNHD, 2022).

### 2.1.1 Terrestrial Habitat

#### *2.1.1.1 AOC 1 – Ammonium Picrate Area*

The Ammonium Picrate Area (AOC 1) is rectangular in shape and is roughly 72.6 acres (see **Figure 2-1**). The terrestrial habitat present is comprised of secondary growth eastern deciduous forest. The forest is dominated by eastern cottonwood (*Populis deltoides*), silver maple (*Acer saccharinum*), green ash (*Fraxinus pennsylvanica*) red maple *(Acer rubrum)*, red oak (*Quercus rubra*), gray birch (*Betula populifolia)*, black cherry (*Prunus serotina*), sweetgum (*Liquidambar styraciflua*), butternut hickory (*Carya coriformis*), tulip tree (*Lirodenendron tulipifera*) and sassafras (*Sassafras albidum*). The understory shrubs are dominated by osier dogwood (*Cornus sericea*), multiflora rose (*Rosa multifora*), Morrow's honeysuckle (*Lonicera morrow*), northern spicebush (*Lindera benzoin*), arrowwood viburnum (*Viburnum dentatum*), black willow (*Salix nigra*) and American hornbeam (*Carpinus caroliniaina*). The herbaceous stratum is dominated by sensitive fern (*Onoclea sensibilis*), garlic mustard (*Alliaria petiolatarough*), rough horsetail (*Equisetum hyemale*), creeping jenny (*Lysimachia nummularia*) and various goldenrod species (Solidago sp.). The AOC 1 has maintained trails and recreational grassy areas interspersed throughout western portion of the Site and is bordered by residential properties to the south and a cleared electric transmission right-of-way to the north.

#### *2.1.1.2 AOC 3-Former Landfill*

The Former Landfill (AOC 3) is a roughly 3.6-acre area dominated by a parking lot and small wooded area to the north. It is not a terrestrial area of concern for surface soil exposure and the vegetated portions are dominated by silver maple, and wild cherry (*Prunus serotina*) along the stream bank (See **Figure 2-2**). The shrub layer is comprised of thickets of blackberry (*Rubus sp*.) multiflora rose and Morrow's honeysuckle. The herbaceous layer of the floodplain wetland is dominated by common reed (*Phragmites australis*), jewelweed (*Impatiens capensis*) and soft rush (*Juncus effuses*).

#### *2.1.1.3 AOC 4 – Bunker Area*

The Bunker Area (AOC 4) is a roughly 104-acre parcel located within the Three Rivers WMA. The bunkers are covered with grass and at most places are periodically managed to discourage the rooting of trees and shrubs on top of the bunkers. A heavily vegetated drainage ditch runs parallel to the road in front of each bunker. Terrestrial habitat bordering Igloo Road and associated bunkers consists primarily of grassy fields and northern deciduous forest (see **Figure 2-3**).

Grass fields are located predominantly along the northern portion of the Bunker Area although smaller grass field patches occur around each of the bunkers. The extent of grass maintenance around the bunkers is limited. Dominant vegetation observed in the grass fields are the herbaceous plants including various grass species (e.g., sweetgrass, bluestem), broomsedge (Andropogon virginicus), common milkweed (Asclepias syriaca), goldenrod, common ragweed (Ambrosia artemisiifolia), mullein (Verbascum spp.), asters (Aster spp.), oxeye daisy (Leucanthemum vulgare), rudbeckia (Rudbeckia spp.), crown vetch (Securigera varia), thistles (Cirsium spp.), and yarrow (Achillea millefolium) among others. Saplings, shrubs, and vines of various sizes (though most appear to be early successional) include arrowwood viburnum (*Viburnum dentatum*), maple leaf viburnum (*Viburnum acerifolium*), smooth sumac (*Rhus glabra*), pin cherry (*Prunus pensylvanica*), gray birch (*Betula populifolia*), red maple, and sweet gum (*Liquidambar styraciflua*).

Eastern deciduous woodlands border the AOC 4 to the north and east; second growth forest of similar composition is located between the two bunker rows except at the northern end. The southeastern site border is a mix of maintained grassy areas and deciduous forest.

Characteristic trees and shrubs observed included red maple, quaking aspen (*Populus tremuloides*), gray birch, red oak, sweet gum, poplar (*Populus spp*.), sassafras, pin cherry, black cherry, eastern white pine (*Pinus strobus*), arrowwood, New York ironweed (*Vernonia noveboracensis*), smooth sumac, maple leaf viburnum, greenbrier (*Smilax spp*.), and oriental bittersweet (*Celastrus orbiculatus*).

#### *2.1.1.4 AOC 5 – Former Power Plant Area*

The Former Power Plant Area (AOC 5) is a roughly 9.3-acre area. AOC 5 is divided into and upland deciduous forest to the east and an extensive forested wetland to the west (see **Figure 2-4**). The forested overstory is dominated by green ash, butternut hickory and red maple. The shrub and herbaceous understory is moderately dense in most areas and is dominated by buckthorn (*Rhamnus cathaitica*), American hornbeam (*Carpus caroliniana*), northern spicebush, red osier dogwood (*Cornus sericea*), Morrow's honeysuckle, Canadian goldenrod (Solidago sempervirens), creeping Jenny (*Lysimachia nummularia*) and multiflora rose.

### 2.1.2 Wetland Habitat

A wetland delineation and vernal pool survey was performed at AOC 1, 3 and 5 in 2020, the results of these field investigations are presented in the *Wetland Delineation and Vernal Pool Survey Report* (Bluestone, 2020). No formal wetland delineation was performed for AOC 4.

There are several forested wetland areas scattered throughout AOC 1, with the majority located in the lower elevation areas adjacent to residential properties. In total, 17.33 acres of Palustrine Forested Wetland (PFO) were identified across four areas. The largest wetland area (Wetland 1C, 10.81 acres) was identified along the northeast basal plain, with pockets of upland hills, between former Dryer Houses 29 and 31. Wetland 1B was identified along the southern portion of the basal plain, between former Dryer Houses 27 and 28. The remaining two wetlands were delineated along the second terrace (Wetlands 1A and 1F). See **Figure 2-1** for locations of wetlands and candidate vernal pools and proposed sampling locations at AOC 1.

In total, 0.26 acres of Palustrine Forested Wetland/Palustrine Emergent Wetland (PFO/PEM) were identified within AOC 3, just north of the parking lot along the stream's floodplain. See **Figure 2-2** for locations of delineated wetlands and proposed sampling locations at AOC 3The only wetland areas associated with AOC 3 are closely associated with the unnamed stream and the northern stream bank.

Roughly 50% (the whole western side) of AOC 5 consists of a forested wetland habitat (see **Figure 2-2**). Similar to AOC 1, AOC 5 has highly mosaic microtopography throughout and an extensive network of drainage ditches from its previous land use. Therefore, wetland boundaries had to be averaged to mappable lines. This means in some areas there are many small wetland depressions and upland mounds on both sides of the boundary. The western portion of AOC 5 was confirmed to have 3.35 acres of PFO wetlands, which likely extends westward beyond the AOC boundary. See **Figure 2-4** for locations of wetlands and candidate vernal pools and proposed sampling locations at AOC 5.

Based on the results of the wetland delineation efforts and vernal pool assessments, approximately 20.44 wetland acres were delineated across the AOCs 1, 3 and 5. Based on the observations of the field teams,

vernal pool resources do not warrant additional consideration as unique or exceptional resources. However, the pools were all found to occur within, or to have nexus to, areas that are probable Jurisdictional Wetlands as defined and regulated by United States Army Corps of Engineers (USACE) under the Clean Water Act.

NYSDEC regulates wetlands that are 12.4 acres (5 hectares) or larger. The NYSDEC Freshwater Wetlands Act protects wetlands smaller than this if they are considered of unusual local importance. None of the wetlands delineated at the NYOW AOCs are larger than 12.4 acres; none are identified as part of a state-mapped New York State (NYS) freshwater wetland; and none contain features of unusual local importance.

According to the National Wetlands Inventory Map managed (see **Appendix K, Attachment A** and **Figure 2-3**), there is a small Palustrine Emergent Wetland in the southwestern portion on the site and two small, Palustrine Forested Wetlands adjacent to western AOC 4 boundary. There are also several larger Palustrine Forested Wetland and Palustrine Emergent Wetland areas west of AOC 4 and numerous smaller Palustrine Forested Wetlands south and east of AOC 4.

## 2.2 WILDLIFE

**Tables 2-1, 2-2 and 2-3** provide species lists for representative vertebrate species that potentially inhabit or utilize AOC 1, 3, 4 and 5. The lists contain species observed on the during site visits, prior wildlife surveys, or are based on known habitat/species associations for this area of northcentral New York. A list of potential wildlife species was obtained from *Checklist of Amphibians, Reptiles, Birds, and Mammals of New York* (NYSDEC, 2019). Species/habitat associations for species other than those previously observed were determined using professional judgement and information presented in *New England Wildlife: Habitat, Natural History and Distribution* (DeGraaf and Yamasaki, 2001). These lists are not intended to be comprehensive, rather they represent species most likely to be present at sometime during their lifecycle.

### 2.2.1 Species and Habitats of Special Concern

The following discussion provides lists of species and habitats of special concern accumulated from several sources including local species accounts and state and federal database searches. The most detailed information available was for AOC 4 which is located in the Three Rivers WMA. No site-specific accounts of species or habitats of concern are available for AOCs 1,3 and 5, however, based on habitat conditions present at those AOCs it is not likely that any species of concern would substantially utilize these areas during their life cycle.

The Three Rivers WMA, where AOC 4 is located, is identified as a NYS Bird Conservation Area (NYSDEC, 2018c). There are several known species of birds that are listed as endangered, threatened, or of special concern that may be present at Three Rivers WMA including:

- American bittern (*Botaurus lentiginosus),* special concern
- Bald eagle (*Haliaeetus leucocephalus*), threatened
- Cerulean warbler (*Dendroica cerulea)*, special concern
- Common nighthawk (*Chordeiles minor)*, special concern
- Common tern (*Sterna hirundo)*, threatened
- Cooper's hawk (*Accipiter cooperii),* special concern
- Eastern whip-poor-will (*Caprimulgus vociferus)*, special concern

- Golden-winged warbler (*Vermivora chrysoptera*), special concern
- Grasshopper sparrow (*Ammodramus savannarum)*, special concern
- Henslow's sparrow (*Ammodramus henslowii),* threatened
- Horned lark (*Eremophila alpestris)*, special concern
- Least bittern (*Ixobrychus exilis)*, threatened
- Northern goshawk (*Accipiter gentilis)*, special concern
- Northern harrier (*Circus cyaneus)*, threatened
- Osprey (*Pandion haliaetus*), special concern
- Peregrine falcon (*Falco peregrinus)*, endangered
- Pied-billed grebe (*Podilymbus podiceps)*, threatened
- Red-headed woodpecker (*Melanerpes erythrocephalus*), special concern
- Red-shouldered hawk (*Buteo lineatus)*, special concern
- Sedge wren (*Cistothorus platensis)*, threatened
- Sharp-skinned hawk (*Accipiter striatus)*, special concern
- Upland sandpiper (*Bartramia longicauda)*, threatened
- Vesper sparrow (*Pooecetes gramineus),* special concern
- Yellow-breasted chat (*Icteria virens*), special concern

Mammals of conservation concern at Three Rivers WMA include the Indiana bat (*Myotis sodalis),* endangered; Northern long-eared bat (*Myotis septentrionalis),* threatened; small-footed bat (*Myotis leibii),* special concern; and the Tricolored bat (*Perimyotis subflavus*) special concern. According to Ms. Bonnie Parton (NYSDEC), the northern long-eared bat and the tricolored bat were detected near AOC 4 in 2019 (NYSDEC, 2022a).

Amphibians and reptiles of special concern include the Jefferson salamander (*Ambystoma jeffersonianum)* and wood turtle (*Clemmys insculpta)*.

### 2.2.2 New York Natural Heritage Database

The Nature Explorer is the NYNHD (NYNHD, 2022) online tool for identifying animals, plants, and habitats in areas of interest. Users may choose a county, town, or watershed, or may specify their own location on a map, and receive a list of the animals, plants, and natural communities that have been found there. Users may also choose a specific animal, plant, or natural community type, and receive a list of the counties, towns, or watersheds where it has been found.

Included in NYDEC Nature Explorer are the rare plants, rare animals, and significant natural communities (such as forests, wetlands, and other habitat types) documented by the NYNHD; birds documented during the second NYS Breeding Bird Atlas from 2000 to 2005; and reptiles and amphibians documented during the NYS Herp Atlas from 1990 to 1999.

The NYSDEC Nature Explorer identified the Red-headed Woodpecker (*Melanerpes erythrocephalus*) as a species of special concern for the town of Lysander.

The NYSDEC Nature Explorer also identified two endangered plants in the Lysander Area (NYSDEC, 2022c): Carey's Smartweed (*Persicaria careyi*) and Creeping Juniper (*Juniperus horizontalis*). Neither of these species in expected in the AOCs under evaluation. Two habitats of concern: floodplain forest and

silver maple-ash swamp were also identified. The information obtained from the Nature Explorer website is provided in Attachment B.

### 2.2.3 U.S. Fish and Wildlife Service IPaC

The USFWS IPaC database was queried for Onondaga County, New York. Results of this query identified the following protected species: Indiana Bat (Endangered), Northern Long-eared Bat (Threatened), and Monarch Butterfly (Candidate). (See **Attachment C**).

# TABLES

*This page was intentionally left blank.*

**Table 2-1**
**Potential Bird Species**

| | | |
|---|---|---|
| Alder flycatcher *(Empidonax alnorum)* | Eastern wood-pewee *(Contopus virens)* | Scarlet tanager *(Piranga olivacea)* |
| American crow *(Corvus brachyrhynchos)* | Field sparrow *(Spizella pusilla)* | Song sparrow *(Melospiza melodia)* |
| American goldfinch *(Setophaga ruticilla)* | Great blue heron *(Ardea Herodias)* | Tufted titmouse *(Baeolophus bicolor)* |
| American redstart *(Setophaga ruticilla)* | Great crested flycatcher *(Myiarchus crinitus)* | Veery (*Catharus fuscescens)* |
| American robin *(Turdus migratorius)* | Gray catbird *(Dumetella carolinensis)* | White-breasted nuthatch *(Sitta carolinensis)* |
| Baltimore oriole *(Icterus galbula)* | Hairy woodpecker *(Leuconotopicus villosus)* | Willow flycatcher *(Empidonax traillii)* |
| Black-capped chickadee *(Poecile atricapillus)* | House wren *(Troglodytes aedon)* | Wood thrush *(Hylocichla mustelina)* |
| Brown-headed cowbird *(Molothrus ater)* | Indigo bunting *(Passerina cyanea)* | Yellow warbler *(Setophaga petechia)* |
| Blue-headed vireo *(Vireo solitarius)* | Least flycatcher *(Empidonax minimus)* | Yellow-shafted flicker *(Colaptes auratus)* |
| Blue jay *(Cyanocitta cristata)* | Mourning dove *(Zenaida macroura)* | Yellow-throated vireo *(Vireo flavifrons)* |
| Bobolink *(Dolichonyx oryzivorus)* | Northern cardinal *(Cardinalis cardinalis)* | Red-tailed hawk *(Buteo jamaicensis)* |
| Brown creeper *(Certhia americana)* | Northern waterthrush *(Parkesia noveboracensis)* | Broad-winged hawk *(Buteo platypterus)* |
| Blue-winged warbler *(Vermivora cyanoptera)* | Ovenbird *(Seiurus aurocapilla)* | Screech owl *(Megascops)* |
| Cedar waxwing *(Bombycilla cedrorum)* | Rose-breasted grosbeak *(Pheucticus Iudovicianus)* | Great-horned owl (*Bubo virginianus)* |
| Cerulean warbler *(Setophaga cerulea)* | Red-eyed vireo *(Vireo olivaceus)* | Barred owl *(Strix varia)* |
| Common yellowthroat *(Geothlypis trichas)* | Red-winged blackbird *(Agelaius phoeniceus)* | |

**Table 2-2**
**Potential Mammal Species**

| | | |
|---|---|---|
| Virginia opossum<br>*(Didelphis virginiana)* | Northern long-eared bat<br>(*Myotis septentrionalis*) | New England cottontail<br>*(Sylvilagus transitionalis)* |
| Long-tailed shrew<br>*(Sorex dispar)* | Long-tailed weasel<br>*(Mustela frenata)* | Tri-colored bat<br>*(Perimyotis subflavus)* |
| Northern short-tailed shrew<br>*(Blarina brevicauda)* | American mink<br>*(Neovison vison)* | Eastern cottontail<br>*(Sylvilagus floridanus)* |
| Northern least shrew<br>*(Cryptotis parva)* | North American river otter<br>*(Lontra canadensis)* | Striped skunk<br>*(Mephitis mephitis)* |
| Eastern mole<br>*(Scalopus aquaticus)* | White-tailed deer<br>*(Odocoileus virginianus)* | Woodland jumping mouse<br>*(Napaeozapus insignis)* |
| Star-nosed mole<br>*(Condylura cristata)* | Eastern chipmunk<br>*(Tamias striatus)* | American black bear<br>*(Ursus americanus)* |
| Little brown myotis<br>*(Myotis lucifugus)* | Woodchuck<br>*(Marmota monax)* | Brown rat<br>*(Rattus norvegicus)* |
| Tricolored bat<br>*(Perimyotis subflavus)* | Eastern gray squirrel<br>*(Sciurus carolinensis)* | Gray fox<br>*(Urocyon cinereoargenteus)* |
| Big brown bat<br>*(Eptesicus fuscus)* | Red squirrel<br>(*Sciurus vulgaris)* | Southern red-backed vole<br>*(Myodes gapperi)* |
| Eastern red bat<br>*(Lasiurus borealis)* | Northern flying squirrel<br>*(Glaucomys sabrinus)* | Red fox<br>*(Vulpes vulpes)* |
| Hoary bat<br>*(Lasiurus cinereus)* | White-footed Mouse<br>*(Peromyscus leucopus)* | North American deer mouse<br>*(Peromyscus maniculatus)* |
| Indiana bat<br>( *Myotis sodalis*) | Racoon<br>*(Procyon lotor)* | Coyote<br>*(Canis latrans* |

**Table 2-3**
**Potential Reptile and Amphibian Species**

| | | |
|---|---|---|
| Spotted Salamander *(Ambystoma maculatum)* | Wood Turtle *(Glyptemys insculpta)* | Northern Copperhead *(Agkistrodon contortrix mokasen)* |
| Eastern Red-spotted Newt *(Notophthalmus viridescens)* | Eastern Box Turtle *(Terrapene carolina carolina)* | Eastern Milk Snake *(Lampropeltis Triangulum)* |
| Eastern Red-backed Salamander *(Plethodon cinereus)* | Painted Turtle *(Chrysemys picta)* | Pickerel Frog *(Lithobates palustris)* |
| Eastern American Toad *(Anaxyrus americanus)* | Common Five-lined Skink *(Plestiodon fasciatus)* | Smooth Green snake *(Opheodrys vernalis)* |
| Gray Treefrog *(Dryophytes versicolor)* | Northern Red-bellied Snake *(Storeria occipitomaculata occipitomaculata)* | Northern Leopard Frog *(Lithobates pippiens)* |
| Spring Peeper *(Pseudacris crucifer)* | Eastern Garter snake *(Thamnophis sirtalis sirtalis)* | Northern Black Racer *(Coluber constrictor)* |
| Northern Green Frog *(Rana clamitans melanota)* | Eastern Hog-nosed Snake *(Heterodon platirhinos)* | Wood Frog *(Lithobates sylvaticus)* |
| American Bullfrog *(Lithobates catesbeianus)* | Northern Ring-necked Snake *(Diadophis punctatus edwardsii)* | |

**IPaC** **U.S. Fish & Wildlife Service**

# IPaC resource list

This report is an automatically generated list of species and other resources such as critical habitat (collectively referred to as *trust resources*) under the U.S. Fish and Wildlife Service's (USFWS) jurisdiction that are known or expected to be on or near the project area referenced below. The list may also include trust resources that occur outside of the project area, but that could potentially be directly or indirectly affected by activities in the project area. However, determining the likelihood and extent of effects a project may have on trust resources typically requires gathering additional site-specific (e.g., vegetation/species surveys) and project-specific (e.g., magnitude and timing of proposed activities) information.

Below is a summary of the project information you provided and contact information for the USFWS office(s) with jurisdiction in the defined project area. Please read the introduction to each section that follows (Endangered Species, Migratory Birds, USFWS Facilities, and NWI Wetlands) for additional information applicable to the trust resources addressed in that section.

NOT FOR CONSULTATION

## Location

Onondaga County, New York

## Local office

New York Ecological Services Field Office

(607) 753-9334
(607) 753-9699
fw5es_nyfo@fws.gov

3817 Luker Road
Cortland, NY 13045-9385

NOT FOR CONSULTATION

# Endangered species

**This resource list is for informational purposes only and does not constitute an analysis of project level impacts.**

The primary information used to generate this list is the known or expected range of each species. Additional areas of influence (AOI) for species are also considered. An AOI includes areas outside of the species range if the species could be indirectly affected by activities in that area (e.g., placing a dam upstream of a fish population even if that fish does not occur at the dam site, may indirectly impact the species by reducing or eliminating water flow downstream). Because species can move, and site conditions can change, the species on this list are not guaranteed to be found on or near the project area. To fully determine any potential effects to species, additional site-specific and project-specific information is often required.

Section 7 of the Endangered Species Act **requires** Federal agencies to "request of the Secretary information whether any species which is listed or proposed to be listed may be present in the area of such proposed action" for any project that is conducted, permitted, funded, or licensed by any Federal agency. A letter from the local office and a species list which fulfills this requirement can **only** be obtained by requesting an official species list from either the Regulatory Review section in IPaC (see directions below) or from the local field office directly.

For project evaluations that require USFWS concurrence/review, please return to the IPaC website and request an official species list by doing the following:

1. Draw the project location and click CONTINUE.
2. Click DEFINE PROJECT.
3. Log in (if directed to do so).
4. Provide a name and description for your project.
5. Click REQUEST SPECIES LIST.

Listed species[1] and their critical habitats are managed by the Ecological Services Program of the U.S. Fish and Wildlife Service (USFWS) and the fisheries division of the National Oceanic and Atmospheric Administration (NOAA Fisheries[2]).

Species and critical habitats under the sole responsibility of NOAA Fisheries are **not** shown on this list. Please contact NOAA Fisheries for species under their jurisdiction.

---

1. Species listed under the Endangered Species Act are threatened or endangered; IPaC also shows species that are candidates, or proposed, for listing. See the listing status page for more information. IPaC only shows species that are regulated by USFWS (see FAQ).

NOT FOR CONSULTATION

2. NOAA Fisheries, also known as the National Marine Fisheries Service (NMFS), is an office of the National Oceanic and Atmospheric Administration within the Department of Commerce.

The following species are potentially affected by activities in this location:

# Mammals

| NAME | STATUS |
|---|---|
| Indiana Bat Myotis sodalis<br>Wherever found<br>There is **final** critical habitat for this species. The location of the critical habitat is not available.<br>https://ecos.fws.gov/ecp/species/5949 | Endangered |
| Northern Long-eared Bat Myotis septentrionalis<br>Wherever found<br>No critical habitat has been designated for this species.<br>https://ecos.fws.gov/ecp/species/9045 | Threatened |

# Insects

| NAME | STATUS |
|---|---|
| Monarch Butterfly Danaus plexippus<br>Wherever found<br>No critical habitat has been designated for this species.<br>https://ecos.fws.gov/ecp/species/9743 | Candidate |

# Critical habitats

Potential effects to critical habitat(s) in this location must be analyzed along with the endangered species themselves.

THERE ARE NO CRITICAL HABITATS AT THIS LOCATION.

# Migratory birds

Certain birds are protected under the Migratory Bird Treaty Act[1] and the Bald and Golden Eagle Protection Act[2].

NOT FOR CONSULTATION

Any person or organization who plans or conducts activities that may result in impacts to migratory birds, eagles, and their habitats should follow appropriate regulations and consider implementing appropriate conservation measures, as described below.

1. The Migratory Birds Treaty Act of 1918.
2. The Bald and Golden Eagle Protection Act of 1940.

Additional information can be found using the following links:

- Birds of Conservation Concern https://www.fws.gov/program/migratory-birds/species
- Measures for avoiding and minimizing impacts to birds https://www.fws.gov/library/collections/avoiding-and-minimizing-incidental-take-migratory-birds
- Nationwide conservation measures for birds https://www.fws.gov/sites/default/files/documents/nationwide-standard-conservation-measures.pdf

**The birds listed below are birds of particular concern either because they occur on the USFWS Birds of Conservation Concern (BCC) list or warrant special attention in your project location.** To learn more about the levels of concern for birds on your list and how this list is generated, see the FAQ below. This is not a list of every bird you may find in this location, nor a guarantee that every bird on this list will be found in your project area. To see exact locations of where birders and the general public have sighted birds in and around your project area, visit the E-bird data mapping tool (Tip: enter your location, desired date range and a species on your list). For projects that occur off the Atlantic Coast, additional maps and models detailing the relative occurrence and abundance of bird species on your list are available. Links to additional information about Atlantic Coast birds, and other important information about your migratory bird list, including how to properly interpret and use your migratory bird report, can be found below.

For guidance on when to schedule activities or implement avoidance and minimization measures to reduce impacts to migratory birds on your list, click on the PROBABILITY OF PRESENCE SUMMARY at the top of your list to see when these birds are most likely to be present and breeding in your project area.

| NAME | BREEDING SEASON (IF A BREEDING SEASON IS INDICATED FOR A BIRD ON YOUR LIST, THE BIRD MAY BREED IN YOUR PROJECT AREA SOMETIME WITHIN THE TIMEFRAME SPECIFIED, WHICH IS A VERY LIBERAL ESTIMATE OF THE DATES INSIDE WHICH THE BIRD BREEDS ACROSS ITS |
|---|---|

NOT FOR CONSULTATION

ENTIRE RANGE. "BREEDS ELSEWHERE" INDICATES THAT THE BIRD DOES NOT LIKELY BREED IN YOUR PROJECT AREA.)

Bald Eagle Haliaeetus leucocephalus — Breeds Dec 1 to Aug 31
This is not a Bird of Conservation Concern (BCC) in this area, but warrants attention because of the Eagle Act or for potential susceptibilities in offshore areas from certain types of development or activities.
https://ecos.fws.gov/ecp/species/1626

Black-billed Cuckoo Coccyzus erythropthalmus — Breeds May 15 to Oct 10
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.
https://ecos.fws.gov/ecp/species/9399

Blue-winged Warbler Vermivora pinus — Breeds May 1 to Jun 30
This is a Bird of Conservation Concern (BCC) only in particular Bird Conservation Regions (BCRs) in the continental USA

Bobolink Dolichonyx oryzivorus — Breeds May 20 to Jul 31
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.

Canada Warbler Cardellina canadensis — Breeds May 20 to Aug 10
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.

Cerulean Warbler Dendroica cerulea — Breeds Apr 20 to Jul 20
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.
https://ecos.fws.gov/ecp/species/2974

Eastern Whip-poor-will Antrostomus vociferus — Breeds May 1 to Aug 20
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.

Evening Grosbeak Coccothraustes vespertinus — Breeds May 15 to Aug 10
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.

NOT FOR CONSULTATION

Golden Eagle Aquila chrysaetos — Breeds Jan 1 to Aug 31
This is not a Bird of Conservation Concern (BCC) in this area, but warrants attention because of the Eagle Act or for potential susceptibilities in offshore areas from certain types of development or activities.
https://ecos.fws.gov/ecp/species/1680

Golden-winged Warbler Vermivora chrysoptera — Breeds May 1 to Jul 20
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.
https://ecos.fws.gov/ecp/species/8745

Lesser Yellowlegs Tringa flavipes — Breeds elsewhere
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.
https://ecos.fws.gov/ecp/species/9679

Long-eared Owl asio otus — Breeds Mar 1 to Jul 15
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.
https://ecos.fws.gov/ecp/species/3631

Red-headed Woodpecker Melanerpes erythrocephalus — Breeds May 10 to Sep 10
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.

Short-billed Dowitcher Limnodromus griseus — Breeds elsewhere
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.
https://ecos.fws.gov/ecp/species/9480

Wood Thrush Hylocichla mustelina — Breeds May 10 to Aug 31
This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska.

NOT FOR CONSULTATION

# Probability of Presence Summary

The graphs below provide our best understanding of when birds of concern are most likely to be present in your project area. This information can be used to tailor and schedule your project activities to avoid or minimize impacts to birds. Please make sure you read and understand the FAQ "Proper Interpretation and Use of Your Migratory Bird Report" before using or attempting to interpret this report.

**Probability of Presence** (■)

Each green bar represents the bird's relative probability of presence in the 10km grid cell(s) your project overlaps during a particular week of the year. (A year is represented as 12 4-week months.) A taller bar indicates a higher probability of species presence. The survey effort (see below) can be used to establish a level of confidence in the presence score. One can have higher confidence in the presence score if the corresponding survey effort is also high.

How is the probability of presence score calculated? The calculation is done in three steps:

1. The probability of presence for each week is calculated as the number of survey events in the week where the species was detected divided by the total number of survey events for that week. For example, if in week 12 there were 20 survey events and the Spotted Towhee was found in 5 of them, the probability of presence of the Spotted Towhee in week 12 is 0.25.
2. To properly present the pattern of presence across the year, the relative probability of presence is calculated. This is the probability of presence divided by the maximum probability of presence across all weeks. For example, imagine the probability of presence in week 20 for the Spotted Towhee is 0.05, and that the probability of presence at week 12 (0.25) is the maximum of any week of the year. The relative probability of presence on week 12 is 0.25/0.25 = 1; at week 20 it is 0.05/0.25 = 0.2.
3. The relative probability of presence calculated in the previous step undergoes a statistical conversion so that all possible values fall between 0 and 10, inclusive. This is the probability of presence score.

To see a bar's probability of presence score, simply hover your mouse cursor over the bar.

**Breeding Season** (■)
Yellow bars denote a very liberal estimate of the time-frame inside which the bird breeds across its entire range. If there are no yellow bars shown for a bird, it does not breed in your project area.

**Survey Effort** (|)
Vertical black lines superimposed on probability of presence bars indicate the number of surveys performed for that species in the 10km grid cell(s) your project area overlaps. The number of surveys is expressed as a range, for example, 33 to 64 surveys.

To see a bar's survey effort range, simply hover your mouse cursor over the bar.

**No Data** (–)
A week is marked as having no data if there were no survey events for that week.

**Survey Timeframe**
Surveys from only the last 10 years are used in order to ensure delivery of currently relevant information. The exception to this is areas off the Atlantic coast, where bird returns are based on all years of available data, since data in these areas is currently much more sparse.

**Tell me more about conservation measures I can implement to avoid or minimize impacts to migratory birds.**

Nationwide Conservation Measures describes measures that can help avoid and minimize impacts to all birds at any location year round. Implementation of these measures is particularly important when birds are most likely to occur in the project area. When birds may be breeding in the area, identifying the locations of any active nests and avoiding their destruction is a very helpful impact minimization measure. To see when birds are most likely to occur and be breeding in your project area, view the Probability of Presence Summary. Additional measures or permits may be advisable depending on the type of activity you are conducting and the type of infrastructure or bird species present on your project site.

**What does IPaC use to generate the migratory birds potentially occurring in my specified location?**

The Migratory Bird Resource List is comprised of USFWS Birds of Conservation Concern (BCC) and other species that may warrant special attention in your project location.

The migratory bird list generated for your project is derived from data provided by the Avian Knowledge Network (AKN). The AKN data is based on a growing collection of survey, banding, and citizen science datasets and is queried and filtered to return a list of those birds reported as occurring in the 10km grid cell(s) which your project intersects, and that have been identified as warranting special attention because they are a BCC species in that area, an eagle (Eagle Act requirements may apply), or a species that has a particular vulnerability to offshore activities or development.

Again, the Migratory Bird Resource list includes only a subset of birds that may occur in your project area. It is not representative of all birds that may occur in your project area. To get a list of all birds potentially present in your project area, please visit the AKN Phenology Tool.

**What does IPaC use to generate the probability of presence graphs for the migratory birds potentially occurring in my specified location?**

The probability of presence graphs associated with your migratory bird list are based on data provided by the Avian Knowledge Network (AKN). This data is derived from a growing collection of survey, banding, and citizen science datasets .

Probability of presence data is continuously being updated as new and better information becomes available. To learn more about how the probability of presence graphs are produced and how to interpret them, go the Probability of Presence Summary and then click on the "Tell me about these graphs" link.

**How do I know if a bird is breeding, wintering, migrating or present year-round in my project area?**

NOT FOR CONSULTATION

To see what part of a particular bird's range your project area falls within (i.e. breeding, wintering, migrating or year-round), you may refer to the following resources: The Cornell Lab of Ornithology All About Birds Bird Guide, or (if you are unsuccessful in locating the bird of interest there), the Cornell Lab of Ornithology Neotropical Birds guide. If a bird on your migratory bird species list has a breeding season associated with it, if that bird does occur in your project area, there may be nests present at some point within the timeframe specified. If "Breeds elsewhere" is indicated, then the bird likely does not breed in your project area.

**What are the levels of concern for migratory birds?**

Migratory birds delivered through IPaC fall into the following distinct categories of concern:

1. "BCC Rangewide" birds are Birds of Conservation Concern (BCC) that are of concern throughout their range anywhere within the USA (including Hawaii, the Pacific Islands, Puerto Rico, and the Virgin Islands);
2. "BCC - BCR" birds are BCCs that are of concern only in particular Bird Conservation Regions (BCRs) in the continental USA; and
3. "Non-BCC - Vulnerable" birds are not BCC species in your project area, but appear on your list either because of the Eagle Act requirements (for eagles) or (for non-eagles) potential susceptibilities in offshore areas from certain types of development or activities (e.g. offshore energy development or longline fishing).

Although it is important to try to avoid and minimize impacts to all birds, efforts should be made, in particular, to avoid and minimize impacts to the birds on this list, especially eagles and BCC species of rangewide concern. For more information on conservation measures you can implement to help avoid and minimize migratory bird impacts and requirements for eagles, please see the FAQs for these topics.

**Details about birds that are potentially affected by offshore projects**

For additional details about the relative occurrence and abundance of both individual bird species and groups of bird species within your project area off the Atlantic Coast, please visit the Northeast Ocean Data Portal. The Portal also offers data and information about other taxa besides birds that may be helpful to you in your project review. Alternately, you may download the bird model results files underlying the portal maps through the NOAA NCCOS Integrative Statistical Modeling and Predictive Mapping of Marine Bird Distributions and Abundance on the Atlantic Outer Continental Shelf project webpage.

Bird tracking data can also provide additional details about occurrence and habitat use throughout the year, including migration. Models relying on survey data may not include this information. For additional information on marine bird tracking data, see the Diving Bird Study and the nanotag studies or contact Caleb Spiegel or Pam Loring.

**What if I have eagles on my list?**

If your project has the potential to disturb or kill eagles, you may need to obtain a permit to avoid violating the Eagle Act should such impacts occur.

**Proper Interpretation and Use of Your Migratory Bird Report**

NOT FOR CONSULTATION

The migratory bird list generated is not a list of all birds in your project area, only a subset of birds of priority concern. To learn more about how your list is generated, and see options for identifying what other birds may be in your project area, please see the FAQ "What does IPaC use to generate the migratory birds potentially occurring in my specified location". Please be aware this report provides the "probability of presence" of birds within the 10 km grid cell(s) that overlap your project; not your exact project footprint. On the graphs provided, please also look carefully at the survey effort (indicated by the black vertical bar) and for the existence of the "no data" indicator (a red horizontal bar). A high survey effort is the key component. If the survey effort is high, then the probability of presence score can be viewed as more dependable. In contrast, a low survey effort bar or no data bar means a lack of data and, therefore, a lack of certainty about presence of the species. This list is not perfect; it is simply a starting point for identifying what birds of concern have the potential to be in your project area, when they might be there, and if they might be breeding (which means nests might be present). The list helps you know what to look for to confirm presence, and helps guide you in knowing when to implement conservation measures to avoid or minimize potential impacts from your project activities, should presence be confirmed. To learn more about conservation measures, visit the FAQ "Tell me about conservation measures I can implement to avoid or minimize impacts to migratory birds" at the bottom of your migratory bird trust resources page.

NOT FOR CONSULTATION

# Coastal Barrier Resources System

Projects within the John H. Chafee Coastal Barrier Resources System (CBRS) may be subject to the restrictions on federal expenditures and financial assistance and the consultation requirements of the Coastal Barrier Resources Act (CBRA) (16 U.S.C. 3501 et seq.). For more information, please contact the local Ecological Services Field Office or visit the CBRA Consultations website. The CBRA website provides tools such as a flow chart to help determine whether consultation is required and a template to facilitate the consultation process.

THERE ARE NO KNOWN COASTAL BARRIERS AT THIS LOCATION.

**Data limitations**

The CBRS boundaries used in IPaC are representations of the controlling boundaries, which are depicted on the official CBRS maps. The boundaries depicted in this layer are not to be considered authoritative for in/out determinations close to a CBRS boundary (i.e., within the "CBRS Buffer Zone" that appears as a hatched area on either side of the boundary). For projects that are very close to a CBRS boundary but do not clearly intersect a unit, you may contact the Service for an official determination by following the instructions here: https://www.fws.gov/service/coastal-barrier-resources-system-property-documentation

**Data exclusions**

CBRS units extend seaward out to either the 20- or 30-foot bathymetric contour (depending on the location of the unit). The true seaward extent of the units is not shown in the CBRS data, therefore projects in the offshore areas of units (e.g., dredging, breakwaters, offshore wind energy or oil and gas projects) may be

subject to CBRA even if they do not intersect the CBRS data. For additional information, please contact CBRA@fws.gov.

# Facilities

## National Wildlife Refuge lands

Any activity proposed on lands managed by the National Wildlife Refuge system must undergo a 'Compatibility Determination' conducted by the Refuge. Please contact the individual Refuges to discuss any questions or concerns.

THERE ARE NO REFUGE LANDS AT THIS LOCATION.

## Fish hatcheries

THERE ARE NO FISH HATCHERIES AT THIS LOCATION.

# Wetlands in the National Wetlands Inventory

Impacts to NWI wetlands and other aquatic habitats may be subject to regulation under Section 404 of the Clean Water Act, or other State/Federal statutes.

For more information please contact the Regulatory Program of the local U.S. Army Corps of Engineers District.

WETLAND INFORMATION IS NOT AVAILABLE AT THIS TIME

This can happen when the National Wetlands Inventory (NWI) map service is unavailable, or for very large projects that intersect many wetland areas. Try again, or visit the NWI map to view wetlands at this location.

**Data limitations**

The Service's objective of mapping wetlands and deepwater habitats is to produce reconnaissance level information on the location, type and size of these resources. The maps are prepared from the analysis of high altitude imagery. Wetlands are identified based on vegetation, visible hydrology and geography. A margin of error is inherent in the use of imagery; thus, detailed on-the-ground inspection of any particular site may result in revision of the wetland boundaries or classification established through image analysis.

NOT FOR CONSULTATION

The accuracy of image interpretation depends on the quality of the imagery, the experience of the image analysts, the amount and quality of the collateral data and the amount of ground truth verification work conducted. Metadata should be consulted to determine the date of the source imagery used and any mapping problems.

Wetlands or other mapped features may have changed since the date of the imagery or field work. There may be occasional differences in polygon boundaries or classifications between the information depicted on the map and the actual conditions on site.

### Data exclusions

Certain wetland habitats are excluded from the National mapping program because of the limitations of aerial imagery as the primary data source used to detect wetlands. These habitats include seagrasses or submerged aquatic vegetation that are found in the intertidal and subtidal zones of estuaries and nearshore coastal waters. Some deepwater reef communities (coral or tuberficid worm reefs) have also been excluded from the inventory. These habitats, because of their depth, go undetected by aerial imagery.

### Data precautions

Federal, state, and local regulatory agencies with jurisdiction over wetlands may define and describe wetlands in a different manner than that used in this inventory. There is no attempt, in either the design or products of this inventory, to define the limits of proprietary jurisdiction of any Federal, state, or local government or to establish the geographical scope of the regulatory programs of government agencies. Persons intending to engage in activities involving modifications within or adjacent to wetland areas should seek the advice of appropriate federal, state, or local agencies concerning specified agency regulatory programs and proprietary jurisdictions that may affect such activities.

Notes
-- = Not Evaluated
C = Combined Primary/Field Duplicate Sample
CASRN = Chemical Abstracts Service Registry Number
LOD = Limit of Detection
N/A = Not Applicable
N = Primary Sample
ND = Non-Detect or Not Detected
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.

| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.
R – The presence or absence of the analyte cannot be substantiated by the data provided.

ND = Non-Detect or Not Detected
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.

Notes
-- = Not Evaluated
C = Combined Primary/Field Duplicate Sample
CASRN = Chemical Abstracts Service Registry Number
LOD = Limit of Detection
N/A = Not Applicable
N = Primary Sample
ND = Non-Detect or Not Detected
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend
ND — Not detected at the LOD
Detect — Detected result
Detect — Detected result > SL

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).
UJ – The analyte was not detected and was reported as less than the LOD. However, the associated numerical value is approximate.

ND = Non-Detect or Not Detected
SL = Screening Level
(1) See Section 4.0 for data reduction steps.

Legend

| | |
|---|---|
| ND | Not detected at the LOD |
| Detect | Detected result |
| Detect | Detected result > SL |

Qualifier Definitions
J – The reported result was an estimated value (+/- indicates a positive/negative bias).
U – The analyte was not detected and was reported as less than the limit of detection (LOD).

Notes:
% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
J = Estimated Concentration (+/- indicates a positive/negative bias)
LOD = Limit of Detection
LOQ = Limit of Quantitation
MDC = Maximum Detected Concentration
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency
(1) Summary statistics were only evaluated for chemicals with at least two distinct detects.
(2) See Appendix L.1 for screening level determination steps.

Table L.5-10
Ecological Screening Summary – Area of Concern 5 (Possible Dump Area), Surface Soil (0 - 1 ft bgs), Plants
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

Notes:
% = Percent
CASRN = Chemical Abstracts Service Registry Number
COPEC = Chemical of Potential Ecological Concern
ft bgs = feet below gound surface
J = Estimated Concentration (+/- indicates a positive/negative bias)
LOD = Limit of Detection
LOQ = Limit of Quantitation
MDC = Maximum Detected Concentration
N/A = Not Applicable
ND = Non-Detect or Not Detected
USEPA = United States Environmental Protection Agency
(1) Summary statistics were only evaluated for chemicals with at least two distinct detects.
(2) See Appendix L.1 for screening level determination steps.

Table L.5-12
Ecological Screening Summary – Area of Concern 5 (Possible Dump Area), Surface Soil (0 - 1 ft bgs), Plants
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

- Brammer, Dean D CIV USARMY CENAE (USA) (Tentative in Outlook)

AGENDA

- Question from PDT to EMCX about Evaluation of Coal Microscopy Sampling

NOTES

- Grace started call with summary of Questions about coal microscopy sampling at NYOW. Grace explained that we do not know if the PAHs detected in the sample are a result of the coal particulates or PAHs that have leached from the coal to the soil. Therefore, the plan was to eliminate samples that are defined as having “heavy” or “very heavy” coal presence from the risk assessment because it is our understanding that coal is not a hazardous substance and cannot be remediated under CERCLA/ FUDs.
- Walter Roberts indicated he is not familiar with microscopy. Grace and Rick provide an explanation.
- EMCX indicated that they do not understand why we are doing coal microscopy, as we cannot eliminate soil samples from the risk assessment based on coal particulate content because the risk assessment should evaluate the exposure matrix. Walter Roberts says we legally cannot eliminate the samples. He used the example: change "Coal" to "lead based paint" left in the ground. Rick and Glenn said we're essentially dealing with soil, which is a viable exposure medium.
- Amanda indicated this is contradictory to the comments received previously from EMCX on both the Phase 1 RI QAPP and Phase 2 RI QAPP over the past five years.
    - EMCX asked who the reviewer was, and Amanda indicated Tom Georgian. EMCX indicated that Tom is now retired, we won't receive these types of comments anymore, and that they don't agree with Tom's previous comments
    - EMCX said Tom was driven by statistics. Constance said he was also driven by preventing remediation activities where not truly necessary.
    - Amanda indicated that a change in direction at this late stage is incredibly frustrating, because we’ve already spent 9 months going back and forth with EMCX on the Phase 2 RI QAPP, and this issue was previously resolved - but now we’re still not aligned on the approach for the coal microscopy. Meanwhile, the Contractor is expected to finalize the QAPP by the end of this week so the field team can begin work today (Monday, August 4). The coal microscopy sampling is scheduled for a couple of weeks out.

    - Walter said we cannot generalize for EMCX input because he is EMCX and has not reviewed this document/ Site.
    - Heather provided an example of the types of comments provided by Tom regarding coal. She indicated there were 46 comments on the Phase 2 RI QAPP and they were all consistent. One of Tom's comments was: "Present valid well-defined decision criteria on how the proposed sampling results will be used to distinguish metal and PAH contamination in coal at AOC 5 EUs/DUs from metal and PAH contamination absorbed to soils at AOC 5 EUs/DUs. Alternatively, remove the proposed chemical soil analyses for PAHs and metals."
    - EMCX reiterated they do not agree with Tom and that we should document that a decision was made on this day, by these people, in a memo for the record
- Glenn stated this is a similar scenario to site with clay target fragments, for which they used a sieve analysis and found increasing particle size correlates with PAH concentrations versus increasing particle size inverse to PAH concentrations. They found decreasing PAH concentrations as you went to finer fractions indicates the PAHs were less from leaching, more from the particles of clay targets themselves. Glenn indicated he believes the adherable fraction is the risk driver, so the EMCX directed the PDT that the exposure medium is the driver, regardless of whether it is coal or not, if there are PAHs that cause risk in the adherable fraction (i.e., 250 micron or less), it has to be remediated.
    - Grace asked: what about larger particles that will eventually weather in the future to the adherable fraction? Eventually, this could cause a risk in the future. She noted that the PAH concentrations in the two smaller areas of AOC 5 are elevated enough to trigger an unacceptable risk. Glenn acknowledged that point and then noted that it may be more practical to remediate, especially for a smaller site, instead of going through this process of trying to distinguish what's leaching from the coal using other methods like the sieving process.
    - We did not sieve the Phase 1 RI data and are not planning to sieve the Phase 2 RI data. Amanda indicated that we cannot add additional analyses at this point. Julie reiterated this point and asked what else the EMCX would recommend using the data already planned for collection. Glenn indicated he does not have any other ideas.
- EMCX clarified that we remediate CERCLA releases from DoD activities that pose an unacceptable risk. If those releases are from/associated with the coal, then we remediate. We can remediate soil that is mixed with coal particulates, if there are CERCLA contaminants in the media (combined soil/ coal particulate mix) that pose risk, even though we don't know if the elevated concentrations of CERCLA contaminants are attributable to coal particles or leaching of coal. Additionally, we would remediate coal alone (not mixed with soil), if it posed a risk. Coal itself is not automatically considered a hazardous substance.
- Rick asked how deep NAE evaluates surface soil.
    - Amanda said 0-1 ft bgs based on NY guidance.
    - Constance pointed out that PAHs are tightly bound in the coal matrix so less likely to leach.
    - Grace pointed out that the site is currently a grassy, undeveloped field surrounded by forested area. From the site visit, there are no coal piles, and she could not tell that coal was stored there (i.e., did not see large pieces of coal). Constance pointed out that the analyses show particles too small to be visually identified (e.g. around 100 micron and up to 200 ish, from what I can see), but later clarified that does not mean there are not larger particles there. The point is there are particles of coal present that are at least this small.
    - Rick said that suggests we're essentially dealing with soil, which is a viable exposure medium.
- Walter indicated the PDT should elevate comments to division and HQ if they do not agree. Heather indicated that we did elevate these comments multiple times to both division and HQ, had multiple lengthy resolution calls between PDT and EMCX, involved EMCX management, and

presented issues with the EMCX review of this QAPP (but not necessarily this specific topic) at the FUDS Focus Review

- Constance asked the team is there is value in collecting this data for the RI and may help with any potential remedial action - Amanda agreed.
- EMCX indicated that “the PDT needs to convince itself” of the path forward
- Rick said he isn't experienced with coal sites so this conversation was very educational.
- Grace stated that since the coal particles could be an exposure medium, we will include it in the risk assessment to determine if the area warrants remediation. And since the Phase 1 RI data showed elevated concentrations that could warrant an actional risk, we will likely remediate these small areas.
- Walter chimed in, in closing, that we do not remediate coal because it is not a hazardous substance. We remediate CERCLA releases from DoD activities that pose an unacceptable risk, no matter what that medium they are in.

# 1.0 INTRODUCTION

This Baseline Human Health Risk Assessment (BHHRA) Work Plan in support of the Phase 2 Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) Remedial Investigation (RI) at the New York Ordnance Works (NYOW) Formerly Used Defense Site (FUDS) in Baldwinsville, New York (hereafter referred to as the "Site"). The former NYOW is located in Onondaga County, New York, near the Finger Lakes, about one-mile northeast of the Village of Baldwinsville and approximately 13 miles north of Syracuse, New York. Portions of the Site are currently owned by the Radisson Community, the State of New York, and private owners.

A Phase 1 RI was initiated and completed by Bluestone Environmental, Inc. (Bluestone) in 2021 at the former NYOW Site. The Phase 1 RI investigated four areas of concern (AOCs); AOC 1 – Former Ammonium Picrate Building Area; AOC 3 – Former Landfill Area; AOC 4 – Former Bunker Area; and AOC 5 – Former Power Plant. The Phase 2 RI includes the same four AOCs.

As part of the Phase 2 RI, a BHHRA for these AOCs is required. The BHHRA will be performed to assess whether potential unacceptable health risks are present if people are exposed to CERCLA constituents in soil, groundwater, hydric soils, surface water, or sediment related to historical Department of Defense (DoD) activities, and then to determine if remedial measures are needed.

This BHHRA Work Plan has been prepared as a planning step for conducting the BHHRA to address requirements of CERCLA and the National Contingency Plan (NCP) 40 Code of Federal Regulations (CFR) Part 300 (United States Environmental Protection Agency [USEPA], 1988) and is included as Appendix B of the Phase 2 Uniform Federal Policy Quality Assurance Project Plan (UFP-QAPP). Because this work plan is included as an appendix to the Phase 2 UFP-QAPP, detailed information describing the Site characteristics, operational history, physical setting, and summaries of the previous investigations are not included in the Appendix, but rather the reader is referred to the Phase 2 UFP-QAPP.

## 1.1 OBJECTIVES AND REGULATORY FRAMEWORK

The purpose of the Work Plan is to document the methods and procedures for evaluating potential human health risks associated with exposure to contaminants of potential concern (COPCs) identified in environmental media associated with each of the AOCs identified at the Site.

The BHHRA will be conducted in accordance with CERCLA requirements and consistent with USEPA and USACE risk assessment guidance and all applicable New York State Department of Environmental Conservation (NYSDEC) requirements as appropriate.

The BHHRA will be performed in general accordance with USEPA guidance including, but not limited to the following documents:

- Risk Assessment Guidance for Superfund (RAGS). Volume 1: Human Health Evaluation Manual
    - Part A, Baseline Risk Assessment, Interim Final, (USEPA, 1989)
    - Part D, Standardized Planning, Reporting and Review of Superfund Risk Assessments, (USEPA, 2002a)

    - Part E, Supplemental Guidance for Dermal Risk Assessment, (USEPA, 2004)
    - Part F, Supplemental Guidance for Inhalation Risk Assessment, Final, (USEPA, 2009)
- Guidance for Data Usability in Risk Assessment (USEPA, 1992)
- Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites (USEPA, 2002b)
- Exposure Factors Handbook: 2011 Edition (USEPA, 2011) and recent updates
- OSWER Directive 9283.1-42. Determining Groundwater Exposure Point Concentrations, Supplemental Guidance (USEPA, 2014a)
- OSWER Directive 9200.1-120. Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. Attachment 1. Recommended Default Exposure Factors, (USEPA, 2014b)
- Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites. OSWER 9355.4-24 (USEPA, 2002c)
- Human Health Toxicity Values in Superfund Risk Assessments (USEPA, 2003)
- Guidelines for Carcinogen Risk Assessment, Final (USEPA, 2005a)
- Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005b)
- Updated Residential Soil Lead Guidance for CERCLA Sites and RCRA Corrective Action Facilities (USEPA, 2024a)

### 1.2 WORK PLAN ORGANIZATION

This Work Plan includes the following components:

- **Section 1, Introduction.** Provides the scope, objectives, and regulatory framework of the Work Plan.
- **Section 2, BHHRA Approach.** Provides an overview of the process and methods that will be used to conduct the BHHRA, including:
    - **Hazard Identification.** Provides details on the methods used for data compilation and evaluation, selection of data to be considered in the BHHRA, summarization of the analytical data considered for the BHHRA, and selection of COPCs for quantitative evaluation.
    - **Preliminary Conceptual Site Model and Exposure Assessment.** Describes the preliminary conceptual site model and identifies the exposure assumptions and receptor- specific exposure parameters for the BHHRA exposure assessment.
    - **Toxicity Assessment.** Provides a description of the types of toxicological information and provides the toxicity criteria that will be used to evaluate exposure to COPCs.
    - **Risk Characterization and Uncertainty Assessment.** Describes the process that will be used to integrate the information from the exposure assessment and toxicity assessment to characterize the human health risk posed by the Site in the BHHRA.
- **Section 3, References.** Provides a list of references used in the preparation of this document.

## 2.0 BASELINE HUMAN HEALTH RISK ASSESSMENT APPROACH

USEPA uses risk assessment as a tool to evaluate the likelihood and degree of chemical exposure and the possible adverse health effects associated with such exposure. The BHHRA will be conducted using reasonable but conservative exposure and dose-response assumptions to characterize the range of potential Site risks and Site-specific exposure information will be incorporated, when available, to reduce the uncertainty in the risk characterization for the Site. The overall approach entails the use of discrete samples to demonstrate no actionable risks for each AOC. If risks are unacceptable for a given AOC, the risk assessment may be refined or potentially areas where further investigations are warranted may be identified.

The risk assessment will be conducted by completing a four-step process: hazard identification, exposure assessment, toxicity assessment, and risk characterization. Key aspects of the BHHRA methods are summarized here and described in more detail in the following subsections below.

- **Hazard Identification.** The purpose of the hazard identification process is to summarize data and identify COPCs to be evaluated in the HHRA. The hazard identification step enables the chemicals detected in each medium to be divided into two groups: (1) chemicals that have negligible potential for adverse effects to humans and therefore do not need to be evaluated further; and (2) chemicals that have potential for adverse effects to humans and therefore require further evaluation - these are the COPCs.
- **Preliminary Conceptual Site Model (CSM) and Exposure Assessment.** The preliminary CSM identifies the way a human population may be exposed to constituents at a site, guides data collection and analysis, and ultimately facilitates the calculation of media-specific exposure point concentrations (EPCs) for each contaminant of concern. The objective of the exposure assessment is to estimate the magnitude, frequency, duration, and routes of current and reasonably anticipated future exposure to COPCs associated with the Site. The extent of a receptor's exposure is estimated by identifying exposure scenarios that describe the potential pathways of exposure to COPCs and the specific activities and behaviors of individuals that might lead to contact with COPCs in the environment. The exposure assessment is based on the potential receptors, exposure pathways, described in the CSM.
- **Toxicity Assessment.** The toxicity assessment determines the relationship between the magnitude of exposure to a COPC and the nature and magnitude of adverse health effects that may result from such exposure. Adverse effects are classified by USEPA as potentially carcinogenic or noncarcinogenic (i.e., potential health effects other than cancer). Toxicity criteria will be selected following USEPA policy and guidance.

**Risk Characterization** The risk characterization combines the results of the exposure assessment and toxicity assessment to calculate cancer risks and noncancer health hazards. The risk characterization will convey the nature of potential risks present at the Site in quantitative and qualitative terms and will

evaluate uncertainties and variability in the findings in order to provide an understanding of the strengths and potential uncertainties of the calculated risks and hazards.

## 2.1 HAZARD IDENTIFICATION

This section provides details on the procedures that will be used to complete the Hazard Identification step of the BHHRA. The hazard identification includes the data compilation, data evaluation, processing and summarization of analytical data considered in the BHHRA, and selection of COPCs.

### 2.1.1 Data Compilation

Historical chemistry data are available for the Site from reports ranging from 1981 through 2008. During preparation of the Phase 1 UFP-QAPP (USACE, 2020), it was determined that those data are of limited use due to issues associated with their age (e.g., comparability with recently collected data). Therefore, only data collected during the Phase 1 and Phase 2 RI field efforts will be considered for the BHHRA.

Phase 1 RI data were collected in 2021 and include analytical results for soil and groundwater samples collected at AOC 1, AOC 3, AOC 4, AOC 5, and background locations. All work was completed in accordance with applicable Federal, State, and local regulations, as well as industry standards and best management practices. In general, samples were collected and analyzed in accordance with the Final Uniform UFP-QAPP (USACE, 2020), with any deviations noted in the RI Phase 1 Field Reports (USACE, 2021 and 2022). Field documents, field data, and laboratory data were loaded into and managed within the Formerly Used Defense Sites Chemical (FUDSChem) database. With the exception of incremental sampling methodology (ISM) samples collected from surface soil (0 to 1 feet below ground surface [ft bgs]) in the bunker aprons of AOC 4, all samples collected were discrete soil samples collected from 0 to 10 ft bgs (i.e., 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs). Table 2.1-1 summarizes the data available from the Phase 1 field efforts, including the number of samples per medium (and depth interval for soils) and analyses conducted.

**Table 2.1-1: Available Data from Phase 1**

| Area Sampled | Number of Samples per Medium | | | | Analyses |
|---|---|---|---|---|---|
| | Soil (0-1 ft bgs) | Soil (1-5 ft bgs) | Soil (5-10 ft bgs) | Groundwater | |
| AOC 1 | 30 | 11 | 11 | NA[(a)] | 2,4-DNP, 2,4-DNCB, picric acid, inorganics |
| AOC 3 | 16 | 18 | None | NA[(a)] | VOCs, SVOCs, picric acid, PAHs, Aroclors, inorganics |
| AOC 4 – Discrete | 16 | 85 | 16 | NA[(a)] | 2,4-DNP, 2,4-DNCB, picric acid |
| AOC 4 - ISM | NA[(a)] | None | None | | |
| AOC 5 | 25 | 25 | 25 | NA[(a)] | VOCs, SVOCs, PAHs, Aroclors, inorganics |
| Background | 45 | 45 | 45 | NA[(a)] | PAHs and inorganics |

Notes:

(a) Data were obtained during the Phase 1 field investigations; however, these data have been determined to be not useful for risk assessment purposes and will therefore not be included in the BHHRA. See text narrative for why these data were eliminated from the BHHRA.

Acronyms:

2,4-DNCB = 2,4-dinitrochlorobenzene
2,4-DNP = 2,4-dinitrophenol
AOC = area of concern
ft bgs = feet below ground surface
ISM = incremental sampling methodology
NA = not applicable
PAHs = polycyclic aromatic hydrocarbons
SVOCs = semivolatile organic compounds
VOCs = volatile organic compounds

The ISM approach at AOC 4 was selected for sampling around the ammonium picrate bunkers at AOC 4 to generate a versatile data suite that could be applied to risk-based objectives and provide opportunities to evaluate total concentrations of any contaminants. Based on the assessment of data quality indicators (DQIs) that was performed as part of the Phase 1 Risk Screening and Data Gap Analysis, the ISM data at AOC 4 was determined to have data usability issues. The results of the data usability assessment and screening comparisons at AOC 4 indicated the following issues with the ISM data (Bluestone, 2023):

- 2,4-dinitrochlorobenzene (2,4-DNCB) in ISM surface soil had low bias attributable to low surrogate recoveries for 33 of 34 samples (97%). 2,4-Dinitrophenol (2,4-DNP) had low bias attributable to low surrogate recoveries for 27 of 29 samples (93%). Picric acid had low bias attributable to low surrogate and matrix spike recoveries at a frequency of 9 of 36 samples (25%). The uniformly low bias of results reported as non-detect represents a data gap within the bunker areas at AOC 4.
- For ISM Decision Unit (DU) 1, all three replicates had results rejected for low bias of 2,4-DNP based on low matrix spike/matrix spike duplicate (MS/MSD) recoveries. For ISM DU 5, one replicate had results rejected for 2,4-DNCB and 2,4-DNP due to holding time exceedances. For ISM DU 9, all three replicates had results rejected for low bias of 2,4-DNP due to an MSD that did not recover. For DU 10, one replicate had the result for 2,4-DNCB rejected based on a low surrogate recovery. Three valid ISM replicates are considered necessary to provide information regarding the reproducibility and heterogeneity of the data; therefore, the lack of three valid replicates represent a data gap within the bunker areas at AOC 4.

The Phase 2 field effort includes a discrete surface soil sampling program in all of the DUs of AOC 4 for 2,4-DNCB and 2,4-DNP in surface soil to address the low bias that is prevalent in the analytical data seemingly due to using ISM sample processing. The Phase 2 sampling also includes analysis of picric acid from the samples for confirmation of ISM sampling results. Obtaining these data should meet the Phase 1 objectives of determining presence/absence and characterizing a potential source area.

Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling during the Phase 1 investigation. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Additionally, temporary wells provide only limited hydrogeologic information; therefore, they are not sufficient to fully evaluate hydrogeologic conditions and aquifer characteristics. Lastly, the HHRA requires the use of total, not dissolved metals concentrations. Therefore, groundwater data from Phase 1 field investigations will not be used in the BHHRA. Installation of permanent monitoring wells along with well development will be performed during the Phase 2 investigation. As such, Phase 2 groundwater data will be the only groundwater data utilized in the BHHRA.

For Phase 2 of the RI, additional investigations into the nature and extent, investigations into potential impacts to additional media (i.e., surface water, porewater, hydric soils, and sediment), and Site-

hydrogeological conditions (e.g., groundwater flow) are planned as detailed in Worksheet #15 of the Phase 2 UFP-QAPP. Table 2.1-2 summarizes the number of proposed samples per medium (and depth interval for soils) that will be available from the Phase 2 field effort for use in the BHHRA.

**Table 2.1-2: Proposed Available Data from Phase 2**

| Area Sampled | Number of Samples per Medium | | | | | | Analyses |
|---|---|---|---|---|---|---|---|
| | Soil (0-1 ft bgs) | Soil (1-5 ft bgs) | Soil (5-10 ft bgs) | Groundwater[(a)] | Sediment or Hydric Soils[(b)] (0-1 ft bgs) | Surface Water | |
| AOC 1 | 16 | 16 | 16 | 20 | 12 | None | 2,4-DNP, 2,4-DNCB, picric acid, TAL metals |
| AOC 3 | 7 | 7 | 7 | 14 | 16 | 16 | VOCs, SVOCs, PAHs, Aroclors, picric acid, TAL metals |
| AOC 4 – Discrete | 60 | None | None | None | None | None | 2,4-DNP, 2,4-DNCB, picric acid |
| AOC 5 | 25 | 25 | 25 | 20 | 5 | None | PAHs and TAL metals, Aroclors[(c)] |
| Background | None | None | None | 12 | 8 (hydric soils) 16 (stream sediment) | 16 | PAHs and TAL metals |

Notes:
(a) Includes semiannual sampling for one year.
(b) Samples from AOC 1 and AOC 5 will be collected in the wetlands area and are considered hydric soil samples. Samples collected from AOC 3 are sediment samples associated with a stream.
(c) Aroclors only proposed for soils from the electric substation and for groundwater from the electric substation, possible dump and two wells downgradient of the substation.

Acronyms:
2,4-DNCB = 2,4-dinitrochlorobenzene
2,4-DNP = 2,4-dinitrophenol
AOC = area of concern
ft bgs = feet below ground surface
ISM = incremental sampling methodology
PAHs = polycyclic aromatic hydrocarbons
SVOCs = semivolatile organic compounds
TAL = target analyte list
VOCs = volatile organic compounds

Except for the ISM data and groundwater data obtained from temporary groundwater wells during the Phase 1 field investigation, all of the analytical data generated from the Phase 1 and Phase 2 field efforts will be considered for quantitative evaluation in the BHHRA as appropriate (See Section 2.1.2). As contaminants present in the environment may have originated from sources within each AOC, each AOC will be thought of as a separate exposure area for evaluating risk. Phase 1 and Phase 2 data will be combined as a single dataset to select COPCs within each AOC. The ISM data from AOC 4 may be used qualitatively to support the presence or absence of COPCs (i.e., 2,4-DNP, 2,4-DNCB, and picric acid) in AOC 4 as part of the risk characterization and uncertainty sections of the BHHRA.

Although the type of environmental sampling performed in the Phase 1 and Phase 2 field efforts may have differed (e.g., biased versus random sampling), all the samples are discrete samples and can be used to represent potential exposures. All discrete samples from the Phase 1 and Phase 2 sampling events will be

combined to provide better spatial coverage of the exposure areas. Although "bias" sampling will be used to evaluate risks, the data will be used to show the absence of actionable risk based on the low concentrations observed in the Phase I data. If risks are unacceptable, exposure and subsequent risks will be refined. Uncertainties associated with combining the datasets for the BHHRA and the impact it has on risk will be addressed in the uncertainty section.

### 2.1.2 Data Evaluation

The data evaluation and selection of data for quantitative use in the BHHRA will be conducted to identify data that are: (1) representative of existing (and to the extent possible, reasonably foreseeable) conditions related to current and potential future use and the associated receptor exposure scenarios; and (2) "usable" (that is, of sufficient quality) for BHHRA purposes, consistent with the Data Evaluation Chapter of the USEPA RAGS, Volume 1, Part A (USEPA, 1989) and the associated Guidance for Data Usability in Risk Assessment (USEPA, 1992a). Analytical data collected during Phase 1 and Phase 2 of the RI and deemed usable following data validation and according to the project-specific UFP-QAPPs will be evaluated in the BHHRA.

The data evaluation will include an assessment of the analyte specific limits of detection (LODs). Achieved LODs are a major issue affecting data usability for risk (USEPA, 1992a). If the LOD is higher than concentrations known to cause toxicity or adverse effects to human receptors, the actual contaminant concentration cannot be quantified, and risks cannot be evaluated. Because some contaminants cause human health effects at low levels, there may be cases where the LOD is higher than concentrations known to cause toxicity or adverse effects to human receptors. Therefore, a qualitative evaluation of the LOD for nondetect constituents will be performed as part of the preliminary COPC screening. These analytes will be discussed in the uncertainty section with respect to any historical use, analytical, or toxicological reasons as to why the analyte may be a COPC.

### 2.1.3 Processing and Summarization of Analytical Data Considered in the BHHRA

Summary statistics will be compiled for each medium and exposure area, by COPC, including minimum and maximum detected concentrations, frequency of detection, range of reporting limits for non-detects, and arithmetic mean concentrations.

Values reported as estimated (i.e., "J" qualified data) will be used at the concentration reported. Data rejected during the data usability evaluation (i.e., "R" qualified data) will be excluded from the dataset and will not be evaluated further in the BHHRA. Nondetected values (i.e., "U" qualified data) will be evaluated at their reporting limit (i.e., LOD), unless otherwise described.

Prior to summarizing the analytical data, the data will be processed and simplified, eliminating duplication for field sample/field duplicate pairs. This process identifies a single result for each parameter within each sampling location/event for use in the data summary. For sample locations in which a duplicate sample has also been collected, use of duplicate results will be resolved as follows:

- For each field sample/field duplicate sample pair, if one was a detection and the other was a non-detect, the detected concentration will be selected for use in the risk assessment.

- For each field sample/field duplicate sample pair, if each analytical result was a non-detect then the lower of the two Reporting Limits (RLs) from the two analyses will be selected for use in the risk assessment.
- For each field sample/field duplicate sample pair, if each analytical result was a detection, then the arithmetic mean of the detects will be calculated and used in the risk assessment.

### 2.1.4 Selection of Contaminants of Potential Concern

COPCs for the combined Phase 1 and Phase 2 data will be identified consistent with the screening methodology used in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). The Phase 1 Risk Screening approach was developed in conjunction with the NYOW Site USACE project delivery team (PDT) and Environmental and Munitions Center of Expertise (EMCX).

The identification of COPCs is based on a compilation of usable data for the exposure media identified as being associated with the potentially complete exposure pathways. Screening of COPCs will be performed for soil, groundwater, hydric soils, sediment, and surface water by AOC. The general screening methodology is summarized below but as stated previously, will be consistent with the screening methodology used in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023).

1. As stated in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023), the essential and generally nontoxic "macro elements," calcium, magnesium, potassium, and sodium will not be considered COPCs.
2. Concentrations of chemicals detected in the environmental medium will be compared to medium-specific background threshold values (BTVs) for those analytes having BTVs (e.g., PAHs and metals). A conclusion of a potential site-related release will be made if the maximum concentration for site data sets with ≤ 20 samples is greater than the BTV or if more than 5% of the results for site data sets > 20 samples are greater than the BTV. Soil BTVs were developed for use in the phased site assessment process as described in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). These soil BTVs will be used in the screening of the Phase 2 RI data. Development of new BTVs following methodology in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023) will be provided for background data collected during the Phase 2 investigation (new background data will include groundwater, surface water, hydric soils, and sediment). Given how BTVs are defined (i.e., the null hypothesis is that the site concentrations are consistent with background concentrations), false positives (Type I error or the incorrect rejection of the null hypothesis) overestimate contamination and false negatives (Type II error or failure to reject the null hypothesis) underestimate contamination. BTVs typically control false positives only. From a statistical perspective, results greater than BTVs demonstrate likely site-related releases but results less than BTVs are inconclusive. PDT concurrence will be requested prior to eliminating contaminants less than BTVs from further evaluation in the BHHRA. Hypothesis testing for centrality can simultaneously control Type I and Type II errors for background comparisons and although not currently scoped as part of the BHHRA, may be an option as an additional risk refinement if warranted. The uncertainty associated with using BTVs

to screen the data for selection of COPCs will be addressed in the Uncertainty Analysis in the BHHRA.

3. For those chemicals exceeding BTVs and for those chemicals without BTVs, maximum concentrations will be compared to USEPA risk-based values at a target hazard quotient (HQ) of 0.1 or a target cancer risk of $1\times10^{-6}$ (whichever is lower) as follows:

    a. For screening soil, hydric soils, and sediment data, the screening levels will be based on current USEPA RSLs for residential soils as well as USEPA's 2024 guidance for lead which recommends an updated residential soil lead RSL of 200 mg/kg (USEPA, 2024a).

    b. For groundwater data, the screening levels will be based on current USEPA RSLs for tap water. In addition, for VOCs that are detected in groundwater, concentrations also will be compared to USEPA Vapor Intrusion Screening Levels (VISL, USEPA, 2022).

    c. For surface water data, screening levels will be calculated using USEPA's RSL calculator for a recreational receptor's exposure to surface water using the exposure parameters for incidental ingestion and dermal contact with COPCs in surface water for a trespasser/visitor scenario listed in Table A2.2-3 of Attachment 1.

Chemicals with maximum detected concentrations greater than their respective screening level are retained as COPCs; maximum concentrations detected less than the screening level are not selected as a COPC.

The Phase 1 groundwater data screened in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone Environmental Group, 2023) consisted of grab groundwater samples collected from temporary groundwater monitoring wells that were not developed prior to sampling during the Phase 1 investigation. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the Phase 1 groundwater data may not be representative of groundwater conditions. Therefore, groundwater data from Phase 1 field investigations will not be used in the BHHRA. Installation of permanent monitoring wells along with well development will be performed during the Phase 2 investigation; the Phase 2 data will be the only groundwater data utilized in the BHHRA. The Phase 2 groundwater data will be screened using the methodology in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone Environmental Group, 2023). Table 2.1-3 summarizes the Phase 1 soil COPCs by AOC. The results of the Phase 1 groundwater screening also are provided in Table 2.1-3. Note that the groundwater COPCs have been designated as preliminary because the Phase 1 groundwater data were collected from temporary wells. The number and types of COPCs that may be identified in groundwater collected from permanent monitoring wells during the Phase 2 investigation may be different than the preliminary groundwater COPCs listed in Table 2.1-3.

**Table 2.1-3: Phase 1 COPCs**

| AOC 1 | | AOC 3 | | AOC 4 | | AOC 5 | |
|---|---|---|---|---|---|---|---|
| **Soil** | **Preliminary GW (a)** | **Soil** | **Preliminary GW (a)** | **Soil** | **Preliminary GW (a)** | **Soil** | **Preliminary GW (a)** |
| Aluminum<br>Arsenic<br>Cadmium<br>Cobalt<br>Iron<br>Manganese | Aluminum<br>Barium<br>Iron<br>Manganese<br>Nickel<br>Vanadium | Benz(a)anthracene<br>Benzo(b)pyrene<br>Benzo(b)fluoranthene<br>Dibenz(a,h)anthracene<br>Indeno(1,2,3-cd)pyrene<br>Aluminum<br>Arsenic<br>Cobalt<br>Iron<br>Manganese<br>Thallium | Benzene<br>4-Nitroaniline<br>Arsenic<br>Cobalt<br>Manganese<br>Nickel<br>Vanadium | (a) | (b) | Benzo(b)pyrene<br>Benzo(b)fluoranthene<br>Dibenz(a,h)anthracene<br>Indeno(1,2,3-cd)pyrene<br>Naphthalene<br>Aluminum<br>Arsenic<br>Cadmium<br>Cobalt<br>Iron<br>Manganese<br>Thallium | Benz(a)anthracene<br>Benzo(b)pyrene<br>Benzo(b)fluoranthene<br>Dibenz(a,h)anthracene<br>Naphthalene<br>1,2,3-Trichloropropane<br>Antimony<br>Arsenic<br>Cobalt<br>Iron<br>Manganese<br>Nickel<br>Vanadium |

Notes:

(a) The groundwater COPCs have been designated as preliminary because the Phase 1 groundwater data were collected from temporary wells may not be representative of groundwater conditions. Installation of permanent monitoring wells along with well development will be performed during the Phase 2 investigation. Groundwater collected from permanent monitoring wells will be used to identify COPCs for the BHHRA.

(b) Nondetect for picric acid, 2,4-dinitrochlorobenzene, and 2,4-dintirophenol; Reporting limits less than residential USEPA RSL with HQ=0.1.

(c) Nondetect for picric acid, 2,4-dinitrochlorobenzene, and 2,4-dintirophenol; Reporting limits less than residential USEPA RSL with HQ=0.1 for picric acid. The other reporting limits for 2,4-dinitrochlorobenzene and 2,4-dinitrophenol were greater than RSL adjusted for HQ of 0.1; however, reporting limits were less than RSL at HQ of 1.

Acronyms:
AOC = area of concern
GW = groundwater
HQ = hazard quotient
RSL = regional screening level

Comparison of nondetect LODs to screening levels will be performed as part of the COPC selection process and will follow methodology used in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023).

## 2.2 PRELIMINARY CONCEPTUAL SITE MODEL AND EXPOSURE ASSESSMENT

As defined in Engineer Manual 200-1-12 - Environmental Quality, Conceptual Site Models (USACE, 2023), a CSM describes sources of possible DoD-impacts, as well as complete, potentially complete, or incomplete human and ecological exposure pathways; current, determined, or reasonably anticipated future use of property; and human and ecological potential receptors. A CSM is an iterative planning and communication tool that provides a structure to summarize and display information and to identify additional information needed to develop technically sound decisions; therefore, data collected as part of the Phase 2 RI will be used to revise these CSMs as appropriate.

The purpose of the exposure assessment is to estimate the magnitude and frequency of potential human exposure to COPCs present in media of interest at each exposure area. The exposure assessment is based on the CSM.

### 2.2.1 Preliminary CSM

The preliminary CSM identifies contaminant sources, release mechanisms, affected media, transport routes, current and future land use and human receptors, and associated exposure scenarios. These preliminary CSMs were constructed based on what is currently known about the Site in general and what is known specifically with regard to each of the AOCs based on historical and Phase 1 RI data collected. The general and specific information used to construct the CSMs are provided in Worksheet #10 of the UFP-QAPP. The potential receptors, exposure media, exposure routes, and rational for selection or exclusion of exposures that have been considered relevant for each of the AOCs for the BHHRA are listed in Table 2.2-1. The preliminary CSMs developed for each of the AOCs based on information provided in Worksheet #10 of the Phase 2 UFP-QAPP and Table 2.2-1, are presented here in Figures 2.2-1 through 2.2-4. The AOC-specific CSMs also were informed by the COPCs identified in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). These preliminary CSMs may be revised based on risk screening results of the combined Phase 1 and Phase 2 RI data.

### 2.2.2 Exposure Assessment

The first step in the exposure assessment process is determining potential receptors (i.e., people who may contact the impacted environmental media of interest). The exposure assessment is based on the receptor scenarios that define the conditions of exposure to Site-related COPCs. The extent of a receptor's exposure is estimated by identifying exposure scenarios that describe the potential pathways of exposure to COPCs that might lead to contact with COPCs in the environment.

All likely exposure scenarios that could exist under the intended current and potential future use of the Site are considered in this BHHRA. Exposure scenarios are identified by evaluating potential receptors and exposure pathways. Receptors may be exposed to COPCs either directly, through activities that result in contact with contaminated environmental media (e.g., digging in contaminated soil), or indirectly, as a result of COPC migration to locations where contact with receptors can occur (e.g., fugitive dust). An exposure pathway defines the most probable pathway in which a receptor may come into contact with contaminated media. In order for an exposure pathway to be complete, the following four elements must be present: (1) a source and mechanism of COPC release; (2) a retention or transport medium; (3) a point of contact between the human receptor and the medium; and (4) a route of exposure for the potential human receptor at the contact point.

The exposure pathway must be complete from the source of COPCs in the environment to human receptors in order for COPC intake to occur. If all exposure pathways are incomplete for human receptors, no COPC intake occurs, and no human health effects are associated with Site-related COPCs.

Each receptor may be evaluated for one or more exposure points, and receptors exposed to soil may be evaluated for exposure to 0-1 ft soils under current conditions, 0-5 ft for excavation activities, or 0-10 ft soils under future conditions assuming regrading and redevelopment of the site.

Potential receptors identified across AOCs include the following:

- On-Site Current and Future Trespasser/Visitor (including golf course users and recreational visitors);
- On-Site Current and Future Outdoor Maintenance Worker;
- On-Site Future Utility Worker;
- On-Site Future Construction Worker;
- On-Site Future Resident;
- On-Site Future Commercial Worker; and
- On-Site Resident or Off-Site Nearby Resident utilizing private groundwater wells for potable water.

**Table 2.2-1. Receptor Selection and Exposure Pathways**

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population (a) | Receptor Age | Exposure Route (b) | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway (c) |
|---|---|---|---|---|---|---|---|---|
| **Current and/or Future** | **Soil** | **Surface Soil (0-1 ft)** | AOC 1 | Current Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | This AOC is in primarily residential area where there are paved walking paths and grassy areas between homes and wooded areas containing the old loading ramps, storage bunkers, and loading dock structures. Activities of adolescents in these unrestricted open areas may lead to exposure to COPCs in surface soil. Similarly, outdoor workers performing grounds maintenance in these areas may lead to exposure to COPCs in surface soil. See potential future exposure to mixed subsurface soil below. |
| | | | | Current Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | AOC 3 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | AOC 3 is a golf course. While golfers are present in this AOC, visitors (golfers) are typically not exposed to soils while golfing. Therefore, only trespassers are expected to be exposed to soils. Activities of adolescents in the open areas may lead to exposure to COPCs in surface soil. Similarly, outdoor workers performing grounds maintenance in these areas may lead to exposure to COPCs in surface soil. Current and future exposures are expected to be the same as there would be no heavy construction which would bring soil from below 1 ft bgs to the surface during regrading. |
| | | | | Current/Future Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | AOC 4 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | None (c) | This AOC is currently located within Three Rivers Wildlife Management Area (WMA). Several of the remaining bunkers are used for equipment and vehicle storage. Activities of adolescents in these unrestricted open areas may lead to exposure to COPCs in surface soil. Similarly, outdoor workers performing grounds maintenance in these areas may lead to exposure to COPCs in surface soil. The Phase 1 soil sampling did not identify any COPCs. Therefore, although there are potential receptors who may come into contact with surface soil, there are no COPCs identified for the soil. Exposure routes and analysis may change depending on the results of the Phase 2 sampling effort. Note that current and future exposures are expected to be the same as there are no heavy construction activities planned for the AOC that would bring soils greater than 1 ft to the surface. |
| | | | | Current/Future Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | None (c) | |
| | | | AOC 5 | Current Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | This AOC is mostly an uninhabited wooded area west of a residential area. Activities of adolescents in these unrestricted open areas may lead to exposure to COPCs in surface soil. Similarly, outdoor workers performing grounds maintenance in these areas may lead to exposure to COPCs in surface soil. See potential future exposure to mixed subsurface soil below. |
| | | | | Current Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| **Future** | **Soil** | **Surface and Subsurface Soil (0-5 ft)** | AOC 1 | Future Utility Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | Underground utilities are common in residential and commercial areas, and often are located around roads and the areas between the roads and buildings. The residential area of AOC 1 contains underground utilities, and future development would need installation of utilities. Thus, it is assumed that soil from the surface to 5 ft bgs could be excavated, mixed, and used to regrade the Site while installing or repairing utility lines. |
| | | | AOC 3 | Future Utility Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | Underground utilities are common in residential and commercial areas, and often are located around roads and the areas between the roads and buildings. As a developed commercial area (i.e., golf course), utilities are assumed to be present at AOC 3. Thus, it is assumed that soil from the surface to 5 ft bgs could be excavated, mixed, and used to regrade the Site while installing or repairing utility lines. |

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population (a) | Receptor Age | Exposure Route (b) | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway (c) |
|---|---|---|---|---|---|---|---|---|
| **Future** | **Soil** | **Surface and Subsurface Soil (0-5 ft)** | AOC 4 | Future Utility Worker | Adult | None | None | AOC 4 located in Three Rivers Wildlife Management Area, an undeveloped, natural environment. No utility lines are present in AOC 4, nor are utility lines expected to be installed in the future. |
| | | | AOC 5 | Future Utility Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | Underground utilities are common in residential and commercial areas, and often are located around roads and the areas between the roads and buildings. AOC 5 is slated for future redevelopment, either as commercial or multiple residential housing. As such, utility lines are expected to be installed in the future. Thus, it is assumed that soil from the surface to 5 ft bgs could be excavated, mixed, and used to regrade the Site while installing or repairing utility lines. |
| **Future** | **Soil** | **Surface and Subsurface Soil (0-10 ft)** | AOC 1 | Future Resident | Adult | Ingestion/Dermal/Inhalation | Quantitative | This AOC is in primarily residential area in the Radisson Community which is a planned development that consists of homes, a large Corporate Park, and a wide range of recreational, educational, cultural, shopping, and community services. Although homes are not currently built on areas of potential impacts; homes or commercial structures may in the future be built on those potential areas of impact if results of the RI indicated those areas are not impacted. Therefore, future residential, commercial and construction worker exposure scenarios have been included. Soils at depth are assumed to be mixed with surface soil such that exposure to soils for future scenario entails contact with soils from 0-10 ft being as this interval would be used to regrade the Site. The future scenario for the trespasser/visitor and outdoor maintenance worker assumes contact with soils after regrading of the Site occurs so that exposure is to COPCs in 0-10 ft bgs interval. |
| | | | | | Child | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Construction Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | AOC 3 | Future Resident | Adult | None | None | This AOC is a former landfill located within the golf course property. Future residential homes or commercial structures will not be constructed over the golf course or areas of the golf course. Therefore, residents, commercial workers, and construction workers will not be exposed to COPCs in subsurface soil in the future. |
| | | | | | Child | None | None | |
| | | | | Future Commercial Worker | Adult | None | None | |
| | | | | Future Construction Worker | Adult | None | None | |
| | | | AOC 4 | Future Resident | Adult | None | None | AOC 4 located in Three Rivers Wildlife Management Area; no future development is expected. Therefore, residents, commercial workers, and construction workers will not be exposure to COPCs in subsurface soil in the future. |
| | | | | | Child | None | None | |
| | | | | Future Commercial Worker | Adult | None | None | |
| | | | | Future Construction Worker | Adult | None | None | |
| | | | AOC 5 | Future Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | This AOC will be developed in the future and based on current surrounding land use future redevelopment may include residential and/or commercial settings. Therefore, residents, commercial workers, and construction workers may be exposure to COPCs in subsurface soil in the future. Soils at depth are assumed to be mixed with surface soil such that exposure to soils for future scenario entails contact with soils from 0-10 ft being as this interval would be excavated during construction, mixed, and used to regrade the Site. The future scenario for the trespasser/visitor and outdoor maintenance worker assumes contact with soils after regrading of the Site occurs so that exposure is to COPCs in 0-10 ft bgs interval. |
| | | | | Future Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Resident | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | | Child | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Commercial Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Construction Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population (a) | Receptor Age | Exposure Route (b) | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway (c) |
|---|---|---|---|---|---|---|---|---|
| **Future** | **Groundwater (g)** | **On-Site Groundwater** | AOC 1 | Future Resident | Adult | Ingestion/Dermal | Quantitative | Groundwater on-Site is not currently used as a drinking water source and potable water is supplied by the Onondaga County Water Authority; therefore, a groundwater potable use scenario for the on-Site future residents will not be included. Regardless, hypothetical future potable use of groundwater will be evaluated for AOCs 1 and 5 because there are no current restrictions in place that preclude this use. There are no VOCs among contaminants of potential concern at this AOC; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater are considered incomplete exposure pathways. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| **Future** | **Groundwater (g)** | **On-Site Groundwater** | | Future Utility Worker | Adult | Dermal | Quantitative | The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers and construction workers are likely to encounter groundwater during excavation activities. Metals were identified as COPCs in the Phase I data; therefore, inhalation exposure is not associated with groundwater and excavation activities. The groundwater ingestion pathway for the future utility and construction workers is an insignificant exposure pathway which will not be quantitatively evaluated in the risk assessment but will be addressed as part of the uncertainty evaluation. |
| | | | | Future Construction Worker | Adult | Dermal | Quantitative | |
| | | | AOC 3 | Future Maintenance Worker | Adult | Ingestion/Dermal | Qualitative | These receptors are evaluated for potential exposure to groundwater under a hypothetical future scenario where a well is installed at the golf course and used as a source for potable water for a water fountain. The maintenance worker will be evaluated qualitatively using the results of the evaluation for the future golfer as a more highly exposed receptor (ingestion while golfing versus incidental ingesting during irrigation). The golfer will be evaluated using the same exposure assumptions as for an adult visitor. |
| | | | | Future Golfer | Adult | Ingestion/Dermal | Quantitative | |
| | | | | Future Utility Worker | Adult | Dermal | Quantitative | The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers are likely to encounter groundwater during excavation activities. COPCs from the Phase I data include primarily metals, 4-nitroaniline, and benzene. Inhalation is not a significant exposure pathway associated with inorganics, and volatilization of benzene outdoors is not expected to be significant and therefore will not be evaluated. The groundwater ingestion pathway has been deemed insignificant as the amount of water incidentally ingested is going to be de minimis. No major construction is expected in this former landfill area; therefore, construction workers are not included as a potential receptor to groundwater. |
| | | | | Future Construction Worker | Adult | None | None | |
| | | | AOC 4 | Future Recreational Visitor | Adult | Ingestion/Dermal | Quantitative | This receptor is evaluated for potential exposure to groundwater, under a hypothetical future scenario where a well is installed at the Three Rivers Wildlife Management Area and used as a source for potable water for a water fountain. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | | | | Future Utility Worker | Adult | None | None | AOC 4 located in Three Rivers Wildlife Management Area; no future development is expected so exposure to groundwater while excavating is not expected for these potential receptors. |
| | | | | Future Construction Worker | Adult | None | None | |

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population (a) | Receptor Age | Exposure Route (b) | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway (c) |
|---|---|---|---|---|---|---|---|---|
| **Future** | **Groundwater (g)** | **On-Site Groundwater** | AOC 5 | Future Resident | Adult | Ingestion/Dermal | Quantitative | Groundwater on-Site is not currently used as a drinking water source and potable water is supplied by the Onondaga County Water Authority; therefore, a groundwater potable use scenario for the on-Site future residents will not be included. Regardless, hypothetical future potable use of groundwater will be evaluated for AOCs 1 and 5 because there are no current restrictions in place that preclude this use. There are no VOCs among contaminants of potential concern at this AOC; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater are considered incomplete exposure pathways. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | | | | Future Utility Worker | Adult | Dermal | Quantitative | The water table is anticipated to be encountered between 2 to 13 feet bgs in the source areas; therefore, utility workers and construction workers are likely to encounter groundwater during excavation activities. COPCs from the Phase I data include primarily metals and SVOCs; therefore, inhalation of outdoor air is not a significant exposure pathway and will not be evaluated. The groundwater ingestion pathway for the future utility and construction workers is an insignificant exposure pathway which will not be quantitatively evaluated in the risk assessment but will be addressed as part of the uncertainty evaluation. |
| | | | | Future Construction Worker | Adult | Dermal | Quantitative | |
| **Current and Future** | **Groundwater (g)** | **Off-Site Groundwater** | Nearby AOC 1 | Current/Future Resident | Adult | Ingestion/Dermal | Quantitative | There are multiple private wells in the area as per the well survey. Will evaluate groundwater exposure as potable water exposures to current and future nearby residents. There are no VOCs among contaminants of potential concern at this AOC; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater are considered incomplete exposure pathways. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | | | Nearby AOC 3 | Current/Future Resident | Adult | Ingestion/Dermal | Quantitative | There are multiple private wells in the area as per the well survey. Will evaluate groundwater exposure as potable water exposures to current and future nearby residents. Benzene was the only VOC detected in groundwater, but the maximum detected benzene concentration is below the USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for groundwater set to a target cancer risk of 1E-06 and a hazard quotient (HQ) of 0.1; therefore, the inhalation of volatiles exposure route has been designated as potentially complete but insignificant and will not be quantitatively evaluated. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | | | Nearby AOC 4 | Current/Future Resident | Adult | Ingestion/Dermal | None (d) | There are multiple private wells in the area as per the well survey. However, chemicals of potential concern were not identified based on the Phase 1 groundwater analytical results. Therefore, this exposure pathway is considered insignificant and will not be evaluated in the BHHRA. Groundwater sampling is not being performed as part of Phase 2 investigation. |
| | | | | | Child | Ingestion/Dermal | None (d) | |
| | | | Nearby AOC 5 | Current/Future Resident | Adult | Ingestion/Dermal | Quantitative | There are multiple private wells in the area as per the well survey. Will evaluate groundwater exposure as potable water exposures to current and future nearby residents. There is no groundwater USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for 1,2,3-trichlorobenzene because this chemical does not have sufficient inhalation toxicity information. However, the maximum detected 1,2,3-trichlorobenzene concentration is below the 1,2,4-trichlorobenzene VISL (used as a surrogate) for groundwater set to a target risk level of 1E-06 and a hazard quotient of 0.1. Therefore, inhalation exposure is assumed to be insignificant. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population (a) | Receptor Age | Exposure Route (b) | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway (c) |
|---|---|---|---|---|---|---|---|---|
| **Current and Future** | **Surface Water (Unnamed Stream)** | **Surface Water (e)** | AOC 3 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal | Quantitative | This AOC is a golf course and as such access to the stream is not restricted. Adolescents may come in contact with the stream while walking or as part of their outdoor activities. Should VOCs be detected in surface water during the Phase 2 field effort, inhalation of volatiles is assumed to be an insignificant exposure due to ambient air mixing and wind dispersal. |
| | **Sediment (Unnamed Stream)** | **Sediment (e)** | AOC 3 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal | Quantitative | |
| | **Hydric Soils (from Wetland Areas)** | **Hydric Soils (f)** | AOC 1 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal | Quantitative | This AOC is in primarily residential area where there are paved walking paths and grassy areas between homes and wooded areas. Adolescents may come in contact with the hydric soils while walking or as part of their outdoor activities. |
| | | | AOC 5 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal | Quantitative | This AOC is currently undeveloped and there are no restrictions preventing adolescents from traversing the area and coming into contact with COPCs in hydric soils of the wetland areas. |

**Notes:**

(a) Note that trespassers and visitors could be any age, but an adolescent was selected as the receptor because they are more sensitive (higher exposure frequencies than a child and higher dose than an adult).

(b) For soil exposures, inhalation assessed as volatile or soil derived dust (i.e., ambient air).

(c) The AOC-specific CSMs were informed by site-specific information and the COPCs identified in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). These potential receptors and exposure pathways may be revised based on risk screening results of the Phase 2 RI data.

(d) Phase 1 analytical results were nondetect which indicates exposure to environmental medium at this AOC would be insignificant. The receptors and potential exposure pathways will be revisited after completion of the Phase 2 field effort.

(e) Surface water and sediment samples are planned during the Phase 2 investigation for the unnamed stream located north of AOC 3. Should VOCs be detected in surface water, inhalation of volatiles is assumed to be an insignificant exposure due to ambient air mixing and wind dispersal.

(f) Discrete surface soil sampling of hydric soils from wetland areas are planned for the Phase 2 investigation. Standing surface water is not present at the wetlands; therefore, surface water samples will not be collected, and hydric soil samples will be evaluated under a sediment exposure scenario.

(g) Other pathways associated with non-potable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

**Acronyms:**

AOC = area of concern

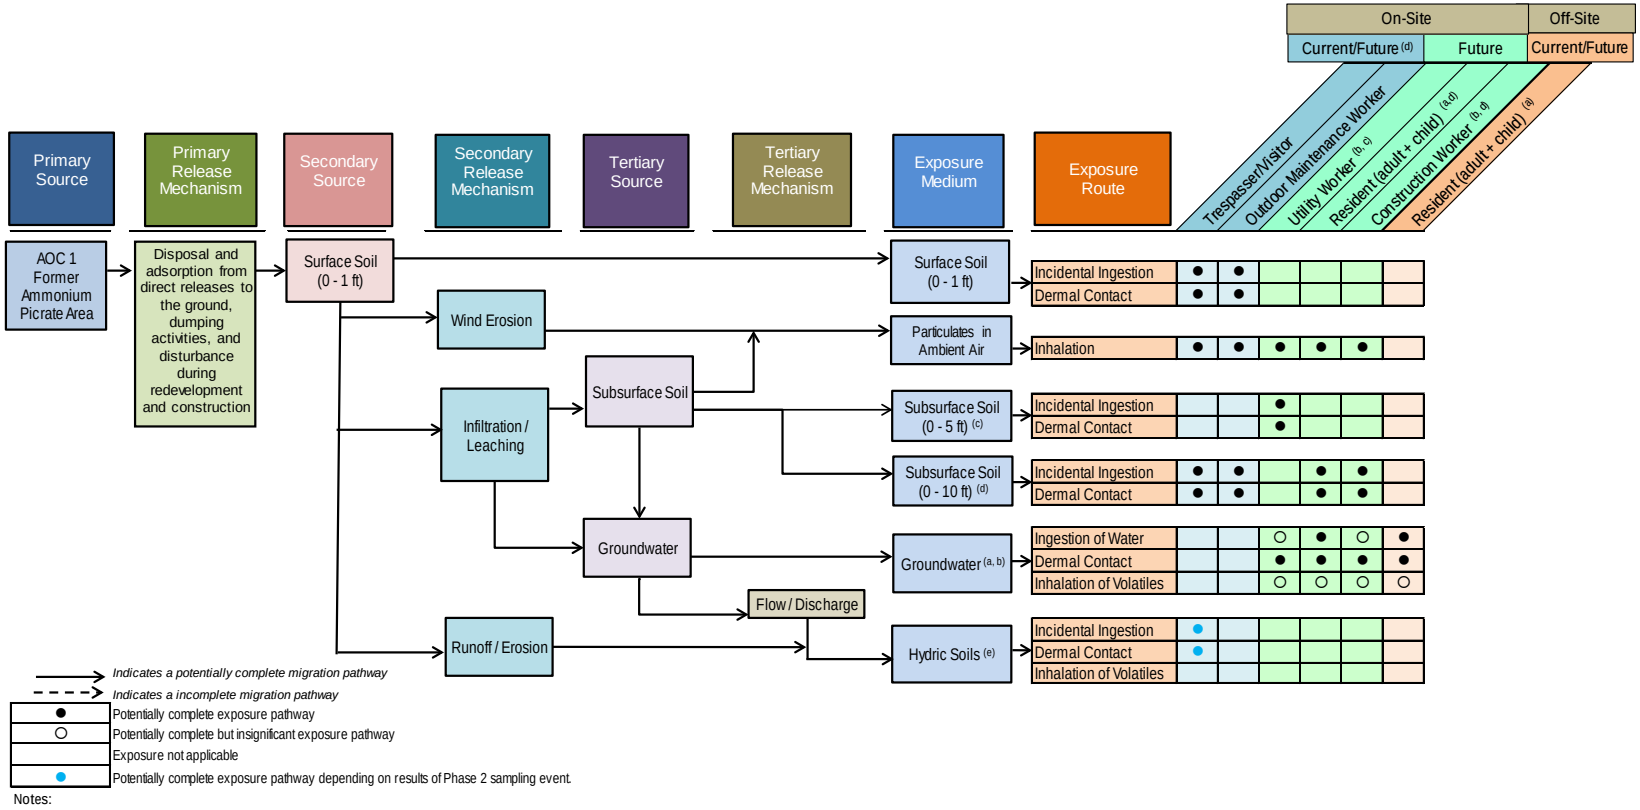
bgs = below ground surface

cont'd = continued

COPC = contaminant of potential concern

ft = feet

This page intentionally left blank.



Notes:

(a) Groundwater on-site is not currently used as a drinking water source and potable water is supplied by the Onondaga County Water Authority; however, no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for the hypothetical residents. In addition, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for the hypothetical residents. There are no VOCs among contaminants of potential concern at this AOC; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater are considered incomplete exposure pathways.

(b) The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers and construction workers are likely to encounter groundwater during an excavation on-Site. The groundwater ingestion pathway has been deemed insignificant as the amount of water incidentally ingested is going to be de minimis. The inhalation of volatiles exposure route is deemed complete but insignificant due to ambient air mixing and wind dispersal and will not be quantitatively evaluated.

(c) Utility workers are assumed to install or repair utility lines such that incidental ingestion, dermal contact, and inhalation exposure to COPCs that are present between surface and 5 ft bgs may potentially occur. The soil is assumed to be placed back in the hole once work has been completed.

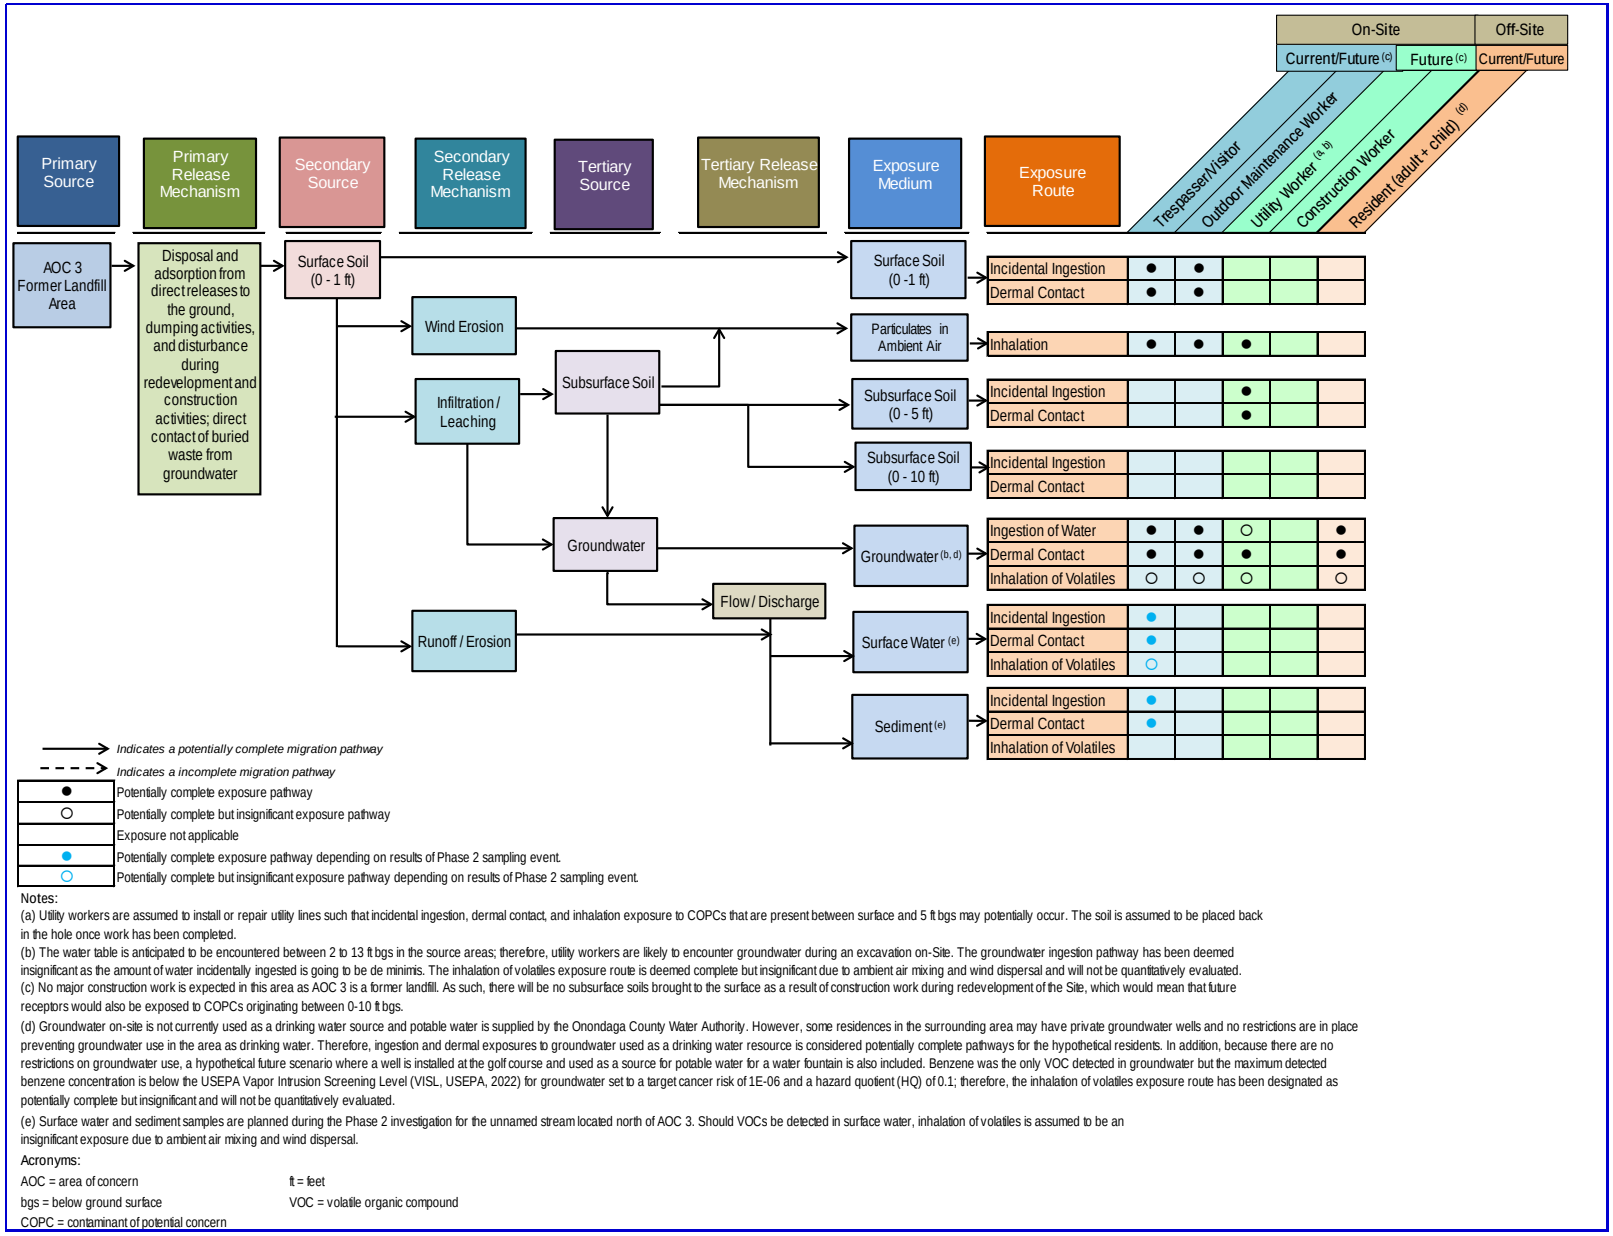
(d) Construction worker is assumed to be exposed to soil within the 0-10 ft bgs interval. It is assumed that subsurface soils are brought to the surface as a result of construction work during redevelopment of the Site, which would mean that future receptors would also be exposed to COPCs in the 0-10 ft range as it is assumed that subsurface soils are brought to the surface, mixed amd used to regrade the Site during redevelopment activities.

(e) Discrete surface soil sampling of hydric soils from wetland areas are planned for the Phase 2 investigation. Standing surface water is not present at the wetlands; therefore, surface water samples will not be collected and hydric soil samples will be evaluated under a sediment exposure scenario.

Acronyms:

AOC = area of concern
bgs = below ground surface
COPC = contaminant of potential concern
ft = feet
VOC = volatile organic compound

**Figure 2.2-1. Conceptual Site Model for AOC 1**



Notes:

(a) Utility workers are assumed to install or repair utility lines such that incidental ingestion, dermal contact, and inhalation exposure to COPCs that are present between surface and 5 ft bgs may potentially occur. The soil is assumed to be placed back in the hole once work has been completed.

(b) The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers are likely to encounter groundwater during an excavation on-Site. The groundwater ingestion pathway has been deemed insignificant as the amount of water incidentally ingested is going to be de minimis. The inhalation of volatiles exposure route is deemed complete but insignificant due to ambient air mixing and wind dispersal and will not be quantitatively evaluated.

(c) No major construction work is expected in this area as AOC 3 is a former landfill. As such, there will be no subsurface soils brought to the surface as a result of construction work during redevelopment of the Site, which would mean that future receptors would also be exposed to COPCs originating between 0-10 ft bgs.

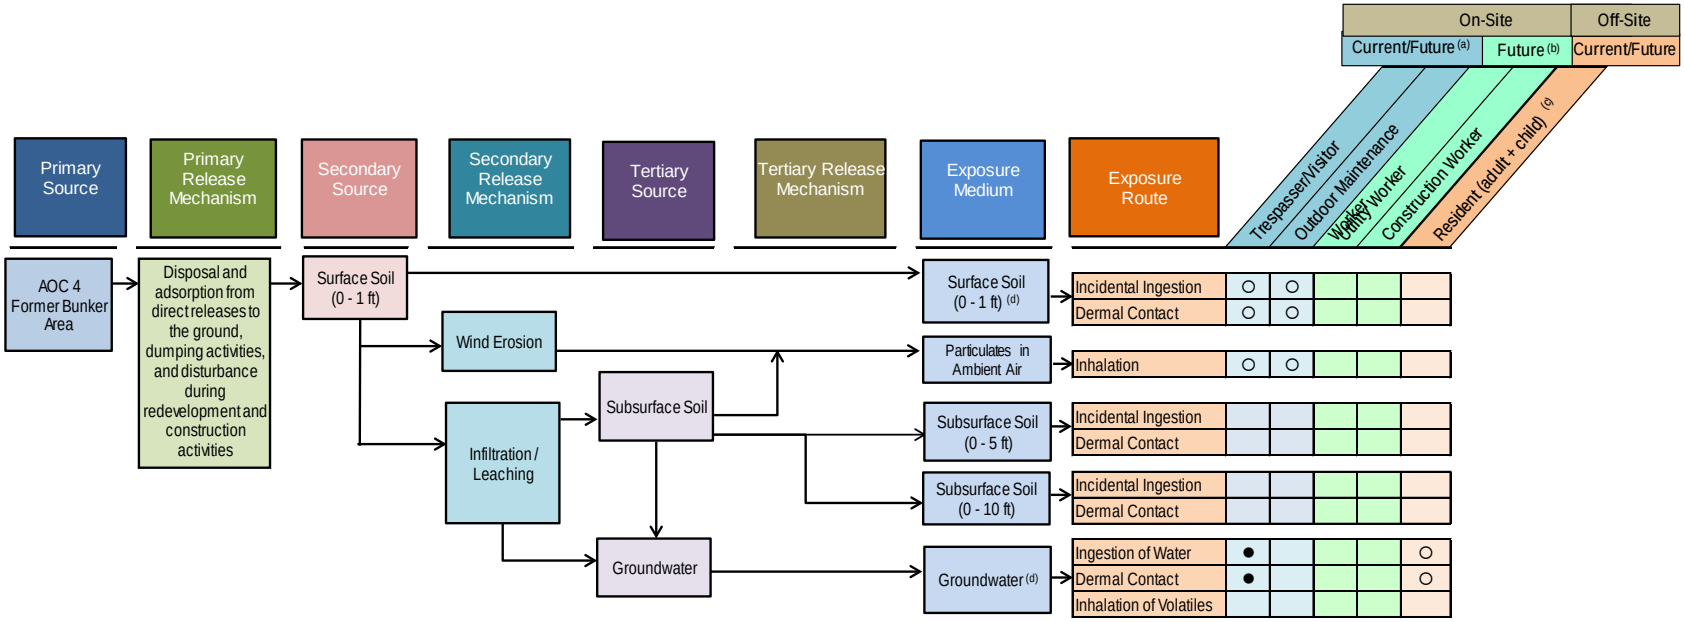
(d) Groundwater on-site is not currently used as a drinking water source and potable water is supplied by the Onondaga County Water Authority. However, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for the hypothetical residents. In addition, because there are no restrictions on groundwater use, a hypothetical future scenario where a well is installed at the golf course and used as a source for potable water for a water fountain is also included. Benzene was the only VOC detected in groundwater but the maximum detected benzene concentration is below the USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for groundwater set to a target cancer risk of 1E-06 and a hazard quotient (HQ) of 0.1; therefore, the inhalation of volatiles exposure route has been designated as potentially complete but insignificant and will not be quantitatively evaluated.

(e) Surface water and sediment samples are planned during the Phase 2 investigation for the unnamed stream located north of AOC 3. Should VOCs be detected in surface water, inhalation of volatiles is assumed to be an insignificant exposure due to ambient air mixing and wind dispersal.

Acronyms:

AOC = area of concern
bgs = below ground surface
COPC = contaminant of potential concern
ft = feet
VOC = volatile organic compound

**Figure 2.2-2. Conceptual Site Model for AOC 3**



Notes:

(a) AOC 4 is located within the Three Rivers State Wildlife Management Area. Current and future use of this area is wildlife management with remaining bunkers used for maintenance equipment and vehicle storage. The only potential current and future receptors are trespasser/visitor and outdoor maintenance worker to COCPs remaining in surface soil. In addition, because use of groundwater is not restricted, it is assumed that in the future, a drinking water fountain could be installed which uses site groundwater as a source, and that visitors could be exposed to groundwater from the drinking fountain via ingestion and dermal contact.

(b) There are no plans for future development thus, no future utility or construction work likely to occur in this AOC.

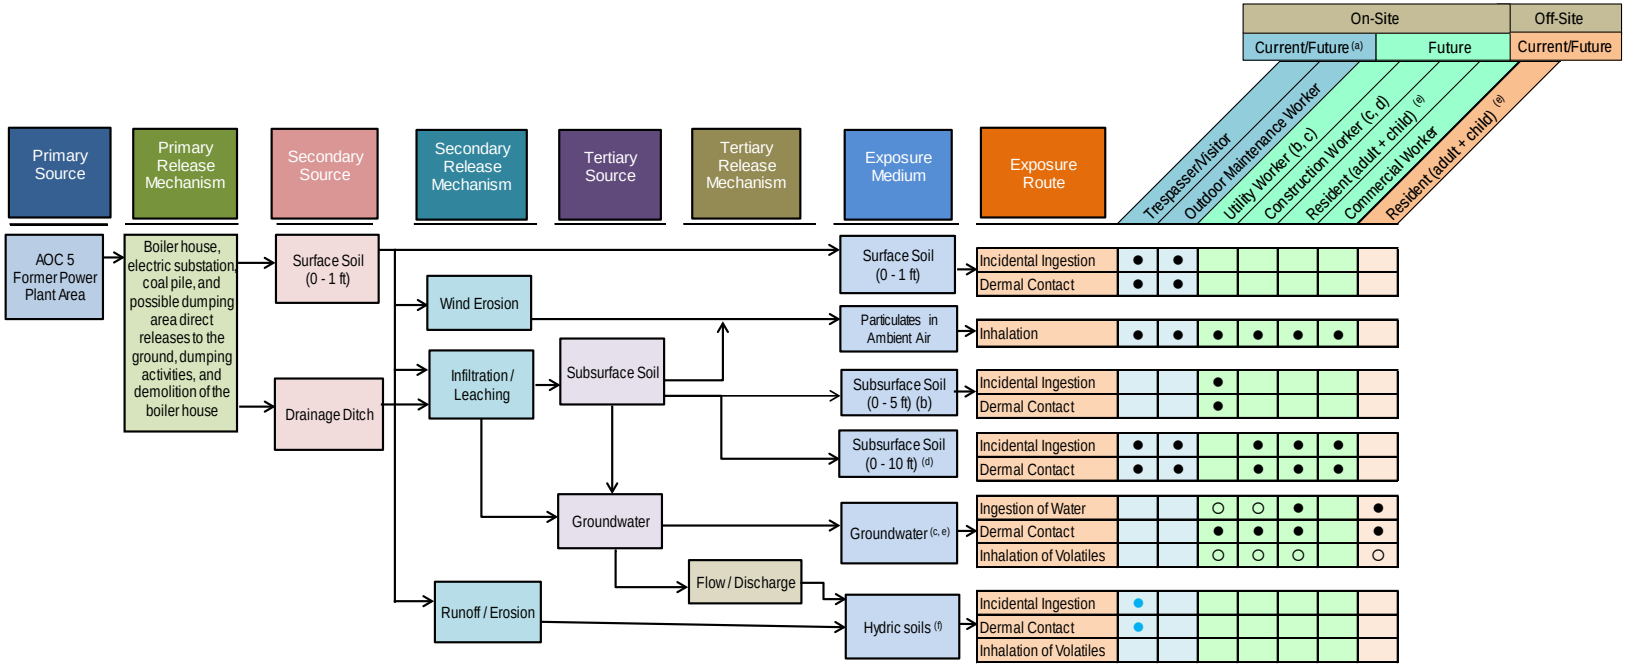
(c) Groundwater on-site is not currently used as a drinking water source; however, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for the hypothetical residents. For on-site visitors (recreational), groundwater exposure will be evaluated assuming that a well is installed on-site and used as a source of water for a drinking fountain. There are no VOCs among contaminants of concern; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater used as drinking water by current or future nearby residents are not considered applicable pathways.

(d) Soil and groundwater samples collected in Phase 1 were nondetect for 2,4-DNCB, 2,4-DNP, and picric acid; therefore, although exposure to surface soil and groundwater may occur, exposures are deemed insignificant. Surface soil sampling during Phase 2 may result in a revised CSM depending on the analytical results.

Acronyms:

2,4-DNP = 2,4-dinitrophenol
2,4-DNCB = 2,4-dinitrochlorobenzene
AOC = area of concern
bgs = below ground surface
COPC = contaminant of potential concern
ft = feet
VOC = volatile organic compound

**Figure 2.2-3. Conceptual Site Model for AOC 4**



*Indicates a potentially complete migration pathway*

|---|---|
| ● | Potentially complete exposure pathway |
| ○ | Potentially complete but insignificant exposure pathway |
| | Exposure not applicable |
| ● | Potentially complete exposure pathway depending on results of Phase 2 sampling event. |

Notes:

(a) Current soil exposures assume no intrusive activities and exposures are associated with COPCs in the surface soil. For future soil exposures, it is assumed that subsurface soils are brought to the surface as a result of construction work during redevelopment of the Site, which would mean that future receptors would be exposed to COPCs in the 0-10 ft range as it is assumed that subsurface soils are brought to the surface and mixed during redevelopment regrading activities.

(b) Utility worker is assumed to be exposed to soil within the 0-5 ft bgs interval while installing or repairing utility lines. The soil is assumed to be placed back in the hole once work has been completed.

(c) The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers and construction workers are likely to encounter groundwater during an excavation on-Site. The groundwater ingestion pathway has been deemed insignificant as the amount of water incidentally ingested is going to be de minimis.The inhalation of volatiles exposure route is deemed complete but insignificant due to ambient air mixing and wind dispersal.

(d) Construction worker is assumed to be exposure to soil within the 0-10 ft bgs interval. Soils at depth are assumed to be mixed with surface soil such that exposure to soils for a future scenario entails contact with soils from 0-10 ft being as this interval would be used to

(e) Groundwater on-site is not currently used as a drinking water source; however, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for the hypothetical residents. There is no groundwater USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for 1,2,3-trichlorobenzene because this chemical does not have sufficient inhalation toxicity information. However, the maximum detected 1,2,3-trichlorobenzene concentration is below the 1,2,4-trichlorobenzene VISL(used as a surrogate) for groundwater set to a target risk level of 1E-06 and a hazard quotient of 0.1. Therefore, inhalation exposure is assumed to be insignificant.

(f) Discrete surface soil sampling of hydric soils from wetland areas are planned for the Phase 2 investigation. Standing surface water is not present at the wetlands; therefore, surface water samples will not be collected and hydric soil samples will be evaluated under a sediment exposure scenario.

Acronyms:

AOC = area of concern

bgs = below ground surface

COPC = contaminant of potential concern

ft = feet

**Figure 2.2-4. Conceptual Site Model for AOC 5**

Based on results of screening the Phase 1 data and identification of preliminary COPCs, human receptors may be exposed to media at the AOCs through the following exposure pathways and routes of exposure:

- Direct contact with soil (incidental ingestion and dermal contact);
- Inhalation of volatiles and fugitive dust from soil;
- Incidental ingestion and dermal contact with groundwater during utility, construction, or maintenance work or during recreational activities;
- Direct contact with hydric soils (incidental ingestion and dermal contact);
- Direct contact with sediment (incidental ingestion and dermal contact);
- Direct contact with surface water (incidental ingestion and dermal contact); and
- Ingestion and dermal contact with groundwater during potable use.

Note that other pathways associated with non-potable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

A description of the selected current and potential future likely receptors for exposure to COPCs in the various media at the Site are described here.

**Current/Future Trespasser/Visitor (AOCs 1, 3, 4, and 5):** This receptor is assumed to be a long-term receptor, either a neighborhood community member adult or an adolescent 7 to 16 years of age, who is exposed to COPCs present in the environment of the uninhabited areas (e.g., wooded, stream) of the Site or in areas where recreational activities could occur (e.g., open fields and the golf course). This receptor is assumed to come into direct contact with COPCs present in surface soil (i.e., 0 – 1 ft bgs), hydric soils, sediment, or surface water as they wander around the Site. Exposures for this receptor would be very similar to exposures a recreational visitor may experience as they also would be exposed to COPCs in surface soil (i.e., 0 – 1 ft bgs), sediment, or surface water associated with open fields and the golf course. As such, a Trespasser/Visitor receptor encompasses exposures a recreational receptor would encounter.

At AOC 3, a golf course user will also be evaluated for potential exposure to groundwater, under a hypothetical future scenario where a well is installed at the golf course and used as a source for irrigation water.

At AOC 4, a recreational visitor will also be evaluated for potential exposure to groundwater, under a hypothetical future scenario where a well is installed and used as a source for potable water for a water fountain.

**Current/Future Outdoor Maintenance Worker (AOCs 1, 3, 4, and 5):** This is a long-term receptor exposed during the workday who is a full-time employee working on-Site and spends most of the workday conducting maintenance activities outdoors. The activities for this receptor (e.g., moderate digging, landscaping) typically involve on-Site exposure to surface soils. The current scenario assumes exposure to COPCs present in the surface soil (i.e., 0 – 1 ft bgs). For this scenario in the future, it is assumed that soil from the surface down to 10 ft bgs could be excavated, mixed, and used to regrade the Site such that exposure to COPCs that were present between surface and 10 ft bgs have now been placed at the surface.

At AOC 3, a maintenance worker will also be evaluated for potential exposure to groundwater, under a hypothetical future scenario where a well is installed at the golf course and used as a source for irrigation water.

**Future Utility Worker (AOCs 1, 3, and 5):** This is a short-term receptor exposed during a typical eight-hour workday. Where installation or repair of water lines, gas line, sanitary sewer lines, etc. would be performed over an extended period but where in most cases it would not require multiple visits to the site once the utility line was repaired or installed. For this scenario, it is assumed that soil from the surface down to 5 ft bgs could be excavated, mixed, and used to regrade the Site while installing or repairing utility lines (e.g., water lines, gas line, sanitary sewer lines) such that exposure to COPCs that are present between surface and 5 ft bgs is a potential possibility for this receptor. Direct contact with COPCs in groundwater, which ranges from 2 ft to 13 ft bgs, also is expected to occur.

**Future Construction Worker (AOCs 1 and 5):** This is a short-term receptor exposed during a typical eight-hour workday. For this scenario, it is assumed that soil from the surface down to 10 ft bgs could be excavated, mixed, and used to regrade the Site such that exposure to COPCs that are present between surface and 10 ft bgs is a potential possibility for the construction receptor. Direct contact with COPCs in groundwater is expected to occur for the construction worker because groundwater is present at depths ranging between 2 ft and 13 ft bgs.

**Future On-Site Resident (AOCs 1 and 5):** AOC 1 is in a primarily residential area in the Radisson Community which is a planned development that consists of homes, a large Corporate Park, and a wide range of recreational, educational, cultural, shopping, and community services. Although homes are not currently built on areas of potential impacts; homes may in the future be built on those potential areas of impact if results of the RI indicated those areas are not impacted. Similarly, future redevelopment of AOC 5 may include residential dwellings.

This is a long-term receptor. The residential receptor is defined as child and adult individuals who spend most, if not all, of the day at home (USEPA, 2024b). The future residential receptor may have exposure to contaminants originating from soil and groundwater. For this scenario in the future, it is assumed that soil from the surface down to 10 ft bgs could be excavated, mixed, and used to regrade the Site such that exposure to COPCs that were present between surface and 10 ft bgs have now been placed at the surface. No potable wells are currently located on the Site or near the source areas. Potable water is supplied to communities in Onondaga County by the Onondaga County Water Authority. Regardless, hypothetical future potable use of groundwater will be evaluated for AOCs 1 and 5 because there are no current

restrictions in place that preclude this use. Other pathways associated with nonpotable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

**Future Commercial Worker (AOC 5)**. AOC 5 also may be developed in the future for commercial use. Currently, AOC 5 is mostly wooded therefore a considerable amount of construction, excavation and dirt moving will be needed to build offices buildings. This is a long-term receptor. Commercial workers are individuals who work mostly inside a building (e.g., office workers) and possibly a limited amount outdoors. Redevelopment of an area for commercial use assumes there will be major construction activities that have to occur such that soil from the surface down to 10 ft bgs could be excavated, mixed, and used to regrade the Site. Therefore, it is assumed that exposure to COPCs that were present between surface and 10 ft bgs have now been placed at the surface and available for contact. Potable water is supplied to communities in Onondaga County by the Onondaga County Water Authority. Therefore, exposure to COPCs in groundwater via a drinking water use exposure scenario will not be included. Other pathways associated with non-potable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

**Current and Future Off-Site Resident (AOCs 1, 3, 4, and 5):** This is a long-term receptor. The residential receptor is defined as child and adult individuals who spend most, if not all, of the day at home (USEPA, 2024b). Some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for an off-Site nearby resident. Other pathways associated with groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

#### 2.2.2.1 Exposure Points

Potential exposure points are identified based on current and anticipated future use and the relationship of use to the presence of contaminated media. A location is identified as an exposure point if a human might contact (e.g., ingest) a contaminated medium (e.g., surface soil) at that location. Exposure points have been identified based on the information used to construct the preliminary CSMs. Further refinement of exposure points will be conducted upon receipt of the full data set; however, anticipated exposure points per medium are discussed below.

Hypothetical future potable use of groundwater may be evaluated within the current property boundaries in a hypothetical future residential use scenario. If multiple groundwater plumes are identified, groundwater will be evaluated separately for each groundwater plume following USEPA groundwater guidance (USEPA, 2014a).

Exposure points are anticipated to include the following. However, these assumptions may change as a result of data collected as part of the Phase 2 RI field investigations:

**AOC 1**: soil (0 - 1 ft bgs, 1 - 5 ft bgs, 5-10 ft bgs), groundwater, hydric soils (from the wetlands area)

**AOC 3**: soil (0 - 1 ft bgs, 1 - 5 ft bgs, 5-10 ft bgs), groundwater, sediment, and surface water

**AOC 4**: soil (0 - 1 ft bgs, 1 - 5 ft bgs, 5-10 ft bgs), groundwater

**AOC 5**: soil (0 - 1 ft bgs, 1 - 5 ft bgs, 5-10 ft bgs), groundwater, hydric soils (from the wetlands area)

#### 2.2.2.2 Estimating Exposure Point Concentrations

Estimates of COPC concentrations at points of potential exposure are necessary for evaluating COPC intake by potentially exposed receptors. The COPC concentrations in the exposure medium at the exposure point are termed the exposure point concentrations (EPCs). An EPC is determined for all impacted media in the identified AOCs. The EPC will be calculated for each of the COPCs within each of the AOCs based on both Phase 1 and Phase 2 analytical data.

USEPA guidance (USEPA, 1989; 1992b) recommends using the average concentration to represent "a reasonable estimate of the concentration likely to be contacted over time" and "because of the uncertainty associated with estimating the true arithmetic average concentration at a site". Therefore, the 95 percent upper confidence limit (95% UCL) on the arithmetic average will be used as the EPC where data are sufficient to calculate the 95% UCL.

Unless otherwise stated, calculation of the EPC will be conducted following guidance provided by USEPA (2002b), using distribution shift tests to determine the underlying population distribution. Specifically, EPCs will be calculated using the most recent version of USEPA ProUCL software (ProUCL 5.2: USEPA, 2022a), which calculates a 95% UCL on the arithmetic mean of the analytical results. The Kaplan-Meier method or Regression on Order Statistics method are used by ProUCL where nondetects are present. The best-fitting data distribution (i.e., normal, gamma, log-normal, or non-parametric [no distribution]) is determined within ProUCL, and generally the statistics appropriate for that distribution are applied to calculate the 95% UCL.

The UCL recommended by ProUCL based on the most appropriate statistical fit (whether 95%, 97.5%, or 99%) will be used in the EPC selection process. The EPCs will generally be expressed as the lower of the 95% UCL and the maximum detected concentration. EPC tables (RAGS Part D Table 3s) will be prepared for each medium and exposure point by AOC. ProUCL outputs documenting the 95% UCL calculations will be included in an appendix. Based on ProUCL guidance recommending a minimum of 10 observations to compute UCLs for discrete datasets (USEPA, 2022b) and professional judgement, UCLs will be calculated where at least six detected results are available. In cases where data sets have fewer than six detections, the maximum detected concentration will be used as the EPC. These recommendations are provided for the purpose of calculating a meaningful UCL. The BHHRA will address the uncertainty associated with calculating EPCs based on a small sample size if relevant. EPCs will be calculated for each COPC in each medium in each of the AOCs and will be used to estimate exposures for each receptor identified in each of the AOCs.

Soil EPCs will be calculated for surface soil (0-1 ft bgs) or combined surface and sub-surface soil (e.g., 0-5 ft bgs or 0-10 ft bgs) as needed to evaluate current or potential future Site conditions for each of the exposure areas and receptors.

Groundwater EPCs to evaluate a hypothetical potable use will be evaluated from the "core of the plume" or multiple cores, per USEPA GW EPC Directive (USEPA, 2014a). The core of the plume will be identified using the full RI dataset (Phase 1 and Phase 2) in the BHHRA. The core will be identified based on concentration gradients detected on-Site and hydrogeologist interpretations of flow dynamics. Groundwater EPCs will also be calculated using the site-wide groundwater dataset. For each COPC, the higher EPC from the two datasets will be selected as the final EPC and will be carried forward into the quantitative risk estimates as a conservative approach. In accordance with USEPA guidance (2014a, 2022b), UCLs will be calculated for each groundwater COPC where at least 10 samples are available and at least six detected concentrations are observed. The EPCs will be calculated as the lower of the UCL and the maximum detected result. Additionally, if less than three wells are within the core of the plume, the maximum detected concentration will be used as the EPC for the dataset representing the core of the plume (USEPA 2014a). Groundwater EPCs will be calculated based on the flow fields. The BHHRA will address the uncertainty associated with small sample size in groundwater datasets as necessary.

Hydric soils, sediment, and surface water EPCs will be calculated as the lower of the 95% UCL and the maximum detected result. Similar to soil, UCLs will be calculated where at least six detected results are available. In cases where data sets have fewer than six detections, the maximum detected concentration will be used as the EPC.

The EPCs for ambient outdoor air resulting from wind suspension of contaminated soil will be calculated by multiplying the 95% UCL of COPC in soil by a particulate emission factor (PEF) for each soil depth. Detailed calculations showing the derivation of outdoor air concentrations will be provided in the BHHRA.

#### 2.2.2.3 Chemical Intake Estimates

Estimates of exposure are based on the EPCs, scenario-specific assumptions, and receptor-specific intake parameters. Exposure estimates (intakes) will be calculated for a reasonable maximum exposure (RME)

scenario for each receptor and exposure pathway. The exposure parameters for each receptor have been selected to represent the RME scenario. The RME represents the highest exposure reasonably expected to occur and is calculated using the EPC and the RME exposure parameters. Site-specific exposure parameters and professional judgement will be used when appropriate. When not appropriate or available, USEPA-recommended default exposure parameters (e.g., body weight, soil ingestion rate, frequency of exposure, duration of exposure) obtained from Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. Attachment 1. Recommended Default Exposure Factors (USEPA, 2014b) will be used.

For each receptor, the exposure (or dose) will be estimated for each COPC via each exposure pathway by which the receptor is assumed to be exposed. Exposure dose equations combine the estimates of COPC concentration in the environmental medium of interest with assumptions regarding the type and magnitude of each receptor's potential exposure to provide a numerical estimate of the exposure dose. The exposure dose or daily intake is defined as the amount of COPC taken into the receptor and is expressed in units of milligrams of COPC per kilogram of body weight per day (mg/kg-day). In accordance with USEPA guidance addressing the inhalation pathway (USEPA, 2009), inhalation exposures are not derived in terms of intake, but rather in terms of exposure concentrations (ECs) in air expressed as mass per unit volume.

The specific exposure parameters and equations used to calculate doses/intakes for soil, groundwater, hydric soils, sediment, and surface water are provided in Table A2.2-1 through Table A2.2-4 in Attachment 1. These tables identify the exposure profiles for each of the receptors, including proposed exposure parameter values used to calculate the daily intake calculations for each of the receptors and exposure pathways.

The relative bioavailability factor (RBA) for soil ingestion for arsenic will be set at 0.6, while the RBA for other COPCs will be set at 1 (USEPA, 2012; USEPA 2024b).

Soil dermal absorption will be evaluated per the methodology in the USEPA dermal guidance (EPA, 2004). Specific equations and exposure parameters for the dermally absorbed dose are provided in Tables A2.2-1 and A2.2-3 in Attachment 1. COPC specific dermal absorption factors will be obtained from the current USEPA RSL Tables.

Similarly, USEPA guidance (2004) will be used to assess dermal exposure to COPCs in water (e.g., surface water and groundwater). Dermal exposure to water differentiates between organic and inorganic COPC s. Specific equations and exposure parameters for the dermally absorbed dose are provided in Tables A2.2-2 and A2.2-4 in Attachment 1. COPC specific parameters needed to assess dermal exposure to water will be obtained from the current USEPA RSL Tables.

#### 2.2.2.4 Intake for Mutagenic COPCs

The carcinogenic PAHs [benz(a)anthracene, benzo(b)pyrene, benzo(b)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene] identified as preliminary COPCs in the Phase 1 data screening operate by a mutagenic mode of action for carcinogenesis. There is reason to surmise that

some COPCs with a mutagenic mode of action, which would be expected to cause irreversible changes to DNA, would exhibit a greater effect in early-life versus later-life exposure (USEPA, 2005b). Thus, cancer risk to children according to USEPA's cancer guidelines (USEPA, 2005a; 2005b) include both early-life exposures that may result in the occurrence of cancer during childhood and early-life exposures that may contribute to cancers later in life. Therefore, in keeping with this guidance, separate cancer risk equations especially for children are presented for the mutagenic COPCs. Intake equations for the residential child receptor are as follows:

Incidental Ingestion of Soil/Hydric Soils/Sediment

$$\mathrm{CDI}_{\mathrm{res-sol-mu-ing}}\left(\frac{\mathrm{mg}}{\mathrm{kg}}-\mathrm{day}\right)=\frac{\mathrm{C}_{\mathrm{soil}}\left(\frac{\mathrm{mg}}{\mathrm{kg}}\right)\times\mathrm{EF}_{\mathrm{r}}\left(\frac{350\mathrm{days}}{\mathrm{year}}\right)\times\mathrm{IFSM}_{\mathrm{adj}}\left(\frac{476.67\ \mathrm{mg}-\mathrm{year}}{\mathrm{Kg}-\mathrm{day}}\right)\times\left(\frac{10^{-6}\mathrm{Kg}}{\mathrm{mg}}\right)}{\mathrm{AT}_{\mathrm{r}}\left(\frac{365\ \mathrm{days}}{\mathrm{year}}\times\mathrm{LT}\ (70\ \mathrm{years})\right)} \quad (2\text{-}1)$$

where:

$$IFSM_{adj-}\left(\frac{476.67\ \mathrm{mg}-\mathrm{Year}}{\mathrm{Kg}-\mathrm{day}}\right)=\frac{\mathrm{ED}_{0-2}(\mathrm{yr})\times\mathrm{IRS}_{\mathrm{c}}\left(\frac{200\ \mathrm{mg}}{\mathrm{day}}\right)\times 10}{\mathrm{BW}_{\mathrm{c}}(15\ \mathrm{kg})}+\frac{\mathrm{ED}_{2-6}(\mathrm{yr})\times\mathrm{IRS}_{\mathrm{c}}\left(\frac{200\ \mathrm{mg}}{\mathrm{day}}\right)\times 3}{\mathrm{BW}_{\mathrm{c}}(15\ \mathrm{kg})}+\frac{\mathrm{CD}_{6-16}(\mathrm{yr})\times\mathrm{IRS}_{\mathrm{a}}\left(\frac{100\ \mathrm{mg}}{\mathrm{day}}\right)\times 3}{\mathrm{BW}_{\mathrm{a}}(80\ \mathrm{kg})}+\frac{\mathrm{CD}_{16-26}(\mathrm{yr})\times\mathrm{IRS}_{\mathrm{a}}\left(\frac{100\ \mathrm{mg}}{\mathrm{day}}\right)\times 1}{\mathrm{BW}_{\mathrm{a}}(80\ \mathrm{kg})} \quad (2\text{-}2)$$

Inhalation of Particulates Emitted from Soil

$$\mathrm{CDI}_{\mathrm{res-sol-mu-inh}}\left(\frac{\mu\mathrm{g}}{\mathrm{m}^3}\right)=\mathrm{C}_{\mathrm{soil}}\left(\frac{\mathrm{mg}}{\mathrm{kg}}\right)\times\mathrm{EF}_{\mathrm{r}}\left(\frac{350\mathrm{days}}{\mathrm{year}}\right)\times\mathrm{ET}_{\mathrm{res}}\left(\frac{24\ \mathrm{hours}}{\mathrm{day}}\right)\times\left(\frac{1\ \mathrm{day}}{24\ \mathrm{hours}}\right)\times\frac{\left(\begin{matrix}(\mathrm{ED}_{0-2}(\mathrm{yrs})\times 10)+ & (\mathrm{ED}_{2-6}(\mathrm{yrs})\times 3)+\\ (\mathrm{ED}_{6-16}(\mathrm{yrs})\times 3)+ & (\mathrm{ED}_{16-26}(\mathrm{yrs})\times 1)\end{matrix}\right)\times\left(\frac{1}{\mathrm{VF}_{\mathrm{s}}\left(\frac{\mathrm{m}^3}{\mathrm{kg}}\right)}+\frac{1}{\mathrm{PEF}_{\mathrm{w}}\left(\frac{\mathrm{m}^3}{\mathrm{kg}}\right)}\right)}{\mathrm{AT}_{\mathrm{r}}\left(\frac{365\ \mathrm{days}}{\mathrm{year}}\times\mathrm{LT}(70\ \mathrm{years})\right)\times\left(\frac{1\ \mathrm{mg}}{1000\mu\mathrm{g}}\right)} \quad (2\text{-}3)$$

Dermal Contact with Soil/Hydric Soils/Sediment

$$\mathrm{CDI}_{\mathrm{res-sol-mu-der}}\left(\frac{\mathrm{mg}}{\mathrm{kg}}-\mathrm{day}\right)=\frac{\mathrm{C}_{\mathrm{soil}}\left(\frac{\mathrm{mg}}{\mathrm{kg}}\right)\times\mathrm{EF}_{\mathrm{r}}\left(\frac{350\mathrm{days}}{\mathrm{year}}\right)\times\mathrm{DFSM}_{\mathrm{adj}}\left(\frac{1358.85\ \mathrm{mg}-\mathrm{Year}}{\mathrm{Kg}-\mathrm{day}}\right)\times\mathrm{ABS}_{\mathrm{d}}*\left(\frac{10^{-6}\mathrm{kg}}{\mathrm{mg}}\right)}{\mathrm{AT}_{\mathrm{r}}\left(\frac{365\ \mathrm{days}}{\mathrm{year}}\times\mathrm{LT}\ (70\ \mathrm{years})\right)} \quad (2\text{-}4)$$

where:

$$\begin{aligned}\mathrm{DFSM_{adj}}\left(\frac{1358.85\ \mathrm{mg-Year}}{\mathrm{Kg-day}}\right) &= \frac{\mathrm{ED_{0-2}(yr)}\times\ \mathrm{AF_C}\left(\frac{0.2\ \mathrm{mg}}{\mathrm{cm^2}}\right)\times \mathrm{SA_C}\left(\frac{2690\mathrm{cm^2}}{\mathrm{day}}\right)\times 10}{\mathrm{BW_C(15\ kg)}} \\ &+ \frac{\mathrm{ED_{2-6}(yr)}\times\ \mathrm{AF_C}\left(\frac{0.2\ \mathrm{mg}}{\mathrm{cm^2}}\right)\times \mathrm{SA_C}\left(\frac{2690\mathrm{cm^2}}{\mathrm{day}}\right)\times 3}{\mathrm{BW_C(15\ kg)}} \\ &+ \frac{\mathrm{ED_{6-16}(yr)}\times\ \mathrm{AF_a}\left(\frac{0.07\ \mathrm{mg}}{\mathrm{cm^2}}\right)\times \mathrm{SA_a}\left(\frac{6032\mathrm{cm^2}}{\mathrm{day}}\right)\times 3}{\mathrm{BW_a(80\ kg)}} \\ &+ \frac{\mathrm{ED_{16-26}(yr)}\times\ \mathrm{AF_a}\left(\frac{0.07\ \mathrm{mg}}{\mathrm{cm^2}}\right)\times \mathrm{SA_a}\left(\frac{6032\mathrm{cm^2}}{\mathrm{day}}\right)\times 1}{\mathrm{BW_a(80\ kg)}}\end{aligned} \quad (2\text{-}5)$$

Ingestion of Water

$$\mathrm{CDI_{water-mu-ing}}\left(\frac{\mathrm{mg}}{\mathrm{kg}}-\mathrm{day}\right)=\frac{\mathrm{C_{water}}\left(\frac{\mathrm{mg}}{\mathrm{L}}\right)\times \mathrm{IFWM_{res-adj}}\left(\frac{1019.9\ \mathrm{L}}{\mathrm{kg}}\right)}{\mathrm{AT_{res}}\left(\frac{365\ \mathrm{days}}{\mathrm{year}}\times \mathrm{LT\ (70\ years)}\right)} \quad (2\text{-}6)$$

and:

$$\begin{aligned}\mathrm{IFWM_{res-adj}}\left(\frac{1019.9\ \mathrm{L}}{\mathrm{kg}}\right) &= \frac{\mathrm{ED_{0-2}(2\ yr)}\times \mathrm{EF_{0-2}}\left(\frac{350\ \mathrm{days}}{\mathrm{year}}\right)\times \mathrm{IRW_{0-2}}\left(\frac{0.78\ \mathrm{L}}{\mathrm{day}}\right)\times 10}{\mathrm{BW_{child}(15\ kg)}} \\ &+ \frac{\mathrm{ED_{2-6}(4\ yr)}\times \mathrm{EF_{2-6}}\left(\frac{350\ \mathrm{days}}{\mathrm{year}}\right)\times \mathrm{IRW_{2-6}}\left(\frac{0.78\ \mathrm{L}}{\mathrm{day}}\right)\times 3}{\mathrm{BW_{child}(15\ kg)}} \\ &+ \frac{\mathrm{ED_{6-16}(10\ yr)}\times \mathrm{EF_{6-16}}\left(\frac{350\ \mathrm{days}}{\mathrm{year}}\right)\times \mathrm{IRW_{6-16}}\left(\frac{2.5\ \mathrm{L}}{\mathrm{day}}\right)\times 3}{\mathrm{BW_{adult}(80\ kg)}} \\ &+ \frac{\mathrm{ED_{16-26}(10\ yr)}\times \mathrm{EF_{16-26}}\left(\frac{350\ \mathrm{days}}{\mathrm{year}}\right)\times \mathrm{IRW_{16-26}}\left(\frac{2.5\ \mathrm{L}}{\mathrm{day}}\right)\times 1}{\mathrm{BW_{adult}(80\ kg)}}\end{aligned} \quad (2\text{-}7)$$

Dermal Contact with Water

$$\begin{aligned}\mathrm{CDI_{water-mu-der}}\left(\frac{\mathrm{mg}}{\mathrm{kg}}-\mathrm{day}\right) &= \frac{\mathrm{DA_{event}}\left(\frac{\mu\mathrm{g}}{\mathrm{cm^2-event}}\right)\times\left(\frac{0.001\ \mathrm{mg}}{\mu\mathrm{g}}\right)\times \mathrm{DFWM_{adj}}\left(\frac{8{,}191{,}633\ \mathrm{cm^2-event}}{\mathrm{kg}}\right)}{\mathrm{AT_{res}}\left(\frac{365\ \mathrm{days}}{\mathrm{year}}\times \mathrm{LT\ (70\ years)}\right)}\end{aligned} \quad (2\text{-}8)$$

where:

$$\mathrm{DFWM_{adj}}\left(\frac{8{,}191{,}633\ \mathrm{cm^2}-\mathrm{event}}{\mathrm{kg}}\right)$$
$$=\frac{\mathrm{EV_{0-2}}\left(\frac{1\ \mathrm{event}}{\mathrm{year}}\right)\times\ \mathrm{EF_{0-2}}\left(\frac{350\ \mathrm{days}}{\mathrm{year}}\right)\times\mathrm{ED_{0-2}}(2\ \mathrm{years})\times\mathrm{SA_{0-2}}(6{,}365\ \mathrm{cm^2})\times 10}{\mathrm{BW_{child}}(15\ \mathrm{kg})}$$
$$+\frac{\mathrm{EV_{2-6}}\left(\frac{1\ \mathrm{event}}{\mathrm{year}}\right)\times\ \mathrm{EF_{2-6}}\left(\frac{350\ \mathrm{days}}{\mathrm{year}}\right)\times\mathrm{ED_{2-6}}(4\ \mathrm{years})\times\mathrm{SA_{2-6}}(6{,}365\ \mathrm{cm^2})\times 3}{\mathrm{BW_{child}}(15\ \mathrm{kg})}$$
$$+\frac{\mathrm{EV_{6-16}}\left(\frac{1\ \mathrm{event}}{\mathrm{year}}\right)\times\ \mathrm{EF_{6-16}}\left(\frac{350\ \mathrm{days}}{\mathrm{year}}\right)\times\mathrm{ED_{6-16}}(10\ \mathrm{years})\times\mathrm{SA_{6-16}}(19{,}652\ \mathrm{cm^2})\times 3}{\mathrm{BW_{adult}}(80\ \mathrm{kg})}$$
$$+\frac{\mathrm{EV_{16-26}}\left(\frac{1\ \mathrm{event}}{\mathrm{year}}\right)\times\ \mathrm{EF_{16-26}}\left(\frac{350\ \mathrm{days}}{\mathrm{year}}\right)\times\mathrm{ED_{16-26}}(10\ \mathrm{years})\times\mathrm{SA_{16-26}}(19{,}652\ \mathrm{cm^2})\times 1}{\mathrm{BW_{adult}}(80\ \mathrm{kg})}$$

and:

| µg | = | microgram |

If additional mutagenic COPCs are identified based on the combined Phase 1 and Phase 2 data, the intake estimates for those COPCs will also follow this methodology.

Calculated COPC intakes for each receptor and COPC will be provided in the receptor-specific risk and hazard calculation RAGS Part D tables.

## 2.3 TOXICITY ASSESSMENT

The purpose of the toxicity assessment (dose-response assessment) is to identify the types of adverse health effects a COPC may potentially cause, and to define the relationship between the dose of a COPC and the likelihood or magnitude of an adverse effect (response) (USEPA, 1989). Adverse effects are classified by USEPA as potentially carcinogenic or noncarcinogenic (i.e., potential health effects other than cancer). For purposes of the BHHRA, COPCs are classified into two broad categories: noncarcinogens and

carcinogens. Toxicity studies with laboratory animals or human epidemiological studies provide the data used to develop toxicity values (e.g., oral cancer slope factor [CSF], inhalation unit risk [IUR], oral reference dose [RfD] and inhalation reference concentration [RfC]). Dose-response relationships are defined by the USEPA for oral and inhalation exposure. In the absence of toxicological data and established values for the dermal route of exposure, oral toxicity values are used to assess dermal exposures, with appropriate adjustment for differences in absorption (USEPA, 2004).

### 2.3.1 Carcinogens

Potential carcinogenic effects are expressed as the probability that an individual will develop cancer over a lifetime based on the exposure assumptions used in the risk assessment. The CSF is a plausible upper bound estimate of carcinogenic potency used to calculate cancer risk from exposure to carcinogens, by relating estimates of lifetime average COPC intake to the incremental probability of an individual developing cancer over a lifetime. CSFs are derived based on an analysis of the animal and/or human data to determine the most appropriate model to use in the extrapolation from animal to humans or direct use of human epidemiological studies (USEPA, 2005a). The CSF is protective and assumes that exposure to any concentration of a carcinogen has the potential to produce an increased risk. The CSFs developed by USEPA are plausible upper-bound estimates, which means that USEPA is reasonably confident that the actual cancer risk will not exceed the estimated risk calculated using the CSF. The CSF is expressed in units of $(mg/kg\text{-}day)^{-1}$; the higher the CSF, the greater the carcinogenic potential. Oral CSFs are divided by the gastrointestinal absorption factor to calculate the dermal CSF. For organic COPCs, gastrointestinal absorption is relatively high; therefore, the absorption factor is 1. For inorganic COPCs, the absorption factor will be obtained from the current USEPA RSL Tables. The IUR is an estimate of the increased cancer risk from inhalation exposure to a concentration of 1 $\mu g/m^3$ for a lifetime (USEPA, 2009). The IUR can be multiplied by an estimate of lifetime exposure (in $\mu g/m^3$) to estimate the lifetime cancer risk.

USEPA's current carcinogen risk assessment guidelines (USEPA, 2005a) emphasize mode of action data, and recognize that some carcinogens may act nonlinearly. Therefore, it is recognized that some carcinogens may have a threshold dose below which effects would not be seen. Cancer risks from exposure to multiple carcinogens and multiple pathways are assumed to be additive (USEPA, 1986; 2000).

Several potentially carcinogenic PAHs were identified as preliminary COPCs for the Site. Carcinogenic PAHs will be evaluated for toxicity based on their relative potency factors, relative to benzo(a)pyrene (USEPA, 1993).

Some carcinogenic COPCs (e.g., PAHs) operate through a mutagenic mode of action, for which USEPA assumes that early-life exposures to these mutagenic COPCs may result in higher carcinogenic risks compared to exposures that occur later in life (USEPA, 2005a). USEPA recommends that dimensionless ADAF be considered when risk to mutagenic COPCs is characterized (USEPA, 2005b). To account for the COPCs that are considered carcinogenic by mutagenic mode of action, age-adjusted exposure parameters used for the age groupings, per USEPA guidance, will be provided (See Section 2.2.2.4). As indicated by USEPA (2005b), and as shown in the intake equations for mutagenic COPCs (Section 2.2.2.4), the following age-dependent adjustment factors (ADAFs) will be applied to mutagenic COPCs in the BHHRA:

- Age <2: ADAF = 10
- Age 2<16: ADAF = 3
- Age ≥16: ADAF = 1

An assessment for early-life exposure also will be conducted for the adolescent using an ADAF of 3, which corresponds to the USEPA age interval of 6 to <16 years (USEPA, 2005b). It should be noted that the ADAFs in the intake equations in Section 2.2.2.4 are typically applied to the toxicity of CSFs. However, mathematically, applying it to the intake is suitable and mimics what is done for the USEPA RSLs.

### 2.3.2 Noncarcinogens

Noncarcinogenic health effects will be evaluated using RfDs developed by USEPA. An RfD is an estimate of a daily oral exposure for a given duration to the human population (including susceptible subgroups) that is likely to be without an appreciable risk of adverse health effects over a lifetime (USEPA's Integrated Risk Information System [IRIS] definition). RfDs are expressed in milligrams of contaminant per kilogram of body weight per day (mg/kg-day). The RfD is a health-based criterion based on the assumption that thresholds exist for noncancer health effects (e.g., liver or kidney damage) over a length of time of exposure (e.g., chronic). Oral RfDs are multiplied by the gastrointestinal absorption factor to calculate the dermal RfD. For organic COPCs, gastrointestinal absorption is relatively high; therefore, the absorption factor is 1. For inorganic COPCs, the absorption factor will be obtained from the current USEPA RSL Tables. Similarly, RfCs are estimates (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. The RfC is expressed in units of milligrams of a chemical per cubic meter of air ($mg/m^3$). Exposure to a COPC below its RfC, even over a long period of time, is not expected to have any negative effect on health.

### 2.3.3 Toxicity Selection

Toxicity criteria will be selected according to the USEPA Office of Solid Waste and Emergency Response (OSWER) Directive 9285.7-53 (2003), which recommends a hierarchy of human health toxicity values for use in risk assessments at Superfund sites as well as the more recent Office of Land and Emergency Management (OLEM) memorandum for which sets recommendations for using chronic or subchronic noncancer values for Superfund risk assessments (USEPA, 2021). The USEPA Superfund hierarchy of sources of toxicity values includes three tiers as follows: (1) USEPA's IRIS; (2) USEPA's Provisional Peer-Reviewed Toxicity Values (PPRTVs); and (3) other sources of information, such as toxicity values from the California EPA and the Agency for Toxic Substances and Disease Registry (ATSDR) minimal risk levels for noncarcinogenic constituents. Tier 2 and Tier 3 toxicity values selected for use in the BHHRA will be obtained from current USEPA Regional Screening Level tables.

Oral toxicity criteria (CSFs and RfDs) will be used to assess dermal exposures in the absence of route-specific dermal CSFs and RfDs (USEPA, 1989). The dermal RfD will be derived by multiplying the COPC - specific oral absorption factor and oral RfD. Similarly, the dermal CSF will be derived by dividing the oral SF by the oral absorption factor.

Noncancer RfDs and RfCs may differ depending on the length of human exposure. Subchronic exposures are defined as lasting for at least 2 weeks but less than seven years, and chronic exposures are defined as lasting seven years or more (USEPA, 2023). The exposure scenario for utility and construction workers, for whom exposure is assumed to last 1 year, is the only exposure scenario that will be evaluated in the BHHRA for which chronic exposure assumptions are not used. In USEPA's soil screening-level guidance (USEPA, 2002c), the Science Advisory Board indicates that, although a conservative assumption, a child scenario with 6 years of exposure can be paired with a chronic RfD. This will be used in those cases where the COPC does not have a subchronic value. Subchronic oral and inhalation noncarcinogenic toxicity values and metadata will be obtained from the Risk Assessment Information System (RAIS) Chemical Toxicity Database (accessed at https://rais.ornl.gov/index.html). For those cases where a subchronic toxicity value does not exist, the chronic value will be used.

Toxicity criteria are summarized in Tables 2.3-1 through 2.3-4 for the preliminary COPCs identified from the Phase 1 data screening process (Table 2.1-3). Additional toxicity information, including, target organ/critical effect, weight of evidence classifications, uncertainty factors, and other relevant information for the COPCs also have been included in these tables. Toxicity for additional COPCs identified during screening of the combined Phase 1 and Phase 2 RI data will be selected as described here.

Note that when no toxicity value is available for a COPC, a value for another chemical will be assigned based on chemical or structural similarity, as appropriate, as denoted in the Tables 2.3-1 through 2.3-4. The uncertainty associated with surrogate assumptions will be addressed in the uncertainty analysis as part of the risk characterization (Section 2.4).

## 2.4 RISK CHARACTERIZATION AND UNCERTAINTY ASSESSMENT

The risk characterization combines the exposure assessment and toxicity values to calculate the total estimated carcinogenic risk and noncarcinogenic hazard for COPCs for each potential exposure pathway considered in the BHHRA (USEPA, 1989). Risk calculations will be performed in accordance with USEPA protocol. All calculations will be documented in RAGS D tables. Cancer risk and non-cancer hazard calculations will be documented in RAGS D Tables 7s and cumulative risks in RAGS D Table 9s.

### 2.4.1 Carcinogenic Risk Characterization

The purpose of carcinogenic risk characterization is to estimate the upper-bound likelihood, over and above the background cancer rate, that a receptor will develop cancer in his or her lifetime as a result of exposure to a chemical in environmental media at the Site. This likelihood is a function of the dose of a chemical and CSF for that chemical. The Excess Lifetime Cancer Risk (ELCR) is the likelihood over and above the background cancer rate. The risk value is expressed as a probability (e.g., $1x10^{-6}$ or one in one million) and is calculated as the product of the estimated lifetime average daily exposure (i.e., lifetime average daily dose, LADD) and the CSF. The following equation and parameters are used to evaluate the ELCR for each COPC and each exposure pathway:

$$ELCR = LADD \times CSF \qquad (2\text{-}12)$$

Where:

ELCR = excess lifetime cancer risk (unitless)

LADD = lifetime average daily dose (mg/kg-day)

CSF = cancer slope factor $(mg/kg\text{-}day)^{-1}$

This page intentionally left blank.

## Table 2.3-1: Noncancer Oral and Dermal Toxicity Values for the Preliminary COPCs

| Chemical of Potential Concern | CAS Number | Chronic Oral RfD (mg/kg-day) | Chronic RfD Source[1] | Oral Absorption for Dermal[2] | Chronic Dermal RfD (mg/kg-day) | Primary Target Organ System(s)[3] | Modifying/ Uncertainty Factors[3] | Chronic RfD Target Organ(s) Source[3] / Date | | Subchronic Oral RfD (mg/kg-day) | Subchronic RfD Source[1] | Subchronic Dermal RfD (mg/kg-day) | Subchronic RfD Primary Target Organ System(s)[3] | Modifying/ Uncertainty Factors[3] | RfD Target Organ(s) Source[3] / Date | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1,2,3-Trichloropropane | 96-18-4 | 4.00E-03 | I | 1 | 4.00E-03 | Hepatic | 300 | I | 11/13/2024 | 3.00E-02 | A | 3.00E-02 | Hematological | 100 | RAIS | 11/13/2024 |

Notes:

(1) Sources of toxicity values: I = IRIS; P = PPRTV; A = ATSDR; X = PPRTV Screening Level; H = HEAST; RAIS = Risk Assessment Information System; S = SCREEN (USEPA PPRTV Appendix Screening Levels).

(2) USEPA RSL Table dated November 2024 (USEPA, 2024b).

(3) Target organs and modifying/uncertainty factors were obtained from the sources listed and from USEPA's Integrated Risk Information System at https://www.epa.gov/iris/iris-descriptions-organssystems.

(4) The oral RfD toxicity value for vanadium is derived from the IRIS oral RfD for vanadium pentoxide by factoring out the molecular weight (MW) of the oxide ion. Vanadium pentoxide (V205) has a molecular weight of 181.88. The two atoms of vanadium contribute 56% of the MW. Vanadium pentoxide's oral RfD of 9E-03 mg/kg-day multiplied by 56% gives a vanadium oral RfD of 5.04E-03 mg/kg-day (USEPA, 2024b).

(5) The IRIS RfD (0.14 mg/kg-day) includes manganese from all sources, including diet. The author of the IRIS assessment for manganese recommended that the dietary contribution from the normal U.S. diet (an upper limit of 5 mg/day) be subtracted when evaluating non-food (e.g., drinking water or soil) exposures to manganese, leading to a RfD of 0.071 mg/kg-day for non-food items. The explanatory text in IRIS further recommends using a modifying factor of 3 when calculating risks associated with non-food sources due to a number of uncertainties that are discussed in the IRIS file for manganese, leading to a RfD of 0.024 mg/kg-day (USEPA, 2024b).

(6) The chronic MRL from ATSDR as the Cadmium RfD instead of the IRIS value in response to an USEPA memo "Recommendations on the Use of Chronic or Subchronic Noncancer Values for Superfund Human Health Risk Assessments" released in May 2021; this memo recommends using lower tier toxicity values that are more recent, credible, and relevant than the values that would be automatically selected from the RSL toxicity hierarchy. In this memo, it was recommended that the ATSDR chronic RfD of 1E-04 mg/kg-day from 2012 be used over the IRIS values (5E-04 and 1E-03 mg/kg-day for water and diet, respectively) from 1989 (USEPA, 2024b).

Notes:
(1) Weight of evidence/cancer guideline descriptions were generated from the USEPA IRIS.
(2) Sources of toxicity values: RSL Table Key: I = IRIS; P = PPRTV; C = Cal EPA; E = relative potency factor
Acronyms:
$\mu g/m^3$ = microgram per cubic meters
CalEPA = California Environmental Protection Agency
CAS = Chemical Abstracts Service
USEPA = U.S. Environmental Protection Agency
IRIS = Integrated Risk Information System
NA = not available
PPRTV = Provisional Peer-Reviewed Toxicity Value
RSL = regional screening level

For inhalation exposures, the ELCR is calculated using the following equation adapted from RAGS Part F (USEPA, 2009):

$$ELCR = EC_{air} \times IUR\ (mg/kg\text{-}day)^{-1} \quad (2\text{-}13)$$

Where:

ELCR = excess lifetime cancer risk (unitless)

$EC_{air}$ = exposure concentration in air ($\mu g/m^3$)

IUR = inhalation unit risk [$(\mu g/m^3)^{-1}$]

The potential carcinogenic risk for each exposure pathway is calculated for each receptor. In current regulatory risk assessments, it is assumed that cancer risks are additive. Risk estimates from different exposure pathways are summed across pathways and COPCs to estimate the total incremental cancer risk for each receptor. The sum of the cancer risk estimates for each receptor will be compared with the USEPA's generally acceptable risk management range of $1\times10^{-6}$ to $1\times10^{-4}$. Cancer risks that are less than the acceptable USEPA risk range will be assumed to indicate that no adverse health effects are predicted from exposures, whereas cancer risks above the upper risk management range of $1\times10^{-4}$, generally require action. A USEPA directive (USEPA, 1991) provides additional guidance on the role of the BHHRA in supporting risk management decisions and evaluating whether a response action is necessary.

### 2.4.2 Noncarcinogenic Hazard Characterization

The potential for exposure to a COPC resulting in potentially adverse noncarcinogenic health effects will be estimated for each receptor by comparing the average daily dose (ADD) for each COPC with the RfD for that COPC. The resulting ratio, which is unitless, is the HQ for that COPC. The HQ is calculated using the following equation:

$$HQ = \frac{ADD}{RfD} \quad (2\text{-}14)$$

Where:

HQ = hazard quotient (unitless)

ADD = average daily dose via the specified exposure route, noncancer (mg/kg-day)

RfD = reference dose (mg/kg-day)

For inhalation exposures, the noncancer HQ is calculated using the following equation adapted from RAGS Part F (USEPA, 2009):

$$HQ = \frac{EC_{air}}{RfC} \quad (2\text{-}15)$$

Where:

HQ = hazard quotient (unitless)

$EC_{air}$ = exposure concentration in air ($mg/m^3$)

RfC = reference concentration ($mg/m^3$)

To evaluate the effects of exposure via multiple exposure pathways for a receptor, the exposure pathway-specific HQs are summed for each COPC to determine a noncancer hazard index (HI) using the following equation:

$$HI = HQ_1 + HQ_2 + \cdots + HQ_i \qquad (2\text{-}16)$$

Where:

HI = hazard index (unitless)

$HQ_i$ = hazard quotient for specified exposure route (unitless)

When the HQ is less than or equal to 1, the RfD/RfC has not been exceeded, and no adverse noncarcinogenic effects are expected. If the HQ is greater than 1, there may be a potential for adverse noncarcinogenic health effects to occur; however, the magnitude of the HQ is not directly equated to a probability or effect level.

Summing the HQs for each individual COPC identifies the total HI for each exposure pathway. Furthermore, the total site HI is calculated for each potential receptor by summing the HIs for each pathway associated with the receptor. Where the total site HI is greater than 1 for any receptor, then the HQs will be segregated by target organ (i.e., hepatic, renal, respiratory, cardiovascular, gastrointestinal, hematological, musculoskeletal, dermal, and ocular effects) or critical effect (e.g., neurotoxicity, developmental toxicity, reproductive toxicity).

If any of the separate HI values exceed 1, adverse noncarcinogenic health effects are possible. If the total segregated HI is less than 1, it indicates that adverse noncarcinogenic health effects are unlikely. If the total segregated HI is greater than 1, it indicates that adverse health effects are possible.

### 2.4.3 Uncertainty Analysis

The process of evaluating cancer risks and noncancer health hazards involves multiple steps. Inherent in each step of the process are uncertainties that ultimately affect the final calculated cancer risks and noncancer health hazard estimates. Uncertainties may exist in areas including environmental contaminant concentration data, selection of COPCs, derivation of toxicity values, and estimation of potential Site exposures. As such, the risk characterization for the BHHRA will contain an uncertainty section to address the significant sources of uncertainty in the four risk assessment steps (hazard identification and data collection/evaluation, exposure assessment, toxicity assessment, and risk characterization). These identified uncertainties will be qualitatively discussed, including the strengths, limitations, and uncertainties inherent in key scientific issues and science policy choices. This section accounts for sources of uncertainty in the various components of the risk assessment analysis in order to provide a full understanding of the accuracy and reliability of calculated risks and hazards. An understanding of the strengths and potential uncertainties of the risk assessment provides the risk manager with additional information for consideration in the risk management decision.

The uncertainty associated with using BTVs to screen the data for selection of COPCs will be addressed in the uncertainty analysis as necessary to assist in distinguishing site contamination from naturally occurring and/or anthropogenic background. For those COPCs that are naturally or anthropogenically occurring that contribute to excess cancer risk and/or noncancer hazard for which site-specific background data exist, further evaluation, potentially, in the form of hypothesis testing may be an option as an additional risk refinement should the PDT determine the need for further evaluation. Guidance from USEPA's Role of Background in the CERCLA Cleanup Program (USEPA, 2002e) and Comparing Background and Chemical Concentration in Soil for CERCLA Sites (USEPA, 2002f) will be followed to assess background contribution to overall risk as a part of the uncertainty analysis.

Potential risks will be estimated using the analytical results from the combined Phase 1 and Phase 2 datasets, which include biased and unbiased samples. In accordance with USEPA guidance (USEPA 1989, 2002b), any potential bias in the EPC estimates should be identified in the BHHRA. The potential impact the biased sampling results have on the estimated EPCs and risk estimates will be evaluated in the uncertainty analysis. If the estimated risks for an exposure area exceed acceptable levels, the sample locations and analytical results that are based on a biased sampling approach will be reviewed to determine their impact on the quantitative risk estimates. The uncertainty assessment may include recalculating potential risks for the risk drivers (COPCs that contribute the most risk) using a refined dataset that excludes biased samples, recalculates EPCs (i.e., volume-weight or area weight EPCs), and/or evaluating smaller exposure areas that are defined based on sample-specific risks. Sample-by-sample risk estimates are useful in determining if there are potentially localized areas of elevated concentrations that may pose an unacceptable risk to receptors, and they also address the uncertainty of potentially underestimating risks associated with evaluating the entire AOC as one exposure area.

If unacceptable risks are identified after refining the risks and reducing the overall uncertainty, the risk drivers will be identified as chemicals of concern (COC) that may warrant remediation.

Acronyms:
ug/m$^3$ - micrograms per cubic meter
cm$^2$ - square centimeters
kg - kilograms
m$^3$/kg - cubic meters per kilogram
mg/kg - milligrams per kilogram
mg/m$^3$ - milligrams per cubic meter
mg/day - milligrams per day
kg/mg - kilograms per milligram
mg/cm$^2$-event - milligrams per square centimeter per event

Notes:
1. Soil exposure is not evaluated for a golfer for AOC 3 because they are assumed not to perform any intrusive activity and would only conduct the equivalent of passive recreational activity (i.e., walking).

## 1.0 INTRODUCTION

WSP USA Federal Programs Inc. (WSP) has prepared this Screening Level Ecological Risk Assessment (SLERA) Work Plan in support of the Phase 2 Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) Remedial Investigation (RI) at the New York Ordnance Works Formerly Used Defense Site (FUDS) in Baldwinsville, New York (hereafter referred to as the "Site"). The former New York Ordnance Works is located in Onondaga County, New York, near the Finger Lakes, about 1 mile northeast of the Village of Baldwinsville and approximately 13 miles north of Syracuse, New York. Portions of the Site are currently owned by the Radisson Community, the State of New York, and private owners.

The RI includes the following Areas of Concern (AOCs):

- AOC 1 – Former Ammonium Picrate area
- AOC 3 – Former Landfill area
- AOC 4 – Former Bunker area
- AOC 5 – Former Power Plant area, which includes five subareas (Boiler House, Coal Storage Area, Sub Station, Possible Dump, and the Coal Aggregate Bins Area)

As part of the Phase 2 RI, a SLERA for these AOCs is required. Because the SLERA is an inherently conservative process and contaminants of potential ecological concern (COPEC) are likely to be identified in the SLERA, an United States Environmental Protection Agency (USEPA) Ecological Risk Assessment Guidance Step 3A Refined SLERA (RSLERA) has been included in this workplan to support Scientific Management Decision Point (SMDP) discussions. Generally, the term SLERA is used to refer to the overall evaluation, and individual Ecological Risk Assessment Guidance components (i.e., Steps 1, 2, and 3A) are identified when referring to specific components. Although the RSLERA is typically considered to be the initial step of the Baseline Ecological Risk Assessment (BERA) (Step 3), this Work Plan follows the U.S. Army Corps of Engineers New England Division (NAE) practice of incorporating the refinements as part of Step 2 of the SLERA. Incorporation of refinements at this stage allows some of the conservatism of the SLERA to be mitigated and provides a technically defensible justification for focusing the BERA to only those receptors for which uncertainty associated with risk findings at the conclusion of Steps 2 indicates further evaluation is required. From a technical perspective, this does not impact the robustness of the risk evaluation and strengthens the risk conclusions for the SMDP at the end of Step 2.

This SLERA Work Plan has been prepared as a planning step for conducting the SLERA to address requirements of CERCLA and the National Contingency Plan, 40 Code of Federal Regulations Part 300 (USEPA, 1988), and is included as Appendix C of the Phase 2 Uniform Federal Policy for Quality Assurance Project Plans (UFP-QAPP). Detailed information describing the Site characteristics, operational history, physical setting, and summaries of the previous investigations are not included in the SLERA Work Plan, and the reader is referred to particular worksheets in the Phase 2 UFP-QAPP.

## 1.1 PURPOSE AND SCOPE OF WORK

The purpose of the SLERA Work Plan is to document the methods and procedures for evaluating potential ecological risks associated with receptor exposure to COPECs identified in environmental media associated with each of the AOCs identified at the Site. The ecological receptors selected for this SLERA include terrestrial plants, terrestrial invertebrates, wildlife, aquatic life (e.g., sediment- and surface water-dwelling organisms), threatened and endangered species, and wetlands or other sensitive habitats associated with the four AOCs.

The SLERA will be conducted in general accordance with CERCLA requirements and is consistent with USEPA guidance including the following:

- Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments (USEPA, 1997)
- Guidelines for Ecological Risk Assessment (USEPA, 1998)
- The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments (USEPA, 2001).

Other guidance documents, including the U.S. Army Corps of Engineers Conceptual Site Models (2012) and Standard Scopes for ERAs (USACE, 2016), will also be considered.

## 1.2 OBJECTIVES

The primary objective of the SLERA/RSLERA is to assess whether potential unacceptable ecological impacts are likely associated with exposure to CERCLA constituents in soil, surface water, porewater, or sediment related to historical Department of Defense (DoD) activities to support a determination whether ecological concerns can be ruled out or if additional ecological evaluation is needed. The overall approach entails the use of discrete samples to demonstrate no actionable risks for each AOC. If risks are unacceptable for a given AOC, the risk assessment may be refined or potentially areas where further investigations are warranted may be identified. These objectives will be met by implementing the process described in the SLERA and RSLERA flow charts presented in the Phase 1 Risk Screening and Data Gaps Analysis report (see Figures 5-1 and 5-2, respectively, in Appendix A). The SLERA/RSLERA report will be included as an appendix to the RI report.

## 1.3 WORK PLAN ORGANIZATION

This Work Plan includes the following components:

- **Section 1, Introduction.** Provides the scope, objectives, regulatory framework of the Work Plan, and Work Plan organization.
- **Section 2, SLERA Data Sources.** Describes the analytical datasets available to support the SLERA along with data reduction and processing steps.
- **Section 3, Problem Formulation – Introduction.** Describes the environmental setting. Based on the preliminary COPECs identified in Phase 1, provides details regarding the preliminary conceptual site model (CSM) that summarizes contamination sources, contaminant migration

pathways, potential exposure pathways for each identified receptor group. Develops assessment and measurement endpoints and risk questions.

- **Section 4, Problem Formulation – Step 1: Screening Level Ecological Effects Evaluation.** Describes the nature of the hazards posed by contaminants and development of media screening levels, wildlife toxicity reference values (TRVs), and how hazards will be quantified.
- **Section 5, Problem Formulation – Step 2: Screening Level Exposure and Risk Calculation.** Describes community receptors, wildlife receptors, quantifying wildlife exposures.
- **Section 6, Step 3A – Refined Problem Formulation/Risk Characterization**. Provides overview of the Step 3A refinement process including CSM, assessment and measurement endpoints, exposure point concentrations (EPCs), and refined effect concentrations.
- **Section 7, Conclusions/Uncertainty Analysis**. Provides a summary of SLERA/RSLERA findings, their sensitivities and key uncertainties that should be considered in decision making.
- **Section 8, References.** Provides a list of references used in the preparation of this document.

## 2.0 SLERA DATA SOURCES

Available analytical data for soil samples collected at all AOCs and aquatic media (surface water, porewater, and sediment) will be evaluated in the SLERA. Site groundwater analytical data will not be evaluated other than to determine whether sampling of downgradient aquatic habitats may be warranted. Although most ecological exposure occurs in the top 2 feet (ft) of soil, subsurface soil (i.e., 1 to 5 ft below ground surface [bgs]) will be used in the SLERA to evaluate potential exposures to burrowing mammals and deep-rooted plants. Historical chemistry data are available for the Site from reports dating from 1981 through 2008. During preparation of the Phase 1 UFP-QAPP (USACE, 2020), it was determined that those data are of limited use due to issues associated with their age with limited relevance to evaluating current exposures. Therefore, only data collected during the Phase 1 and Phase 2 RI field efforts will be considered for the SLERA, and a tiered approach will be used in the evaluation to screen and integrate these two datasets. Although most of the Phase 1 dataset is considered to be biased, the majority of the Phase 2 sampling program will result in unbiased data because sampling locations were selected using a spatially balanced statistical design approach. While the combination of these datasets will represent conservative exposure estimates, some of which can be considered "worse case," the risk assessment will be conducted using a tiered approach that incorporates refinements to reduce overall uncertainties.

### 2.1 PHASE 1 SAMPLING DATA

Phase 1 RI data were collected in 2021 and include analytical results for soil and groundwater samples collected at AOC 1, AOC 3, AOC 4, AOC 5, and background locations. All work was completed in accordance with applicable Federal, State, and local regulations, as well as industry standards and best management practices. In general, samples were collected and analyzed in accordance with the Final Uniform UFP-QAPP (USACE, 2020), with any deviations noted in the RI Phase 1 Field Reports (USACE, 2021 and 2022). Field documents, field data, and laboratory data were loaded into and managed within the FUDS Chemical database. With the exception of incremental sampling methodology samples collected from surface soil (0 to 1 ft bgs) in the bunker aprons of AOC 4, all samples collected were discrete soil samples collected from 0 to 10 ft bgs (i.e., 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs). Table 2-1 summarizes the data available from the Phase 1 field efforts, including the number of samples per medium (and depth interval for soils) and analyses conducted.

### 2.2 PHASE 2 SAMPLING DATA

For Phase 2 of the RI, additional investigations into the nature and extent, investigations into potential impacts to additional media (i.e., surface water, porewater, and sediment), and site-hydrogeological conditions (e.g., groundwater flow) are planned as detailed in the Phase 2 UFP-QAPP. Table 2-2 summarizes the number of proposed samples per medium (and depth interval for soils) that will be available for use from the Phase 2 field effort.

## 2.3 REVIEW, EVALUATION AND PRESENTATION OF ANALYTICAL DATA

Chemical analytical data associated with all previous and ongoing investigations will be reviewed and evaluated for quality, usefulness, and uncertainty. Data identified as being of acceptable quality for use in the SLERA will be summarized in a manner that presents the pertinent information to be applied in the SLERA. For example, soil samples from AOC 4 were collected using incremental sampling methodology (ISM). Given the low bias attributable to low surrogate recoveries for multiple samples, the uniformly low bias of results reported as nondetect was identified as a data gap (USACE, 2022). Phase 2 soil will be collected to confirm the ISM results, and these data will be used to assess risks for AOC 4. The analytical data may have qualifiers from the analytical laboratory quality control or data validation process that reflect the level of confidence in the data. Some of the more common qualifiers and their meanings are as follows (USEPA, 2002a):

- U – Chemical was analyzed for but not detected; the associated value is the sample quantitation limit.
- J – Value is estimated, probably below the contract-required quantitation limit.
- R – Quality control indicates that the data are unusable (chemical may or may not be present).
- B – Concentration of chemical in sample is not sufficiently higher than concentration in the blank (using the 5-times/10-times rule).

Validated data with "J" qualifiers are used in the risk assessment; data assigned "R" and "B" qualifiers following data validation are not. "U"-qualified data (nondetects) will be estimated to be equal to the reporting limit. Analytical data from field duplicates and parent sample results will be combined to yield one result for use in the generation of mean (and Step 3A upper confidence limit [UCL]) concentrations, as follows:

- Use the average of the field duplicate and parent sample if both are positive detections or if both are nondetects.
- Use the detected value if one sample is a positive detection and the other is a nondetect.

Polyaromatic hydrocarbon (PAH) data will be evaluated both as individual chemicals and as total concentrations for chemical subgroups. Total concentrations will be defined as the sum of the detected concentrations of individual chemicals within that chemical group. For the screening evaluation for PAHs, the totals will be calculated and presented assuming a value of half the limit of detection for non-detected results for individual analytes. Total concentrations will be calculated for the following groups:

- Total low molecular weight (LMW) PAHs – sum of acenaphthylene, acenaphthene, anthracene, fluorene, fluoranthene, naphthalene, methylnaphthalene, and phenanthrene
- Total high molecular weight (HMW) PAHs – sum of pyrene, benzo(a)anthracene, chrysene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene
- Total PAHs – sum of each of the analytes listed above for total LMW and HMW PAHs

For each combination of AOC, medium and sampling depth (soil only), available data will be statistically summarized and the following information tabulated: analyte, detection frequency, range of detections or sample limits of quantification (LOQs), location of maximum concentration of LOQ, EPC, ecological screening level (ESL), maximum hazard quotient (HQ), number of samples exceeding ESL, preliminary COPEC (Y/N) and category. Preliminary COPEC categories will include: 1 – detected and HQ>=1; 2 – nondetect and maximum LOQ >= ESL; 3 – detected but no ESL; and 4 – nondetect and no ESL.

## 3.0 PROBLEM FORMULATION – INTRODUCTION

The problem formulation component is a systematic planning and scoping process that establishes the goals, breadth, and focus of the ERA (USEPA 1997, 1998). The problem formulation identifies the:

- Environmental setting and the COPECs known or suspected at the Site;
- Chemical fate and transport mechanisms and contaminated media relevant to the Site;
- Likely ecological receptors;
- Potentially complete exposure pathways (source to receptor); and,
- Assessment and measurement endpoints to focus the assessment.

The Phase 1 Risk Screening and Data Gap Analysis report (USACE, 2023a,b) presents the current problem formulation understanding including the current ecological CSM (Section 3.6). According to the toxicological basis of the ESLs, some receptors will be evaluated as ecological communities (i.e., community specific), while others are evaluated as individual populations or individuals of a species (i.e., receptor specific).

### 3.1 SITE SETTING

This section provides details necessary to understand the potential hazards posed by the Site, along with environmental conditions and the ecosystem (habitats, receptors) present. The SLERA will present a detailed ecological description of each AOC, including a listing of the habitat types, water bodies, flora and fauna assemblages and wetlands present at or near each AOC. Much of this information has been presented in the Phase I reports and will be reviewed and updated as necessary. Resources such as the New York Natural Heritage Database Nature Exposure online tool and the U.S. Fish and Wildlife Service Information for Planning and Consultation database will be required to confirm Phase 1 information including status of special interest species such as bat populations, including the following federally listed endangered mammal species: the Indiana bat (*Myotis sodalis*) and the northern long-eared bat (*M. septentrionalis*). The tricolored bat (*Perimyotis subflavus*) is also proposed to be listed as an endangered species (USFWS, 2022a) and updated information is necessary to determine whether any of these species warrant special consideration in the SLERA.

Prior to preparing the SLERA, a WSP ecologist will conduct a site visit at the AOCs to corroborate information described in the Phase I and to confirm identification of the representative wildlife receptors discussed in Section 3.5. The site visit will also focus on gaining a better understanding of the importance of glacial geology and impacts on topography, soil substrates, and surficial hydrology.

### 3.2 CONTAMINANT SOURCES/MIGRATION PATHWAYS

The primary contaminant sources are the historical activities at the individual AOCs that resulted in the release of contaminants to surface soils (secondary sources) from disposal, burning, and spillage/leakage. Subsequent migration led to contamination of additional downgradient media, including subsurface soil and groundwater (tertiary media) (Figures 3-1 through 3-4). The fate and transport of site-related constituents released into the environment depends on the physicochemical properties of the constituents and environmental media, and the physical characteristics of the migration pathway. The

primary constituent migration pathways from site sources to ecological exposure areas may include overland stormwater runoff associated with precipitation events and infiltration/leaching to groundwater and subsequent discharge to surface water (as evaluated using analytical data for sediment and pore water). Constituents may partition in various environmental media, such as surface water, sediment, and soil, and this affects the potential ecological risks posed to terrestrial and aquatic receptors.

The potential need to assess aquatic exposures in AOCs 1, 4, and 5, will be determined during the Phase 2 study based on review of upgradient soil and/or groundwater data and the determination that a complete migration pathway to aquatic habitat potentially exists (see Figures 3-1, 3-3, and 3-4).

### 3.3 PRELIMINARY COPECS

Table 3-1 summarizes the preliminary COPECs that were identified during the Phase 1 study based on risk screening using soil screening levels for terrestrial plants, terrestrial invertebrates, birds, and mammals. Note that target energetic material-related analytes (picric acid, 2,4-dinitrochlorobenzene [DNCB], and 2,4-dintirophenol) were not detected in Phase 1 surface soils collected at AOC 4. However, due to analytical uncertainty associated with the ISM composite data, additional discrete sampling will be conducted in Phase 2 to verify that these analytes are not COPECs.

### 3.4 SITE RELATED CONTAMINANTS

Section 5.3 of the Phase 1 Risk Screening and Data Gaps Analysis report (USACE, 2023a,b) established a process for categorizing chemical analytes with regard to whether they are likely present in Site media as a result of historical DoD-related activities. As outlined in Figure 5-1 in the Phase 1 Risk Screening and Data Gaps Analysis report (see Appendix A), the following steps were conducted to identify the SLERA dataset that were then screened against conservative benchmarks:

- Analytes related to former DoD activity
- Data of sufficient quality and quantity available
- Site concentrations not consistent with background conditions (including evaluation of PAH ratios and pyrogenic/petrogenic categorization)
- Nature, detection frequency, magnitude, and spatial distribution consistent with a potential source area or release

With respect to evaluating background consistency, soil (and groundwater) samples were collected from areas believed to be unimpacted by historical activities and analyzed for PAHs and metals during Phase 1. Site-specific background threshold values (BTVs) established in the Phase 1 Risk Screening (USACE, 2023a, b) will be used as a first line of evidence to determine whether concentrations detected in site media are attributable to background levels. Comparison to the site-specific BTVs is based on the null hypothesis that the site concentrations are consistent with background concentrations. If comparison to the site-specific BTVs indicates the likelihood of false positives (Type I error or the incorrect rejection of the null hypothesis), either single- or two-sample hypothesis testing may be considered for PAH and/or inorganic analytes as an additional risk refinement. The statewide background values (NYSDEC, 2006) will also be used as a supporting line of evidence in the site-to-background comparisons.

During Phase 2, background samples will be collected from hydric soils (Psc geological unit), sediment, surface water, and pore water media and analyzed for PAHs and metals. Following the statistical analytical procedures used in Phase 1, BTVs will be calculated for hydric soils, sediment, surface water, and pore water and compared with the maximum concentrations in AOC 1 and AOC 5 hydric soil datasets and AOC 3 surface water, pore water, and sediment datasets. Analytes consistent with background (i.e., maximum concentration < BTV) will be eliminated from the ESL screening process. Additional analyses will be conducted for soils in AOC 5 to help differentiate impacts related to historical sources related to coal storage and aggregate bins. Consistent with Phase 1 (USACE, 2023b) analyses, field observations during Phase 2 sampling, a pyrogenic/petrogenic PAH evaluation of the Phase 2 PAH data, and microscopic analysis to detect the presence of coal particles will be used as lines of evidence to identify DoD-related COPECs.

Preliminary COPECs were established using Phase 1 data. The process used in Phase 1 to determine whether analytes are associated with historical activities at the AOCs will also be conducted using the combined Phase 1 and 2 COPEC datasets (see Section 4.1.1). Consistent with the Phase 1 screening process, essential nutrients (calcium, iron, magnesium, potassium, and sodium) will not be identified as COPECs, as they are not related to DoD-related releases. These analytes are necessary for metabolic processes in organisms and at naturally occurring concentrations, receptors can regulate uptake and metabolism of these elements. Conclusions regarding site-related status of detected analytes (including Phase 1 conclusions based on detection frequencies and spatial distribution) will also be reevaluated. The Phase 1 conclusions regarding analytes without ESLs or non-detected analytes with LOQs exceeding project action limits will also be reassessed.

### 3.5 ECOLOGICAL RECEPTORS

Ecological receptors were identified in the Phase 1 Risk Screening and Data Gaps Analysis report (included in Appendix A) based on consideration of available habitat conditions and information obtained from site visits by the Project Delivery Team (PDT) members, observations noted during field sampling events, and a wetland delineation and vernal pool survey (USACE, 2020). In addition, various online resources were queried and state resource personnel contacted. This information was compiled in a Resource Receptor Inventory (Appendix K; USACE, 2023) and was used to identify ecological receptor groups with the potential for adverse effects resulting from exposure to contaminants at the Site (Figures 3-1 through 3-4). Table 3-2 summarizes the types of receptors and level of organization (i.e., community or population) that will be evaluated in the SLERA and provides specifics regarding the AOCs and exposure media (and depths) where those potential exposures will be evaluated. Community-level receptors are defined for specific media to encompass the range of non-wildlife organisms that may be present in a given habitat. For terrestrial habitat, the plant community consist of all rooted vascular plants (ranging from annuals to woody perennial species) and soil invertebrates include various insects, oligochaetes (earthworms), isopods (e.g., woodlice) and chilopods (e.g., centipedes). Terrestrial plants and invertebrates are assumed to be exposed to COPECs in both surface and subsurface (1 to 5 ft bgs) soils. The AOC 3 stream potentially provides aquatic habitat for both pelagic organisms (including insects, amphibians, fish and aquatic plants) and benthic organisms (e.g., oligochaetes, insect larvae, and rooted vascular plants). These two

community-level receptors are assumed to be exposed to COPECs in surface water and sediment/porewater, respectively.

The representative wildlife include both mammal and avian species that were selected based on known or likely occurrence at the Site (see USACE, 2023a,b). In addition, the selected bird and mammal species represent all trophic categories (i.e., herbivores, omnivores, carnivores) anticipated for exposed wildlife receptors. In general, wildlife receptors were preferentially selected to include animals that reflect more conservative exposures (e.g., low body weight, higher soil ingestion rates) appropriate for meeting the SLERA objectives (see Section 1.2). Wildlife receptors at AOCs 1, 4, and 5 are assumed to be exposed to COPECs in surface, soil whereas only burrowing mammals are assumed to be exposed to subsurface (1 to 5 ft bgs) at all AOCs. Although AOC 4 is located within the Three Rivers State Wildlife Management Area, no migration pathway to aquatic habitat is considered likely. As a result, only evaluation of terrestrial endpoints is currently planned; however, this understanding may be revised following review of the Phase 2 groundwater dataset.

### 3.6 PRELIMINARY CONCEPTUAL SITE MODEL

The preliminary ecological CSMs for AOCs 1, 3, 4, and 5 developed in the Phase 1 Risk Screening and Data Gaps Analysis report (USACE, 2023a,b) are presented in Figures 3-1 through 3-4, respectively. For all four AOCs, the principal release mechanisms were historical activities, including dumping that resulted in direct release of contaminated materials to soil and subsequent soil infiltration/leaching that impacted subsurface soils and groundwater. Subsequent discharge of contaminated groundwater to downgradient aquatic habitat (AOC 3) could result in potential ecological exposures to sediment, pore water, and surface water. This latter pathway may also be complete at AOCs 1, 4, and 5 and potentially affected aquatic habitat may be sampled following evaluation of the Phase 2 groundwater data and release mechanisms associated with soil and groundwater.

The CSM also identify potential exposure pathways, including incidental ingestion and dermal/direct contact and receptor categories as discussed in Section 3.5. Note that the Phase 1 CSMs do not include a contaminated prey consumption pathway. The SLERA/RSLERA will also evaluate this pathway using wildlife exposure models that include prey types, ingestion rates, and estimated analyte concentrations in consumed prey. The CSMs will be revised, as necessary following screening of the Phase 2 data and refinement of exposure and effects assumptions in Step 3A.

### 3.7 ASSESSMENT/MEASUREMENT ENDPOINTS/RISK QUESTIONS

According to the USEPA (1998), assessment endpoints are formal expressions of the environmental value or ecological resource to be protected. Assessment endpoints most often describe the environmental effects that drive decision-making, such as reduction of key populations or disruption of biological community structure. Typically, assessment endpoints and receptors are selected for their potential exposure, sensitivity, ecological significance, economic importance, societal relevance, and are generally associated with sensitive populations, communities, or trophic guilds. The assessment endpoints proposed for this SLERA seek to maintain healthy communities/populations of flora and fauna within and around the Site.

Key assessment endpoints for supporting healthy populations typically involve minimizing adverse effects to survival, growth, and reproduction. Because the assessment endpoints cannot be measured directly, a set of surrogate endpoints (known as measurement endpoints or measures of effect) are generally selected that relate to the assessment endpoints and have measurable attributes (e.g., comparison of media concentrations to screening levels) (USEPA 1997, 1998). These measures of effect provide a quantitative metric for evaluating potential effects of COPECs on the ecological components chosen as the assessment endpoints. The measurement endpoints for this evaluation are represented by the HQs, which are intended to quantify potential impacts (or lack of impacts) at the appropriate level of ecological organizations (i.e., population or community). The measurement endpoint is closely linked to the assessment endpoint (healthy populations or communities), and the necessary inferences that can be made (i.e., one can infer the "healthiness" of the population). Where an estimated exposure level or dose is less than the corresponding ESL or TRV (i.e., HQ less than 1), effects on populations or communities of biota are not expected; however, where an estimated exposure level is greater than the corresponding criterion (i.e., HQ greater than 1), harmful effects on populations or communities of biota may or may not occur and further study or response actions may be required.

Based on the preliminary ecological CSMs and site characteristics, assessment endpoints, model species, measurement endpoints, and risk questions were selected for the SLERA. These are presented in Table 3-3.

## 4.0 PROBLEM FORMULATION – STEP 1: SCREENING LEVEL ECOLOGICAL EFFECTS EVALUATION

As specified in the Ecological Risk Assessment Guidance for Superfund, the ecological effects evaluation is part of Step 1 of the SLERA. Protective ESLs are developed for both community-level receptors and wildlife, and chronic no observed adverse effect levels (NOAELs) are also derived for specific wildlife receptors. Conservative media-based ESLs were identified for inorganic and organic analytes detected in soil, sediment, surface water, and porewater for the preliminary evaluation of the potential risks to community-level receptors from exposure to site COPECs. The ESLs and their sources are described below by media. This is followed by a discussion of the wildlife TRVs selected for the initial evaluation of potential risks to wildlife receptors from oral exposure to site COPECs in soils and food/prey tissue.

### 4.1 MEDIA SCREENING LEVELS

Consistent with the screening approach utilized in Phase 1, ESLs were developed for soil, sediment, and aqueous media using datasets compiled by the USEPA and the Los Alamos National Laboratory (LANL). A hierarchical approach was used to preference rank the selected datasets as described in the subsections below for each exposure medium, and the lower of the selected ecological-based values were compared to screening levels protective of human health to identify risk-based project action limits that are presented in the QAPP Worksheet #15.

Media-based ESLs will be used to identify preliminary COPECs for both terrestrial and aquatic community receptors and to identify analytes requiring wildlife exposure modeling in Step 2. As part of the screening process, the ESL sources listed below will be checked to verify that the values used are current.

Soil COPECs have already been identified in Phase 1 (Table 3-1), and a phased process will be used to screen soil analytes in the SLERA. The phased SLERA steps include the following:

1. Use Equation 1 (see Section 4.3), screen media-specific maximum analyte concentrations using the combined Phase 1 and 2 data subsets for each AOC and assessment endpoint receptor specific ESLs (Attachment C.2). For analytes that exceed (or lack) ESLs, compare inorganic and PAH data to appropriate background BTVs, evaluate detection frequencies, exceedance magnitude and spatial distribution, advance all analytes and receptors that cannot be eliminated and update the CSM.
2. For wildlife receptors identified in Step 2 (see Section 4.3), rescreen using Equation 2, maximum analyte concentrations and conservative exposure parameters (Table 5-1) and NOAEL TRVs (Table 4-1).

Phase 1 did not evaluate surface water, sediment, or porewater media, and wildlife exposures to contaminants in these media are not included in the current CSM. Therefore, the screening process will consist of just a single step:

1. Use Equation 1 (see Section 4.3), screen media-specific maximum analyte concentrations and ecological ESLs specific to aquatic and benthic community endpoints (Attachment C.2), compare inorganic and PAH data to appropriate background BTVs, evaluate detection frequencies, exceedance magnitude and spatial distribution, advance all analytes and receptors that cannot be eliminated and update CSM.

Analytes that are not eliminated in the above steps will be evaluated in the RSLERA.

### 4.1.1 Soil

Following an assessment of data usability, the first phase will compare maximum detected concentrations in the validated Phase 2 analytical dataset to the lowest available ESLs presented in Attachment C.2-1. The data for all analytes that are not eliminated in either the Phase 1 or initial Phase 2 risk screenings will then be combined for evaluation in the second phase. Consistent with the Phase 1 risk screening process, the maximum analyte concentrations will be compared to receptor-specific ESLs for terrestrial plants, terrestrial invertebrates, and wildlife receptors in the second phase as described in Sections 4 and 5. Note that the Phase 1 wildlife ESLs were not based on Site-specific exposure assumptions, which will be utilized in Phase 2. Preliminary soil ESLs were selected using the following hierarchy:

1. EPA ecological soil screening levels (Eco-SSLs) (USEPA, 2003a) – the lowest values available for plants, soil invertebrates, birds and mammals were selected.
2. Region 4 Ecological Risk Assessment Supplemental Guidance (USEPA, 2018a) – the lowest value available for plants, soil invertebrates, birds and mammals was selected.
3. EPA Region 5 Resource Conservation and Recovery Act (RCRA) ecological SLs (USEPA, 2003b) – the majority of values are based on small mammal exposure models.
4. LANL EcoRisk screening levels (Intellus, 2024) – the lowest no-effect level values available for plants, soil invertebrates, birds and mammals were selected.

Available soil ESLs for the analytical groups specified in Table 2-2 and the selected ESLs for each analyte are presented in Attachment C-2. Eco-SSL values are available for a majority of the inorganics as well as for LMW and HMW PAHs; whereas the EPA Region 4 compilation was the source for nearly all organic analytes, including 2,4-dinitrophenol (used to develop a surrogate-based value for picric acid as described in Attachment C-1). Finally, the USEPA Region 5 ESL (based on exposure to the masked shrew [*Sorex cinereus*]) for 2,4-dinitrotoluene was used to develop a surrogate value for dinitrochlorobenzene as discussed in Attachment C. Selected preliminary soil ESLs are presented in Attachment C, Table C.2-1.

Following the initial screening of the soil datasets, all analytes that exceed the conservative ESLs and those analytes lacking ESLs will be carried forward to a second screening step. At this point, community-specific ESLs will be identified for terrestrial plants and soil invertebrates for contaminants in surface soil.

Terrestrial Plants. Most of the phytotoxicity ESLs are sourced from the USEPA Region 4 soil ESLs (USEPA, 2018a). Phytotoxicity ESLs were generally only available for metals, some PAHs, some semi-volatile organic compounds, some pesticides, and total polychlorinated biphenyls. The USEPA's Eco-SSLs (USEPA, 2007), ORNL's benchmarks for plants (Efroymson et al., 1997a), and the LANL's no-effect ESLs (Intellus, 2024) will be the primary resources used to identify plant community ESLs. USEPA's Screening Level Ecological Risk Protocol for Hazardous Waste Combustion Facilities (1999a), and the National Oceanic and Atmospheric Administration ESLs (Buchman, 2008) will be reviewed for benchmarks for analytes not included in the primary sources listed above.

Terrestrial Invertebrates. Most of the soil invertebrate ESLs are also sourced from the USEPA Region 4 soil ESLs (USEPA, 2018a). The primary sources utilized by USEPA Region 4 for the soil invertebrate ESLs are the USEPA's Eco-SSLs (USEPA, 2007a), the LANL's no-effect ecological ESLs (Intellus, 2024), and the Ecological Structure Activity Relationship (ECOSAR) and Region 4 soil model which coupled water quality ESLs in ECOSAR with equilibrium partitioning theory to derive soil ESLs.

Wildlife. Wildlife-specific ESLs will be primarily sourced from the USEPA Region 4 soil ESLs (USEPA, 2018) along with Eco-SSLs, EPA Region 5 RCRA ESLs (USEPA, 2003b) and the LANL's no-effect ESLs (Intellus, 2024). Wildlife exposure modeling for the representative wildlife species identified in Table 3-3 will then be performed for all soil analytes that exceed either avian or mammal-specific ESLs.

### 4.1.2 Sediment

Sediment ESLs for the benthic community associated with the creek at AOC 3 will be selected using the following hierarchy: (1) Region 4 Ecological Risk Assessment Supplemental Guidance (USEPA, 2018b), (2) USEPA Region 3 Biological Technical Assistance Group (BTAG) Screening Benchmarks (USEPA, 2006) (3) USEPA Region 5 ESLs (USEPA, 2003b), and (4) LANL EcoRisk screening levels (Intellus, 2024). Table C.2-2 (Attachment C) summarizes the information in these reference sources and identifies sediment ESLs.

### 4.1.3 Surface Water

Aqueous ESLs for screening analytes detected in AOC 3 surface water and porewater analytes will be identified using the following hierarchy: (1) USEPA National Recommended Water Quality Criteria (current), (2) Region 4 Ecological Risk Assessment Supplemental Guidance (USEPA, 2018a), (3) USEPA Region 3 BTAG Screening Benchmarks (USEPA, 2006), (4) USEPA Region 5 RCRA ESLs (2003b), and (5) LANL EcoRisk screening levels (Intellus, 2024). Table C.2-3 (Attachment C) summarizes the information in these reference sources and identifies surface water/pore water ESLs.

## 4.2 WILDLIFE TRVS

To evaluate the potential for adverse effects to mammal and bird wildlife receptors exposed to COPECs at the Site, estimated exposures (as an ingested dose) are compared to TRVs. A TRV is defined as a daily dose of a chemical expressed in milligrams per kilogram (mg/kg) of body weight per day (bw-day). The TRV may be represented as a dose associated with the NOAEL or the lowest observed adverse effect level (LOAEL). Because NOAELs are associated with no effects in a test study, it is uncertain whether they are close to or far below the threshold value at which effects would first be observed. LOAELs therefore serve to bound

the range of NOAELs, and the threshold of toxic effects is assumed to fall between the NOAEL and the LOAEL. Typically, chronic NOAELs or LOAELs are used with endpoints that target effects on reproduction, growth, and/or survival. These endpoints are intended to be protective of populations of wildlife receptors rather than individual animals. In accordance with USEPA Region 3 guidance, TRVs will be determined for any detected COPEC listed in Table 4-2 ("Important Bioaccumulative Compounds" in USEPA [2000]). Additionally, if the maximum concentration for a COPEC exceeded an ESL for community-level receptors, then a TRV will be developed (if possible). Both NOAEL and LOAEL TRVs are discussed here, although the SLERA (Steps 1 and 2) will compare wildlife doses based on maximum exposure concentrations to NOAEL TRVs only. LOAEL TRVS, along with NOAEL TRVs, will be used in the refined risk characterization in Step 3A.

The sources for the TRVs for wildlife indicator species include the USEPA Eco-SSLs (USEPA, 2005a–f, 2006b, 2007b–f, 2008), Toxicological Benchmarks for Wildlife (Sample et al., 1996), USEPA Screening Level Ecological Risk Assessment Protocol for Hazardous Combustion Waste Facilities (1999a), and other scientific literature as necessary and appropriate. Each of these sources and the corresponding TRVs are discussed in more detail in the following paragraphs. TRVs presented in the Eco-SSL documents were derived in a transparent, systematic manner by a multi-stakeholder workgroup consisting of federal, state, consulting, industry, and academic participants led by the USEPA's Office of Superfund Remediation and Technology Innovation (USEPA, 2005i). For many of the NOAEL TRVs where the Eco-SSLs were used as the primary source, the selected NOAEL is the highest bounded NOAEL for growth, reproduction, or survival below the lowest bounded LOAEL for the same endpoints. This is true for antimony, arsenic, cadmium, copper, lead, nickel, selenium, vanadium, LMW PAHs, and HMW PAHs for mammals, and copper, lead, selenium, vanadium for birds. For some NOAEL TRVs, the indicated value is the geometric mean of the TRV values presented for growth, reproduction, and/or mortality endpoints. TRVs developed in this manner include barium, chromium, cobalt, manganese, and zinc for mammals, and cadmium, chromium, hexavalent chromium, cobalt, manganese, nickel, zinc for birds. TRVs for COPECs without Eco-SSLs were based on single studies with growth, reproduction, or mortality endpoints as presented in Sample et al. (1996) and USEPA (1999a).

Extrapolation factors (e.g., 0.1–- LOAEL to NOAEL or 10 -NOAEL to LOAEL) may be used if either a NOAEL or LOAEL is not available (the latter for consideration in Step 3A). Table 4-1 summarizes TRVs for various analytes that will likely need to be evaluated in the SLERA. Additional TRVs will be developed as necessary using the sources described above. A brief summary of the critical effect, test species, source of the TRV, and a short explanation of the derivation process based on the indicated source are provided for each set of values. As noted above, only the NOAEL TRVs will be used in Step 2. A qualitative discussion of the uncertainty associated with the data gaps associated with analytes lacking wildlife TRVs (e.g., bird value for antimony in Table 4-1) will be provided in the Uncertainty Analysis (Section 7).

### 4.3 SCREENING LEVEL RISK ESTIMATION

Section 4.1.1 describes the phased screening approach that will be conducted to reduce the number of Phase 2 soil analytes prior to combining with the data for ecological COPECs previously identified in Phase1. For the SLERA, potential risks posed by site-related chemicals will be determined using the HQ

approach where an HQ was calculated for each chemical and measurement receptor/community pair. For community-level receptors the HQ is the ratio of a potential exposure level to the applicable toxicity-based ESL as reflected in the following equation:

$$HQ = {}^{C_{media}}/_{ESL} \qquad \text{Equation 1}$$

where:

HQ = hazard quotient

$C_{media}$ = maximum concentration in surface water, pore water, soil, and sediment (mg/kg or mg/L).

ESL = Ecological screening level protective of terrestrial plants, terrestrial invertebrates, benthic invertebrates, or aquatic life

Potential risks to wildlife receptors will be characterized by comparing the total calculated ingested dose with the NOAEL TRVs derived from the literature for each endpoint species. Specifically, HQs will be calculated by dividing the total dose (total estimated exposure) by the NOAEL, as shown in the following equation:

$$HQ = {}^{EE_{total}}/_{NOAEL} \qquad \text{Equation 2}$$

where:

HQ = hazard quotient

$EE_{total}$ = Total estimated exposure (mg/kg bw-day)

NOAEL = No observed adverse effect level (mg/kg bw-day).

For a given receptor/chemical pair, an HQ less than 1 suggests negligible potential risk. Conversely, an HQ greater than or equal to 1 suggests that a potential risk may exist, and further evaluation is warranted.

# 5.0 PROBLEM FORMULATION – STEP 2: SCREENING LEVEL EXPOSURE AND RISK CALCULATION

The abiotic screening process includes a comparison of the maximum concentrations of contaminants detected in surface soil, sediment, surface water, and pore water to the respective ESLs discussed in Section 5.1. There are three possible outcomes; the treatment of these outcomes is as follows:

- Outcome 1: The detected contaminant's maximum concentration is below an accepted screening level threshold. These contaminants are considered to present negligible risk for a particular exposure pathway and are eliminated as COPECs.
- Outcome 2: Contaminant is detected at concentrations exceeding its screening threshold (i.e., HQ >1). These contaminants may present potential risks to ecological receptors and are carried forward to Step 3A of the risk assessment.
- Outcome 3: For community-based exposure pathways, a contaminant is detected but no acceptable screening threshold is available. These contaminants are retained for further evaluation and/or discussion in the Step 3A uncertainty analysis.

Analytes will be eliminated from the screening process if not detected at a given exposure point (i.e., AOC), or are essential nutrients (calcium, iron, magnesium, potassium, and sodium). Additionally, aluminum will be eliminated as a soil COPEC. According to the USEPA Eco-SSL document for aluminum (USEPA, 2003a), aluminum is identified as a COPEC only at sites where the soil pH is less than 5.5.

## 5.1 COMMUNITY RECEPTORS

COPECs for the terrestrial-plant community will be selected by comparing maximum contaminant concentrations in surface (0 to 1 ft bgs) and subsurface soil (1 to 5 ft bgs) with the selected soil ESLs for effects on plants. COPECs for the soil-invertebrate community will be selected by comparing maximum contaminant concentrations in surface and subsurface (1 to 5 ft bgs only) soils with ESLs for effects on soil fauna.

COPECs for the aquatic community (including plants, fish, amphibians, and invertebrates [both pelagic and demersal]) will be selected by comparing maximum contaminant concentrations in surface water, pore water, and sediment samples with chronic criteria and standards and other relevant ESLs for the protection of aquatic life.

In addition to screening ESLs for community receptors against maximum concentrations, ESLs will also be compared to analyte concentrations on a sample-by-sample basis and spatial patterns in any identified exceedances evaluated.

## 5.2 WILDLIFE RECEPTORS

Chemical exposure doses will be calculated as the sum of exposures from diet and incidental soil ingestion. Dietary exposure was estimated using the following equation:

$$EE_{diet} = C_f * IR_{f-BW} * AUF * ED \qquad \text{Equation 3}$$

where:

$EE_{diet}$ = Estimated exposure from diet (mg/kg bw-day)
$C_f$ = Contaminant concentration in food (mg/kg, dry weight)
$IR_{f\text{-}BW}$ = Body-weight normalized food ingestion rate (kg dry weight/kg bw/day)
AUF = Area use factor (unitless)
ED = Exposure duration (unitless)

Table 5-1 summarizes wildlife exposure parameters for the six representative wildlife species, and Table 5-2 summarizes contaminant uptake factors used to estimate contaminant transfer between soil and wildlife dietary components including plants, soil invertebrates, and small mammal tissue. Values are provided for individual PAHs and potential inorganic COPECs; additional uptake factors will be developed as necessary once the preliminary wildlife COPECs are identified.

Wildlife exposure to chemicals through incidental soil ingestion will be estimated in a manner similar to that used for dietary exposure, as shown in the following equation:

$$EE_{soil} = C_s * IR_{s-BW} * AUF * ED \qquad \text{Equation 4}$$

where:

$EE_{soil}$ = Estimated exposure from incidental soil ingestion (mg/kg bw-day)
$C_s$ = Contaminant concentration in soil (mg/kg, dry weight)
$IR_{s\text{-}BW}$ = Body-weight normalized soil ingestion rate (kg dry weight/kg bw/day)
AUF = Area use factor (unitless)
ED = Exposure duration (unitless)

For all wildlife exposure pathways, the area use factor (AUF) and exposure duration will be assumed to be 1 (no exposure adjustment) for the SLERA. In addition, the dietary component anticipated to contribute the largest dose will be assumed to represent 100% of a receptor's diet.

The total exposure for a receptor is calculated as the sum of the exposure from diet and incidental soil ingestion as represented by the following equation:

$$EE_{total} = EE_{diet} + EE_{soil} \qquad \text{Equation 5}$$

where:

$EE_{total}$ = Total estimated exposure (mg/kg bw-day)

$EE_{diet}$ = Estimated exposure from diet (mg/kg bw-day)

$EE_{soil}$ = Estimated exposure from incidental soil ingestion (mg/kg bw-day)

Wildlife exposures will be estimated separately for each AOC, assuming their exposure area or exposure unit (EU) is the same as the AOC. Potential risks posed by site-related chemicals will be determined by calculating an HQ for each chemical for each endpoint species using Equation 2 (Section 4.3), and the findings will be summarized by AOC and media.

## 6.0 STEP 3A – REFINED PROBLEM FORMULATION/RISK CHARACTERIZATION

The primary objective of Step 3A is to further refine the list of COPECs identified in the SLERA using less conservative and more realistic assumptions. Additionally, the Step 3A evaluation may incorporate (USEPA, 2001) consideration of background, frequency and magnitude of detection, and varied diet components (for wildlife receptors). By bracketing the HQ estimates for receptors/COPECs that exceed ESLs used in Steps 1 and 2, this additional evaluation is intended to support the SMDP considerations.

The focus of Step 3 is on the preliminary COPECs that are identified based on HQs exceeding 1, and those analytes for which ESLs or TRVs are unavailable, the latter being evaluated along with other SLERA uncertainties. In the SLERA Steps 1 and 2, maximum concentrations detected in soil, sediment, surface water, and sediment porewater will have been compared to ESLs for community receptors. In addition, maximum concentrations of detected analytes detected in soil will have been evaluated through use of food chain exposure models that incorporated conservative life history and exposure parameters for modeled receptor species. In general, similar methods will be used in the Step 3A evaluation to refine the list of COPECs identified in the SLERA; however, where possible, less conservative and more realistic assumptions will be employed in the refinement step.

In Step 3A, the EPCs for the various media will be primarily based on the 95% UCL rather than the maximum concentration assumed for each medium in the SLERA; maximum concentrations will only be used if the 95% UCL estimates are greater. The 95% UCL represents a more realistic yet conservative EPC for populations of wildlife receptors and communities. The 95% UCL values will be determined using the USEPA statistical software package ProUCL Version 5.2 (USEPA, 2022c,d). ProUCL uses Kaplan-Meier methods for handling datasets with nondetects and multiple detection limits for the same compound in different samples in the calculation of UCLs. The input data sets for ProUCL identify nondetects and these are assigned the limit of detection and the 95% UCL considers the dataset distribution in calculating the 95% UCL estimates.

The assessment and measurement endpoints are largely the same in Step 3A. The primary differences are inherent in the EPCs and TRVs used for each measurement endpoint:

- The 95% UCL concentrations for the various COPECs will be used for comparison to community-level ESLs and for the wildlife receptor dose calculations.
- The estimated exposure doses for wildlife receptors will be compared with NOAEL and LOAEL TRVs.
- Evaluation of selected ESLs and TRVs used in Step 2 and potential identification of less conservative values including LOAELs that are more appropriate for Site flora and fauna.
- Consideration of contaminant bioavailability using supplemental parameters for soil (cation-exchange capacity, total organic carbon, and pH), sediment (total organic carbon, grain size) and surface water (dissolved oxygen, pH, and turbidity).

## 6.1 COMMUNITY ENDPOINTS

In addition to quantifying exposures with 95% UCL rather than maximum concentrations, the specific studies used to derive the ESLs for the community endpoints will be reviewed and if other less conservative values may be appropriate, these will also be used to estimate HQs in Step 3A to evaluate the sensitivity of available options. Also, additional surrogate compounds may also be considered to support the evaluation of uncertainties associated with COPECs that lack ESLs.

## 6.2 WILDLIFE

The screening level risk estimation is designed to evaluate risks from exposure to media within an AOC, defined as the EU for all receptors, to demonstrate that there are no actionable risks. The biased data, collected from areas of impact or anticipated impact within these AOCs, will be used conservatively to represent high-end exposure estimates for a given AOC. Although AOC 5 contains multiple decision units (DUs), the entire AOC will initially be identified as the EU.

Refinements from the Step 1 and Step 2 exposure estimates incorporate relevant site-specific factors into the evaluation of potential ecological risks. To refine the COPEC list for wildlife, the wildlife exposure assumptions will be revised to reflect the length of time the wildlife receptor would be expected to be exposed (exposure duration) at the Site, and to reflect the percentage of the receptor's home range within the impacted areas or AUF. AUF adjustments require estimates of home range or foraging range relative to the footprint for the areas of impacted soils. Thus, the extent of soil with detected COPECs at AOCs 1, 4, and 5 will be divided by the estimated home range of each representative wildlife receptor (Table 4-1) and the adjusted AUFs will be used in the Step 3A exposure modeling. The sensitivity of this parameter on the risk estimates for AOC 5 will be evaluated by calculating an overall AUF as well as assuming only exposure to a given DU. Although the assessment endpoints for wildlife receptors are primarily population-level focused, the refinement evaluation will also consider receptors with AUFs smaller than DUs (e.g., voles). For these receptors, a sample-by-sample comparison of COPECs to ESLs will be conducted to assess the importance of the spatial heterogeneity on ecological exposures and potential risks in an AOC or subarea. For wildlife receptors with AUFs larger than a given EU/DU, the sensitivity evaluation will also consider the effect of assuming combined exposures to multiple AOCs/EUs using area-weighted 95% UCL estimates. The appropriateness of aggregating exposures within AOC 5 and the likelihood of exposures to multiple AOCs by wide-ranging wildlife receptors will be assessed during the ecological site visit.

Dietary exposures for the robin and raccoon will be adjusted in the Step 3A evaluation to represent the varied diets of these receptors. The TRVs discussed in Section 4.2 and will also be used in Step 3A; however, as with the community endpoint assessment, alternative values may also be evaluated. In addition, the estimated daily doses for chemicals calculated for each receptor are compared with both the NOAEL and LOAEL-based TRVs.

## 7.0 CONCLUSIONS/UNCERTAINTY ANALYSIS

The refinement step findings will be summarized by AOC, environmental media and receptors categories, and conclusions regarding the assessment endpoints risk questions provided. In addition, the SLERA/RSLERA will include an updated CSM, a refined list of COPECs, and receptors potentially at risk.

The process of evaluating potential ecological risks involves various assumptions and multiple steps, and uncertainties are inherent in each step that may ultimately affect the final hazard estimates. Accordingly, the SLERA/RSLERA will include an uncertainty section to address the significant sources of uncertainty in the following assessment components: data collection/evaluation, problem formulation, exposure assessment, effects assessment, and risk characterization. The uncertainties will be qualitatively discussed, including the strengths and limitations of the available information used in the SLERA, to provide a robust understanding of the accuracy and reliability of the hazard estimates. In addition to the environmental contaminant concentration data evaluated in the SLERA/RSLERA, important uncertainties may be associated with any of the key lines of evidence (LOE) used in the refinement phase. These will be described so that the degree of associated confidence and potential biases are understood. The Figure 5-2 RSLERA flow chart in the Phase 1 Risk Screening and Data Gaps report (USACE, 2023a) identifies key LOE, which include the following:

- Data – sampling/measurement error, distribution (outliers, spatial).
- Toxicity – endpoint relevance, test species similarity to selected representative species. Similarity between test organism and presumed site exposures, dataset robustness, uncertainty factor magnitude.
- Exposure – ingestion rates, dietary preferences, soil ingestion rates, contaminant bioavailability (including supplemental parameters), prey tissue uptake factors, foraging range, and seasonal presence.
- Risk – magnitude and frequence of ESL/TRV exceedances, comparison with background conditions.

As summarized in Exhibit 11-1 in the QAPP, the combined Phase 1 and 2 datasets will include both biased and unbiased data and the potential impacts of using the biased data will be also evaluated for cases where potential risks are identified. One approach to be considered will be calculate HQs for these COPECs with and without consideration of the biased data. Similarly, while various types of data were collected at AOC 4 (ISM, discrete, and confirmation samples), the ISM data will not be used to assess risks due to the uncertainty in the dataset. The uncertainties associated with excluding this dataset from the risk evaluation and how it impacts the overall risk conclusions will be evaluated.

Along with these factors, the uncertainty analysis will also consider potential adverse effects associated with analytes and ecological receptors without toxicity values (e.g., reptiles/amphibians) as well as the potential for adverse effects to species of special concern (e.g., bats).

At the completion of the SLERA, the PDT will review the results and determine whether a BERA (or remedial action to address ecological concerns) is warranted or not.

**TABLES**

**Table 2-1: Available Analytical Data from Phase 1**

| Area Sampled | Number of Samples per Medium | | | | Analyses |
|---|---|---|---|---|---|
| | Soil (0-1 ft bgs) | Soil (1-5 ft bgs) | Soil (5-10 ft bgs) | Groundwater | |
| AOC 1 | 30 | 11 | 11 | 10 | 2,4-DNP, DNCB, picric acid, inorganics |
| AOC 3 | 16 | 18 | None | 7 | VOCs, SVOCs, picric acid, PAHs, Aroclors, inorganics |
| AOC 4 - Discrete | 16 | 85 | 16 | 16 | 2,4-DNP, DNCB, picric acid |
| AOC 4 - ISM | 36 | None | None | | |
| AOC 5 | 25 | 25 | 25 | 12 | VOCs, SVOCs, PAHs, Aroclors, inorganics |
| Background | 45 | 45 | 45 | 9 | PAHs and inorganics |

Acronyms:
2,4-DNP = 2,4-dinitrophenol
AOC = area of concern
DNCB = 2,4-dinitrochlorobenzene
ft bgs = feet below ground surface
ISM = incremental sampling methodology
PAHs = polycyclic aromatic hydrocarbons
SVOCs = semivolatile organic compounds
VOCs = volatile organic compounds

**Table 2-2: Proposed Available Data from Phase 2**

| Area Sampled | Number of Samples per Medium[(a)] | | | | | | Analyses[d] |
|---|---|---|---|---|---|---|---|
| | Soil (0-1 ft bgs) | Soil (1-5 ft bgs) | Soil (5-10 ft bgs) | Surface Water[(b)] | Pore Water[(b)] | Sediment[(b,c)] (0-1 ft bgs) | |
| AOC 1 | 16 | 16 | 16 | None | None | 12 | 2,4-DNP, DNCB, picric acid, TAL metals |
| AOC 3 | 7 | 7 | 7 | 16 | 16 | 16 | VOCs, SVOCs, PAHs, Aroclors, picric acid, TAL metals |
| AOC 4- discrete | 60 | None | None | None | None | None | 2,4-DNP, DNCB, picric acid |
| AOC 5 | 25 | 25 | 25 | None | None | 5 | PAHs and TAL metals |
| Background | None | None | None | 16 | None | 8 (hydric)<br>16 (stream sediment) | PAHs and TAL metals |

Notes:

(a) Although groundwater data will also be collected in Phase II, the medium will not be evaluated in the SLERA, rather analytical data for downgradient ecological exposure media (i.e., surface water, porewater and sediment) will be evaluated pending evaluation of this potential migration pathway for AOCs 1, 4 and 5. In addition, no ecological exposure to contaminants detected in the 5-10 ft bgs soil interval is assumed in the SLERA.

(a) Includes semiannual sampling for one year.

(b) Sediment samples from AOC 1 and AOC 5 will be collected in the wetlands area and are considered hydric samples.

(c) Geochemical parameters will also be collected.

Acronyms:

2,4-DNP = 2,4-dinitrophenol

AOC = area of concern

DNCB = 2,4-dinitrochlorobenzene

ft bgs = feet below ground surface

PAHs = polycyclic aromatic hydrocarbons

SVOCs = semivolatile organic compounds

TAL = target analyte list

VOCs = volatile organic compounds

**Table 2-3: Combined Phase 1 and 2 Datasets**

| Area Sampled | Number of Samples per Medium[a] | | | | | | Analyses[d] |
|---|---|---|---|---|---|---|---|
| | Soil (0-1 ft bgs) | Soil (1-5 ft bgs) | Soil (5-10 ft bgs) | Surface Water[b] | Pore Water[b] | Sediment[b,c] (0-1 ft bgs) | |
| AOC 1 | 46 | 27 | 27 | None | None | 12 | 2,4-DNP, DNCB, picric acid, TAL metals |
| AOC 3 | 23 | 25 | 7 | 16 | 16 | 16 | VOCs, SVOCs, PAHs, Aroclors, picric acid, TAL metals |
| AOC 4- discrete | 76 | 85 | 16 | None | None | None | 2,4-DNP, DNCB, picric acid |
| AOC 4 - ISM | 36 | None | None | | | | |
| AOC 5 | 50 | 50 | 50 | None | None | 5 | PAHs and TAL metals |
| Background | 45 | 45 | 45 | 16 | None | 8 (hydric)<br>16 (stream sediment) | PAHs and TAL metals |

Notes:

(b) Although groundwater data will also be collected in Phase II, the medium will not be evaluated in the SLERA, rather analytical data for downgradient ecological exposure media (i.e., surface water, porewater and sediment) will be evaluated pending evaluation of this potential migration pathway for AOCs 1, 4 and 5. In addition, no ecological exposure to contaminants detected in the 5-10 ft bgs soil interval is assumed in the SLERA.

(c) Includes Phase 2 semiannual sampling for one year.

(d) Phase 2 sediment samples from AOC 1 and AOC 5 will be collected in the wetlands area and are considered hydric samples.

(e) Geochemical parameters also available.

Acronyms:

2,4-DNP = 2,4-dinitrophenol

AOC = area of concern

DNCB = 2,4-dinitrochlorobenzene

ft bgs = feet below ground surface

PAHs = polycyclic aromatic hydrocarbons

SVOCs = semivolatile organic compounds

TAL = target analyte list

Notes:

(a) Phase I analytes with maximum concentrations exceeding screening levels. Superscript numbers indicate type of screening levels exceeded: [1] terrestrial plants, [2] terrestrial invertebrates, [3] birds, and [4] mammals (**bolded analytes** are preliminary wildlife soil COPECs).

(b) Based on screening of subsurface soil data only (i.e., no wildlife screening).

(c) Nondetect for picric acid, 2,4-dinitrochlorobenzene, and 2,4-dintirophenol.

Acronyms:

AOC = area of concern

LMW PAHs = Low Molecular Weight Polycyclic Aromatic Hydrocarbons

HMW PAHs = High Molecular Weight Polycyclic Aromatic Hydrocarbons

**Table 3-2: Ecological Receptors[a]**

| Level of Organization | Receptor Type | Trophic Level | AOC | Exposure Media[b] | Selected Representative Taxa |
|---|---|---|---|---|---|
| Community | Terrestrial Plants | Producer | 1, 3[c], 4, 5 | Soil (0-1 ft, 1-5 ft) | All plant species that obtain nutrients primarily from soil |
| Community | Terrestrial Invertebrates | Various | 1, 3[c], 4, 5 | Soil (0-1 ft, 1-5 ft bgs) | All soil invertebrates (e.g., earthworms, insect larvae, arthropods, isopods) |
| Population | Small Mammal | Herbivorous | 1, 3[c], 4, 5 | Soil (0-1 ft bgs) | Meadow vole (*Microtus pennsylvanicus*) |
| Population | Small Mammal | Omnivorous | 1, 3[c], 4, 5 | Soil (0-1 ft bgs) | Northern short-tailed shrew (*Blarina brevicauda*) |
| Population | Medium Mammal | Carnivorous | 1, 3[c], 4, 5 | Soil (0-1 ft, 1-5 ft) | Red fox (*Vulpes vulpes*) |
| Population | Medium Mammal | Omnivorous | 1, 4, 5 | Soil (0-1 ft bgs) | Raccoon (*Procyon lotor*) |
| Population | Small Bird | Herbivorous | 1, 3[c], 4, 5 | Soil (0-1 ft bgs) | Mourning dove (*Zenaida macroura*) |
| Population | Small Bird | Omnivorous | 1, 3[c], 4, 5 | Soil (0-1 ft bgs) | American robin (*Turdus migratorius*) |
| Community | Aquatic Organisms[d] | Various | 3[d] | Water column; Pore water | Aggregate community components (i.e., fish, aquatic invertebrates, aquatic plants) |
| Community | Benthic Invertebrates[d] | Various | 3[d] | Sediment (0-0.5 ft bss); Pore water | Aggregate community components |

Note:

(a) The Phase 1 analysis concluded that large herbivorous mammals (e.g., deer) and carnivorous birds (e.g., owls, hawks) occur in the vicinity of the individual AOCs and that exposure pathways are potentially complete; however, these pathways were determined to be insignificant due to the wide-ranging foraging behavior of these receptors.

(b) Surface soils (i.e., 0-1 ft bgs) include both terrestrial and "hydric" soils; the latter will be collected at both AOCs 1 and 5.

(c) No ecological exposure to surface soils at AOC3; however, burrowing mammals (e.g., red fox) could be exposed to subsurface soils.

(d) Aquatic organisms including benthic invertebrates may be exposed to contaminants in discharging groundwater downgradient of AOCs 1, 4 and 5. If so, analytical data for aquatic media will be collected and evaluated in the SLERA.

**Table 3-3: Assessment Endpoints, Representative Species, Risk Questions and Measurement Endpoints Screening Level Ecological Risk Assessment**

| Assessment Endpoint | Community or Population Attribute | Level of Organization | Model Species | Risk Question | Measure/ Exposure Route | Measurement Endpoint/ Analysis Approach |
|---|---|---|---|---|---|---|
| **TERRESTRIAL RECEPTORS** | | | | | | |
| **Terrestrial Plants** | | | | | | |
| Protection of terrestrial plant communities from the toxic effects (on survival, reproduction, and growth) of COPECs in surface soils. | Plants provide structure and function to the terrestrial habitat. Plants are primary producers and form the basis of the food web for most consumers; adverse effects on the plant community could reduce the quantity and quality of food available to higher-trophic-level consumers. Plants also reduce soil erosion and provide nesting and cover for wildlife. | Local Community | All plants that obtain nutrients primarily from soil. | Are contaminant concentrations in surface soil greater than screening levels for effects on survival, growth, or reproduction of plants such that the terrestrial plant community is impacted? | Measure contaminant levels in surface soil. Direct exposure to soil. | Compare soil contaminant concentrations (maxima) with soil screening levels for effects on plants. For refinement: use central tendency concentrations and both NOAEL and LOAEL ESLs if available, evaluate impact of outliers if present, background risk estimates, contaminant bioavailability and magnitude/spatial distribution and ESL exceedance frequencies. |
| **Terrestrial Invertebrates** | | | | | | |
| Protection of soil invertebrate communities from the toxic effects (on survival, growth, and reproduction) of COPECs in surface soils. | The terrestrial soil invertebrate community is typically diverse taxonomically, morphologically and physiologically, and are often numerically abundant. Soil invertebrates play an important role in ecosystem functions such as nutrient cycling and organic matter processing, soil formation and stabilization, maintenance of soil porosity, control of microbial communities and enhancement of microbial biochemical ecosystem functions, seed dispersion, pest and disease control, natural attenuation of pollutants. Soil invertebrates represent an important food source for upper trophic level birds, mammals, and reptiles. | Local Community | All soil invertebrates (e.g., earthworms, insect larvae, arthropods) | Are contaminant concentrations in surface soil greater than screening levels for effects on survival, growth, or reproduction of soil invertebrates such that the terrestrial invertebrate community is impacted? | Measure contaminant levels in surface soil. Direct exposure to soil. | Compare soil contaminant concentrations with soil screening levels for effects on soil invertebrates. For refinement: use central tendency concentrations and both NOAEL and LOAEL ESLs if available, evaluate impact of outliers if present, background risk estimates, contaminant bioavailability and magnitude/spatial distribution and ESL exceedance frequencies. |

**Table 3-3: Assessment Endpoints, Representative Species, Risk Questions and Measurement Endpoints Screening Level Ecological Risk Assessment**

| Assessment Endpoint | Community or Population Attribute | Level of Organization | Model Species | Risk Question | Measure/ Exposure Route | Measurement Endpoint/ Analysis Approach |
|---|---|---|---|---|---|---|
| **Terrestrial Mammals and Birds** | | | | | | |
| Herbivores - Protection of herbivorous mammal and bird populations from the toxic effects (on survival, growth, or reproduction) of site-related chemicals present in plant tissue and soil. | Herbivorous birds and mammals play an important role in the transfer of energy and nutrients from plants to animals. These animals forage primarily on vegetation (thereby contributing to a balanced vegetative community), and provide food for upper-trophic-level consumers. Herbivores are also important for seed dispersal and pollination and dispersal of lichens and fungi. Adverse effects on these primary consumers could reduce the amount of food available to higher-trophic-level consumers. Small herbivorous mammals have a high potential for direct exposure to soil COPECs. | Local Populations | Meadow vole, mourning dove. | Does the daily dose of contaminants received from ingestion of soil and food items (i.e., vegetation) exceed TRVs protective of survival, growth, or reproduction of mammals or birds? | Measure contaminant levels in surface soil. Incidental ingestion of soil and ingestion of site vegetation. | Modeled dose from ingestion of surface soil and food items (vegetation) compared with literature-based TRVs. Estimate concentrations in plant tissue using soil-to-plant uptake factors. For refinement: use central tendency concentrations and both NOAEL and LOAEL TRVs if available and site- and receptor-specific exposure parameters (spatial/temporal use factors), evaluate impact of outliers if present, background risk estimates, contaminant bioavailability and magnitude/spatial distribution and TRV exceedance frequencies. |
| Insectivores/Invertivores - Protection of insectivorous/invertivorous mammal and bird populations from the toxic effects (on survival, growth, or reproduction) of site-related chemicals present in invertebrate tissue and soil. | Invertivorous birds and mammals represent an energy and nutrient pathway between soil invertebrates and plants (that may be in direct contact with soil COPECs) and upper trophic level receptors. Additionally, insectivorous vertebrates regulate insect population size, diversity, and species abundance. These animals provide food for upper-trophic-level consumers. Adverse effects on these secondary consumers could reduce the amount of food available to higher-trophic-level consumers and could impact the population density of lower trophic levels. | Local Populations | Northern short-tailed shrew, American robin | Does the daily dose of contaminants received from ingestion of soil and food items (i.e., invertebrates) exceed TRVs protective of survival, growth, or reproduction of mammals or birds? | Measure contaminant levels in surface soil. Incidental ingestion of soil and ingestion of site invertebrates. | Modeled dose from ingestion of surface soil and food items (invertebrates) compared with literature-based TRVs. Estimate concentrations in invertebrate tissue using soil-to-invertebrate uptake factors. For refinement: use central tendency concentrations and both NOAEL and LOAEL TRVs if available and site- and receptor-specific exposure parameters (spatial/temporal use factors), evaluate impact of outliers if present, background risk estimates, contaminant bioavailability and magnitude/spatial distribution and TRV exceedance frequencies. |

**Table 3-3: Assessment Endpoints, Representative Species, Risk Questions and Measurement Endpoints Screening Level Ecological Risk Assessment**

| Assessment Endpoint | Community or Population Attribute | Level of Organization | Model Species | Risk Question | Measure/ Exposure Route | Measurement Endpoint/ Analysis Approach |
|---|---|---|---|---|---|---|
| Carnivores - Protection of carnivorous mammal and bird populations from the toxic effects (on survival, growth, or reproduction) of site-related chemicals present in animal tissue and soil. | Carnivorous birds and mammals are important consumers that rely primarily on terrestrial vertebrates for prey. Adverse effects on these top predators would be undesirable because the loss of top predators can lead to disruption of lower trophic levels (density, abundance, diversity). | Local Populations | Red fox | Does the daily dose of contaminants received from ingestion of soil and food items (i.e., small mammals) exceed TRVs protective of survival, growth, or reproduction of mammals or birds? | Measure contaminant levels in surface soil. Incidental ingestion of soil and ingestion of small mammal prey. | Modeled dose from ingestion of surface soil and food items (small mammals) compared with literature-based TRVs. Estimate concentrations in prey tissue using soil-to-mammal uptake factors. For refinement: use central tendency concentrations and both NOAEL and LOAEL TRVs if available and site- and receptor-specific exposure parameters (spatial/temporal use factors), evaluate impact of outliers if present, background risk estimates, contaminant bioavailability and magnitude/spatial distribution and TRV exceedance frequencies. |
| Omnivores - Protection of the omnivorous mammal populations from the toxic effects (on survival, growth, or reproduction) of site-related chemicals present in plants, invertebrate and fish tissue, soil, and sediment. | Omnivorous mammals consume plant and animal tissue from several trophic levels, linking energy pathways between upper trophic level carnivorous receptors (i.e., bobcat, mountain lion) and community-level receptors (fish, invertebrates) and small mammals. Adverse effects on these secondary consumers could reduce the amount of food available to higher-trophic-level consumers and could impact the population density of lower trophic levels. | Local Populations | Raccoon | Does the daily dose of contaminants received from ingestion of soil and food items (i.e., invertebrates, plants, fish) exceed TRVs protective of survival, growth, or reproduction of mammals? | Measure contaminant levels in surface soil. Incidental ingestion of soiland ingestion of sediment and soil invertebrates, aquatic and terrestrial plants, and fish. | Modeled dose from ingestion of surface soil and food items (invertebrates, fish, plants) compared with literature-based TRVs. Estimate concentrations in food items using literature-based uptake factors. For refinement: use central tendency concentrations and both NOAEL and LOAEL TRVs if available and site- and receptor-specific exposure parameters (spatial/temporal use factors), evaluate impact of outliers if present, background risk estimates, contaminant bioavailability and magnitude/spatial distribution and TRV exceedance frequencies. |

**Table 3-3: Assessment Endpoints, Representative Species, Risk Questions and Measurement Endpoints Screening Level Ecological Risk Assessment**

| Assessment Endpoint | Community or Population Attribute | Level of Organization | Model Species | Risk Question | Measure/ Exposure Route | Measurement Endpoint/ Analysis Approach |
|---|---|---|---|---|---|---|
| **AQUATIC RECEPTORS** | | | | | | |
| **Aquatic Community** | | | | | | |
| Protection of aquatic organisms from the toxic effects (on survival, growth, or reproduction) of COPECs in surface water, pore water, and sediment. | Aquatic communities provide a variety of processes in aquatic ecosystems, including oxygen production, substrate stabilization, nutrient cycling, improved water quality, and phytoplankton reduction. | Local Communities | Aggregate Community Components | Are contaminant concentrations in surface water, pore water, or sediment sufficient to cause adverse effects on the survival, growth, or reproduction of aquatic organisms in the water column? | Measure contaminant concentrations in the water column and pore water. Direct exposure COPECs in surface water and porewater. | Compare surface water and pore water contaminant concentrations with water quality standards and applicable screening levels. For refinement: use central tendency concentrations and both NOAEL and LOAEL ESLs if available, evaluate impact of outliers if present, background risk estimates, contaminant bioavailability and magnitude/spatial distribution and ESL exceedance frequencies. |
| **Benthic Macroinvertebrates** | | | | | | |
| Protection of benthic macroinvertebrate communities from the toxic effects (on survival, growth, or reproduction) of COPECs in sediment and pore water. | The benthic macroinvertebrate community plays a key role in ecosystem functions such as nutrient cycling, sediment bioturbation, and organic matter processing, and is a food resource for fisheries, other macroinvertebrates (e.g., crayfish), and riparian animals. | Local Communities | Aggregate Community Components | Are contaminant concentrations in sediment or pore water sufficient to cause adverse effects on the survival and growth, or reproduction of benthic invertebrates? | Contaminant concentrations in sediment and pore water. Direct exposure to sediment and pore water. | Compare sediment and pore water contaminant concentrations to sediment screening levels for effects on benthic macroinvertebrates. For refinement: use central tendency concentrations and both NOAEL and LOAEL ESLs if available, evaluate impact of outliers if present, background risk estimates, contaminant bioavailability and magnitude/spatial distribution and ESL exceedance frequencies. |

**Kev:**
COPEC = constituent of potential ecological concern
ERA = ecological risk assessment
ESL - ecological screening level
LOAEL = lowest observed adverse effect leve
NOAEL = no observed adverse effect level
TRV = toxicity reference value

**Table 4-1: Wildlife Toxicity Reference Values Screening Level Ecological Risk Assessment**

| Analyte | Category | NOAEL[a] | Endpoint | LOAEL[a] | Endpoint | Test Taxa | Notes | Source[b] |
|---|---|---|---|---|---|---|---|---|
| Antimony | Birds | NA | NA | NA | NA | NA | NA | - |
| Antimony | Mammals | 0.059 | Reproduction | 0.59 | Reproduction | rat | Highest bounded NOAEL (0.059 mg/kg-d) for growth or reproduction below the lowest bounded LOAEL (0.59 mg/kg-d) for growth or reproduction from 20 laboratory toxicity studies. | 1 |
| Arsenic | Birds | 2.24 | Reproduction and growth | 3.55 | Growth | chicken | Lowest NOAEL for growth, reproduction, or survival from six laboratory toxicity studies. Lowest LOAEL for growth, reproduction, or survival greater than selected NOAEL. | 2 |
| Arsenic | Mammals | 1.04 | Growth | 1.66 | Growth | dog | Highest bounded NOAEL for growth, reproduction, or survival less than lowest bounded LOAEL for growth, reproduction, or survival from 43 laboratory toxicity studies (with a NOAEL endpoint). The LOAEL is the paired value from the same study. | 2 |
| Barium | Birds | 20.8 | Survival | 41.7 | Survival | chicken | NOAEL and LOAEL from Sample et al. (1996). 4-week diet study using barium hydroxide. | 3 |
| Barium | Mammals | 63.8 | Reproduction, growth, and survival | 121 | Growth | mouse & rat (N) rat (L) | Geometric mean NOAEL for growth, reproduction, and survival from 11 laboratory toxicity studies. Lowest bounded LOAEL for reproduction, growth, or survival greater than geometric mean NOAEL. | 3 |
| Cadmium | Birds | 1.47 | Reproduction and growth | 6.34 | Reproduction and growth | multiple | Geometric mean NOAEL for growth and reproduction from 20 laboratory toxicity studies. LOAEL is the geometric mean for growth and reproduction from 27 laboratory toxicity studies. | 4 |
| Cadmium | Mammals | 0.77 | Growth | 7.7 | Growth | rat | The NOAEL is the highest bounded NOAEL below the lowest bounded LOAEL for reproduction, growth, or survival. LOAEL is the paired value from the same study. | 4 |
| Chromium | Birds | 2.66 | Reproduction and growth | 15.6 | Reproduction and growth | multiple | Geometric mean NOAEL for growth and reproduction from 12 laboratory toxicity studies (with a NOAEL endpoint). LOAEL is the geometric mean for growth and reproduction and growth from 4 laboratory toxicity studies. | 5 |
| Chromium | Mammals | 2.4 | Growth | 9.62 | Reproduction | multiple (N) mouse (L) | Geometric mean NOAEL for growth from 9 studies with trivalent chromium. LOAEL is the lowest value for reproduction above the geometric mean NOAEL value. | 5 |
| Hexavalent Chromium | Birds | 0.402 | Reproduction | 4.02 | Reproduction | chicken | LOAEL based on a 32-week diet study using potassium dichromate. NOAEL is a factor of 10 below the LOAEL. This was also the only avian LOAEL provided in Appendix 5.2 of USEPA (2008a) for hexavalent chromium. | 6 |
| Hexavalent Chromium | Mammals | 9.24 | Reproduction and growth | 37.4 | Reproduction and growth | multiple | Geometric mean NOAEL for growth and reproduction from 21 laboratory toxicity studies. LOAEL is the geometric mean for growth and reproduction from 23 laboratory toxicity studies. | 5 |
| Copper | Birds | 4.05 | Reproduction | 12.1 | Reproduction | chicken | Highest bounded NOAEL for reproduction, growth, or survival lower than the lowest bounded LOAEL for reproduction, growth, or survival (4.68 mg/kg-day). LOAEL is the paired value from the same study. | 7 |
| Copper | Mammals | 5.6 | Reproduction | 9.34 | Reproduction | pig | Highest bounded NOAEL for reproduction, growth, or survival (5.6 mg/kg-day) lower than the lowest bounded LOAEL for reproduction, growth, or survival (6.79 mg/kg-day). LOAEL is the paired value from the same study. | 7 |

**Table 4-1: Wildlife Toxicity Reference Values Screening Level Ecological Risk Assessment**

| Analyte | Category | NOAEL[a] | Endpoint | LOAEL[a] | Endpoint | Test Taxa | Notes | Source[b] |
|---|---|---|---|---|---|---|---|---|
| Lead | Birds | 1.63 | Reproduction | 3.26 | Reproduction | chicken | Highest bounded NOAEL (1.63 mg/kg-d) for growth, reproduction, or survival lower than the lowest bounded LOAEL (1.94 mg/kg-d) for growth, reproduction, or survival. LOAEL is the paired value from the same study. | 8 |
| Lead | Mammals | 4.7 | Growth | 8.9 | Growth | rat | Highest bounded NOAEL (4.7 mg/kg-d) for growth, reproduction, or survival lower than the lowest bounded LOAEL (5 mg/kg-d) for growth, reproduction, or survival. LOAEL is the paired value from the same study. | 8 |
| Manganese | Birds | 179 | Reproduction and Growth | 348 | Growth | multiple (N) chicken (L) | Geometric mean NOAEL for reproduction and growth. Lowest bounded LOAEL for reproduction or growth greater than geometric mean NOAEL. | 9 |
| Manganese | Mammals | 51.5 | Reproduction and Growth | 65 | Growth | multiple (N) cattle (L) | Geometric mean NOAEL for reproduction and growth. Lowest bounded LOAEL for reproduction or growth greater than geometric mean NOAEL. | 9 |
| Mercury | Birds | 0.45 | Reproduction | 0.9 | Reproduction | Japanese quail | One-year diet study using mercuric chloride. Reduced fertility and hatchability. | 10 |
| Mercury | Mammals | 1 | Reproduction | 10 | Reproduction | mink | 6-month diet study using mercuric chloride. Reduced kit weight. LOAEL is estimated as a factor of 10 above the NOAEL. | 10 |
| Selenium | Birds | 0.29 | Survival | 0.579 | Survival | chicken | Highest bounded NOAEL for reproduction, growth, or survival below lowest bounded LOAEL for reproduction, growth, or survival. LOAEL is the paired value from the same study. | 11 |
| Selenium | Mammals | 0.143 | Growth | 0.215 | Growth | pig | Highest bounded NOAEL for reproduction, growth, or survival below lowest bounded LOAEL for reproduction, growth, or survival. LOAEL is the paired value from the same study. | 11 |
| Thallium | Birds | 0.35 | Survival | 3.5 | Survival | starling | Based on an $LD_{50}$ of 35 adjusted using an uncertainty factor of 0.01 for the NOAEL. | 12 |
| Thallium | Mammals | 0.0074 | Reproduction | 0.074 | Reproduction | rat | Based on an 60 day dietary subchronic LOAEL exposure that resulted in reduced sperm motility adjusted using uncertainty factors of 0.01 to estimate a chronic NOAEL. | 12 |
| Vanadium | Birds | 0.344 | Growth | 0.688 | Reproduction | chicken | Highest bounded NOAEL (0.344 mg/kg-d) for growth, reproduction, or survival less than lowest bounded LOAEL (0.413 mg/kg-d) for reproduction, growth, or survival. LOAEL is the paired value from the same study. | 13 |
| Vanadium | Mammals | 4.16 | Reproduction | 8.31 | Reproduction | mouse | Highest bounded NOAEL (4.16 mg/kg-d) for growth or reproduction less than lowest bounded LOAEL (5.11 mg/kg-d) for growth, reproduction, or survival. LOAEL is the paired value from the same study. | 13 |
| Zinc | Birds | 66.1 | Reproduction and growth | 171 | Reproduction and growth | multiple | Geometric mean NOAEL and LOAEL for reproduction and growth. | 14 |

**Table 4-1: Wildlife Toxicity Reference Values Screening Level Ecological Risk Assessment**

| Analyte | Category | NOAEL[a] | Endpoint | LOAEL[a] | Endpoint | Test Taxa | Notes | Source[b] |
|---|---|---|---|---|---|---|---|---|
| Zinc | Mammals | 75.4 | Reproduction and growth | 297 | Reproduction and growth | multiple | Geometric mean NOAEL and LOAEL for reproduction and growth. | 14 |
| Total LMW PAHs | Birds | 8.45 | Growth | 34.6 | Growth | Japanese quail | 14-week study using naphthalene. | 15 |
| Total LMW PAHs | Mammals | 65.6 | Growth | 110 | Growth | rat (N) & mouse (L) | Highest bounded NOAEL (65.5 mg/kg-d) below the lowest bounded LOAEL (110 mg/kg-d) for reproduction, growth, or survival. | 16 |
| Total HMW PAHs | Birds | 2 | Growth | 20 | Growth | European starling | From Appendix 5.2 for 7,12-dimethylbenz(a)anthracene. | 16 |
| Total HMW PAHs | Mammals | 0.615 | Survival | 3.07 | Survival | mouse | Highest bounded NOAEL (0.615 mg/kg-day) below the lowest bounded LOAEL (3.07 mg/kg-day) for reproduction, growth, or survival. LOAEL is the paired value from the same study. | 16 |
| Picric Acid | Birds | 1.5 | Survival | 7.5 | Survival | Japanese quail | Selected ingestion TRVs for DNAN (surrogate) based on female $LD_{50}$ value with 100- and 20-fold uncertainty factors applied for $TRV_{low}$ and $TRV_{high}$, respectively. | 17 |
| Picric Acid | Mammals | 2 | Survival | 10 | Survival | rat | Selected ingestion TRVs based on female $LD_{50}$ value with 100- and 20-fold uncertainty factors applied for NOAEL and LOAEL, respectively. Autopsy suggested that mortality was due to severe blood acidosis. | 18 |

**Key:**
AUF = area use factor
BW = body weight
d = day
dw = dry weight
ED = exposure duration
FI = food ingestion
g/day = grams per day
ha = hectare

**Key (Continued):**
IR = Ingestion rate
kg = kilogram
kg/d = kilograms per day
km = kilometer
L/kg = Liters per kilogram
PF = Problem Formulation
SLERA = Screening Level Ecological Risk Assessment
wt = weight

**Notes:**

a. Body weight average of averages for males and females for eastern race (Otis et al. 2020). Food ingestion rate based on allometric equation for all birds from Nagy 2001: FI (g/day) = 0.638 wt ^ (0.685). Diet comprised primarily of seeds of herbaceous plants or agricultural crops (Otis et al. 2020). Percent soil in diet based on the 90th percentile value from USEPA (2007a), Table 3. Dove home range from Baskett et al. (1993).

b. Body weight from Clench and Leberman (1978) as cited in USEPA (1993b). Food ingestion rate based on allometric equation for all birds from Nagy 2001: FI (g/day) = 0.638 wt ^ (0.685). Diet comprised of 50% fruits and 50% earthworms (conservatively simplified from Wheelwright 1986 for the Eastern US; as cited in from USEPA 1993b). Percent soil in diet based on value for American Woodcock (10.4%) in Beyer et al. (1994) assuming a diet of 50% invertebrates (10.4 x 0.5). Robin home range from Pitts (1984) as cited in USEPA (1993b).

c. Adult body weight from Reich (1981). Food ingestion rate based on allometric equation for herbivorous mammals from Nagy (2001): FI (g/day) = 0.859 wt ^ (0.628). Diet comprised primarily of grasses, sedges, and herbaceous plants (Reich 1981). Percent soil in diet from Beyer et al. (1994). Home range for females from Ostfeld, et al. (1988) as referenced in USEPA (1993b).

d. Body weight mean of adult values for studies in Illinois, Missouri, and Alabama as provided in USEPA (1993b). Food ingestion rate based on allometric equation for omnivorous mammals from Nagy 2001: FI (g/day) = 0.432 wt ^ (0.678). Raccoons assumed to forage in the river and in terrestrial areas so AUF based on combined areas of impacted soils (on and off-site and river). Combined diet simplified from information from Tabatabai and Kennedy (1988) and Tyson (1950) as referenced in USEPA (1993b). Percent sediment or soil in diet from Beyer et al. (1994). Home range based on Michigan riparian area study by Stuewer (1943) as provided in USEPA (1993b).

e. Body weight from Schlesinger and Potter (1974) as cited in USEPA (1993b). Food ingestion rate based on allometric equation for all mammals from Nagy 2001: FI (g/day) = 0.323 wt ^ (0.744). Diet comprised primarily of invertebrates (earthworms, slugs, arthropods, insects) (Whitaker and Ferraro (1963) and Hamilton (1941), as referenced in USEPA (1993b)). Small mammals and vegetation are also consumed but diet assumed to be 100% invertebrates to be conservative. Percent soil in diet based on the 90th percentile value from USEPA (2007a), Table 3. Shrew home range from Platt (1976) as referenced in USEPA (1993b).

f. Adult body weight from average for averages of males and females from Storm et al. 1976 as cited in USEPA (1993b). Food ingestion rate based on allometric equation for carnivorous mammals from Nagy 2001: FI (g/day) = 0.153 wt ^ (0.834). Diet assumed to be 100% small mammals although birds, arthropods and plants can comprise approximately 34% of the total diet on average (Knable 1974 as referenced in USEPA 1993b). Percent soil in diet from Beyer et al. (1994). Average home range for males and females in Minnesota and Wisconsin (USEPA 1993b).

g. No adjustment for AUF and ED for the SLERA (values of 1 assumed). Values the Step 3a refinement will be calculated based on spatial extent of soil samples in the SLERA dataset for each AOC.

## ATTACHMENT C.1
## Surrogate Compound Selection

Ecological screening benchmarks are not available for two of the main contaminants of potential ecological concern (COPECs) at the New York Ordnance Works Formerly Used Defense Site in Baldwinsville, New York: 2,4,6-trinitrophenol (picric acid) and 2,4-dinitrochlorobenene (DNCB). In order to have a project action limit with which to determine whether or not the selected analytical methods have limits of quantification (LOQs) sufficiently low to meet data quality objectives, benchmarks from surrogate compounds were selected. Appropriate surrogates should have similar chemical properties and available toxicity benchmarks. The selection of surrogates for picric acid and DNCB are presented below. Picric acid is an aromatic compound with three electron-withdrawing (nitro) substituents at the para and at both ortho positions relative to the hydroxyl group; as a result, the phenolic proton is quite acidic (acid dissociation constant [pKa] < 1). As a starting point, the minimum requirements for finding an acceptable surrogate for picric acid included finding another phenolic compound with similar substituents in terms of steric hindrance, location on the aromatic ring and electron-withdrawing capacity (see Table A.1-1 in the Phase 1 Quality Assurance Project Plan for candidate structural analogs). Although chlorine and bromine are electron-withdrawing substituents, they are not the best choices as nitro group replacements, as they are single atoms and would not help delocalize the charge of a phenoxide ion in the same manner as the nitro groups. Therefore, a reasonable compromise was a nitro-substituted phenol with substitution in the ortho- and/or para- positions. The compounds 2,4-dinitrophenol (pKa ≈ 4) and 2,5-dinitrophenol (pKa ≈ 5) were the closest matches. The substitution pattern of 2,4-dinitrophenol (ortho-, para-) is more favorable than the substitution pattern of 2,5-dinitrophenol (ortho, meta-) for stabilization of charge, as both of its nitro groups are positioned on the aromatic ring to delocalize charge relative to the hydroxyl group. In addition, 2,4-dinitrophenol has available U.S. Environmental Protection Agency (Region 4 and Region 5) ecological screening benchmarks, whereas 2,5-dinitrophenol does not (see tables in Attachment C.2). As a result of these considerations, 2,4-dinitrophenol was selected as the best surrogate for picric acid. A safety factor of 10 has been applied to the 2,4-dinitrophenol benchmarks to account for potential differences between picric acid and 2,4-dinitrophenol toxicity.

| Medium | 2,4-Dinitrophenol Value[1] | Values used for Picric Acid PAL in Worksheet #15[2] |
|---|---|---|
| Surface water | 71 ug/L | 7.1 ug/L |
| Sediment | 0.22 mg/kg | 0.022 mg/kg |
| Soil | 0.061 mg/kg | 0.0061 mg/kg |

Notes:
[1]USEPA, 2018
[2]2,4-Dinitrophenol values divided by 10
Key: mg/kg = milligrams per kilogram; PAL = project action limit; ug/L = micrograms per liter

DNCB is an aromatic compound with two nitro substituents at the ortho- and para- positions relative to the chlorine substituent. The minimum requirements for finding an acceptable substitute for DNCB included finding another polynitrobenzene with a similar substituent pattern on the aromatic ring (see

Table A.1-2 in the Phase 1 Quality Assurance Project Plan for candidate structural analogs). Although an alternate 2,4-dinitrohalobenzene would be most similar, there are no compounds of that type with available toxicity benchmarks. Therefore, a dinitro-substituted benzene with the nitro groups oriented in the meta position relative to each other was first choice. The compounds 2,4-dinitrotoluene and 1,3-dinitrobenzene are both reasonable choices; both have toxicity benchmarks available from acceptable regulatory guidance sources. The compound 2,4-dinitrotoluene has water solubility and log Kow values closer to those of DNCB than does 1,3-dinitrobenzene. In addition, 2,4-dinitrotoluene has a methyl group at the same position on the aromatic ring as the chloride in DNCB, giving a similar steric hindrance to the adjacent nitro group, though the methyl group is a neutral substituent with regards to stabilizing ionization in an aromatic ring system. As a result of these considerations, 2,4-dinitrotoluene was selected as the best surrogate for DNCB. No safety factor was applied to the surrogate benchmarks to account for the difference between DNCB and 2,4-dinitrotoluene structures due to the difference in the structures being the methyl substituent.

| Medium | 2,4-Dinitrotoluene Value[1] | Values used for DNCB PAL in Worksheet #15 |
|---|---|---|
| Surface water | 44 ug/L | 44 ug/L |
| Sediment | 0.29 mg/kg | 0.29 mg/kg |
| Soil | 6 mg/kg | 6 mg/kg |

Notes:
[1]USEPA, 2018
Key: mg/kg = milligrams per kilogram; PAL = project action limit; ug/L = micrograms per liter

The above ESLs are considered to be adequately conservative for the initial ecological screening for these energetic compounds. If either picric acid or dinitrochlorobenzene is carried forward to Step 3, these values will be reassessed following review of available literature (e.g., Lotufo et al., 2013; USAPHC, 2019, 2020a, 2020b; USBRDL, 1975).

**Notes:**

Highlighting = Value selected for ecological PAL.

Aluminum is identified as a COPC only for those soils with a pH less than 5.5. The technical basis for this procedure is that the soluble and toxic forms of aluminum are only present in soil under soil pH values of less than 5.5. Site -specific considerations could, however warrant inclusion of aluminum as a COPC.

Chromium by method SW6020 is total chromium. The Eco-SSL is for trivalent chromium because the value is more conservative than that for hexavalent chromium. The Region 4, Region 5, and Iron narrative statement (EPA Eco SSL, 2003): The main concern from an ecological risk perspective for iron is not direct chemical toxicity per se, but the effect of iron as a mediator in the geochemistry of other (potentially toxic) metals and the potential physical hazard of depositing flocculent. Soil pH and Eh should be included as standard soil chemical field parameters when conducting any field investigation. Although some EPA analytical methods require the collection of soil pH prior to analysis, this information is not always made available to the ultimate data users. In addition, the pH measured in the lab may no longer be representative of field conditions since the samples can be exposed to oxygen during storage prior to analysis. A determination of the geochemical conditions (i.e., pH and Eh at a minimum) of the environmental setting, as well as the presence of iron floc and the toxic metals, is critical to the determination of the relative importance of iron at a site.

EPA Eco SSL - Environmental Protection Agency Ecological Soil Screening Values.
HMW PAHs = High molecular weight polycyclic aromatic hydrocarbons.
LANL = Los Alamos National Laboratory.
LMW PAHs = Low molecular weight polycyclic aromatic hydrocarbons.
mg/kg = Milligrams per kilogram.
NA = Not available.
PAL = Project Action Limit.
RCRA = Resource Conservation and Recovery Act.

**Notes:**

Highlighting = Value selected for ecological PAL.

1. Selected value is the lowest of the individual isomers (i.e., p-cresol).

HMW PAHs = High molecular weight polycyclic aromatic hydrocarbons.
LANL = Los Alamos National Laboratory.
LMW PAHs = Low molecular weight polycyclic aromatic hydrocarbons.
mg/kg = Milligrams per kilogram.
NA = Not available.
PAL = Project Action Limit.
RCRA = Resource Conservation and Recovery Act.

# Appendix D Field Standard Operating Procedures and Field Forms

This page intentionally left blank.

# FIELD STANDARD OPERATING PROCEDURE #1

# NOTE TAKING AND FIELD BOOK ENTRIES PROCEDURE

The field book is a record of the day's activities that serves as a reference for future reporting and analyses. The field book is also a legal record for projects that may be used during legal proceedings. It is of the utmost importance that all notes are complete and comprehensive. The user is advised to read the entire standard operating procedure (SOP) and review the project site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities.

## 1.1 ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| HASP | Health and safety plan |
| IDW | Investigation-derived waste |
| PSP | Project safety plan |
| SOP | Standard operating procedure |

## 1.2 MATERIALS

- Permanently-bound waterproof field book (e.g., Rite-in-the-Rain® #550, or equivalent)
- Black or blue ballpoint pen (waterproof ink recommended; do not use felt-tip pens)

## 1.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company's SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field standard operating procedures, and the Quality Management System.

The purpose of the field book is to provide a written log of all of field events and conditions. The notes must include sufficient detail (i.e., who, what, when, where, why, and how) to enable others to reconstruct the day's activities for analysis, reporting, or litigation. It is important to be objective, factual, and thorough. Language must be free of personal comments or terminology that might prove inappropriate. Additional data logs or worksheets, such as low flow groundwater sampling sheets, may be used as a supplement; however, under no circumstances should the data sheets be used as a substitute for the daily record of events to be recorded in the field book.

The field book forms the foundation upon which most of the project work (reports, subsequent work plans, etc.) is based. It is critical that the field book's chain of custody be maintained at all times.

## 1.4 SET-UP PROCEDURES

The first step in setting up a new field book is to add the information necessary for you to identify the field book in the future and for others to return the book to the company, should it be lost. On the first page of the field book (or, for some field books, the inside cover), place a "Return for Reward" notice. Include the following information:

- An "If Found – Return for Reward" notice in bold letters
- Our company name
- Our company address (usually the office where the project is being managed)
- Our company phone number

Reserve the second page of the field book for project-specific information, such as:

- The project name and number
- The project manager's name
- The site telephone number, address, and onsite contact (if appropriate)
- The names and telephone numbers for all key (onsite) personnel
- The emergency telephone numbers including the police, fire, and ambulance (found in the HASP)

Business cards from individuals who visit the site, (including the person in charge of the field book) can be affixed to the inside back cover.

## 1.5 FIELD BOOK ENTRIES

Start each day on a new page. Include the following information in the header of the first page (and all subsequent pages):

- The date
- The project name
- The page number (if not pre-printed in the field book)

Precede field book entries by the time entered along the left margin of the page using a 24-hour or military clock (e.g., 1330 for 1:30 PM). The first entry of the day must include your and your subcontractor's arrival time at the site, a description of the planned activities, key onsite personnel (including subcontractors), and the weather forecast. The first entry must also detail the tailgate review of the site-specific HASP or PSP with the onsite personnel. Be sure that field book entries are LEGIBLE and contain factual, accurate, and inclusive documentation of project field activities. Blank lines between field book entries should not be included unless necessary to accommodate a large entry (e.g., table or sketch); if blank lines are necessary, draw a line diagonally through any blank lines and initial at the end of the diagonal line. If a mistake is made in an entry, cross out the mistake with a single line and place your initials at the end of the line. Any acronyms written in the field book (including your initials) must be spelled out prior to the first use.

Subsequent log entries must document the day's activities in sequence and must be completed throughout the day as events occur (i.e., do not wait until the end of the work day to complete the notes); should notes need to be entered out of sequence, please identify the non-sequential entries using a footnote or by clearly indicating "Late Entry." Notes must be descriptive and provide location information or diagrams (if appropriate) of the work area or sample locations. Note any changes in the weather and document all deviations from the work plan. Arrival and departure times of all personnel, operational periods of standby, decontamination, and specific activities must be recorded.

Include the following information in entries describing field activities:

- The equipment, materials and methods used by subcontractors, if appropriate (e.g., drill rig type, boring diameters, well casing materials, etc.)
- The equipment, materials and methods used to obtain samples (e.g., split-spoon sampler, polyethylene bailer, pump types, geochemical, water or air monitoring equipment, low-flow purging procedures, etc.)
- The sample identification, which should include the location and depth, as appropriate
- The sample location, including a description of the approximate location as measured from a known point (e.g., 50 feet north of the building entrance; for points not yet surveyed)

- Any air or water monitoring equipment used, associated calibration activities, and measurements
- The sample collection time
- The sample identification of associated quality assurance/quality control samples (e.g., blind duplicate)
- The sample media and analyses to be performed; sizes, numbers, and types of containers; preservation (if any), and any resulting reactions (e.g., effervescence)
- If supplemental data recording logs (digital or hard copy) are used, such as groundwater sampling logs, chains-of-custody, and shipping records, the above information must be entered in the field book and the supplemental records cross-referenced
- The decontamination and disposal procedures for all equipment, samples, and personal protective equipment
- An inventory of the investigation-derived waste (IDW) materials generated during the site activities
- A description of the IDW labeling procedures and the onsite staging information; other sampling-specific information to be included in the IDW log is provided in SOP 5

Maintain a sequential log if the sample locations and areas of interest are photographed (strongly recommended). The photographic log must include:

- The date and time of the photograph
- The sequential number of the photograph (e.g., photograph-1, photograph-2, etc.)
- The general direction faced when the photograph was made
- A description of the subject in the image

## 1.6 CLOSING NOTES

The last entry of the day must include a brief wrap up of the work accomplished, a description of how the site is being secured, and a description of any near hits, accidents, and incidents that occurred during the day's work. Draw a line through the remainder of the page from the row of text diagonally through any blank lines and initial at the end of the diagonal line.

# FIELD STANDARD OPERATING PROCEDURE #3

# SAMPLE PACKAGING AND SHIPMENT PROCEDURE

Shipping samples is a basic but important component of field work. The majority of field activities include the collection of environmental samples. Proper packing and preservation of those samples is critical to ensuring the integrity of our work product. The user is advised to read the entire standard operating procedure (SOP) and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP or PSP, proper personal protective equipment (PPE) must be selected and used appropriately.

## 3.1 ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| CFR | Code of Federal Regulations |
| DOT | U.S. Department of Transportation |
| IATA | International Air Transport Association |
| HASP | Health and safety plan |
| PPE | Personal protective equipment |
| PSP | Project safety plan |
| SOP | Standard operating procedure |

## 3.2 MATERIALS

- Suitable shipping container (e.g., plastic cooler)
- Chain-of-custody forms
- Custody seals
- Sample container custody seals (as necessary)
- Mailing address labels (as necessary)
- Shipping form (with account number, as necessary)
- Tape (e.g., strapping, clear packing)
- Permanent marker
- PPE
- Bubble wrap or other packing material

Temperature-preserved samples:

- Large plastic garbage bag
- Wet ice
- Heavy-duty zipper-style plastic bags
- Universal sorbent materials

Note: Some materials will be supplied by the laboratory, while others are must be supplied by the sampler. Confirm supplier of materials prior to mobilizing to the field.

## 3.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel

and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field standard operating procedures, and the Quality Management System.

This SOP is designed to provide the user with a general outline for shipping samples and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), sample collection and quality assurance procedures (SOP 4), and investigation derived waste management procedures (SOP 5).

Most environmental samples are classified non-hazardous materials due to unknown characteristics and hazardous classes, however environmental samples can meet the definition of U.S. Department of Transportation (DOT) hazardous materials when shipped by air, ground, or rail from a project site to the laboratory (e.g., free product, samples preserved with a hazardous material [TerraCore® samplers]). As such, field staff must work with their assigned company compliance professional to determine whether the sample shipment is subject to any specific requirements (e.g., packaging, marking, labeling, and documentation) under the DOT hazardous materials regulations.

## 3.4 SAMPLE SHIPMENT PROCEDURES

The two major concerns in shipping samples are incidental breakage during shipment and complying with applicable DOT and courier requirements for hazardous materials shipments.

> **NOTE: Many couriers, including Federal Express and United Parcel Service, have requirements that the company register with them before shipping hazard materials. In most cases, it is the sampling location, not the company office address, which needs to be registered. Therefore, each project will likely have unique requirements. Please contact your company compliance professional to determine whether or not you will be required to register for your shipment.**

Protecting the samples from incidental breakage can be achieved using "common sense." Pack all samples in a manner that will prevent them from moving freely about in the cooler or shipping container. Do not allow glass surfaces to contact each other. When possible, repack the sample containers in the same materials that they were originally received in from the laboratory. Cushion each sample container with plastic bubble wrap, styrofoam, or other nonreactive cushioning material. A more detailed procedure for packing environmental samples is presented below.

### 3.4.1 NON-HAZARDOUS MATERIAL ENVIRONMENTAL SAMPLES

The first step in preparing your samples for shipment is securing an appropriate shipping container. In most cases, the analytical laboratory will supply the appropriate container for bottle shipment, which can be used to return samples once they have been collected. Be sure that the container is large enough to contain the samples plus a sufficient amount of packing materials, and if applicable, enough wet ice to maintain the samples at the preservation temperature (usually 4 degrees Celsius). Use additional shipping containers as needed so that sample containers are protected from breakage due to overcrowding. Do not use lunch-box sized coolers or soft sided coolers, which do not offer sufficient insulation or protection from damage.

### 3.4.1.1 TEMPERATURE-PRESERVED SAMPLE CONTAINER PREPARATION

Temperature-preserved samples should be shipped to the laboratory in an insulated container (e.g., cooler). If using a plastic cooler with a drain, securely tape the inside of the drain plug with duct tape or other material to ensure that no water leaks from the cooler during shipment. Place universal sorbent materials (e.g., sorbent pads) in the bottom of the insulated container. The amount of sorbent material must be sufficient to absorb any condensation from the wet ice and a reasonable volume of water from melted wet ice (if a bag were to rupture) or a damaged (aqueous) sample container.

The next step is to line the insulated container with a large, heavy-duty plastic garbage bag. If shipping breakable sample containers (e.g., glass), place bubble wrap or other packing materials on the bottom of the container. Place the samples, including a temperature blank, on the packing materials with sufficient space to allow for the addition of more bubble wrap or other packing material between the sample containers. Place large or heavy sample containers on the bottom of the cooler with lighter samples placed on top to minimize the potential for breakage. Place all sample containers in the shipping container right-side up. Do not overfill the cooler with samples; room must be left for a sufficient volume of wet ice. Wet ice must be double-bagged in heavy-duty zipper-style plastic bags (1 gallon-sized, or less); properly seal both bags before placing in the insulated container. Place the bags of ice on top of or between the samples. Place as much ice as possible into the cooler to ensure the samples arrive at the lab at the required preservation temperature, even if the shipment is delayed. Fill any remaining space in the container with bubble wrap or other packing material to limit the airspace and minimize the shifting of the sample containers and in-transit melting of ice. Securely close the top of the heavy-duty plastic bag and knot or seal with tape.

### 3.4.1.2 NON-TEMPERATURE-PRESERVED SAMPLE CONTAINER PREPARATION

Non-temperature-preserved samples should be shipped to the laboratory in a durable package (e.g., hard plastic container or cardboard box). If shipping breakable sample containers (e.g., glass), place bubble wrap or other packing materials on the bottom of the container. Place the samples on the packing materials with sufficient space to allow for the addition of more bubble wrap or other packing material between and on top of the sample containers. Place large or heavy sample containers on the bottom of the container with lighter samples placed on top to minimize the potential for breakage. Place all sample containers within the shipping container right-side up. Fill any remaining space in the container with bubble wrap or other packing material to limit the airspace and minimize the shifting of the sample containers and in-transit melting of ice.

### 3.4.1.3 CONTAINER SHIPMENT

Samples in the container should be cross-checked against the chain-of-custory before signing off on the form and sealing the cooler. Place the original chain-of-custody form (i.e., laboratory copy) into a heavy-duty zipper-style plastic bag, affix/tape the bag to the shipping container's inside lid, and then close the shipping container; as required, include return shipping labels for the laboratory to return company-owned coolers. Only one chain-of-custody form is required to accompany one of the shipping containers per sample shipment; the other coolers in the shipment do not need to include chain-of-custody forms, unless required by the project. At this point, sample shipment preparations are complete if using a laboratory courier.

Once the shipping container is sealed, shake test the shipping container to make sure that there are no loose sample containers. If loose sample containers are detected, open the shipping container, repack the contents, and reseal the shipping container. If sending the sample shipment through a commercial shipping vendor, place two signed and dated chain-of-custody seals on alternate sides of the shipping container lid so that it cannot be opened without breaking the seals. Securely fasten the top of the shipping container shut with clear packing tape; carefully tape over the custody seals to prevent damage during shipping.

Affix a mailing label with the ship to and return to addresses to the top of the shipping container using clear shipping tape. Use the pre-printed return mailing label from the laboratory, if provided, or complete a new mailing label from the shipping carrier. Ship environmental samples to the contracted analytical laboratory using an appropriate delivery schedule. **Note: Samples can be shipped for Saturday delivery once the lab has been verified to be open and receiving samples on the weekend.**

Verify whether the shipment cost should be billed to the sender or recipient, and ensure the internal billing reference section on the mailing label includes either the laboratory's billing reference number, if the shipment is billed to the laboratory, or the project billable number, if the shipment is billed to WSP.

Declare the value of samples on the shipping form for insurance purposes, if applicable. When shipping samples to a lab, identify a declared value equal to the carrier's default value ($100); additional fees will be charged based on a higher value declared. Our preferred carrier, Federal Express, will only reimburse for the actual value of the cooler and its contents if a sample shipment is lost; they will not reimburse for the cost of having to re-collect the samples. [Please note: if you are shipping something other than samples, such as field equipment, declare the replacement value of the contents.]

Record the tracking numbers from the shipping company forms (i.e., the airbill number) in the field book and retain a copy of the shipping airbill. On the expected delivery date, confirm sample receipt by contacting the laboratory or tracking the package using the tracking number; provide this confirmation information to the project manager.

> **NOTE: Most shipping carriers adhere to transit schedules with final pickup times each day; these schedules are subject to change and vary by service location. If shipping containers are dropped off at a service location after the final pickup time, transit to the laboratory will not be initiated until the following day, and samples may not be properly preserved. Therefore, confirm transit schedules in advance of each sampling event, and ensure samples are delivered to the carrier before the final pickup time of the day.**

### 3.4.2 HAZARDOUS MATERIALS SAMPLES

Employees rarely ship hazardous materials due to DOT shipping requirements. If you find that your samples could be considered a DOT hazardous material, first coordinate with the assigned company compliance professional and project manager to make a hazardous material classification and, if necessary, establish the necessary protocols and to receive the appropriate training/certification.

> **NOTE: Employees shipping samples regulated as hazardous materials or exempt hazardous materials by air must have International Air Transport Association (IATA) training. IATA training is a separate training required in addition to DOT hazardous materials training for such shipments. Most of our employees do not have IATA training and therefore, anyone who needs to ship by air MUST consult with a company IATA-trained compliance professional.**

# FIELD STANDARD OPERATING PROCEDURE #5

# INVESTIGATION DERIVED WASTE MANAGEMENT PROCEDURE

The purpose of this standard operating procedure (SOP) is to provide instructions for handling, storing, and managing investigation derived waste (IDW) pending disposal. All IDW, which includes (but is not limited to) soil cuttings, development water, purge water, drilling fluids, decontamination fluids, personal protective equipment (PPE), and sampling equipment, must be managed in compliance with applicable or relevant and appropriate requirements. The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP or PSP, proper PPE must be selected and used appropriately.

## 5.1 ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| DOT | U.S. Department of Transportation |
| EPA | U.S. Environmental Protection Agency |
| HASP | health and safety plan |
| IDW | investigation derived waste |
| PCB | polychlorinated biphenyl |
| PPE | personal protective equipment |
| PSP | project safety plan |
| RCRA | Resource Conservation and Recovery Act |
| SOP | standard operating procedure |
| TSCA | Toxic Substances Control Act |

## 5.2 MATERIALS

- Pre-printed weatherproof waste labels (e.g., non-hazardous waste, hazardous waste, polychlorinated biphenyls [PCBs], etc.)
- IDW log (Figure 1)
- Permanent ink marking pen, paint, stick/pen
- Sampling equipment (refer to sampling SOPs)
- Impermeable covers (tarps), as needed
- Duct tape, rope, or other material to secure tarp
- Copy of the waste manifest or bill of lading

## 5.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version

of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field standard operating procedures, and the Quality Management System.

This SOP is designed to provide the user with a general outline for handling, storing, and managing IDW pending disposal and assumes the user has received current U.S. Department of Transportation (DOT) training, Hazardous Waste Operations and Emergency Response training, and Resource Conservation and Recovery Act (RCRA) training (if required) and is familiar with basic field procedures, such as recording field notes (SOP 1), sample shipment procedures (SOP 3), sample collection and quality assurance procedures (SOP 4), and equipment decontamination (SOP 6). The SOP does not cover investigation planning; DOT, RCRA, and Toxic Substances Control Act (TSCA) regulations; nor does it cover the evaluation of the analytical results. **Consult and involve the company's compliance professionals during all phases of IDW management and disposal.**

***It is important to note that information contained in this SOP is based on federal regulations and interpretive guidance provided by the U.S. Environmental Protection Agency (EPA) and other federal regulatory sources; therefore, information provided in this SOP may be superseded by state or local-specific statutes or regulations. Field personnel must plan for and discuss the handling procedures with the project manager and assigned company compliance professional before mobilizing to the field.***

## 5.4 IDW GENERAL PROCEDURES

Nearly all intrusive field activities will generate solid or liquid wastes. Examples include:

**Solid Waste**

- Soil cuttings
- Drilling mud
- Plastic sheeting
- Spent carbon or filters
- PPE (e.g., Tyvek coveralls, gloves, respirator cartridges)
- Disposable or dedicated sampling equipment (e.g., bailers, hoses, clamps, buckets, cartridge filters)
- Field analytical waste (e.g., HACH kits, Chlor-n-Soil kits, Gastech tubes)
- Compressed gas cylinders (e.g., isopropylene, helium)
-
- Disposable cleaning materials (e.g., wipes or rags)

**Liquid Waste**

- Decontamination water
- Development water
- Drilling fluids
- Purge water
- Soap or wash solutions
- Reagents (e.g., hexane, nitric acid, methanol)

The specific procedures for dealing with these materials after the field activities have been completed will vary depending on whether the materials are considered to be non-hazardous, RCRA hazardous (characteristic or listed wastes), TSCA-regulated PCB waste, and/or DOT hazardous materials. The characterization of the wastes to be generated should be determined in conjunction with a company compliance professional before the field event occurs, based on previously generated data; however, in some cases, particularly for new sites, the status of the wastes may not be known. In these cases, handle IDW as hazardous waste until the status can be verified. Field personnel must consult their assigned company compliance professionals for assistance in proper waste characterization and to determine waste management requirements applicable to the site.

### 5.4.1 WASTE MINIMIZATION

As possible, select investigation methods and techniques that will minimize the amount of wastes generated during field activities, particularly if the IDW is hazardous. Examples include using direct-push methods instead of hollow stem augers (to minimize soil cuttings) during a soil investigation, if appropriate, eliminating the use of solvents or solvent-based cleaners for decontamination, if

possible, and limiting contact with the materials to reduce the amount of PPE required. Minimizing the amount of waste generated will reduce handling requirements and overall project costs, and is consistent with the company's corporate goals for sustainability.

## 5.5 ONSITE IDW MANAGEMENT PROCEDURES

Onsite handling procedures typically involve containerization of the IDW for offsite disposal at a regulated facility or, in the case of certain non-hazardous wastes, onsite disposal. Should more than one waste stream be present onsite, segregate the IDW containers by waste stream to facilitate the future waste disposal. The procedures for each type of waste are presented below.

### 5.5.1 NON-HAZARDOUS WASTE MANAGEMENT

If the IDW is classified as non-hazardous waste, the following procedures must be implemented only if approved by the applicable regulatory agency and after being discussed and approved by the project manager, project compliance professional, client, and facility personnel:

- Soil can be either:
  - spread around the borehole or other onsite location
  - placed back in the boring or excavated test pit
  - containerized and disposed of offsite
- Groundwater and decontamination fluids can be either:
  - poured onto the ground next to the well to allow infiltration
  - discharged to either the publically-owned treatment works or storm sewer
  - discharged to the onsite wastewater treatment plant
  - containerized and disposed of offsite
- After rendering the IDW unusable (e.g., cutting or tearing material), PPE, plastic sheeting, disposable cleaning materials, and spent bag filters can be double bagged and disposed of as general trash or containerized and disposed of offsite.
- Compressed gas cylinders should be depressurized and disposed of as general trash, recycled as scrap metal, or containerized and disposed of offsite.
- Field analytical waste (e.g., HACH® kits, Chlor-n-Soil® kits) can be disposed of in accordance with the manufacturer's instructions provided the disposal method is approved by the company's project manager and compliance professional.
- Minimize the volume of reagents as much as possible. Consult a company compliance professional to determine the proper disposal of any quantity of unused reagents. Empty reagent containers may be disposed of as general trash after removing all chemical name and warning labels, or may be containerized and disposed of offsite.
- Spent water treatment media (e.g., carbon, resin) should be containerized and disposed of offsite.
- Exploration and production exempt waste derived from material that was downhole at an oil and gas production site.

If the IDW is containerized and is classified as non-hazardous, the following procedures will apply:

- Place the non-hazardous IDW in DOT-compliant containers (e.g., 55-gallon drum, roll-off container, or temporary storage tank). Before placing IDW in the containers, ensure that the containers are in good condition and will not leak.
- Drums used as containers must remain closed except when adding, sampling, or inspecting the waste. The drums cannot be used as a work surface once waste is put in the container.
- Mark the container with the appropriate waterproof, self-adhesive non-hazardous waste label. The label must include a description of the contents of the container (e.g., soil cuttings, purge water) and the generator name (the client or the facility, never the company). **Field personnel must consult the project compliance professional for help in properly completing the labels.**
- Complete the IDW Log (Figure 1) before leaving the site. Present one copy of the log to the site contact and the original to the project manager.
- The IDW containers must be properly closed, wiped clean, and stored in a secure onsite location.

### 5.5.2 HAZARDOUS WASTE MANAGEMENT

If site data or generator knowledge indicates that the IDW is RCRA hazardous, the following procedures will apply:

- Place IDW in DOT-compliant containers (e.g., 55-gallon drum, roll-off container, or temporary storage tank). Before placing IDW in the containers, ensure that the containers are appropriate for the type of IDW generated (e.g., solid in containers authorized for transport of solids), in good condition and will not leak.

- Containers must remain closed except when adding, sampling, or inspecting the material. The containers cannot be used as a work surface once waste is put in the container.
- Mark the container with an appropriate waterproof, self-adhesive hazardous or radiological waste label. The label must include the accumulation start date, a description of the contents of the container (e.g., soil cuttings, purge water), the EPA identification number, the generator name (the client or the facility, never the company), and the hazardous waste codes, if known. **Field personnel must consult the project compliance professional for help in properly completing the labels.**
- The IDW containers must be properly closed, wiped clean, and stored in a secure onsite location (i.e., a designated facility hazardous waste storage area) to limit access. At a minimum, place the drums on an impermeable surface (if available) in an area of limited access. If stored outside, cover the containers with a secured tarp at the end of each field day until the containers are picked up for disposal.
- Complete the IDW Log (Figure 1) before leaving the site. Present one copy of the log to the site contact and the original to the project manager.
- If applicable, ensure that weekly inspections are conducted, and the proper inspection forms for documentation are completed during the entire time the waste is stored onsite. **Field personnel must consult the project compliance professional for help to determine if weekly inspections are required.**

If the IDW is presumed to be hazardous and sampling is required to confirm its classification, it must be labeled "Hazardous Waste-Pending Analysis" and sampled for the parameters specified by the project compliance professional or project manager before leaving the site. Any waste confirmation samples must be collected in accordance with the company's SOPs. Treatment, storage, and disposal facilities will usually specify the required analysis for waste profiles.

### 5.5.3 PCB WASTE MANAGEMENT

If information exists to classify PCB-containing IDW as TSCA-regulated IDW (i.e., PCBs greater than 50 milligrams per kilogram), the following procedures must be implemented:

- Place the PCB-containing IDW in DOT-compliant containers (e.g., 55-gallon drum, roll-off container, or temporary storage tank). Before placing IDW in the containers, ensure that the containers are in good condition and will not leak.
- Containers must remain closed except when adding, sampling, or inspecting the material. The containers cannot be used as a work surface once waste is put in the container.
- Mark the container with an appropriate waterproof, self-adhesive yellow label with the words "Caution Contains PCBs", the "removed from service" date (the accumulation start date), and a description of the contents of the container (e.g., soil cuttings). Complete the label with the name and phone number of the company personnel to contact in the event of an accident or spill. **Field personnel must consult the project compliance professional for help in properly completing the labels.**
- The IDW containers must be properly closed, wiped clean, and stored in a secure PCB storage area onsite. If a PCB storage area is not available, construct a temporary PCB storage area. Cover the containers with a secured tarp at the end of each field day until the drums are picked up for disposal. Place one yellow 6" x 6" "Caution Contains PCBs" label on the outside of the tarp, and note the "Removed from service date" on the label.
- Complete the IDW Log (Figure 1) before leaving the site. Present one copy of the log to the site contact and the original to the project manager.
- If applicable, inspect the area and the containers for leaks once every 30 days in accordance with TSCA requirements during the entire period the waste is stored onsite. **Field personnel must consult the project compliance professional for help to determine if weekly inspections are also required.**

## 5.6 POST-FIELD IDW MANAGEMENT ACTIVITIES

Field personnel must follow up on the management of the IDW after returning from the field. RCRA hazardous and TSCA-regulated PCB-containing wastes have storage time limits and periodic inspection requirements to remain in compliance with federal, state, or local regulations. Arrangements for proper disposal of wastes must be made within the required time limits and must be consistent with all applicable regulatory requirements, as well as the company's contracting procedures and policies for waste disposal. Copies of waste disposal documentation (e.g., bill of lading, waste manifest, land disposal restriction form, etc.) should be provided to the project manager and saved with the project files.

# FIELD STANDARD OPERATING PROCEDURE #6

# DECONTAMINATION PROCEDURE

The decontamination procedures outlined in this standard operating procedure (SOP) are designed to ensure that all sampling equipment is free from the analytes that could potentially interfere with sample results. The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP or PSP, proper personal protective equipment (PPE) must be selected and used appropriately.

## 6.1 ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| DI | deionized water |
| DOT | U.S. Department of Transportation |
| EPA | U.S. Environmental Protection Agency |
| HASP | health and safety plan |
| PPE | personal protective equipment |
| PSP | project safety plan |
| QAPP | quality assurance project plan |
| SOP | standard operating procedure |

## 6.2 MATERIALS

- Field book
- PPE
- Polyethylene sheeting and/or garbage bags
- Laboratory-grade non-phosphate detergent[1] (e.g., Luminox® or Liquinox®)
- Cleaning reagents, as needed (e.g., isopropyl alcohol, methanol, hexane, nitric acid)
- Potable water
- Deionized (DI) water
- Containers (e.g., plastic buckets)
- Bristle brushes
- Aluminum foil
- Spray bottles
- Paper towels
- Pressurized steam cleaner (e.g., steam jenny), as needed
- Waste collection containers (e.g., drums), as needed
- Decontamination pad, as needed

## 6.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel

[1] Not all laboratory-grade detergents are phosphate free. Be sure to verify the detergent's phosphate content before use.

and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company's SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field SOPs, and the Quality Management System.

This SOP is designed to provide the user with a general outline for decontamination and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), sample shipment procedures (SOP 3), sample collection and quality assurance procedures (SOP 4), and investigation-derived waste management procedures (SOP 5). All decontamination references must be available for consultation in the field, including:

- Company's SOPs
- Applicable state and federal guidelines or procedures
- Manufacturer's manuals
- Project-specific work plan, PSP and/or HASP, and QAPP

## 6.4 GENERAL PROCEDURES

The cleaning and decontamination procedures described below are designed to ensure that the equipment used for sample collection is free of analytes that could potentially alter the analytical results. These procedures are primarily targeted at preventing the incidence of cross-contamination (i.e., compounds of interest being transferred on the sampling equipment from one sample to another) in order to produce high quality, representative sample results. As with all analytical sampling, the effectiveness of the cleaning procedures must be demonstrated with the collection of equipment blanks; equipment blank sample collection procedures and frequency are discussed in SOP 4.

### 6.4.1 EQUIPMENT AND REAGENT SELECTION

It is important for employees to evaluate the expected types of contamination before mobilization to a site. State programs (or the U.S. Environmental Protection Agency [EPA], depending on the site) may require more stringent decontamination procedures than those listed in this SOP, specify the types and grades of various cleaning detergents and reagents (e.g., acids and solvents), or allow the use of phosphate-containing detergents, such as Liquinox® liquid detergent (preferred[2]) or the powdered Alconox®. Decontamination equipment (e.g., spray bottles, brushes, etc.) should be constructed of non-reactive, non-leachable materials (e.g., metal, glass, Teflon®-coated, polyethylene, etc.) which are compatible with the reagents and solvents being used for decontamination.

Many of the cleaning reagents (e.g., nitric acid, hexane, methanol) are U.S. Department of Transportation (DOT) hazardous materials and must be shipped using a ground delivery service. The Safety Data Sheets (SDSs) for any hazardous cleaning reagents to be used onsite must be reviewed before the commencement of work, and the potential hazards and protective measures to be employed must be addressed in the HASP. Do not use decontamination liquids that have been improperly stored (e.g., unsealed containers).

In specific cases, it may be necessary to steam clean the field equipment before proceeding with the decontamination steps presented in Section 6.5 (e.g., hollow stem augers). Generally, the company's subcontractors are responsible for bringing or building a decontamination pad, if necessary, to contain the spray from a steam jenny. As possible, decontamination pads should be constructed on a level, paved surface in an area known or believed to be free of surface contamination, and should be of sufficient size to contain the decontamination water. Equipment that is steam cleaned should be placed on racks or saw horses and not on the floor of the

[2] Liquinox® liquid detergent, manufactured by Alconox, Inc., is phosphate-free and does not contribute to nutrient loading or algae blooms in the environment.

decontamination pad. Decontamination water should be removed from the decontamination pad frequently to minimize the potential for leaks or overflow.

***Consult and involve the company's compliance professionals for storage procedures and disposal requirements of cleaning reagents, detergents, wastes, and other decontamination-related materials.***

### 6.4.2 OTHER CONSIDERATIONS

In preparing for decontamination, you should perform the following activities (with all observations and measurements noted in the field book):

- Perform a quick reconnaissance of the site to identify a decontamination (pad) area and evaluate the accessibility to and safety of the location.
- If working in a hazardous waste exclusion area, the decontamination area should be located in the contaminant reduction zone.
- Record a description of the decontamination (pad) area.

Survey the breathing zone around the decontamination area with the appropriate air quality meter(s), as necessary (see HASP), to ensure that the level of PPE is appropriate. When decontaminating equipment, it is important to find a suitable location away from any sources of cross-contamination that could compromise the integrity of the decontamination. As possible, position the decontamination area away from fuel-powered equipment, such as drill rigs or excavators, and upwind of other site activities (e.g., purging, sampling).

## 6.5 DECONTAMINATION PROCEDURES

The decontamination procedures described below are a four- to nine-step process, depending on the the applicable federal or state guidelines, the project-specific work plan, or the QAPP. Sampling activities must be initiated with clean, decontaminated equipment. Decontaminate all non-dedicated equipment that contacts the sample directly (e.g., spoons, trowels, pumps), before and between each sample location and sampling interval. record decontamination procedures in the field book. Disposable, single use items, such as bailers or tubing, do not require decontamination.

The decontamination process includes the following four basic steps:

1. Physical removal of soil or debris
2. Wash with non-phosphate detergent, such as Liquinox®, and nylon brush
3. Potable water rinse
4. Laboratory-supplied deionized (DI), analyte-free water rinse (distilled water can be used as a substitute, if necessary)

The first step is to remove as much soil or other debris from the sampling device as possible near the sampling area to limit the spread of potentially-contaminated materials into clean areas of the site. Containerize all soil or debris in DOT-compliant containers in accordance with SOP 5 or the project-specific work plan. Dispose of all wastes in conformance with the project-specific work plan and applicable regulations.

Cleaning and decontamination should occur at a designated area(s) (i.e., decontamination pad) on the site. If gross contamination or an oily film or residue is observed on the equipment, use a steam jenny or wash by hand, using a brush, to remove the particulate matter or surface film. Heavy oils or grease may be initially removed with paper towels soaked with isopropyl alcohol.

The physical removal of debris process is followed by soaking (a simple dunk of the equipment is insufficient) and hand scrubbing the equipment with a solution of potable water and non-phosphate detergent (mixed to the manufacturer's instructions) followed by a potable water rinse. If not using a decontamination pad, the most common set-up uses multiple 5-gallon plastic buckets (or equivalent) for washing and rinsing. The decontamination containers should be labeled as to their contents and pertinent information from original source, such as the date opened or transferred, and the expiration date (as well as any applicable hazardous labels), placed on polyethylene sheeting (to contain drips of decontamination fluids during the decontamination process), and sealed when not in use to prevent accidental release of the fluids. If decontaminating sealed submersible pumps, pump both the non-phosphate detergent wash

fluid and the potable water rinse through the pump body itself (usually done in separate buckets) to ensure that the internal components are thoroughly cleaned. Replace the detergent solution and rinse water at least daily or when it becomes oily or silty.

Next, place the DI water for the rinse in a small spray bottle or pour over the equipment after the potable water rinse.

**Typically, this level of decontamination (i.e., steps 1 through 4) is sufficient.**

Following Steps 1 through 4, additional decontamination (steps 5 through 9) may be required by the applicable federal or state guidelines, the project-specific work plan, or the QAPP. Typically, these decontamination steps are performed when sampling for inorganics or oil-related substances using non-motorized equipment. These steps include:

5 10% nitric acid rinse (if metals are part of the analyses)
6 Laboratory-supplied DI water rinse
7 Pesticide-grade solvent rinse (e.g., acetone [preferred], hexane, or isopropyl alcohol)
8 Air dry (solvent must evaporate)
9 Laboratory-supplied DI water rinse

Isopropyl alcohol is the recommended solvent for organic contaminants because it is readily available and is not a DOT hazardous material; where possible, lab-grade isopropyl alcohol should be used . However, other solvents (e.g., hexane and methanol) may be more effective in removing certain contaminants, such as oils or polychlorinated biphenyls, but any waste generated using these solvents must be managed accordingly. Solvents are never used for decontamination if sampling for volatiles organic compounds.

Handle the solvents and acid with care and store unused chemicals in their original, labeled, protective containers when not in use. It is a good idea to transfer small quantities of each solution into labeled, laboratory-grade spray bottles, which offer a convenient and controllable way to rinse the equipment. The equipment can then be rinsed over a 5-gallon plastic bucket or other suitable container placed on plastic sheeting as with the first part of the cleaning process. Nitric acid rinses must be used only on non-carbon steel sampling devices. Do not spray acid or solvent into pumps.

Decontamination steps used at sites where radioactive materials are contaminants of concern are similar with a few special considerations. Radiation contamination monitoring is used to help locate contamination and guide the success of the decontamination process. The liberal use of water and fluids as a decontamination agents are minimized, where practicable, because of the expense that can be incurred with disposing of radioactively contaminated decontamination water. Containerized decontamination wastes must be evaluated for radioactive content and disposed of appropriately depending on their content.

## 6.6 HANDLING DECONTAMINATED EQUIPMENT

Handle any decontaminated equipment using clean gloves to prevent re-contamination. Place the equipment away (preferably upwind) from the decontamination area once the process has been completed on clean plastic sheeting to allow it to air-dry. Once the equipment is dry, protect it from re-contamination by securely wrapping and sealing with aluminum foil (shiny side out) or clean, disposable plastic bags (inorganics only). Plastic bags may be wrapped directly around wet or dry equipment except when the expected contaminants include volatile and extractable organics; under those circumstances, allow the equipment to completely dry or wrap it in aluminum foil.

All sampling equipment must be decontaminated at the end of the investigation (i.e., prior to departure from the site). Label each piece of equipment with the date of decontamination, the initials of personnel performing the decontamination, and the type of decontamination solution(s) used. Containerize all decontamination fluids, and other disposable decontamination materials in DOT-compliant containers in accordance with SOP 5 or the project-specific work plan. Dispose of all wastes, including open and unused solvents or acids, in conformance with the project-specific work plan and applicable regulations.

# FIELD STANDARD OPERATING PROCEDURE #7

# WATER QUALITY MONITORING EQUIPMENT PROCEDURE

The procedures outlined in this Standard Operating Procedure (SOP) are designed to ensure that water quality monitoring equipment is calibrated and used properly. Specifically, this SOP addresses the short-term or discrete-measurement use of portable water quality monitoring equipment for the collection of physical, chemical, or biological field measurements. Common field parameters include temperature, pH, specific conductance (SC), turbidity, oxidation-reduction potential (ORP), and dissolved oxygen (DO). The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP or PSP, proper personal protective equipment (PPE) must be selected and used appropriately.

## 7.1 ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| DI | deionized water |
| DO | dissolved oxygen |
| °F | degrees Fahrenheit |
| HASP | health and safety plan |
| IDW | investigation derived waste |
| mg/l | milligrams per liter |
| mV | millivolts |
| NTU | nephelometric turbidity units |
| ORP | oxidation-reduction potential |
| PPE | personal protective equipment |
| PSP | project safety plan |
| QAPP | quality assurance project plan |
| SC | specific conductance |
| SDS | safety data sheets |
| SOP | standard operating procedure |
| SU | standard units |
| µS/cm | microsiemens per centimeter |
| (mS/cm) | millisiemens per centimeter |

## 7.2 MATERIALS

- Field book
- PPE
- Water quality meter
- Flow-through cell, as appropriate
- Display/logger
- Communication cables
- Calibration cup or beaker

- Calibration reagents and standard solutions, as appropriate
- Deionized water (DI) or distilled water
- Decontamination supplies

## 7.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field SOPs, and the Quality Management System.

This SOP is designed to provide the user with a general outline for preparing water quality monitoring equipment for use and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), investigation derived waste (IDW) management procedures (SOP 5), and equipment decontamination (SOP 6). This SOP does not cover the selection of water quality monitoring equipment, nor does it cover water quality monitoring equipment-specific instructions. These topics require a significant amount of planning and are more appropriately addressed in a project-specific work plan. Be sure to review the project-specific work plan or Quality Assurance Project Plan (QAPP) and any applicable state and federal guidelines or calibration procedures. The sampler should be familiar with the use and calibration of all sampling and monitoring equipment. All sampling references must be available for consultation in the field, including:

- Company's SOPs
- Applicable state and federal guidelines or sampling procedures
- Manufacturer's manuals
- Project-specific work plan, PSP and/or HASP, and QAPP

## 7.4 GENERAL EQUIPMENT HANDLING AND MANAGEMENT PROCEDURES

Multi-parameter water quality meters are typically bundled in a single housing unit known as a sonde. These types of units offer a single, convenient device that is capable of measuring most or all of the parameters monitored during a typical sampling event. Individual parameter water quality meters are available and, in some cases, offer a higher degree of accuracy, although the difficulty in deploying multiple meters for most tasks relegates them to specialty use.

***Field personnel must consult their assigned company compliance professionals for assistance in proper use, storage, and disposal of all calibration standard solutions.***

The manufacturer's recommendations and instructions vary from one instrument to the next; however, all types of water quality monitoring equipment share common handling and management procedures designed to ensure the integrity of the measurements collected. Based on these procedures, the user should:

- Follow the manufacturer's instructions for transportation, assembly, operation, calibration, and maintenance specific to your equipment. The manufacturer's instructions should be followed explicitly in order to obtain accurate results.
- Keep either the sensor guard or transportation/calibration cup installed when not in use to avoid damaging the sensors. Some sensors require a small amount of water in the transportation/calibration cup; follow the manufacturer's recommendations.
- Inspect the sensors to be sure that they are clean, installed properly and are not damaged.

- Ensure that all equipment is in proper working condition, and that batteries are properly charged before using the equipment for field testing measurements.
- Protect instruments that are sensitive to static electricity.
- Record manufacturer name and model number for each instrument used in the field book.
- Calibrate the instrument, as close to the time of use as possible, and repeat at the frequency suggested by the project-specific work plan, QAPP, or manufacturer. All calibration records must be maintained in the project files.
- Protect the instrument from direct sunlight, precipitation, and extremely hot or cold temperatures.
- Store cables only after they are clean, dry, and neatly coiled – do not bend or crimp cables, and attach any provided storage caps.
- Protect cables from abrasion or unnecessary tension when in use.
- Unless otherwise instructed by the manufacturer, decontaminate water quality monitoring equipment using a non-phosphate detergent solution with a small, nonabrasive brush, cotton swab or cloth, followed by a thorough DI water rinse.

## 7.5 CALIBRATION PROCEDURES

Water quality monitoring equipment must be inspected and the sensors calibrated before use. Calibration frequency is dependent upon project specifications, instrument performance, and manufacturer's recommendations; repeat the calibration procedures as directed in the project-specific work plan, QAPP, or manufacturer's guidance. Consult the manufacturer's guidelines before beginning the calibration process and contact the manufacturer's technical support if problems or questions arise. Maintain all calibration records in the project files.

Conduct the following procedures to ensure proper calibration and record observations in the field book:

- Complete field calibration in an area sheltered from wind, dust, and temperature/sunlight fluctuations such as inside a room or vehicle in which the ambient temperature of the standards is maintained at a temperature greater than 40 degrees Fahrenheit (°F) and less than 100°F, unless otherwise specified by the manufacturer.
- Use standard calibration solutions in accordance with the project-specific work plan, QAPP, or manufacturer's guidance. Allow water quality monitoring equipment to equilibrate to the air temperature for at least 15 minutes after being powered on, or for the specified time period recommended by the manufacturer.
- Record the brand, concentration, lot numbers and expiration dates of standard solutions in the field book.
- Handle standard solutions in a manner that prevents their dilution or contamination. Do not use expired standard solutions. Do not reuse standard solutions or pour solutions back into the bottle; ensure that proper chain-of-custody has been followed for standard solutions stored at a site.
- Ensure that the water quality monitoring equipment has been set to display or record the appropriate measurement units, as available – be sure to record the units of measure in the field book or field form.
- Unless otherwise instructed by the manufacturer, use the calibration cup that comes with the instrument for calibration.
- Use the recommended volume of standard solution when filling the calibration cup (e.g., the standard solution must cover the temperature sensor, as most sensors require temperature compensation).
- Be careful not to over tighten the calibration cup; many calibration cups have vents that allow their equilibration with ambient pressure.
- Rinse sensors thoroughly with DI water after use of each standard solution, followed by a rinse with the next standard solution to be used.
- Wait for readings to stabilize (approximately 30 seconds under normal conditions) before adjusting and saving the calibration point.
- If calibration fails to meet criteria, follow the manufacturer's instructions for corrective action to adjust instrument performance and note any indication of a substandard calibration.
- If the instrument does not start up, meet the requirements above, or calibrate properly, the instrument should not be used.
- Document the time, date, serial number (or other identifier) and calibration status for each instrument.

### 7.5.1 SPECIFIC CONDUCTANCE

Specific conductance, or, more commonly conductivity, measures the ability of water to conduct an electric current. It is generally reported in either microsiemens per centimeter ( $\mu$ S/cm) or millisiemens per centimeter (mS/cm); be sure to note the units used in the field book. Natural waters, including groundwater, commonly exhibit SC below 1 $\mu$ S/cm. Elevated SC measurements (i.e., greater

than 500 $\mu$ S/cm) are a proxy for the amount of dissolved solids, which may be indicative of inadequate well development, grout contamination (or an inadequate grout seal), or contamination.

When calibrating water quality monitoring equipment for SC:

- If not specified in the project-specific work plan, choose a SC standard solution recommended by the instrument manufacturer; otherwise, select a standard that is similar to the anticipated conductivity of the water being sampled.
- The presence of air bubbles in conductivity electrodes will cause erroneous readings and incorrect calibration. Transmission lines, alternating-current electrical outlets and radio-frequency noise sources may cause interference; check with the instrument manufacturer's specifications for troubleshooting procedures.

### 7.5.2 DISSOLVED OXYGEN

Dissolved oxygen measurements are used to assess the water quality with respect to certain metals (the amount of oxygen can control the valence state of metals) and, more typically, biological activity. Concentrations of DO in groundwater under ambient conditions generally range from 1 to 4 milligrams per liter (mg/l). Erratic or elevated (greater than 4 mg/l) DO readings may indicate equipment maintenance issues, such as a fouled sonde, torn membrane, a sensor out of calibration range; or inappropriate monitoring procedures that are causing excessive agitation and aeration of the water column. The meters are sensitive to atmospheric interference: *ex situ* measurements (i.e., those measured outside of the well itself) should only be collected using a flow-through cell.

Dissolved oxygen meters vary widely in their sensitivity. Select the type of DO sensor (i.e., the polarographic [or Clark cell] sensor or the luminescent [optical] sensor) that is most appropriate for the scope of work detailed in the project-specific work plan. The guidance below is for the more common polarographic sensor; consult the manufacturer's guidance for maintenance and calibration procedures specific to optical DO meters.

- Check the DO membrane for bubbles, wrinkles or tears. If necessary, install a new membrane and replace worn or stretched O-rings. Manufacturer guidance generally specifies membrane replacement should be completed at least 3 to 4 hours before use.
- Most manufacturers recommend that the sensor be allowed to equilibrate to the temperature of the water-vapor-saturated air before calibration, as specified in the manufacturer's instructions.
- Fill the calibration cup with less than 1/8 inch of water, or as recommended by the manufacturer.
- Remove any water droplets from the sensor without wiping the membrane. Water droplets on the sensor can cause a temperature compensation error in the DO calibration.
- Do not submerge or wet the sensor when loosely attaching the calibration cup.
- Enter the barometric pressure and wait for readings to stabilize before adjusting and saving the calibration point.

### 7.5.3 PH

The effective concentration (or activity) of hydrogen ions on a numerical scale known as pH, which is expressed as the negative base-10 logarithm of the hydrogen-ion activity in moles per liter. Natural (uncontaminated) waters typically exhibit a pH ranging from 5 to 9 Standard Units (SU). Deviation of pH from background may indicate the presence of groundwater contamination or well construction problems.

Typically, a two-point calibration is used for pH (i.e., a zero-point and span calibration[s]):

- If not specified in the project-specific work plan, select a 7 SU buffer (zero-point) plus a second pH buffer (4 SU or 10 SU) that brackets the range of expected pH.
- If applicable, calibrate the conductivity and DO sensors before calibrating the pH sensor. This helps prevent cross-contamination of the conductivity sensor from pH buffer solutions (pH buffers have much higher conductivities than most environmental waters).
- Allow time for the pH and temperature sensors to equilibrate to the temperature of the buffer and stabilize before adjusting and saving the calibration point. Record the temperature reading and use the chart provided by the buffer manufacturer to determine the true pH of the buffer at that temperature and adjust the calibration reading to that value.
- Repeat the calibration process with the second buffer.

### 7.5.4 OXIDATION-REDUCTION POTENTIAL

Oxidation-reduction potential is a numerical index of the intensity of the oxidizing or reducing conditions within an aqueous solution. Oxidizing conditions are indicated by positive potentials and reducing conditions are indicated by negative potentials. These values are frequently used when evaluating the biodegradation capacity of a system. The ORP of natural (uncontaminated) waters typically ranges from +500 to -100 millivolts (mV). The meters for ORP, like those for DO, are sensitive to atmospheric interference and must be measured using a flow-through cell. Avoid touching the sensors during calibration and measurement as calibration can be affected by static electricity.

A one-point calibration, at a known temperature, is used to calibrate the ORP sensor:

- Fill the calibration cup with enough standard solution (i.e., ZoBell's solution) to completely cover the temperature and ORP sensors.
- Allow time for the ORP and temperature sensors to equilibrate to the temperature of the buffer and stabilize before adjusting and saving the calibration point. Record the temperature reading and use the chart provided by the manufacturer to determine the true ORP of the solution at that temperature and adjust the calibration reading to that value.

### 7.5.5 TURBIDITY

Turbidity is the presence of suspended mineral and organic particles in a water sample. Turbid water may indicate inadequate well construction, development or improper sampling procedures, such as purging at an excessive rate that exceeds the well yield. Purging and sampling in a manner that minimizes turbidity is particularly important when analyzing for total metals and other hydrophobic compounds, such as polychlorinated biphenyls, which may exhibit artificially elevated concentrations in high-turbidity samples due to their adsorption to colloidal material. Generally, the turbidity of *in situ* groundwater is very low (at or below 10 nephelometric turbidity units, NTUs); however, some groundwater zones may have natural turbidity higher than 10 NTUs.

Standard turbidity solutions are not necessarily interchangeable. Serious calibration errors can result from using inappropriate standards. Use only those standard turbidity solutions that are prescribed for the sensor by the instrument manufacturer.

Turbidity consists of a zero-point calibration and a span calibration(s):

- Fill the calibration cup to the reference line with DI or a zero-point standard.
- Allow time for the turbidity sensors to stabilize before adjusting and saving the calibration point.
- Record the temperature and use the chart provided by the manufacturer to determine the true turbidity of the standard and adjust the calibration reading to that value.
- Repeat the calibration process with the standard span calibration standard(s).

## 7.6 EQUIPMENT USE PROCEDURES

The monitoring equipment is ready to use once the calibration has been completed. The specific use of the device will be dictated by the project-specific work plan or QAPP; however, all projects should follow these general procedures during use:

- Charge instrument batteries per the manufacturer's instructions, as necessary.
- Ensure that instrument is warmed up and the measured value(s) on the water quality monitoring equipment are equilibrated (i.e., readings are representative of the solution, not ambient air) before recording in the field book.
- Biological growth or debris in the water can foul sensors; as possible, avoid inserting the sonde in areas that will result in having to stop and clean algae, sediment, or debris from the sensors (e.g., do not place on bottom of a well or streambed).
- If continuous monitoring is required, follow the manufacturer's instructions for performing continuous data logging events.

For flow through cells:

- Inspect the integrity of the flow-through cell and O-rings.
- Connect the discharge tubing to the bottom of the flow-through cell using properly-sized tubing and fittings. Connect the effluent tubing to the top of the flow-through cell and secure the end of the tubing into the designated groundwater purge container.
- Shield the flow-through cell from direct sunlight to minimize changes in the temperature.

- Do not record any measurements until all the air from the flow-through cell and the effluent tubing has been displaced and the sensors have equilibrated. The presence of air bubbles in the flow-through cell will result in highly biased readings.
- Do not collect samples for laboratory analysis from the groundwater in the flow-through cell.

## 7.7 CLOSING NOTES

Once field activities are complete, secure the site in accordance with the project-specific work plan. Decontaminate all equipment prior to departure and properly manage all PPE and IDW in conformance with SOP 6, the project-specific work plan, and applicable regulations.

# FIELD STANDARD OPERATING PROCEDURE #9

# SOIL SAMPLING PROCEDURE

The soil sampling procedures outlined in this standard operating procedure (SOP) are designed to ensure that collected soil samples are representative of current site conditions. Soil samples can be collected for onsite screening or for laboratory analysis. The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP, proper personal protective equipment (PPE) must be selected and used appropriately.

## 9.1 ACRONYMS AND ABBREVIATIONS

## 9.2 MATERIALS

- Field book
- PPE
- Air quality monitoring equipment, (e.g., photoionization detector [PID]), as needed
- Field test kits, as needed
- Sampling containers and labeling/shipping supplies
- Ruler or tape measure
- Zipper-style plastic bags, as needed
- Plastic sheeting
- Soil sampling method specific materials, as needed:
- Stainless steel trowels, probes, or shovels
- Stainless steel spatulas or spoons
- Bucket augers, auger extension rods, auger handle, pipe wrenches
- Split-spoon samplers, pipe wrenches
- Direct-push acetate liners, including catchers and opening tools, as needed
- Shelby tube samplers, plastic or wax caps
- Mixing tray or bowl
- Munsell color chart
- Decontamination supplies

## 9.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field SOPs, and the Quality Management System.

This SOP is designed to provide the user with a general outline for conducting soil sampling and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), utility location (SOP 2), sample shipment procedures (SOP 3), sample collection and quality assurance procedures (SOP 4), investigation-derived waste (IDW) management procedures (SOP 5), equipment decontamination (SOP 6), and use and calibration of sampling and monitoring equipment (SOPs 7 and 8). This SOP does not cover investigation planning, nor does it cover the evaluation of the analytical results. These topics are more appropriately addressed in a project-specific work plan. Before soil sampling, be sure to review the project-specific work plan or Quality Assurance Project Plan (QAPP) and any applicable state and federal guidelines or sampling procedures.

***Consult and involve your assigned compliance professional during all phases of soil sampling. Do not ship hazardous waste samples without first consulting a company compliance professional.***

All sampling and monitoring references must be available for consultation in the field, including:

- Company's SOPs
- Applicable state and federal guidelines or sampling procedures
- Manufacturer's manuals
- Project-specific work plan, PSP and/or HASP, and QAPP

## 9.4 GENERAL PROCEDURES

Soil samples are collected using a variety of techniques and equipment, depending on the type (e.g., surface, subsurface) and purpose (e.g., lithological logging, headspace evaluation, laboratory analysis) of the sampling, and most sampling events employ more than one equipment type or methodology. Subsurface soil sampling, for example, often includes sample collection from split-spoon, macro-core, or other dedicated sampling devices advanced into the subsurface. Recovered cores are often logged (using a Munsell color chart and other logging aids), screened for volatile organic compounds (VOCs) using a PID, and sampled for laboratory analysis using disposable stainless steel spoons or other discrete sampling devices.

Each sampling configuration is associated with a unique set of sampling equipment requirements and techniques. The selected procedures and equipment are project-specific and should be discussed by the project team before arriving onsite. All types of soil sampling, regardless of the equipment used, share common handling and management procedures that are designed to ensure the integrity of the samples collected. These procedures include:

- The use of new, disposable or decontaminated sampling equipment
- The use and rotation of the appropriate PPE
- Selection of a suitable sampling location and staging area

Wear a clean pair of new, disposable gloves each time a different sample is collected and don the gloves immediately prior to collection. This limits the possibility of cross-contamination from accidental contact with gloves soiled during collection of the

previous sample. The gloves must not come in contact with the medium being sampled and must be changed any time during sample collection when their cleanliness is compromised. ***Gloved hands should not be used as a sampling device; always use the appropriate equipment to move the sample from the sampling device to the laboratory-supplied containers.*** If the soil cannot be transferred directly from the sampling device to the laboratory-supplied containers, use a stainless steel spoon or spatula to transfer the soil from the sampling device to the laboratory-supplied containers.

### 9.4.1 EQUIPMENT SELECTION

Collect all samples using either new, disposable equipment, such as polyethylene liners or single-use stainless steel spoons; or properly decontaminated sampling equipment, such as hand augers, split-spoon samplers, or trowels. Soil sampling equipment should be selected based on the analytical requirements of the project and the project-specific conditions likely to be encountered. The equipment should be constructed of non-reactive, non-leachable materials (e.g., stainless steel, Teflon®, Teflon®-coated steel, polyethylene, polypropylene) which are compatible with the chemical constituents at the site. When choosing sampling equipment, give consideration to:

- the types of soil or fill present
- the required depth of the sample
- the volume of sample required
- the analytes of interest

Select the types of equipment and decontamination procedures based on the types of sampling to be performed. Decontamination may require multiple steps or differing cleaning methods, depending on the sampling goals (see SOP 6 for decontamination procedures). In no case should disposable, single use materials (e.g., acetate liners, soil baskets) be used to collect more than one sample.

### 9.4.2 SAMPLING CONSIDERATIONS

In preparing for sampling, you should perform the following activities (with all observations and measurements noted in the field book):

- Perform a quick reconnaissance of the site to identify sampling locations and evaluate the accessibility (physical obstructions, slope, overhead and underground utilities) to the sampling location.
- Record the approximate ambient air temperature, precipitation, wind (direction and speed), tide, and other field conditions in the field book. In addition, any site-specific conditions or situations that could potentially affect the samples should be recorded.
- Record a description of the sampling location and the approximate distance to and direction from at least one permanent feature.
- Should any sample location require a vertical or horizontal offset from the proposed location, indicate the reason and record the actual sample location in the field book.

Survey the breathing zone around the sampling location with the appropriate air quality meter(s), as necessary (see HASP), to ensure that the level of PPE is appropriate. When sampling soil, it is important to find a suitable sampling location away from any sources of cross-contamination that could compromise the integrity of the samples. Consider the following:

- Position the sample collection area away from fuel-powered equipment, such as drill rigs or excavators, and upwind of other site activities (e.g., purging, sampling, decontamination) that could influence the sample. This is particularly important when screening samples in the field for VOCs with a PID, but should not be limited to the active sample collection.
- Store samples already collected from the field for laboratory analysis in clean containers in an ice-filled cooler (as required) and securely stage, if possible, in an uncontaminated area of the site.

## 9.5 SOIL SAMPLE COLLECTION

Soil samples can be collected from surface or subsurface depths, depending on the project requirements. Surface soils are generally those collected at depths less than 2 feet below ground surface (bgs) and can be collected using trowels, soil probes, shovels, or hand augers. Be aware that some states have specific definitions of what constitutes a surface soil sample. Subsurface soils are generally

deeper and require specialized equipment to recover the samples. In most cases, subsurface soils will be collected using a drill rig or excavator to prevent the soil from being mixed with soils from a shallower interval.

Push or drive the method-specific sampling equipment (e.g., trowel, hand auger, hollow corers, split-spoon, direct push sampler, rotosonic core barrel sampler, excavator bucket) into the soil to the desired sampling depth using decontaminated equipment. Record in the field book the depth interval through which the sampler was advanced and, when using a drilling rig and split-spoon sampler, the number of blows needed to drive the sampler 6 inches. If additional soil is needed to provide sufficient sample volume, repeat this step taking care to ensure that the same depth interval is collected during the resample. Use core catchers on the leading end of the sampler (if available) for soils that lack cohesiveness and are subject to falling out of the sampler (i.e., poor recovery).

Withdraw the sampling equipment from the interval, open the sampler (as appropriate), and collect the sample in a safe location (e.g., avoid entering an excavation by collecting the sample from an excavator bucket at ground surface). When collecting a sample from an excavator bucket, the sampler should watch the bucket as the excavated material is retrieved and collect the sample from the desired sampling material.

Recovered soils should be placed on plastic sheeting in a consistent manner such that the orientation of the sample (i.e., which end is "up") and the depth interval is readily apparent to the sampling personnel. Measure the length of the material recovered relative to the interval the sampler was advanced in percent notation (e.g., 75%) or as a fraction of the total length of the sample interval (i.e., [3/4] indicating 3 out of 4 feet) and record this information in the field book. If field screening for organic vapors is required, break or cut the soil core every 3 to 4 inches and quickly scan the breaks in the core material with the appropriate air quality monitoring equipment (e.g., PID) and record the readings and approximate depth in the field book. These measurements can be used to select appropriate soil samples for VOC or headspace analysis, if required (see procedures below).

### 9.5.1 UNDISTURBED SAMPLE COLLECTION

Undisturbed soil samples collected for geotechnical parameters (e.g., porosity, permeability) generally require the use of specialized undisturbed sampling equipment (e.g., Shelby tube or sealed Geoprobe® liner) and collection procedures. The sampling device, once retrieved, is typically capped or sealed (to maintain the sample in its relatively undisturbed state), labeled with the sample name, orientation of the sample (i.e., top and bottom), depth interval, and shipped to the appropriate geotechnical laboratory. Follow sample labeling, preparation, and shipping procedures in SOPs 3 and 4.

### 9.5.2 VOLATILE ORGANIC COMPOUND SAMPLING

Analytical soil samples for VOC analysis should be collected immediately after screening with the PID to avoid loss of constituents to the atmosphere. Transfer the soil from the portion of the soil core to be sampled (usually the area where the highest PID readings were observed) directly into the sample containers; do not homogenize soils for VOC analysis. Place the soil in the sampling container such that no headspace is present above the soil when the cover is placed on the jar. If U.S. Environmental Protection Agency Method 5035 (e.g., Encore® samplers) is required, follow manufacturer's specifications and company recommended shipping procedures.

When using an Encore® sampler, soil from the sampling device will be placed in pre-preserved sampling containers (40 ml VOA vial). It is important to ensure that the appropriate volume of soil is collected and is not increased or decrease due to overpacking/underpacking the sampler. Five (5) grams is the target volume of soil, plus or minus 10 percent. Preservative in the sample container should completely cover the sample mass. Care will be taken to ensure that container threads are free of soil to allow for the VOA vial to be sealed and not leak during transport. Each VOA vial will weighed prior to the addition of soil and after sample has been added. These weights will be compared to the laboratory weight upon sample receipt to ensure that preservative was not lost during transit.

Collect quality assurance/quality control (QA/QC) samples, if appropriate, in accordance with SOP 4, the project-specific work plan, and the QAPP.

### 9.5.3 SOIL HEADSPACE ANALYSIS

Collect soil samples for field-based headspace analysis, if required as part of the project-specific work plan, after collecting the VOC sample. First, examine the soil and remove coarse gravel, organic material (e.g., roots, grass, and woody material) and any other debris. Transfer the soil from the portion of the soil core to be sampled and place in a heavy-duty zipper-style plastic bag and seal the bag. Label the sample indicating the sampling location, depth, and date. Shake the sample vigorously for approximately 15 seconds to disaggregate the sample and expose as much surface area of the soil as possible (to release the VOCs to the atmosphere within the bag). If necessary, warm the sample to room temperature (70º Fahrenheit, [ºF]) by placing the bag in a heated room or vehicle. This step is critical when the ambient temperature is below 32ºF.

The VOCs, if present, will volatilize into the sealed bag. Allow the bag to stand (to achieve equilibrium) for approximately 15 minutes. Carefully open the bag slightly and place the tip of the PID into the opening. Do not insert the tip of the probe into the soil material and avoid the uptake of water droplets. Allow the PID to equilibrate and record the highest PID measurement noted. Erratic PID responses may result from high organic vapor concentrations or elevated headspace moisture. If these conditions exist, qualify the headspace data in the field book. It is also important to record the ambient temperature, humidity, and whether moisture was present in plastic bag. Duplicate 10% of the headspace samples by collecting two samples from the same location. Generally, duplicate sample values should be consistent to ±20%. Samples collected for headspace screening cannot be retained for laboratory analysis.

### 9.5.4 SEMI- AND NON-VOLATILE ANALYTICAL SAMPLE COLLECTION

For metal sulfide analysis, sediment should be maintained in anoxic conditions to limit exposure to oxygen. Samples should be collected immediately and stored with zero headspace.

Collect remaining organic samples then inorganic samples in the following order of volatilization sensitivity:

- Extractable organics, petroleum hydrocarbons, aggregate organics, and oil and grease
- Metals
- Inorganic non-metallic and physical and aggregate properties
- Microbiological samples
- Radionuclides

If homogenization is required, mix the soils (using stainless steel bowls and spoons, or other appropriate equipment) to a homogeneous particle size and texture. Transfer the soils from the sampler or mixing bowl to the sample container using a decontaminated or dedicated stainless steel spoon or spatula. Collect QA/QC samples in accordance with SOP 4, the project-specific work plan, and the QAPP.

If approved by the appropriate regulatory agency and specified in the project-specific work plan, composite soil samples can be collected to minimize the total number of analytical samples. Composite samples consist of equal aliquots (same sample size) of soil from each location being sampled (e.g., from each borehole or from multiple areas of a soil pile), by mixing the soil to a homogeneous particle size and texture using new or decontaminated stainless steel bowls and a stainless steel spoon or trowel. Transfer the contents to the appropriate laboratory supplied sample container using a stainless steel spoon. Collect QA/QC samples in accordance with SOP 4, the project-specific work plan, and the QAPP, if required.

If necessary, conduct field tests or screening on soils in accordance with the project-specific work plan and manufacturer's specifications for field testing equipment.

### 9.5.5 SAMPLE LABELING AND PREPARATION FOR SHIPMENT

Once collected, prepare the soil samples for offsite laboratory analysis:

1. Clean the outside of the sample container with paper towels or appropriate materials, if necessary
2. Affix a sample tag or label to each sample container and complete all required information (sample number, date, time, depth interval, sampler's initials, analysis, preservatives, place of collection)

3 Place clear tape over the tag or label (if non-waterproof labels are used)
4 Preserve samples immediately after collection by placing them into an insulated cooler filled with bagged wet ice to maintain a temperature of approximately 4°Celcius (if required by analytical method)
5 Record the sample designation, date, time, depth interval, number of sampling containers, analytical methods, and the sampler's name in the field book and on the chain-of-custody form
6 Complete the chain-of-custody forms with appropriate sampling information, including:
   — Location
   — Sample name
   — Sample collection date and time
   — Number of sample containers
   — Analytical method
7 Complete sample packing and ship in accordance with proper procedures

***Do not ship hazardous waste samples without first consulting a company compliance professional.***

## 9.6 SOIL CLASSIFICATION

Soil classification should be performed whenever soil samples are being collected to provide context for the analysis. Unless required to follow a different soil classification (e.g., US Department of Agriculture), follow the Unified Soil Classification System (USCS) logging procedures as described in ATSM D2488[1] . The emphasis of soil classification in the field must be on describing the soils using ALL of the required descriptors; categorization of the USCS group name or symbol alone may not provide details about the soils that could later prove useful. Avoid geologic interpretation or the use of local formation names, which are often difficult to determine in the field without the regional framework. Record ALL of the following information for each sample interval/soil type in the field book:

— Depth interval
— USCS group name (e.g., lean clay, elastic silt, well-graded gravel)
— USCS group symbol (e.g., cl, mh, gw)
— Color, using Munsell chart (in moist condition)
— Percent of cobbles, boulders, gravel, sand, and fines (approximate; by volume). Use the following standard descriptors for the textural percentages:
— Trace: <5%[2]
— Few: 5-10%
— Little: 15-25%
— Some: 30-45%
— Mostly: 50-100%
— Particle-size range:
— Gravel—fine (0.2-inch to 0.75-inch), medium, coarse (0.75-inch to 3 inch)
— Sand—fine (0.003-inch to 0.02-inch), medium (0.02-inch to 0.08-inch), coarse (0.08-inch to 0.2-inch)
— Fines – clay or silt
— For gravel and sand:
— Particle angularity: angular, subangular, subrounded, rounded
— Particle shape: (if appropriate) flat, elongated, flat and elongated
— Maximum particle size or dimension
— Hardness (under hammer blow) of coarse sand and larger particles
— For fine-grained soil (i.e., clay and silt):
— Plasticity: non-plastic, low, medium, high
— Dry strength: none, low, medium, high, very high
— Dilatancy: none, slow, rapid
— Toughness: low, medium, high
— Odor (mention only if organic or unusual; factual descriptions only, no interpretations)
— Moisture: dry, moist, wet
— Additional comments: presence of roots or root holes, presence of mica, gypsum, etc., surface coatings on coarse-grained particles, caving or sloughing of auger hole or trench sides, difficulty in augering or excavating, etc.

For intact samples also include:

- Consistency (fine-grained soils only): very soft, soft, firm, hard, very hard
- Structure: stratified, laminated, fissured, lensed, homogeneous
- Cementation: weak, moderate, strong

Example descriptions, using the information listed above, would read as follows:

- 8-10' – Well Graded Sand, SW (5YR 2/6) fine- to medium-grained sand, trace medium sub-angular rounded gravel (less than 0.5-inch diameter); medium dense to dense; wet; moderate petroleum-like odor between 9 feet bgs and 10 feet bgs.
- 10-12' – Lean Clay with Gravel, CL (5YR 2/6) some fine- to coarse-grained angular to subangular gravels (less than 0.25-inch diameter), trace fine- to medium-grained rounded sands; very stiff; low plasticity; low dry strength; no dilatancy; moist; no odors.

## 9.7 CLOSING NOTES

Once sampling is completed, restore and mark all sample locations with spray paint, stakes, or other appropriate marker for future reference or survey, including collecting Global Positioning System coordinates and photographs, or survey in accordance with the project-specific work plan. Decontaminate all equipment prior to departure and properly manage all PPE and IDW in conformance with SOP 6, the project-specific work plan, and applicable regulations.

[1] Note that certain states/regulatory programs may require soil classification under a secondary system (e.g., US Department of Agriculture) or the use of hydrochloric acid to test the reaction with soil (none, weak, strong).

[2] The use of "Trace" for describing the fraction of clay soils is inappropriate for field-based logs as clay contents of less than 20% in fine-grained soils cannot be reliably determined in the field.

# FIELD STANDARD OPERATING PROCEDURE #10

# SEDIMENT SAMPLING PROCEDURE

The sediment sampling procedures outlined in this standard operating procedure (SOP) are designed to ensure that collected sediment samples are representative of current site conditions. Sedimentsamples can be collected for onsite screening or for laboratory analysis. The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP, proper personal protective equipment (PPE) must be selected and used appropriately.

## 10.1 ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| ºF | degrees Fahrenheit |
| HASP | health and safety plan |
| IDW | investigation derived waste |
| PID | photoionization detector |
| PPE | personal protective equipment |
| PSP | project safety plan |
| QAPP | quality assurance project plan |
| QA/QC | quality assurance/quality control |
| SOP | standard operating procedure |
| USCS | Unified Soil Classification System |
| VOC | volatile organic compounds |

## 10.2 MATERIALS

- Field book
- PPE
- Air quality monitoring equipment, (e.g., photoionization detector [PID]), as needed
- Field test kits, as needed
- Sampling containers and labeling/shipping supplies
- Ruler or tape measure
- Zipper-style plastic bags, as needed
- Plastic sheeting
- Hip-waders or rubber boots, as necessary
- Sediment sampling method specific materials, as needed:
  - Stainless steel trowels, shovels, or spoons
  - Stainless steel spatulas or spoons
  - Bucket augers, auger extension rods, auger handle, pipe wrenches
  - Vibracore
  - Eckman Grab Sampler (soft sediment)
  - Ponar Grab Sampler (hard sediment)
  - Split-spoon samplers, pipe wrenches
  - Direct-push acetate liners including catchers and opening tools, as needed
  - Shelby tube samplers

- Mixing tray or bowl
- Munsell color chart
- Decontamination supplies

## 10.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field SOPs, and the Quality Management System.

This SOP is designed to provide the user with a general outline for conducting sediment sampling and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), utility location (SOP 2), sample shipment procedures (SOP 3), sample collection and quality assurance procedures (SOP 4), investigation-derived waste (IDW) management procedures (SOP 5), equipment decontamination (SOP 6), use and calibration of all sampling and monitoring equipment (SOPs 7 and 8), and soil and groundwater sampling procedures (SOPs 9 and 11). This SOP does not cover investigation planning, waste storage, waste characterization, or waste profiling, nor does it cover the evaluation of the analytical results. These topics are more appropriately addressed in a project specific work plan. Before sampling, be sure to review the project-specific work plan or quality assurance project plan (QAPP) and any applicable state and federal guidelines or sampling procedures.

***Consult and involve your assigned compliance professional during all phases of sediment sampling. Do not ship hazardous waste samples without first consulting a company compliance professional.***

All sampling and monitoring references must be available for consultation in the field, including:

- Company SOPs
- Applicable state and federal guidelines or sampling procedures
- Manufacturer's manuals
- Project-specific work plan, PSP and/or HASP, and QAPP

## 10.4 GENERAL PROCEDURES

Sediment samples are collected using a variety of techniques and equipment, depending on the type (e.g., surface, subsurface) and purpose (e.g., lithological logging, headspace evaluation, laboratory analysis) of the sampling, and most sampling events employ more than one equipment type or methodology. Recovered cores are often logged (using a Munsell color chart and other logging aids), screened for volatile organic compounds (VOCs) using a PID, and sampled for laboratory analysis using disposable stainless steel spoons or other discrete sampling devices.

Each sampling configuration is associated with a unique set of sampling equipment requirements and techniques. The selected procedures and equipment are project-specific and should be discussed by the project team before arriving onsite. All types of sediment sampling, regardless of the equipment used, share common handling and management procedures that are designed to ensure the integrity of the samples collected. These procedures include:

- The use of new, disposable or decontaminated sampling equipment

- The use and rotation of the appropriate PPE (e.g., hip-waders or rubber boots and gloves, and Saranex® or Tyvek® sleeves duct taped onto nitrile gloves)
- Selection of a suitable sampling location and staging area

Wear a clean pair of new, disposable gloves each time a different sample is collected and don the gloves immediately prior to collection. This limits the possibility of cross-contamination from accidental contact with gloves soiled during collection of the previous sample. The gloves must not come in contact with the medium being sampled and must be changed any time during sample collection when their cleanliness is compromised. ***Gloved hands should not be used as a sampling device; always use the appropriate equipment to move the sample from the sampling device to the laboratory-supplied containers.***

## 10.4.1 EQUIPMENT SELECTION

Collect all samples using either new, disposable equipment, or properly decontaminated sampling equipment. Follow the manufacturer's operation manual for proper sampling procedures. Sediment sampling equipment should be selected based on the analytical requirements of the project and the project-specific conditions likely to be encountered. The equipment should be constructed of non-reactive, non-leachable materials (e.g., stainless steel, Teflon®, Teflon®-coated steel, polyethylene, and polypropylene) which are compatible with the chemical constituents at the site. Extension rods or other appropriate devices can be used, as necessary, to allow the sample to be collected at a distance (or through deeper water) to minimize the risk to the sampler. When choosing sampling equipment, give consideration to:

- the depth and flow of any associated surface water body
- the required depth of the sample
- the volume of sample required
- the analytes of interest

Select the decontamination procedures based on the types of sampling to be performed and decontamination may require multiple steps or differing cleaning methods, depending on the sampling goals (see SOP 6 for decontamination procedures). In no case should disposable, single use materials be used to collect more than one sample.

## 10.4.2 SAMPLING CONSIDERATIONS

In preparing for sampling, you should perform the following activities (with all observations and measurements noted in the field book):

- Perform a quick reconnaissance of the site to identify sampling locations and evaluate the accessibility (physical obstructions, slope, overhead and underground utilities) to the sampling location.
- Record the approximate ambient air temperature, precipitation, wind (direction and speed), tide, and other field conditions in the field book. In addition, any site-specific conditions or situations that could potentially affect the samples at the sample locations should be recorded.
- Record a description of the sampling location and the approximate distance to and direction from at least one permanent feature.
- Describe the sampling location including width of stream or diameter of pipe, depth of stream or discharge, water color and clarity (transparency), and approximate surface flow (e.g., slow, fast moving).
- Should any sample location require a vertical or horizontal offset from the proposed location, indicate the reason and record the actual sample location in the field book.

Survey the breathing zone around the sampling location with the appropriate air quality meter(s), as necessary (see HASP), to ensure that the level of PPE is appropriate. When sampling sediment, it is important to find a suitable sampling location away from any sources of cross-contamination that could compromise the integrity of the samples. Consider the following:

- Position the sample collection area away from fuel-powered equipment, such as drill rigs or excavators, and upwind of other site activities (e.g., purging, sampling, decontamination) that could influence the sample. This is particularly important when screening samples in the field for VOCs with a PID, but should not be limited to the active sample collection.
- If collecting several samples from a stream or river, start sampling at the downstream location and progressively move upstream.

- Always approach the location from the downstream direction and face upstream (into the current) when collecting the sediment sample.
- Collect surface water samples, if being collected concurrently, before collecting the stream sediment samples from the same location. This procedure will eliminate the introduction of sediment and turbulence in the surface water that is to be sampled.
- Avoid wading into surface water, if possible, to avoid sediment suspension and potential cross-contamination.
- If not possible to avoid wading into the water for sample collection, use extreme caution and carefully approach the sample location to minimize disturbance of fine sediments.
- If using watercraft, collect samples near the bow, away and upwind from any fuel powered equipment; orient the watercraft so that the bow is positioned in the upstream direction. This is particularly important when screening for VOCs with a PID, but should not be limited to the active sample collection.
- Store samples already collected from the field for laboratory analysis in clean containers in an ice-filled cooler (as required) and securely stage, if possible, in an uncontaminated area of the site.

### 10.4.3 SAFETY CONSIDERATIONS

Sediment sampling presents a number of unique challenges for safe collection. All water bodies, particularly those with moving water, are inherently dangerous and must be approached with caution. Steep embankments, loose footing, and the potential presence of subsurface hazards (or dangerous plants or wildlife, for some parts of the country) can lead to serious injury or even death.

**A minimum of two people may be required to be present** during collection and samplers must use appropriate safety equipment (as outlined in the project HASP), such as insulated waders, snake chaps, and flotation devices. If possible, avoid wading into surface water. Be aware of recent weather conditions, tidal changes, or other events (e.g., a dam releases), which may result in unexpectedly higher water, flow conditions, or temperature changes. **Do not** attempt to sample surface impoundments used to manage potentially hazardous wastes from a boat; all sampling should be conducted from the banks or piers of surface impoundments.

**Do not** bodily enter pipes, such as storm sewers or other drainage conveyances, during sediment collection as these may be considered confined spaces.

## 10.5 SEDIMENT COLLECTION

In accordance with the project-specific work plan, collect sediment samples using the appropriate equipment: (1) scoops or trowels, (2) corers, or (3) grab samplers or dredges.

Push, drive, or drop the method-specific sampling equipment into the sediment to the desired sampling depth using decontaminated equipment. Do not use scoops or trowels in water deeper than 12 inches. Slowly retrieve the sediment sample. As applicable, tilt the sampling equipment at a slight angle in the upstream direction to minimize the disturbance and to avoid losing the sediment. If additional sediment is needed to provide sufficient sample volume, repeat this step. Occasionally sediments lack cohesiveness and are subject to falling out of the sampler. The use of core catchers on the leading end of the sampler may help retain the sample until it is retrieved to the surface; core catchers must be evaluated for compatibility with the proposed analytical program before use.

Withdraw the sampling equipment from the interval, open the sampler (as appropriate), and collect the sample safely (e.g., avoid entering an excavation by collecting the sample from an excavator bucket at ground surface). Samples collected from an excavator bucket should be taken from the center of the material to ensure material is representative of the desired sampling interval.

Recovered sediment should be placed on plastic sheeting in a consistent manner such that the orientation of the sample (i.e., which end is “up”) and the depth interval is readily apparent to the sampling personnel. Measure the length of the material recovered relative to the interval the sampler was advanced in percent notation (e.g., 75%) or as a fraction of the total length of the sample interval (e.g., [3/4] indicating 3 out of 4 feet) and record this information in the field book. If field screening for organic vapors is required, scan the recovered sediments quickly with the appropriate air quality monitoring equipment (e.g., PID), or for sediment cores break or cut the sediment every 3 to 4 inches and quickly scan the breaks in the core material with the appropriate air quality monitoring equipment (e.g., PID). Record the readings and approximate depth in the field book. These measurements can be used to select appropriate waste material samples for VOC or headspace analysis, if required (see procedures below).

### 10.5.1 UNDISTURBED SAMPLE COLLECTION

Undisturbed sediment samples collected for geotechnical parameters (e.g., porosity, permeability) generally require the use of specialized undisturbed sampling equipment (e.g., Shelby tube or sealed direct-push acetate liner) and collection procedures. The sampling device, once retrieved, is typically capped or sealed (to maintain the sample in its relatively undisturbed state), labeled with the sample name, orientation of the sample (i.e., top and bottom), depth interval, and shipped to the appropriate geotechnical laboratory. Follow sample labeling, preparation, and shipping procedures in SOPs 3 and 4.

### 10.5.2 INTERSTITIAL WATER

Interstitial water, or pore water, is the water occupying the space between sediment particles. It can be isolated to provide either a matrix for toxicity testing or an indication of the concentration and partitioning of contaminants with a sediment matrix. Interstitial water samples may be collected in the field using any available technology that will preserve the integrity of the analytes of interest during collection (e.g., temporary well) or extracted in the laboratory from field-collected sediments. Sandy sediments retain less water than fine sediments do; thus, the substrate type will dictate the amount of additional sample needed. In all cases, consult the laboratory conducting the analyses to provide estimates of the amount of sediment necessary to obtain the desired quantity of pore water.

If necessary, conduct field tests or screening of sediments in accordance with the project-specific work plan and manufacturer's specifications for field testing equipment.

### 10.5.3 VOLATILE ORGANIC COMPOUND SAMPLING

Analytical samples for VOC analysis should be collected immediately after screening with the PID to avoid loss of the constituents to the atmosphere. Transfer the sediment from the center portion of the sample interval to be sampled directly into the sample containers; do not homogenize sediments for VOC analysis. Place the sediment in the sampling container such that no headspace is present above the sediment when the cover is placed on the jar. If sampling by US Environmental Protection Agency Method 5035 is required, follow manufacturer's specifications to use a closed-system sampler (e.g., Encore® samplers). Collect quality assurance/quality control (QA/QC) samples in accordance with SOP 4 and the project-specific work plan or QAPP.

### 10.5.4 SEDIMENT HEADSPACE ANALYSIS

Although headspace analysis is typically not performed on saturated sediments, other sediments, such as those from pipes and pits, may be appropriate for headspace analysis.

Collect sediment samples for field-based headspace analysis, if required as part of the project-specific work plan, after collecting the VOC sample. First, examine the sediment and remove coarse gravel, organic material (e.g., roots, grass, and woody material) and any other debris. Collect the sample using decontaminated or dedicated spoons or trowels and place in a heavy-duty zipper-style plastic bag and seal the bag. Label the sample indicating the sampling location, depth, and date. Shake the sample vigorously for approximately 15 seconds to disaggregate the sample and expose as much surface area of the sediment as possible (to release the VOCs to the atmosphere within the bag). If necessary, warm the sample to room temperature (70º Fahrenheit, [ºF]) by placing the bag in a heated room or vehicle. This step is critical when the ambient temperature is below 32ºF.

VOCs, if present, will volatilize into the sealed bag. Allow the bag to stand (to achieve equilibrium) for approximately 15 minutes. Carefully open the bag slightly and place the tip of the PID into the opening. Do not insert the tip of the probe into the sediment and avoid the uptake of water droplets. Record the highest meter response, which typically occurs within the first 2 to 5 seconds. Erratic PID response may result from high organic vapor concentrations or elevated headspace moisture. If these conditions exist, qualify the headspace data in the field book. It is also important to record the ambient temperature, humidity, and whether moisture was present in plastic bag. Duplicate 10% of the headspace samples by collecting two samples from the same location. Generally, duplicate sample values should be consistent to ±20%. Samples collected for headspace screening cannot be retained for laboratory analysis.

## 10.5.5 SEMI- AND NON-VOLATILE ANALYTICAL SAMPLE COLLECTION

For metal sulfide analysis, sediment should be maintained in conditions to limit exposure to oxygen. Samples should be collected immediately and stored with zero headspace.

Collect remaining organic samples then inorganic samples in the following order of volatilization sensitivity:

- Extractable organics, petroleum hydrocarbons, aggregate organics, and oil and grease
- Metals
- Inorganic non-metallic and physical and aggregate properties
- Microbiological samples
- Radionuclides

If homogenization is required, mix the sediments (using stainless steel bowls and spoons, or other appropriate equipment) to a homogeneous particle size and texture. Transfer the sediments from the sampler or mixing bowl to the sample container using a decontaminated or dedicated stainless steel spoon or spatula. Collect QA/QC samples in accordance with SOP 4, the project-specific work plan, and the QAPP.

If approved by the appropriate regulatory agency and specified in the project-specific work plan, composite sediment samples can be collected to minimize the total number of analytical samples. Composite samples consist of equal aliquots (same sample size) of waste material from each location being sampled (e.g., from multiple areas of a site), by mixing the waste to a homogeneous particle size and texture using new or decontaminated stainless steel bowls and a stainless steel spoon or trowel. Transfer the contents to the appropriate laboratory-supplied sample container using a stainless steel spoon. Collect QA/QC samples in accordance with SOP 4 and the project specific work plan or QAPP, if required.

## 10.5.6 NON-AQUEOUS PHASE LIQUID SAMPLING PROCEDURES

Non-aqueous phase liquids (NAPL) are not typically collected from sediments. However, if NAPL samples are required, the sampling options and techniques should be discussed with the assigned company compliance professional and project manager to ensure that the NAPL is not considered to be a hazardous material for the purpose of shipping to the laboratory (SOP 3). Samples of NAPL should be collected using the same procedures as above and placed in the appropriate laboratory-supplied containers, packed on ice, and shipped to the analytical laboratory using procedures outlined in SOP 3.

## 10.5.7 SAMPLE LABELING AND PREPARATION FOR SHIPMENT

Once collected, prepare the samples for laboratory analysis:

1. Clean the outside of the sample container with paper towels or appropriate materials, if necessary
2. Affix a sample tag or label to each sample container and complete all required information (sample number, date, time, depth interval, sampler's initials, analysis, preservatives, place of collection)
3. Place clear tape over the tag or label (if non-waterproof labels are used)
4. Preserve samples immediately after collection by placing them into an insulated cooler filled with bagged wet ice to maintain a temperature of approximately 4°Celcius
5. Record the sample designation, date, time, depth interval, and the sampler's initials in the field book and on a sample tracking form, if appropriate
6. Complete the chain-of-custody forms with appropriate sampling information, including:
   - Location
   - Sample name
   - Sample collection date and time
   - Number of sample containers
   - Analytical method
7. Complete sample packing and ship in accordance with proper procedures

***Do not ship hazardous waste samples without first consulting a company compliance professional.***

## 10.5.8 SEDIMENT CLASSIFICATION

Sediment classification should be performed whenever samples are being collected to provide context for the analysis. Unless required to follow a different soil classification (e.g., US Department of Agriculture), follow the Unified Soil Classification System (USCS) logging procedures as described in ATSM D2488[1] . The emphasis of sediment classification in the field must be on describing the sediments using ALL possible descriptors; categorization of the USCS group name or symbol alone may not provide details that could later prove useful. Avoid geologic interpretation or the use of local formation names, if applicable, which are often difficult to determine in the field without the regional framework. Record ALL of the following information for each sediment type:

- Depth interval
- USCS group name (e.g., lean clay, elastic silt, well-graded gravel)
- USCS group symbol (e.g., cl, mh, gw)
- Color, using Munsell chart (in moist condition)
- Percent of cobbles or boulders, or both (approximate; by volume)
- Percent of gravel, sand, or fines, or all three (approximate; by dry weight)
- Particle-size range:
- Gravel—fine, medium, coarse
- Sand—fine, medium, coarse
- Fines – clay or silt
- For gravel and sand:
- Particle angularity: angular, subangular, subrounded, rounded
- Particle shape: (if appropriate) flat, elongated, flat and elongated
- Maximum particle size or dimension
- Hardness of coarse sand and larger particles
- For clay and silt:
- Plasticity: non-plastic, low, medium, high
- Dry strength: none, low, medium, high, very high
- Dilatancy: none, slow, rapid
- Toughness: low, medium, high
- Odor (mention only if organic or unusual; factual descriptions only, no interpretations)
- Moisture: dry, moist, wet
- Additional comments: presence of roots or root holes, presence of mica, gypsum, etc., surface coatings on coarse-grained particles, caving or sloughing of auger hole or trench sides, difficulty in augering or excavating, etc.

For intact samples also include:

- Consistency (fine-grained [clay] soils only): very soft, soft, firm, hard, very hard
- Structure: stratified, laminated, fissured, lensed, homogeneous
- Cementation: weak, moderate, strong

Use the following standard descriptors for the textural percentages:

- Trace: <5%[2]
- Few: 5-10%
- Little: 15-25%
- Some: 30-45%
- Mostly: 50-100%

[1] Note that certain states/regulatory programs may require classification under a secondary system (e.g., US Department of Agriculture) or the use of a hydrochloric acid to reaction test (none, weak, strong).

[2] The use of "Trace" for describing the fraction of clay soils is inappropriate for field-based logs as clay contents of less than 20% in fine-grained soils cannot be reliably determined in the field.

Example descriptions, using the information listed above, would read as follows:

- 8-10' – Well Graded Sand, SW (5YR 2/6) fine- to medium-grained sand, trace medium sub-angular rounded gravel (less than 0.5-inch diameter); medium dense to dense; wet; moderate petroleum-like odor between 9 feet bgs and 10 feet bgs.
- 10-12' – Lean Clay with Gravel, CL (5YR 2/6) some fine- to coarse-grained angular to subangular gravels (less than 0.25-inch diameter), trace fine- to medium-grained rounded sands; very stiff; low plasticity; low dry strength; no dilatancy; moist; no odors.

## 10.6 CLOSING NOTES

Once sampling is completed, restore and mark all sample locations with spray paint, stakes, or other appropriate marker for future reference or survey, including collecting Global Positioning System coordinates and photographs, in accordance with the project-specific work plan. Decontaminate all equipment prior to departure and properly manage all PPE and IDW in conformance with SOP 6, the project-specific work plan, and applicable regulations.

# FIELD STANDARD OPERATING PROCEDURE #11

# GROUNDWATER SAMPLING PROCEDURE

Groundwater sampling procedures outlined in this Standard Operating Procedure (SOP) are designed to ensure that collected samples are representative of current site conditions. These procedures can be applied to permanently or temporarily installed monitoring wells, direct-push sample points, water supply wells with installed plumbing, extraction wells for remedial groundwater treatment systems, and excavations where groundwater is present. The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP, proper personal protective equipment (PPE) must be selected and used appropriately.

## 11.1 ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| ID | inside diameter |
| DI | deionized |
| DNAPL | dense non-aqueous phase liquid |
| DO | dissolved oxygen |
| DTW | depth-to-water |
| HASP | health and safety plan |
| IDW | investigation-derived waste |
| l/min | liters per minute |
| LNAPL | light non-aqueous phase liquid |
| mg/l | milligrams per liter |
| mV | millivolts |
| NAPL | non-aqueous phase liquid |
| NTU | nephelometric turbidity unit |
| ORP | oxygen reduction potential |
| PID | photoionization detector |
| PPE | personal protective equipment |
| PSP | project safety plan |
| QAPP | quality assurance project plan |
| SOP | standard operating procedure |
| SU | standard units |
| TD | total depth |
| TOC | top-of-casing |
| VOCs | volatile organic compounds |

## 11.2 MATERIALS

- Field book
- PPE
- Air quality monitoring equipment (e.g., photoionization detector [PID]) with calibration reagents and standards, as needed
- Electronic water level indicator or interface probe
- Water quality meter(s) with a flow-through cell, and calibration reagents and standards, as needed
- Field test kits, as needed
- Adjustable wrench or manhole wrench, as needed
- Well key(s), as needed
- Power supply, as needed
- Sampling containers and labeling/shipping supplies
- Deionized (DI) water
- Container(s) for water storage (e.g., bucket, drum)
- Pump or bailers, tubing, and associated lanyard materials
- Filters, as needed
- Decontamination supplies

## 11.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe, consistent manner; are in accordance with federal and state guidance; and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field SOPs, and the Quality Management System.

This SOP is designed to provide the user with a general outline for conducting groundwater sampling and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), utility location (SOP 2), sample shipment procedures (SOP 3), sample collection and quality assurance procedures (SOP 4), investigation derived waste (IDW) management procedures (SOP 5), equipment decontamination (SOP 6), and use and calibration of all sampling and monitoring equipment (SOPs 7 and 8). This SOP does not cover investigation planning, nor does it cover the analysis of the analytical results. These topics are more appropriately addressed in a project-specific work plan. Before groundwater sampling, be sure to review the project-specific work plan or quality assurance project plan (QAPP) and any applicable state and federal guidelines or sampling procedures. All sampling and monitoring references must be available for consultation in the field, including:

- Company SOPs
- Applicable state and federal guidelines or sampling procedures
- Manufacturer's manuals
- Project-specific work plan, PSP and/or HASP, and QAPP

## 11.4 GENERAL PROCEDURES

Although the techniques used to sample groundwater are varied, most sampling events can be broken down into a three-step sequence:

1. Gauging: The measurement of the water column height (i.e., total well depth less depth-to-water) within the well.

2 Purging: The removal of stagnant water from the well bore to ensure that samples collected are representative of groundwater conditions in the water-bearing zone surrounding the well.
3 Sample Collection: After purging, the collection of aliquots of groundwater in method-specific, preserved (as needed) containers.

The procedures and equipment that are used to accomplish these steps are project-specific and should be discussed by the project team before arriving onsite. All types of groundwater sampling, however, regardless of the equipment used, share common handling and management procedures that are designed to ensure the integrity of the samples collected. These procedures include:

— The use of new, disposable, decontaminated, or dedicated sampling equipment
— The use and rotation of the appropriate PPE
— Selection of a suitable sampling location and staging area

Wear a clean pair of new, disposable gloves each time a different sample is collected and don the gloves immediately prior to collection. This limits the possibility of cross-contamination from accidental contact with gloves soiled during collection of the previous sample. The gloves must not contact the medium being sampled and must be changed any time during sample collection when their cleanliness is compromised. ***Gloved hands should not be used as a sampling device; always use the appropriate equipment to move the sample from the sampling device to the laboratory-supplied containers.***

## 11.5 EQUIPMENT SELECTION

Collect all samples using either new, disposable equipment or properly decontaminated sampling equipment. Groundwater purging and sampling equipment should be selected based on the analytical requirements of the project and the project-specific conditions (e.g., well diameter, depth to water, dissolved constituents, etc.) likely to be encountered. The equipment should be constructed of non-reactive, non-leachable materials (e.g., stainless steel, Teflon®, Teflon®-coated steel, polyethylene, polypropylene, etc.) that are compatible with the chemical constituents at the site. Note that project or regulatory guidance may limit the type of equipment for groundwater sampling.

Consider the following when choosing groundwater purging and sampling equipment:

— the diameter and depth of the well
— the depth to groundwater
— the volume of water to be withdrawn
— the sampling and purging technique
— the volume of sample required
— the analytes of interest

Select the decontamination procedures based on the types of sampling to be performed and media encountered; decontamination may require multiple steps or differing cleaning methods (see SOP 6 for decontamination procedures). In no case, should disposable, single-use materials be used to collect more than one sample.

## 11.6 PRE-SAMPLING CONSIDERATIONS

You should perform the following activities in preparing for sampling with all observations and measurements noted in the field book and on the project-specific groundwater monitoring log, if appropriate:

— Perform a quick reconnaissance of the site to identify sampling locations and evaluate the accessibility to the sampling location.
— Record the approximate ambient air temperature, precipitation, wind (direction and speed), tide, and other field conditions. In addition, any site-specific conditions or situations that could potentially affect the samples at the sample locations should be recorded.
— Record temporary sampling locations with respect to approximate distance to and direction from at least one permanent feature.
— Survey the breathing zone around the sampling location with the appropriate air quality meter(s), as necessary (see HASP), to ensure that the level of PPE is appropriate.
— Install the pump, tubing, passive sampler or other appropriate sampling equipment to the depth prescribed in the project-specific work plan or QAPP.

- Containerize and manage purge water in accordance with the project-specific work plan.

It is important to minimize any sources of cross-contamination that could compromise the integrity of the groundwater samples. Consider the following:

- Position fuel-powered equipment away from the sample collection area, such as drill rigs or excavators, and upwind of other site activities (e.g., purging, sampling, decontamination) that could influence the sample. This is particularly important when screening samples in the field for volatile organic compounds with a PID but should not be limited to the active sample collection.
- Establish a secure sample staging area in an uncontaminated area of the site.

## 11.7 GAUGING PROCEDURES

All wells should be opened to the atmosphere in advance of sampling to allow any pressure differentials, which could artificially raise or depress the water column in the well, to dissipate. The wells should be inspected to ensure that the protective casing is intact and has not been damaged. Remove the well covers and all standing water around the top of the well casing (for flush mounted-protective covers), as necessary, before opening the inner well cap or plug. Unlock and carefully remove well cap and allow the well to stand undisturbed for a minimum of 15 minutes, or as required by the project-specific work plan, before conducting any down-hole testing or measurements. If required by the HASP, survey the open well casing and the breathing zone around the wellhead with a PID to ensure that the level of PPE is appropriate.

### 11.7.1 GROUNDWATER LEVEL AND TOTAL DEPTH MEASUREMENT PROCEDURES

Depth to water (DTW) and total depth (TD) measurements are collected prior to sampling and are used to determine the volume water to be purged from the well (if using techniques other than no-purge or low flow sampling). The DTW measurements are also used after the field event to establish the groundwater elevation, flow direction, and gradient. Unless otherwise directed, do not place any objects inside the casing of private water wells; accordingly, DTW and TD measurements should not be collected at private water wells. Measurements of TD are not required for low flow and no-purge sampling applications and should not be measured before sampling the well.

Water level measurements must be collected within the shortest interval possible from all the wells to be gauged during the event before beginning any purge and sampling procedures at the site. This will ensure a nearly instantaneous snapshot of the water levels before the formations are disturbed by pumping or acted upon by other outside influences, such as tides, precipitation, barometric pressure, river stage, or intermittent pumping of production, irrigation, or supply wells.

Record the following observations and measurements (and the time when they were collected) in the field book:

- Measure the casing inside diameter (ID) and record in inches
- Measure the DTW with an electronic water level indicator (or an interface meter, if non-aqueous phase liquid [NAPL] is potentially present – see procedures below) from the top-of-casing (TOC) at the surveyor's mark, if present, and record the depth (to the nearest 0.01 foot) in feet below TOC
- If no mark is present, measure from the north side of the casing and mark the measuring point with a knife, metal file (if the inner casing is metal) or indelible marker for future reference
- Measure the TD from TOC at the surveyor's mark or north side of the casing, as appropriate.

Measuring the depth of deep wells with long water columns can be problematic due to tape buoyancy and weight effects or sediment in the bottom of the well casing. Care must be taken, and proper equipment selection must be used in these situations to ensure accurate measurements. Multiple TD measurements in silt-laden wells can provide a more precise assessment of the bottom depth.

### 11.7.2 GAUGING WELLS WITH NON-AQUEOUS PHASE LIQUID

If NAPL is potentially present at the site, the DTW and NAPL thickness measurements are collected using an interface meter capable of distinguishing between the NAPL and the groundwater, or a weighted tape coated with the appropriate reactive indicator paste for the suspected NAPL. Measuring NAPL thicknesses must be done with care to avoid agitating the liquids and generating an emulsion. This is particularly the case for light NAPL (LNAPL; those having a density less than water), which are typically viscous oils that

cling to the probe. Oil coating the probe can result in thickness measurements that are biased high (i.e., overestimate the thickness of the NAPL).

Conduct the following procedures to ensure an accurate measurement of the NAPL thickness:

- For LNAPL, slowly lower the electronic interface probe in the well casing until the electronic tone indicates the probe is at the top of the LNAPL layer; measure the depth below the TOC to the nearest 0.01 foot.
- To gauge the NAPL thickness, advance the probe slowly through the layer until the electronic tone indicates top of the water column and then slowly bring the probe back up to the bottom of the LNAPL. Repeat this process several times to ensure an accurate measurement of the bottom of the LNAPL layer (which can include bubbles and an emulsion layer).
- For dense NAPL (DNAPL), advance the probe through the water column until the tone indicates the top of the DNAPL layer; record the depth below TOC.
- To gauge the DNAPL thickness, advance the probe through the layer to the bottom of the well.

## 11.8 GROUNDWATER PURGING PROCEDURES

Purging is a process whereby potentially stagnant water is removed allowing the collection of samples that are representative of groundwater conditions in the water-bearing zone. The water in a well bore that has not been purged may be different than the surrounding formation due to exposure to ambient air. There are several purging (and no-purge) methods that may be used, depending on specific conditions encountered (e.g., DTW, hydraulic conductivity of the formation, etc.) and the sampling requirements. The purge/no purge options are described below.

- *Multiple Volume Purge:* Traditional well purging technique that relies on the withdrawal of the volume of the well bore and the surrounding filter pack (if present); three to five well volumes are typically removed using pumps or bailers. This methodology relies on equipment that is easy to obtain and use and is generally accepted in most states as an appropriate purging method.
- *Temporary Well Purge:* A variation of the multiple volume purge technique that often uses inertia lift pumps, peristaltic pumps, or bailers to remove water from a temporary well or discrete groundwater sampler (e.g., a groundwater profiler or direct-push screen point sampler). This is a less stringent technique that is typically done to minimize the turbidity of the samples, which can be high due to the lack of a well filter pack.
- *Private Water Well or In-Place Plumbing Purge:* A variation on the multiple volume purge technique whereby a tap or faucet is opened on a fixed water supply pipe and is allowed to remain open until the potentially stagnant water within the well casing and other components of the system (e.g., fixed piping, pressure tanks, etc.) has been removed and groundwater representative of the water-bearing zone is discharged at the tap.
- *Low Flow (Minimal Drawdown/Low Stress) Purge (and Sampling):* A modified purging technique that establishes an isolated, discrete, horizontal flow zone directly adjacent to the pump intake; this method requires the pump to be placed within a screened-interval or open borehole. Pumping rates are typically 0.1 to 0.5 liters per minute (l/min) or less to minimize the stress on the surrounding formation and reduce the geochemical alteration of the groundwater caused by pumping.
- *No-Purge/Passive Sampling Techniques:* These techniques use specialized equipment, such as trap-style samplers or permeable diffusion bags, to sample the undisturbed water column within a screened interval or open borehole. This methodology assumes that the water in the well is representative of the surrounding formation. This approach is well suited for some volatile organic compounds (VOCs), metals, and hydrophobic compounds, depending on the sampling device used.

### 11.8.1 CALCULATING ONE PURGE VOLUME

Multiple volume purging techniques require that a ***minimum*** of three well volumes of water must be removed before sample collection. The actual amount of water removed may be greater than the three volumes, depending on geochemical parameter stabilization (the field measurement of these parameters is discussed below).

Calculate the volume of water in a well or boring using the following equation:

$$\textbf{Volume (gallons)} = (\textbf{TD} - \textbf{DTW}) \times \textbf{ID}^2 \times \textbf{0.041}$$

where:

TD = total depth (feet)

DTW = depth to water (feet)

ID = inner diameter (inches)

Alternately, the volume of water in a well or boring may also be calculated by multiplying the water column height by the gallons per foot of water for the appropriate well or boring diameter:

| ID | Gallons per foot of water | Gallons per three water columns |
|---|---|---|
| 1-inch | 0.04 | 0.12 |
| 2-inch | 0.16 | 0.48 |
| 3-inch | 0.37 | 1.11 |
| 4-inch | 0.65 | 1.98 |

Calculate the total volume of the pump, associated tubing and container for in situ measurements (flow-through cell), using the following equation:

**Volume (in gallons) = P + ((0.0041)*D2*L) + fc**

where:

P = volume of pump (gallons)
D = tubing diameter (inches)
L = length of tubing (feet)
fc = volume of flow-through cell (gallons)

## 11.8.2 MULTIPLE VOLUME PURGE PROCEDURES

Begin purging at a rate that will not cause excessive turbulence and drawdown in the well; commonly less than 1 gallon per minute for a typical 2-inch diameter monitoring well. You may need to observe the water elevation after the pump is started and adjust the flow rate to minimize the amount of drawdown in the well casing. The objective is to remove the stagnant water in the casing and surrounding filter pack or open borehole allowing water from the surrounding water-bearing zone to enter the well for sampling with as little disturbance as possible. Excessive pump rates or well dewatering can result in higher turbidity, potential volatilization, and geochemical alteration of dissolved parameters.

Typically collect geochemical parameters (i.e., pH, specific conductance, dissolved oxygen [DO], oxygen-reduction potential [ORP], and temperature) at a minimum frequency of once for every well volume of water removed during the purge process. Record the measurements in the field book along with any other pertinent details, such as the visual quality of the water (e.g., color, odor, and presence of suspended particulates) and the approximate withdrawal rate (this can be estimated using a calibrated container and stopwatch). Review the geochemical measurements to ensure that readings have stabilized (after the minimum purge volume has been achieved). This is a proxy for determining that you are purging formation water rather than potentially stagnant water in the casing. Stabilization occurs when at least three consecutive measurements are within the following tolerances:

| Multiple Volume Purge Stabilization Parameters | |
|---|---|
| pH | ± 0.1 standard units (SU) |
| Specific Conductance | ± 3% |
| Temperature | ± 3% |
| Dissolved Oxygen (DO) | ± 0.2 milligrams per liter (mg/l) or 10% (flow-through cell only) |
| Turbidity | ± 10% for values greater than 10 nephelometric turbidity units (NTU) |
| Oxygen Reduction Potential (ORP) | ± 10 millivolts (mV; flow-through cell only) |

Parameter stabilization that does not occur within five well volumes may require you consult your project manager to decide whether to collect a sample or to continue purging. Wells with extremely slow recharge may also be problematic. Purging these wells, in some cases, may result in dewatering the well before the minimum purge can be completed. Allow wells or borings purged dry to recharge to a level of approximately 90% of the static (pre-purge) water elevation and proceed immediately to sample collection. If recovery exceeds 2 hours, sample as soon as sufficient sample volume is available, in accordance with applicable regulations.

### 11.8.3 LOW FLOW PURGE PROCEDURES

Low flow purging and sampling is used to obtain representative groundwater samples without removing all the water within the well. The protocol uses relatively low pumping rates (i.e., less than 0.5 l/min) to establish an isolated zone around the inlet of the pump where flow is horizontal (i.e., from the water bearing zone) rather than from the stagnant water in the well casing above and below the pump. Selection of an appropriate pump is critical to establishing the flow zone: it must be well suited for both low pumping rates and the analytes being sampled. Bailers are not appropriate for low flow sampling.

The set-up for low flow sampling includes positioning the pump at the appropriate depth within the casing such that the pump inlet is within the screened section of the well. Slowly lower the pump, where appropriate, and tubing into the water column to avoid agitating the water column; use of a lanyard is recommended (i.e., do not use the extraction tubing to lift or lower the pump). Secure the pump and/or tubing at the wellhead once the specified sampling depth has been achieved and record the depth in the field book. Avoid contacting the bottom of the well by using pre-cut tubing at the appropriate length or by lowering the pump/tubing simultaneously with an electronic water level indicator. Once the pump/tubing has been inserted and secured, allow the water levels to return to static conditions before initiating the purge.

The discharge tubing must be connected to an in-line flow-through cell equipped with a multi-parameter real-time water quality meter. The flow-through cell minimizes the exposure of the groundwater to ambient air, which can influence DO and ORP measurements.

Start the pump and maintain a steady flow rate that results in a stabilized water level (less than 0.3 feet of drawdown or as specified in the project-specific work plan). The pumping rate may need to be adjusted depending on the response of the water levels in the well. Record each adjustment made to the pumping rate and the water level measured immediately after each adjustment. Purging should not exceed 0.5 l/min.

During purging, monitor and record the flow rate and geochemical parameters at 30 seconds to 5-minute intervals (depending on the hydraulic conductivity of the aquifer, diameter of the well, and pumping rate). Stabilization occurs once the following criteria have been met over three successive measurements made at least three minutes apart:

| Low Flow Purge Stabilization Parameters | |
|---|---|
| Water Level Drawdown | <0.3 feet |
| pH | ± 0.1 SU |
| Specific Conductance | ± 3% |
| Temperature | ± 3% |
| DO | ± 0.2 mg/l or 10% (flow-through cell only) |
| Turbidity | ± 10% for values greater than 10 NTU |
| ORP | ± 10 mV (flow-through cell only) |

Record any other notable observations in the field book (e.g., groundwater color).

## 11.8.4 NO-PURGE SAMPLING TECHNIQUES

Several alternate sampling devices are available, such as equilibrated grab samplers, passive diffusion samplers, and other in situ sampling devices, that will allow sample collection without purging the well. These devices may be particularly useful for sampling low permeability geologic materials, assuming the device is made of materials compatible with the analytical parameters, meets data quality objectives, and has been properly evaluated.

No-purge grab or trap samplers are placed in the well before sampling and typically remain closed (i.e., no water is allowed into the sampler during insertion) until the sampler is activated. This allows the sampler device to equilibrate with the surrounding groundwater (to prevent adsorption to the sampler materials) and for the groundwater to recover and re-establish the natural flow after the disturbance caused by the sampler insertion into the well. Typical equilibration times depend on the well recovery rates and the type of sampler used. Samples recovered using the no-purge devices are either transferred to containers at the well head or the sampler itself is shipped to the laboratory for analysis. Examples of equilibrated grab samplers include HydraSleeve™, Snap Sampler™, and Kemmerer samplers.

Equilibration time for diffusion samplers are generally dictated by the diffusion rate through the permeable membrane and, thus, are less sensitive to changes induced within the well during deployment. Most diffusion bag samplers have a minimum equilibration time of 14 days prior to sample collection. The samplers may be deployed for an extended period (e.g., three months or longer), although the continuous exchange between the sampler and the well water means that the sampler will likely reflect only the conditions in the few days preceding the sample collection.

## 11.8.5 TEMPORARY WELL PURGE PROCEDURES

Procedures used to purge temporary groundwater monitoring wells differ from permanent wells because temporary wells are installed for immediate sample acquisition. Wells of this type may include open bedrock boreholes, standard polyvinyl chloride well screen and riser placed in open boreholes, or drilling rod-based sampling devices (e.g., Wellpoint®, Geoprobe® screen point or Hydropunch® samplers). Purging temporary wells of this type may not be necessary because stagnant water is typically not present. However, if water is used in the drilling process, purging would be necessary. Purging can minimize the turbidity in the sample, which can be significant due to the disturbance caused by the sampler installation and to rinse the sampling system with groundwater. The exception is for groundwater profiling applications (e.g., using a Waterloo Profiler®) where a more rigorous purge is used (using the multiple volume purge techniques described above) to limit the potential for cross-contamination between sample intervals.

## 11.8.6 PRIVATE WATER WELL OR IN-PLACE PLUMBING PURGE PROCEDURES

The configuration and construction of private water wells varies widely and access points for obtaining groundwater samples may be limited. WSP personnel should coordinate with the property owner or site representative to access functioning ports and valves to avoid causing any inadvertent damage.

Collect the groundwater sample as close to the well as possible (e.g., from a sample port at the well head) to ensure the sample is representative. Ideally, the sample should be collected upstream of the piping and treatment equipment (e.g., particulate filter, water softener, carbon filters, ultra-violet lights), heating unit, or storage tanks. The following potential sampling locations are presented in order of preference:

- Sampling port or spigot near the well head or piping system prior to entry into the storage tank
- Sampling port or spigot at storage tank
- Sampling port or spigot downstream of the pressure tank or holding tank but upstream of any water treatment equipment
- Tap or faucet

If purging from a tap or faucet, try to remove any aerators, filters, or other devices from the tap before purging and work with the property owner or site representative to bypass any water treatment systems. Document where the sample was collected and any steps that were taken to minimize the potential alteration of the water sample in the field book.

Purge the system by opening the tap or spigot and allowing the water to run for several minutes. Observe and record the purge rate for the system. The minimum purge volume must be more than the combined volume of the pump, tanks, piping, etc. Review the geochemical measurements (after the minimum purge volume has been removed) to ensure that readings have stabilized using the same procedures as those used for the multiple volume purge detailed above. Purge the system for a minimum of 15 minutes if the minimum volume is unknown. Sample only after the geochemistry parameters have stabilized and no there are no suspended particles (e.g., iron or rust) visible. Record the final purge volume in the field book and any water quality observations.

## 11.9 GROUNDWATER SAMPLE COLLECTION PROCEDURES

Collect groundwater samples as soon as possible after the geochemical parameters indicate representative groundwater is present. As practically possible, reduce the pump flow rate, but maintain a flow rate high enough to deliver a smooth stream of water without splashing or undue agitation. Collect samples directly from the tubing as it exits the well bore; do not sample on the downstream side of flow-through cells or any other instrumentation. If using a bailer for sample collection, lower and raise the bailer slowly and smoothly to minimize the disturbance to the water within the well.

Collect groundwater samples in order of volatilization sensitivity with organic compounds sampled first followed by inorganic compounds:

- VOCs
- Extractable organics, petroleum hydrocarbons, aggregate organics, and oil and grease
- Per- and Polyfluoroalkyl substances
- Total metals
- Dissolved metals (see filtering procedures below)
- Inorganic non-metallic and physical and aggregate properties
- Microbiological samples
- Radionuclides

Collect quality assurance/quality control samples in accordance with SOP 4 and the project-specific work plan or QAPP.

As necessary, conduct field tests or screening in accordance with the project-specific work plan and manufacturer's specifications for field testing equipment. Field samples must be directly transferred from the sampling equipment to the container that has been specifically prepared for that given parameter; intermediate containers should be avoided. If field chemical preservation is required, check the pH preservation by pouring a small portion of sample onto a pH test strip Adjust pH with additional preservative, if necessary.

Record the sample depth interval, if applicable, in the field book. Note the volume, phases, odor, and color of the groundwater.

### 11.9.1 GROUNDWATER FILTRATION PROCEDURES

Filtered groundwater samples are sometimes used for field kit analyses and should only be collected for laboratory analysis after approval from the appropriate regulatory agency or project manager. The filtered samples can be collected by attaching the in-line filter directly to the outlet tubing for a pressurized bailer, a submersible pump or a peristaltic pump. Intermediate containers can be used with a peristaltic pump if the well is too deep to use the pump to recover the sample directly. The intermediate container should be unpreserved laboratory-supplied glassware to avoid any cross-contamination during the filtering process.

Filtered samples using pumps should use the following procedures:

- Use a variable speed peristaltic pump with the in-line filter fitted on the outlet end of the tubing and the pump inlet tubing into the intermediate container holding the unpreserved groundwater sample; or,
- If a submersible pump is used to collect the groundwater sample, attached the in-line filter to the outlet end of the tubing (do not allow the groundwater to pass through flow-through cells or any other instrumentation while sampling)

Once the filter is connected:

- Turn on the pump and maintain a flow rate high enough to deliver a smooth stream of water without splashing or undue agitation. Hold the filter upright with the inlet and outlet in the vertical position and pump groundwater through the filter until all atmospheric oxygen has been removed and the minimum volume of water has been flushed through the filter, in accordance with the manufacturer's specifications
- Collect the filtered samples by placing the filtered output directly into the sample container
- If sediment is visible in the sample container after filtration, filter break-through has occurred and the sampling and filtering process should be repeated
- Discard the tubing and filter appropriately

Record sample filtration in the field book.

### 11.9.2 NON-AQUEOUS PHASE LIQUID SAMPLING PROCEDURES

Non-aqueous phase liquid is typically sampled to identify the compound, usually through an analytical "fingerprint" analysis. If samples are to be collected, the sampling options and techniques should be discussed with the assigned WSP compliance professional and project manager to ensure that the NAPL is either not considered to be a hazardous material for shipping to the laboratory or is properly shipped by qualified personnel using appropriate shipping containers (SOP 3). Samples of NAPL should be collected using the same procedures as above and placed in the appropriate laboratory-supplied containers, packed on ice, and shipped to the analytical laboratory using procedures outlined in SOP 3.

### 11.9.3 SAMPLE LABELING AND PREPARATION FOR SHIPMENT

Groundwater samples for offsite laboratory analysis should be prepared as follows:

1. Clean the outside of the sample container, if necessary
2. Affix a sample tag or label to each sample container and complete all required information (sample number, date, time, sampler's initials, analysis, preservatives, place of collection)
3. Place clear tape over the tag or label (if non-waterproof labels are used), as needed
4. If needed, preserve samples immediately after collection by placing them into an insulated cooler filled with bagged wet ice to maintain a temperature of approximately 4°Celcius
5. Record the sample designation, date, time, and the sampler's initials in the field book and on a sample tracking form, if appropriate
6. Complete the chain-of-custody forms with appropriate sampling information, including:
   - location
   - sample name
   - sample collection date and time
   - number of sample containers

- analytical method
- field filtration status

7 Secure the sample packing and shipping in accordance with proper procedures

***Do not ship hazardous waste samples without first consulting a WSP compliance professional.***

## 11.10 CLOSING NOTES

Secure and restore the site once sampling is completed. This may include locking permanent monitoring wells, staging the IDW, and disposing of (in conformance with applicable regulations) sampling expendables, such as plastic sheeting, tubing, and PPE. All locations where temporary wells or other sampling devices (e.g., profilers or direct-push equipment) should be marked with spray paint, stakes, or other appropriate method for future reference or survey, including collecting Global Positioning System coordinates and photographs, in accordance with the project-specific work plan. Decontaminate all equipment prior to departure and properly manage all PPE and investigation-derived wastes in conformance with SOP 6, the project-specific work plan, and applicable regulations.

# FIELD STANDARD OPERATING PROCEDURE #12

# SURFACE WATER SAMPLING PROCEDURE

Surface water sampling procedures outlined in this Standard Operating Procedure (SOP) are designed to ensure that surface water samples are representative of the water body from which they were collected and that they have not been altered or contaminated by the sampling and handling methods. Potential surface water sample locations include freshwater and marine environments such as streams, rivers, ponds, lakes, canals, ditches, wetlands, lagoons, and estuaries. Surface water samples are collected for onsite screening or for offsite laboratory analysis. The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP or PSP, proper personal protective equipment (PPE) must be selected and used appropriately.

## 12.1 ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| HASP | health and safety plan |
| IDW | investigation derived waste |
| NAPL | non-aqueous phase liquid |
| PPE | personal protective equipment |
| PSP | project safety plan |
| QAPP | quality assurance project plan |
| SOP | standard operating procedure |

## 12.2 MATERIALS

- Field book
- PPE
- Air quality monitoring equipment (e.g., photoionization detector [PID]) with calibration reagents and standards, as needed
- Electronic water level indicator or interface probe
- Water quality meter(s) with calibration reagents and standards, as needed
- Field test kits, as needed
- Power supply, as needed
- Sampling containers and labeling/shipping supplies
- Hip-waders or rubber boots, as needed
- Personal flotation device, as needed
- Expanding ruler or tape measure
- Surface sampler (e.g., dipper, pump, bailer, composite sampler)
- Tubing, as needed
- Lanyard materials (e.g., nylon rope, steel cable), as needed
- Filters, as needed
- Decontamination supplies

## 12.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel

and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company's SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field SOPs, and the Quality Management System.

This SOP is designed to provide the user with a general outline for conducting groundwater sampling and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), sample shipment procedures (SOP 3), sample collection and quality assurance procedures (SOP 4), investigation derived waste (IDW) management procedures (SOP 5), equipment decontamination (SOP 6), and use and calibration of all sampling and monitoring equipment (SOPs 7 and 8). This SOP does not cover investigation planning, nor does it cover the analysis of the analytical results. These topics are more appropriately addressed in a project-specific work plan. Before sampling, be sure to review the project-specific work plan or Quality Assurance Project Plan (QAPP) and any applicable state and federal guidelines or sampling procedures.

All sampling and monitoring references must be available for consultation in the field, including:

- Company SOPs
- Applicable state and federal guidelines or sampling procedures
- Manufacturer's manuals
- Project-specific work plan, PSP and/or HASP, and QAPP

## 12.4 GENERAL PROCEDURES

Although the sampling equipment and techniques used to sample surface water are varied, most sampling can be broken down into a two-step sequence:

1. Gauging: provides an indication of the surface water elevation
2. Sample Collection: collection of aliquots in method-specific, preserved (as needed) containers that are representative of the conditions in the surface water body

Be aware that stagnant and moving water bodies may require varying the sampling order and could also require concurrent monitoring and recording of geochemical parameters to assist with identifying a sample interval. Follow your project-specific work plan to accommodate any variances in sampling order.

The procedures and equipment that are used to accomplish these steps are project-specific and should be discussed by the project team before arriving onsite. All types of surface water sampling, regardless of the equipment used, share common handling and management procedures that are designed to ensure the integrity of the samples collected. These procedures include:

- The use of new, disposable or decontaminated sampling equipment
- The use, changing, and disposal of the appropriate PPE
- Selection of a suitable sampling location and staging area

Wear a clean pair of new, disposable gloves each time a different sample is collected and don the gloves immediately prior to collection. This limits the possibility of cross-contamination from accidental contact with gloves soiled during collection of the previous sample. The gloves must not contact the medium being sampled and must be changed any time during sample collection when their cleanliness is compromised. ***Gloved hands should not be used as a sampling device; always use the appropriate equipment to move the sample from the sampling device to the laboratory-supplied containers.***

## 12.4.1 EQUIPMENT SELECTION

Collect all samples using either new, disposable equipment, or properly decontaminated sampling equipment. Surface water gauging and sampling equipment should be selected based on the analytical requirements of the project and the project-specific conditions (e.g., water body depth, sample volume, chemical constituents in sample water, etc.) likely to be encountered. The equipment should be constructed of non-reactive, non-leachable materials (e.g., stainless steel, Teflon®, Teflon®-coated steel, polyethylene, polypropylene, etc.). Extension rods or other appropriate devices can be used, as necessary, to allow the sample to be collected from a distance (or through deeper water) to minimize the safety risk to the sampler. Note that project or regulatory guidance may limit the type of equipment for sampling.

Consider the following when choosing sampling equipment:

- the type and location of the surface water
- the required depth of the sample
- the volume of sample required
- the analytes of interest

Select the decontamination procedures based on the types of sampling to be performed and decontamination may require multiple steps or differing cleaning methods, depending on the sampling goals (see SOP 6 for decontamination procedures). In no case should disposable, single use materials be used to collect more than one sample.

## 12.4.2 PRE-SAMPLING CONSIDERATIONS

You should perform the following activities in preparing for sampling with all observations and measurements noted in the field book and on the project-specific groundwater monitoring log, if appropriate:

- Perform a quick reconnaissance of the site to identify sampling locations. Note that project or regulatory guidance may limit the type of equipment for surface water sampling.
- Record the approximate ambient air temperature, precipitation, wind (direction and speed), tide, and other field conditions. In addition, any site-specific conditions or situations that could potentially affect the samples at the sample locations should be recorded.
- Describe the sampling location including the width of the surface water, depth of surface water, water color and clarity (transparency), and approximate surface flow (e.g., slow, fast moving, etc.).
- Record sampling locations with respect to approximate distance to and direction from at least one permanent feature.
- Survey the breathing zone around the sampling location with the appropriate air quality meter(s), as necessary (see HASP), to ensure that the level of PPE is appropriate.

When sampling surface water, it is important to find a suitable sampling location away from any sources of cross-contamination that could compromise the integrity of the samples. Consider the following:

- Position the sample collection area away from fuel-powered equipment, such as drill rigs or excavators, and upwind of other site activities (e.g., purging, sampling, decontamination) that could influence the sample. This is particularly important when screening samples in the field for volatile organic compounds, but should not be limited to the active sample collection.
- If sediment samples are being collected concurrently, collect the surface water samples first to avoid disturbing the bottom and suspending sediment in the water column.
- Avoid wading into surface water, if possible, to avoid sediment suspension and potential cross-contamination.
- If collecting several surface water samples from a stream or river, start sampling at the downstream location and progressively move upstream.
- If using watercraft, orient the watercraft so that the bow is positioned in the upstream direction; collect samples near the bow, away and upwind from any fuel-powered equipment.
- Establish a secure sample staging area in an uncontaminated area of the site.

### 12.4.3 SAFETY CONSIDERATIONS

Surface water sampling presents a number of unique safety challenges. All water bodies, particularly those with moving water, are inherently dangerous and must be approached with caution. Steep embankments, loose footing, and the potential presence of subsurface hazards (or dangerous plants or wildlife, for some parts of the country) can lead to serious injury or even death.

A minimum of two people must be present during collection and samplers must use appropriate safety equipment (as outlined in the project HASP), such as insulated waders, snake chaps, and flotation devices. If possible, avoid wading into surface water. Be aware of recent weather conditions, tidal changes, or other events (e.g., a dam release), which may result in unexpectedly higher water or flow conditions (or temperature changes) at different times of the year. Do not bodily enter pipes, such as storm sewers or other drainage conveyances during surface water collection as these may be considered confined spaces.

## 12.5 SURFACE WATER LEVEL MEASUREMENT PROCEDURES

Surface water level measurements are typically collected prior to surface water sampling and are used after the sampling event is completed to establish surface water elevation, discharge, and groundwater/surface water interaction (e.g., gaining or losing stream, flow direction).

Surface water level measurements **MUST** be collected within the shortest interval possible from **all selected existing stream gauges or established measuring points** during the event. If groundwater level measurements are to be collected, gauging should be performed concurrently in accordance with SOP 11. This will ensure a nearly instantaneous snapshot of the water levels before the water body is acted upon by other outside influences, such as tides, precipitation, barometric pressure, river stage, or intermittent pumping of nearby production, irrigation, or supply wells.

Measure the surface water level on the stream gauge or depth to water and total depth from an established measuring point (e.g., bridge) with an electronic water level tape or appropriate equipment and record observations and measurements in the field book. If non-aqueous phase liquids (NAPL) are present on the surface water body, measure the NAPL thickness using the stream gauge (or other appropriate equipment) and record observations and measurements in the field book.

## 12.6 SURFACE WATER SAMPLE COLLECTION PROCEDURES

Collect surface water samples using the appropriate sampling vessel in accordance with the project-specific work plan. Slowly lower the method-specific sampling vessel (e.g., dippers, sampling container, etc.) into the surface water to the desired sampling depth; Kemmerer, Niskin, Van Dorn, or similar samplers, pumps equipped with tubing, or double check valve bailers can be used to collect samples 12 inches or deeper below the water surface. Allow surface water to slowly enter the sampling vessel until the necessary sample volume has been collected. Once filled, slowly retrieve the sampling vessel and transfer the surface water directly to the sample containers. As applicable, retrieve the sampler at a slightly tilted angle in the upstream direction to minimize the disturbance. If necessary, collect additional surface water to provide sufficient sample volume. Field samples must be directly transferred from the sampling equipment to the container that has been specifically prepared for that given parameter; intermediate containers should be avoided.

Automatic composite samplers are frequently deployed at sites needing long-term surface water sampling. In some sampling situations, automatic composite samplers are permanently installed at surface water stations and remain in the field for months or even years.

Collect surface water samples in order of volatilization sensitivity with organic compounds sampled first followed by inorganic compounds:

- Volatile organic compounds
- Extractable organics, petroleum hydrocarbons, aggregate organics, and oil and grease
- Per- and Polyfluoroalkyl substances
- Total metals

- Dissolved metals (see filtering procedures below)
- Inorganic non-metallic and physical and aggregate properties
- Microbiological samples
- Radionuclides

Water quality parameters (e.g.,temperature, depth, dissolved oxygen, pH, total dissolved solids, specific conductance, turbidity, salinity, oxidation reduction potential, and others) are typically measured in the field as specified in the project planning documents. Collect quality assurance/quality control samples in accordance with SOP 4 and the project-specific work plan or QAPP.

As necessary, conduct field tests or screening in accordance with the project-specific work plan and manufacturer's specifications for field testing equipment. Field samples must be directly transferred from the sampling equipment to the container that has been specifically prepared for that given parameter; intermediate containers should be avoided. If field chemical preservation is required, check the pH preservation by pouring a small portion of sample onto a pH test strip. Adjust pH with additional preservative, if necessary.

Record the depth interval, if applicable, which the sample was collected in the field book. Note the volume, phases, and color of the surface water in the field book.

## 12.6.1 SURFACE WATER FILTRATION PROCEDURES

Filtered surface water samples are sometimes used for field kit analyses and should only be collected for laboratory analysis after approval from the appropriate regulatory agency and/or project manager. If surface water sample filtration is necessary, the following procedures should be followed:

Filtered samples using pumps should use the following procedures:

- Use a variable speed peristaltic pump with the in-line filter fitted on the outlet end; pressurized bailers or submersible pumps can also be used if sampling the surface water body directly.
- Insert the pump inlet tubing into the intermediate container holding the unpreserved surface water sample or surface water body.

Once the filter is connected:

- Turn on the pump and reduce the flow rate, but maintain a flow rate high enough to deliver a smooth stream of water without splashing or undue agitation, hold the filter upright with the inlet and outlet in the vertical position and pump surface water through the filter until the minimum volume of water has been flushed through the filter, in accordance with the manufacturer's specifications.
- Collect the filtered samples directly into the sample container from the pump-filter assembly.
- If sediment is visible in the sample container after filtration, filter break-through has occurred and the sampling and filtering process should be repeated; the sediment-containing sample should be discarded appropriately.
- Discard the tubing and filter appropriately.
- Record sample filtration in the field book.

## 12.6.2 NAPL SAMPLING PROCEDURES

NAPL samples are not typically collected from surface water. If samples are to be collected, sampling options and techniques should be discussed with the assigned project compliance professional and project manager; ensure that the NAPL is not considered to be a hazardous material for the purpose of shipping to the laboratory (SOP 3). Samples of NAPL should be placed in the appropriate laboratory-supplied containers, packed on ice, and shipped to the analytical laboratory using procedures outlined in SOP 3.

## 12.6.3 SAMPLE LABELING AND PREPARATION FOR SHIPMENT

Samples for offsite laboratory analysis should be prepared as follows:

1. Clean the outside of the sample container, if necessary

2. Affix a sample tag or label to each sample container and complete all required information (sample number, date, time, sampler's initials, analysis, preservatives, place of collection)
3. Place clear tape over the tag or label (if non-waterproof labels are used)
4. If needed, preserve samples immediately after collection by placing them into an insulated cooler filled with bagged wet ice to maintain a temperature of approximately 4°Celcius
5. Record the sample designation, date, time, and the sampler's initials in the field book and on a sample tracking form, if appropriate
6. Complete the chain-of-custody forms with appropriate sampling information, including:
   - location
   - sample name
   - sample collection date and time
   - number of sample containers
   - analytical method
   - field filtration status
7. Secure the sample packing and shipping in accordance with proper procedures

***Do not ship hazardous waste samples without first consulting a WSP compliance professional.***

## 12.7 CLOSING NOTES

Once sampling is completed, secure the locations in accordance with the project-specific project work plan. Mark all sample locations with stakes or other appropriate markers for future reference or survey, including collecting Global Positioning System coordinates and photographs, in accordance with the project-specific work plan. Decontaminate all equipment prior to departure and properly manage all PPE and IDW in conformance with SOP 6, the project-specific work plan, and applicable regulations.

# 1 General Information

## 1.1 Purpose

This document describes general and specific procedures, methods and considerations to be used and observed when designing and installing permanent and temporary groundwater monitoring wells to be used for collection of groundwater samples.

## 1.2 Scope/Application

The procedures contained in this document are to be used by field personnel when designing, constructing and installing groundwater monitoring wells. On the occasion that SESD field personnel determine that any of the procedures described in this section are either inappropriate, inadequate or impractical and that another procedure must be used for any aspect of the design, construction and/or installation of a groundwater monitoring well, the variant procedure will be documented in the field log book, along with a description of the circumstances requiring its use. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

## 1.3 Documentation/Verification

This procedure was prepared by persons deemed technically competent by SESD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the SESD local area network (LAN). The Document Control Coordinator is responsible for ensuring the most recent version of the procedure is placed on the LAN and for maintaining records of review conducted prior to its issuance.

## 1.5 General Precautions

### *1.5.1 Safety*

Proper safety precautions must be observed when constructing and installing groundwater monitoring wells. Refer to the SESD Safety, Health and Environmental Management Program Procedures and Policy (SHEMP) Manual (Most Recent Version) and any pertinent site-specific Health and Safety Plans (HASPs) for guidelines on safety precautions. These guidelines should be used to complement the judgment of an experienced professional. When using this procedure, minimize exposure to potential health hazards through the use of protective clothing, eye wear and gloves. Address chemicals that pose specific toxicity or safety concerns and follow any other relevant requirements, as appropriate. Section 2.6, Safety Procedures for Drilling Activities, contains detailed and specific safety guidelines that must be followed by Branch personnel when conducting activities related to monitoring well construction and installation.

### *1.5.2 Procedural Precautions*

The following precautions should be considered when constructing and installing groundwater monitoring wells.

- Special care must be taken to minimize or prevent inadvertent cross-contamination between borehole locations. Equipment, tools and well materials must be cleaned and/or decontaminated according to procedures found in SESD Operating Procedure for Field Equipment Cleaning and Decontamination (SESDPROC-205).
- All field activities are documented in a bound logbook according to the procedures found in SESD Operating Procedure for Logbooks (SESDPROC-010).

# 2 Permanent Monitoring Well Design Considerations

## 2.1 General

The design and installation of permanent monitoring wells involves drilling into various types of geologic formations that exhibit varying subsurface conditions. Designing and installing permanent monitoring wells in these geologic environments may require several different drilling methods and installation procedures. The selection of drilling methods and installation procedures should be based on field data collected during a hydrogeologic site investigation and/or a search of existing data. Each permanent monitoring well should be designed and installed to function properly throughout the duration of the monitoring program. When designing monitoring wells, the following should be considered:

- Short-and long-term objectives;
- Purpose of the well(s);
- Probable duration of the monitoring program;
- Contaminants likely to be monitored;
- Surface and subsurface geologic conditions;
- Properties of the aquifer(s) to be monitored;
- Well screen placement;
- General site conditions; and
- Potential site health and safety hazards.

In designing permanent monitoring wells, the most reliable, obtainable data should be utilized. Once the data have been assembled and the well design(s) completed, a drilling method(s) must be selected. The preferred drilling methods for installing monitoring wells are those that temporarily case the borehole during drilling and the construction of the well, e.g. hollow-stem augers and sonic methods. However, site conditions or project criteria may not allow using these methods. When this occurs, alternate methods should be selected that will achieve the project objectives. The following discussion of methods and procedures for designing and installing monitoring wells will cover the different aspects of selecting materials and methods, drilling boreholes, and installing monitoring devices.

## 2.2 Drilling Methods

The following drilling methods may be used to install environmental monitoring wells or collect samples under various subsurface conditions. In all cases the preferred methods are those that case the hole during drilling, i.e. Hollow Stem Augers (HSA) and sonic methods using an override system. Other methods may be used where specific subsurface or project criteria dictate.

### *2.2.1 Hollow Stem Auger (HSA)*

This type of auger consists of a hollow, steel stem or shaft with a continuous, spiraled steel flight, welded onto the exterior. A hollow auger bit, generally with

carbide teeth, disturbs soil material when rotated, whereupon the spiral flights transport the cuttings to the surface. This method is best suited in soils that have a tendency to collapse when disturbed. A monitoring well can be installed inside of hollow-stem augers with little or no concern for the caving potential of the soils. If caving sands exist during monitoring well installations, a drilling rig must be used that has enough power to extract the augers from the borehole without having to rotate them. A bottom plug, trap door, or pilot bit assembly can be used at the bottom of the augers to keep out most of the soils and/or water that have a tendency to enter the bottom of the augers during drilling. Potable water (analyzed for contaminants of concern) may be poured into the augers during drilling to equalize pressure so that the inflow of formation materials will be held to a minimum. Water-tight center bits are not acceptable because they create suction when extracted from the augers. This suction forces or pulls cuttings and formation materials into the augers, defeating the purpose of the center plug. Augering without a center plug or pilot bit assembly is permitted, provided that the soil plug, formed in the bottom of the augers, is removed before sampling or installing well casings. Removing the soil plug from the augers can be accomplished by drilling and washing out the plug using a rotary bit, or augering out the plug with a solid-stem auger bit sized to fit inside the hollow-stem auger. Bottom plugs can be used where no soil sampling is conducted during the drilling process. The bottom plug is wedged into the bottom of the auger bit and is knocked out at depth with drill pipe or the weight of the casing and screen assembly. The plug material should be compatible with the screen and casing materials. The use of wood bottom plugs is not acceptable. The type of bottom plug, trap door, or pilot bit assembly proposed for the drilling activity should be approved by a senior field geologist prior to drilling operations. Boreholes can be augered to depths of 150 feet or more (depending on the auger size), but generally boreholes are augered to depths less than 100 feet.

### *2.2.2 Solid Stem Auger*

This type of auger consists of a sealed hollow or solid stem or shaft with a continuous spiraled steel flight welded on the outside of the stem. An auger bit connected to the bottom disturbs soil material when rotated and the helical flights transport cuttings to the surface. At the desired depth the entire auger string is removed to gain access to the bottom of the borehole. This auger method is used in cohesive and semi-cohesive soils that do not have a tendency to collapse when disturbed. Boreholes can be augered to depths of 200 feet or more (depending on the auger size), but generally boreholes are augered to depths less than 100 feet.

Both of the previously discussed auger methods can be used in unconsolidated soils and semi-consolidated (weathered rock) soils, but not in competent rock. Each method can be employed without introducing foreign materials into the borehole such as water and drilling fluids, minimizing the potential for cross contamination. Minimizing the risk of cross contamination is one of the most important factors to consider when selecting the appropriate drilling method(s) for a project.

### *2.2.3 Sonic Methods*

These methods generally alternately advance concentric hollow drill stems using rotation in conjunction with axial vibration of the drill stem. After each stage of drill stem advancement, the inner string is removed with a core of drill cuttings while the outer 'override' string remains to hold the borehole open. The cuttings can be removed nearly intact from the inner casing for examination of the stratigraphy prior to sampling or disposal. Because there are no auger flights to increase the borehole diameter, the quantity of cuttings removed from the hole is minimized as compared to hollow stem augering. With moderate rotation, smearing of the formation materials on the borehole walls is reduced as well. This drilling method is useful in a variety of materials, from flowing sands to heavily consolidated or indurated formations.

In flowing sands, the drill casings can be filled and/or pressurized with potable water to prevent excess entry of formation materials into the drill string. The same QA/QC requirements for sampling of material introduced to the borehole apply as in other drilling methods. Because the amount of water introduced into the borehole can be significant, an approximation of the water used in the drilling process should be logged for use in estimating appropriate well development withdrawal.

Sonic drilling allows a larger diameter temporary casing to be set into a confining layer while drilling proceeds into deeper aquifers. This temporary casing is then removed during the grouting operation. In many cases this will be acceptable technique. However, the level of contamination in the upper aquifer, the importance of the lower aquifers for drinking water uses, the permeability and continuity of the confining layer, and state regulations should be taken into account when specifying this practice as opposed to permanent outer casing placed into the confining unit. Note that when using the temporary casing practice, it is critical that grout be mixed and placed properly as specified elsewhere in this section.

Because the total borehole diameter in sonic drilling is only incrementally larger than the inner casing diameter, particular care should be taken that the well casing is placed in the center of the drill stem while placing the filter pack. Centralizers should be used in most cases to facilitate centering, particularly in the case of deep wells with PVC casing.

### *2.2.4 Rotary Methods*

These methods consist of a drill pipe or drill stem coupled to a drilling bit that rotates and cuts through the soils. The cuttings produced from the rotation of the drilling bit are transported to the surface by drilling fluids which generally consist of water, drilling mud, or air. The water, drilling mud, or air are forced down through the drill pipe, and out through the bottom of the drilling bit. The cuttings

are then lifted to the surface between the borehole wall and the drill pipe, (or within a concentric drill stem in reverse rotary). Except in the case of air rotary, the drilling fluid provides a hydrostatic pressure that reduces or prevents borehole collapse. When considering this method, it is important to evaluate the potential for contamination when fluids and/or air are introduced into the borehole.

Due to the introduction of the various circulating fluids, the use of rotary methods requires that the potential for contamination by these fluids be evaluated. Water and mud rotary methods present the possibility of trace contamination of halogenated compounds when municipal water supplies are used as a potable water source. Air rotary drilling can introduce contamination through the use of lubricants or entrained material in the air stream. Unless contaminated formations are cased off, the circulation of drilling fluids presents a danger of cross contamination between formations. In any of the rotary (or sonic) methods, care must be exercised in the selection and use of compounds to prevent galling of drill stem threads.

#### 2.2.4.1 Water Rotary

When using water rotary, potable water (that has been analyzed for contaminants of concern) should be used. If potable water (or a higher-quality water) is not available on-site, then potable water will have to be transported to the site or an alternative drilling method will have to be selected. Water does not clog the formation materials, but the suspended drilling fines can be carried into the formation, resulting in a very difficult to develop well. This method is most appropriate for setting isolation casing.

#### 2.2.4.2 Air Rotary

Air rotary drilling uses air as a drilling fluid to entrain cuttings and carry them to the surface. High air velocities, and consequently large air volumes and compressor horsepower are required. "Down-the-hole" (DTH) percussion hammers driven by the air stream can be used with this method to rapidly penetrate bedrock materials. Where a casing through unconsolidated material is required to prevent borehole collapse, it can be driven in conjunction with advancement of the drill stem.

When using air rotary drilling in any zone of potential contamination, the cuttings exiting the borehole must be controlled. This can be done using the dual-tube reverse circulation method where cuttings are carried to the surface inside dual-wall drill pipe and separated with a cyclone separator. An air diverter with hose or pipe carrying cuttings to a waste container is also an acceptable alternative. Allowing cuttings to blow uncontrolled from the borehole is not acceptable.

When using air rotary, the issue of contaminants being introduced into the borehole by the air stream must be addressed. Screw compressor systems

should have a coalescing filter system in good working order to capture excess entrained compressor oils. The lubricant to be used with DTH hammers as well as thread lubricants to be used on drill stem should be evaluated for their potential impact on analytical samples.

#### 2.2.4.3 Mud Rotary

Mud rotary is an undesirable drilling method because contamination can be introduced into the borehole from the constituents in the drilling mud, cross contamination can occur along the borehole column, and it is difficult to remove the drilling mud from the borehole after drilling and during well development. The drilling mud can also carry contaminates from a contaminated zone to an uncontaminated zone thereby cross-contaminating the borehole. If mud rotary is selected, only potable water and pure (no additives) bentonite drilling muds should be used. All materials used should have adequate documentation as to manufacturer's recommendations and product constituents. QA/QC samples of drilling muds and potable water should be sampled at a point of discharge from the circulation system to assure that pumps and piping systems are not contributing cross-contamination from previous use.

### *2.2.5 Direct Push Technology*

Direct Push Technology (DPT) uses hollow drive rods either driven percussively or by large forces from a rig weighted or anchored to the ground. Percussive rigs are used for general soil and groundwater investigations and the push only rigs are generally used for cone penetrometer testing (CPT). DPT does not bring cuttings to the surface but instead compresses them into the borehole walls. A variety of tool systems are available to perform soil sampling, groundwater sampling, well installation, and to profile contamination with in situ systems. The light tooling, small crews required, and reduced IDW can make DPT operations an economical investigation tool. Although significant depths have been explored with DPT, investigations are generally limited to 100 ft (and more practically 50 ft.) in unconsolidated materials.

### *2.2.6 Other Methods*

Other methods such as the cable-tool method, jetting method, and boring (bucket auger) method are available. If these and/or other methods are selected for monitoring well installations, they should be approved by a senior field geologist before field work is initiated.

## 2.3 Borehole Construction

### *2.3.1 Annular Space*

The borehole or hollow stem auger should be of sufficient diameter so that well construction can proceed without major difficulties. For open boreholes, the annular space should be approximately 2" to allow the uniform deposition of well materials around the screen and riser, and to allow the passage of tremie pipes and well materials without unduly disturbing the borehole wall. For example, a 2" nominal diameter (nom.) casing would require a 6" inside diameter (ID) borehole.

In hollow stem augers and sonic method drill casing, the ID should be of sufficient size to allow the passage of the tremie pipe to be used for well grout placement, as well as free passage of filter sands or bentonite pellets dropped through the auger or casing. In general, 4-1/4" ID should be the minimum size used for placement of 2" nom. casing and 8-1/4" ID for 4" nom. casing. Larger augers should be used where installation difficulties due to geologic conditions or greater depths are anticipated, e.g. larger augers might be required to place a bentonite pellet seal through a long water column.

### *2.3.2 Over-drilling the Borehole*

Sometimes it is necessary to over-drill the borehole in anticipation of material entering the augers during center bit removal or knocking out of the bottom plug. Normally, 3 to 5 feet is sufficient for over-drilling. The borehole can also be over-drilled to allow for an extra space or a "sump" area below the well screen. This "sump" area provides a space to attach a 5 or 10 foot section of well casing to the bottom of the well screen. The extra space or "sump" below the well screen serves as a catch basin or storage area for sediment that flows into the well and drops out of suspension. These "sumps" are added to the well screens when the wells are screened in aquifers that are naturally turbid and will not yield clear formation water (free of visible sediment) even after extensive development. The sediment can then be periodically pumped out of the "sump" preventing the well screen from clogging or "silting up". If the borehole is inadvertently drilled deeper than desired, it can be backfilled to the design depth with bentonite pellets, chips, or the filter sand that is to be used for the filter pack.

### *2.3.3 Filter Pack Placement*

When placing the filter pack into the borehole, a minimum of 6-inches of the filter pack material should be placed under the bottom of the well screen to provide a firm base. Also, the filter pack should extend a minimum of 2-feet above the top of the well screen to allow for settling and to isolate the screened interval from the grouting material. In open boreholes, the filter pack should be placed by the tremie or positive displacement method. Placing the filter pack by pouring the sand into

an open drill stem is acceptable with the use hollow stem augers, and other methods where the borehole is temporarily cased down to the filter pack.

### *2.3.4 Filter Pack Seal – Bentonite Pellet Seal (Plug)*

Bentonite pellets consist of ground, dried bentonite compacted into pellets available in several sizes. Bentonite pellets are compressed to a bulk density of 70-80 lbs/ft$^3$ and hydrate to a 30% min. solids material. Where neat cement grouts are to be used, the placement of a bentonite pellet seal above the filter pack is mandatory to prevent the possibility of grout infiltration into the screened interval prior to setting. Bentonite chips or other sealing products should not be substituted in this application. Where bentonite grouts are to be used, the placement of a bentonite pellet seal is optional, but desirable.

Since bentonite pellets begin hydrating rapidly, they can be very difficult to place properly. They are generally placed by pouring slowly into open boreholes, hollow stem augers or sonic drill pipe. In some cases, pellets are placed by tremie pipe and flushed into place with potable water. A tamper can be used to ensure that the material is being placed properly and to rapidly break up any pellet bridging that occurs.

Pellet seals should be designed for a two-foot thickness of dry pellets above the filter pack. Hydration may extend the height of the seal. Where neat cement grouts are to be used, the pellets should be hydrated for eight hours, or the manufacturer's recommended hydration time, whichever is greater. Where the water table is temporarily below the pellet seal, potable (or higher quality) water should be added repeatedly to hydrate the pellets prior to grouting.

### *2.3.5 Grouting the Annular Space*

The annular space between the casing and the borehole wall should be filled with either a 30% solids bentonite grout, a neat cement grout, or a cement/bentonite grout. Each type of grout selected should be evaluated as to its intended use and integrity. Bentonite grouts are preferred unless the application dictates the use of another material.

Bentonite grout shall be a 30% solids pure bentonite grout. Drilling muds are not acceptable for grouting. The grout should be placed into the borehole, by the tremie method, from the top of the bentonite seal to within 2-feet of the ground surface or below the frost line, whichever is the greater depth. The bentonite pellet seal or filter pack should not be disturbed during grout placement, either by the use of a side discharge port on the tremie tube, or by maintaining clearance between the bottom of the tremie tube and the bentonite seal or filter pack. The grout should be allowed to cure for a minimum of 24 hours before the concrete surface pad is installed. The preferred method of achieving proper solids content is by measurement of ingredients per the manufacturer's specifications during mixing with a final check by grout balance after mixing. Bentonite grouts should have a

minimum density of 10 lbs/gal to ensure proper gelling and low permeability. The density of the first batch of grout should be measured while mixing to verify proper measurement of ingredients. In addition, the grouting operation should not cease until the bentonite grout flowing out of the borehole has a minimum density of 10 lbs/gal. Estimating the grout density is not acceptable.

Cement grouts are generally dictated where a high level of dissolved solids or a particular dissolved constituent would prevent proper gelling of a bentonite grout. Neat cement grouts (cement without additives) should be mixed using 6 gallons of water per 94-lb bag of Type 1 Portland cement to a density of 15lbs/gal. The addition of bentonite (5 to 10 percent) to the cement grout can be used to delay the "setting" time and may not be needed in all applications. The specific mixtures and other types of cement and/or grout proposed should be evaluated on a case by case basis by a senior field geologist.

### *2.3.6 Above Ground Riser Pipe and Outer Casing*

The well casing, when installed and grouted, should extend above the ground surface a minimum of 2.5 feet. A vent hole should be drilled into the top of the well casing cap to permit pressure equalization, if applicable. An outer protective casing should be installed into the borehole after the annular grout has cured for at least 24 hours. The outer protective casing should be of steel construction with a hinged, locking cap. Generally, outer protective casings used over 2-inch well casings are 4 inches square by 5 feet long. Similarly, protective casings used over 4-inch well casings are 6 inches square and 5 feet long. Other types of protective casing including those constructed of pipe are also acceptable. All protective casings should have sufficient clearance around the inner well casings, so that the outer protective casings will not come into contact with the inner well casings after installation. The protective casings should have a weep hole to allow drainage of accumulated rain or spilled purge water. The weep hole should be approximately 1/4-inch in diameter and drilled into the protective casings just above the top of the concrete surface pad to prevent water from standing inside of the protective casings. Protective casings made of aluminum or other soft metals are normally not acceptable because they are not strong enough to resist tampering. Aluminum protective casing may be used in very corrosive environments such as coastal areas.

Prior to installing the protective casing, the bentonite grout in the borehole annulus is excavated to a depth of approximately two feet. The protective casing is installed by pouring concrete into the borehole on top of the grout. The protective casing is then pushed into the wet concrete and borehole a minimum of 2 feet. Extra concrete may be needed to fill the inside of the protective casing so that the level of the concrete inside of the protective casing is at or above the level of the surface pad. In areas where frost heave of the surface pad is possible, the protective casing should first be pressed into the top surface of the bentonite grout seal and concrete poured around the protective casing. A granular material such as sand or gravel can then be used to fill the space between the riser and protective casing. The use of granular material instead of concrete between the protective casing and riser will also facilitate the future conversion of the well to a flush-mount finish, if required.

The protective casing should extend above the ground surface to a height so that the top of the inner well casing is exposed when the protective casing is opened. At each site, all locks on the outer protective casings should be keyed alike.

### *2.3.7 Concrete Surface Pad*

A concrete surface pad should be installed around each well at the same time as the outer protective casing is being installed. The surface pad should be formed around the well casing. Concrete should be placed into the pad forms and into the borehole (on top of the grout) in one operation making a contiguous unit. The size of the concrete surface pad is dependent on the well casing size. If the well casing is 2 inches in diameter, the pad should be 3 feet x 3 feet x 4 inches. If the well casing is 4 inches in diameter, the pad should be 4 feet x 4 feet x 6 inches. Round concrete surface pads are also acceptable. The finished pad should be slightly sloped so that drainage will flow away from the protective casing and off of the pad. A minimum of one inch of the finished pad should be below grade to prevent washing and undermining by soil erosion.

### *2.3.8 Surface Protection – Bumper Guards*

If the monitoring wells are located in a high traffic area, a minimum of three bumper guards consisting of steel pipes 3 to 4 inches in diameter and a minimum 5-foot length should be installed. These bumper guards should be installed to a minimum depth of 2 feet below the ground surface in a concrete footing and extend a minimum of 3 feet above ground surface. Concrete should also be placed into the steel pipe to provide additional strength. Substantial steel rails and/or other steel materials can be used in place of steel pipe. Welding bars between the bumper posts can provide additional strength and protection in high traffic areas, but the protective bumpers should not be connected to the protective casing.

## 2.4 Construction Techniques

### *2.4.1 Well Installation*

The borehole should be bored, drilled, or augered as close to vertical as possible, and checked with a plumb bob or level. Deviation from plumb should be within 1° per 50ft of depth. Slanted boreholes are undesirable and should be noted in the boring logs and final construction logs. The depth and volume of the borehole, including the over-drilling if applicable, should have been calculated and the appropriate materials procured prior to drilling activities.

The well casings should be secured to the well screen by flush-jointed threads and placed into the borehole and plumbed by the use of centralizers and/or a plumb bob and level. Another method of placing the well screen and casings into the borehole and plumbing them at the same time is to suspend the string of well screen and casings in the borehole by means of a hoist on the drill rig. This wireline method is especially useful if the borehole is deep and a long string of well screen and casings have to be set and plumbed.

No lubricating oils or grease should be used on casing threads. No glue of any type should be used to secure casing joints. Viton® O-rings can be used where the joints are designed for same.

Before the well screen and casings are placed on the bottom of the borehole, at least 6 inches of filter material should be placed at the bottom of the borehole to serve as a firm footing. The string of well screen and casings should then be placed into the borehole and plumbed. Centralizers can be used to plumb a well, but centralizers should be placed so that the placement of the filter pack, bentonite pellet seal, and annular grout will not be hindered. Centralizers placed in the wrong locations can cause bridging during material placement. Monitoring wells less than 50 feet deep generally do not need centralizers. If centralizers are used they should be placed below the well screen and above the bentonite pellet seal. The specific placement intervals should be decided based on site conditions.

When installing the well screen and casings through hollow-stem augers, the augers should be slowly extracted as the filter pack, bentonite pellet seal, and grout are tremied and/or poured into place. The gradual extraction of the augers will allow the materials being placed in the augers to flow out of the bottom of the augers into the borehole. If the augers are not gradually extracted, the materials (sand, pellets, etc.) will accumulate at the bottom of the augers causing potential bridging problems.

After the string of well screen and casing is plumb, the filter pack material should then be placed around the well screen to the designated depth. With cased drilling methods, the sand should be poured into the casing or augers until the lower portion is filled. The casing or augers are then withdrawn, allowing the sand to flow into the evacuated space. With hollow stem augers, sand should always fill the augers 6-12 inches, maintained by pouring the sand while checking the level with a weighted tag line. The filter pack sand in open boreholes should be installed by tremie methods, using water to wash the sand through the pipe to the point of placement.

After the filter pack has been installed, the bentonite pellet seal (if used) should be placed directly on top of the filter pack to an unhydrated thickness of two feet. When installing the seal for use with cement grouts, the bentonite pellet seal should be allowed to hydrate a minimum of eight hours or the manufacturer's recommended hydration time, whichever is longer.

After the pellet seal has hydrated for the specified time, the grout should then be pumped by the tremie method into the annular space around the casings. The grout should be allowed to set for a minimum of 24 hours before the surface pad and protective casing are installed.

After the surface pad and protective casing are installed, bumper guards should be installed (if needed). The bumper guards should be placed around the concrete surface pad in a configuration that provides maximum protection to the well. Each

piece of steel pipe or approved material should be installed into an 8-to 10-inch diameter hole, to a minimum depth of 2 feet below ground surface, and filled with concrete. As previously stated, the bumper guard should extend above the ground surface a minimum of 3 feet. The total length of each bumper guard should be a minimum of 5 feet.

After the wells have been installed, the outer protective casing should be painted with a highly visible paint. The wells should be permanently marked with the well number, date installed, site name, elevation, etc., either on the cover or an appropriate place that will not be easily damaged and/or vandalized.

If the monitoring wells are installed in a high traffic area such as a parking lot, in a residential yard, or along the side of a road it may be desirable to finish the wells to the ground surface and install water-tight flush mounted traffic and/or man-hole covers. Flush mounted traffic and man-hole covers are designed to extend from the ground surface down into the concrete plug around the well casing. Although flush mounted covers may vary in design, they should have seals that make the unit water-tight when closed and secured. The flush mounted covers should be installed slightly above grade to minimize standing water and promote runoff. Permanent identification markings should be placed on the covers or in the concrete plug around the cover. Expansive sealing plugs should be used to cap the well riser to prevent infiltration of any water that might enter the flush cover.

### *2.4.2 Double-Cased Wells*

Double-cased wells should be constructed when there is reason to believe that interconnection of two aquifers by well construction may cause cross-contamination or when flowing sands make it impossible to install a monitoring well using conventional methods. A highly contaminated surface soil zone may also be cased off so that drilling may continue below the casing with reduced danger of cross contamination. A pilot borehole should be bored through the overburden and/or the contaminated zone into the clay confining layer or bedrock. An outer casing (sometimes called surface or pilot casings) should then be placed into the borehole and sealed with grout. The borehole and outer casing should extend into tight clay a minimum of two feet and into competent bedrock a minimum of 1 foot. The total depths into the clay or bedrock will vary, depending on the plasticity of the clay and the extent of weathering and\or fracturing of the bedrock. The final depths should be approved by a senior field geologist. The size of the outer casing should be of sufficient inside diameter to contain the inner casing, and the 2-inch minimum annular space. In addition, the borehole should be of sufficient size to contain the outer casing and the 2-inch minimum outer annular space, if applicable.

The outer casing should be grouted by the tremie, displacement, grout shoe, or Halliburton method from the bottom to the ground surface. The grout should be pumped into the annular space between the outer casing and the borehole wall. A minimum of 24 hours should be allowed for the grout plug (seal) to cure before attempting to drill through it. The grout mixture used to seal the outer annular space should be either a neat cement, cement/bentonite, cement/sand, or a 30% solids

bentonite grout. However, the seal or plug at the bottom of the borehole and outer casing should consist of a Type I portland cement/bentonite or cement/sand mixture. The use of a pure bentonite grout for a bottom plug or seal is not acceptable, because the bentonite grout cures to a gel-like material, and is not rigid enough to withstand the stresses of drilling. When drilling through the seal, care should be taken to avoid cracking, shattering, or washing out the seal. If caving conditions exist so that the outer casing cannot be sufficiently sealed by grouting, the outer casing should be driven into place and a grout seal placed in the bottom of the casing.

#### 2.4.2.1 Bedrock Wells

The installation of monitoring wells into bedrock can be accomplished in two ways:

1. The first method is to drill or bore a pilot borehole through the soil overburden into the bedrock. An outer casing is then installed into the borehole by setting it into the bedrock, and grouting it into place as described in the previous section. After the grout has set, the borehole can then be advanced through the grout seal into the bedrock. The preferred method of advancing the borehole into the bedrock is rock coring. Rock coring makes a smooth, round hole through the seal and into the bedrock without cracking and/or shattering the seal. Roller cone bits are used in soft bedrock, but extreme caution should be taken when using a roller cone bit to advance through the grout seal in the bottom of the borehole because excessive water and "down" pressure can cause cracking, eroding (washing), and/or shattering of the seal. Low volume air hammers may be used to advance the borehole, but they have a tendency to shatter the seal because of the hammering action. If the structural integrity of the grout seal is in question, a pressure test can be utilized to check for leaks. A visual test can also be made by examining the cement/concrete core that is collected when the seal is cored with a diamond coring bit. If the seal leaks (detected by pressure testing) and/ or the core is cracked or shattered, or if no core is recovered because of washing, excessive down pressure, etc., the seal is not acceptable. The concern over the structural integrity of the grout seal applies to all double cased wells. Any proposed method of double casing and/or seal testing will be evaluated on its own merits, and will have to be approved by a senior field geologist before and during drilling activities, if applicable. When the drilling is complete, the finished well will consist of an open borehole from the ground surface to the bottom of the well. There is no inner casing, and the outer surface casing, installed down into bedrock, extends above the ground surface, and also serves as the outer protective casing. If the protective casing becomes cracked or is sheared off at the ground surface, the well is open to direct contamination from the ground surface and will have to be repaired

immediately or abandoned. Another limitation to the open rock well is that the entire bedrock interval serves as the monitoring zone. In this situation, it is very difficult or even impossible to monitor a specific zone, because the contaminants being monitored could be diluted to the extent of being non-detectable. The installation of open bedrock wells is generally not acceptable in the Superfund and RCRA programs, because of the uncontrolled monitoring intervals. However, some site conditions might exist, especially in cavernous limestone areas (karst topography) or in areas of highly fractured bedrock, where the installation of the filter pack and its structural integrity are questionable. Under these conditions the design of an open bedrock well may be warranted.

2. The second method of installing a monitoring well into bedrock is to install the outer surface casing and drill the borehole (by an approved method) into bedrock, and then install an inner casing and well screen with the filter pack, bentonite seal, and annular grout. The well is completed with a surface protective casing and concrete pad. This well installation method gives the flexibility of isolating the monitoring zone(s) and minimizing inter-aquifer flow. In addition, it gives structural integrity to the well, especially in unstable areas (steeply dipping shales, etc.) where the bedrock has a tendency to shift or move when disturbed. Omitting the filter pack around the well screen is a general practice in some open rock borehole installations, especially in drinking water and irrigation wells. However, without the filter pack to protect the screened interval, sediment particles from the well installation and/or from the monitoring zone could clog the well screen and/or fill the screened portion of the well rendering it inoperable. Also, the filter pack serves as a barrier between the bentonite seal and the screened interval. Rubber inflatable packers have been used to place the bentonite seal when the filter pack is omitted, but the packers have to remain in the well permanently and, over a period of time, will decompose and possibly contribute contaminants to the monitoring zone.

## 2.5 Well Construction Materials

### *2.5.1 Introduction*

Well construction materials are chosen based on the goals and objectives of the proposed monitoring program and the geologic conditions at the site(s). In this section, the different types of available materials will be discussed.

### *2.5.2 Well Screen and Casing Materials*

When selecting the materials for well construction, the prime concern should be to select materials that will not contribute foreign constituents, or remove contaminants of concern from the ground water. If the monitoring program is designed to analyze for organic compounds, stainless steel materials are the preferred choice. If the monitoring program calls for the analyses of only inorganic compounds or the contaminants or formation are highly corrosive, then rigid PVC materials meeting National Sanitary Foundation (NSF) Standard 14 type WC (Well Casing) are acceptable. PVC materials may be acceptable for monitoring identified organic compounds in a soluble aqueous phase where incompatibilities are known to not exist. EPA document EPA/540/S-95/503, *Nonaqueous Phase Liquids Compatibility with Materials Used in Well Construction, Sampling, and Remediation* should be used for guidance in this area and in the use of PVC with non-aqueous phase liquids (NAPLs). Another concern is to select materials that will be rugged enough to endure the entire monitoring period. Site conditions will generally dictate the type of materials that can be used. A preliminary field investigation should be conducted to determine the geologic conditions, so that the most suitable materials can be selected. The best grade or highest quality material for that particular application should be selected. Each manufacturer can supply the qualitative data for each grade of material that is being considered. All materials selected for monitoring well installation should be evaluated and approved by a senior field geologist prior to field activities.

Well screen and casing materials generally used in monitoring well construction on RCRA and Superfund sites are listed in order of preference:

1. Stainless Steel (304 or 316)
2. Rigid PVC meeting NSF Standard 14 (type WC)
3. Other (where applicable)

There are other materials used for well screens and casings such as black iron, carbon steel, galvanized steel, and fiberglass, but these materials are not recommended for use in long term monitoring programs at hazardous waste sites, because of their low resistance to chemical attack and potential constituent contribution to the ground water. In cases where a driven casing is used, or a high strength outer casing is needed, carbon steel may be acceptable in non-corrosive aquifers. This outer casing should have threaded connections. Welding casing is not an acceptable practice unless all relevant safety issues have been adequately addressed.

The minimum nominal casing size for most permanent monitoring wells will be 2". Where a complete program of installation, monitoring, and abandonment is being designed, smaller wells may be installed if suitable purging and sampling equipment for the smaller diameter wells can be specified and obtained. The length of well screens in permanent monitoring wells should be long enough to effectively monitor the interval or zone of interest. However, well screens designed for long

term monitoring purposes should normally not be less than 5 feet in length. Well screens less than 5 feet long are generally only used in temporary monitoring wells where ground water samples are collected for screening purposes.

### *2.5.3 Filter Pack Materials*

The filter pack materials should consist of clean, rounded to well-rounded, hard, insoluble particles of siliceous composition. The required grain-size distribution or particle sizes of the filter pack materials should be selected based upon a sieve analysis conducted on the soil samples collected from the aquifer materials and/or the formation(s) to be monitored. Filter pack materials should not be accepted unless proper documentation can be furnished as to the composition, grain-size distribution, cleaning procedure, and chemical analysis. If a data search reveals that there is enough existing data to adequately design the well screen and filter pack, then it may not be necessary to conduct a sieve analysis on the formation materials to be monitored. However, all data and design proposals will be evaluated and approved by a senior staff geologist before field activities begin.

### *2.5.4 Filter Pack and Well Screen Design*

The majority of monitoring wells are installed in shallow ground water aquifers that consist of silts, clays, and sands in various combinations. These shallow aquifers are not generally characteristic of aquifers used for drinking water. Therefore, modifications to the procedures used for the design of water well filter packs may be required. In cases where insufficient experience exists with local or similar materials, the filter pack and well screen design should be based on the results of a sieve analysis conducted on soil samples collected from the aquifer or the formation(s) that will be monitored.

In formations consisting primarily of fines (silts and clays), the procedures for water well screen design may result in requirements for filter packs and screen slot sizes that are not available. In those cases the selection of 0.010" screen slots with a 20-40 sand filter pack, or 0.005" screen slots with 100 sand filter pack for very fine formations, will be acceptable practice. Table 6.6.1 provides size specifications for the selection of sand packs for fine formation materials. ASTM standard D5092, *Design and Installation of Ground Water Monitoring Wells in Aquifers*, may be consulted for further guidance on specifications for sand appropriate for these applications.

**Table 6.6.1**
**Sand Pack Specifications**

| Screen Opening (in) | Sand Pack Mesh Name | 1% Passing Size (d-1) (in) | 10% Passing Size (d-10) (in) | 30% Passing Size (d-30) (in) | Derived 60% Passing Size (d-60) (in) | Range for Uniformity Coefficient |
|---|---|---|---|---|---|---|
| 0.005-0.006 | 100 | .0035 - .0047 | .0055 - .0067 | .0067 - .0083 | .0085 - .0134 | 1.3 - 2.0 |
| 0.010" | 20-40 | .0098 - .0138 | .0157 - .0197 | .0197 -.0236 | .020 - .0315 | 1.1 - 1.6 |

The following procedure should be used in coarser grained formations:

The data from the sieve analysis are plotted on a grain-size distribution graph, and a grain-size distribution curve is generated. From this grain-size distribution curve, the uniformity coefficient (Cu) of the aquifer material is determined. The Cu is the ratio of the 60 percent finer material (d60) to the 10 percent finer material (d10)

$$Cu = (d60/d10)$$

The Cu ratio is a way of grading or rating the uniformity of grain size. For example, a Cu of unity means that the individual grain sizes of the material are nearly all the same, while a Cu with a large number indicates a large range of particle sizes. As a general rule, a Cu of 2.5 or less should be used in designing the filter pack and well screen.

Before designing the filter pack and well screen, the following factors should be considered:

1. Select the well screen slot openings that will retain 90 percent of the filter pack material.

2. The filter pack material should be of the size that minimizes head losses through the pack and also prevents excessive sediment (sand, silt, clay) movement into the well.

3. A filter material of varying grain sizes is not acceptable because the smaller particles fill the spaces between the larger particles thereby reducing the void spaces and increasing resistance to flow. Therefore, filter material of the same grain size and well-rounded is preferred.

4. The filter pack design is based on the gradation of the finest aquifer materials being analyzed.

Steps to design a filter pack in aquifers:

1. Construct a grain-size distribution curve, on a grain-size distribution graph, from the sieve analysis of the aquifer materials. The filter pack design (as stated above) is based on the gradation of the finest aquifer materials.

2. Multiply the d30 size from the grain-size distribution graph by a factor of four to nine (Pack-Aquifer ratio). A factor of four is used if the formation is fine-grained and uniform (Cu is less than 3), six if it is coarse-grained and non-uniform, and up to nine if it is highly non-uniform and contains silt. Head losses through filter packs increase as the Pack-Aquifer (P-A) ratios decrease. In order to design a fairly stable filter pack with a minimum head loss, the d30 size should be multiplied by a factor of four.

3. Plot the point from step 2 on the d30 abscissa of a grain-size distribution graph and draw a smooth curve with a uniformity coefficient of approximately 2.5.

4. A curve for the permissible limits of the filter pack is drawn plus or minus 8 per cent of the desired curve with the Cu of 2.5.

5. Select the slot openings for the well screen that will retain 90 per cent or more of the filter pack material.

The specific steps and procedures for sieve analysis and filter pack design can be found in soil mechanics, ground water, and water well design books. The staff geologists and/or engineers should be responsible for the correct design of the monitoring wells and should be able to perform the design procedures.

## 2.6 Safety Procedures for Drilling Activities

A site health and safety plan should be developed and approved by the Branch Safety Officer or designee prior to any drilling activities, and should be followed during all drilling activities. The driller or designated safety person should be responsible for the safety of the drilling team performing the drilling activities. All personnel conducting drilling activities should be qualified in proper drilling and safety procedures. Before any drilling activity is initiated, utilities should be marked or cleared by the appropriate state or municipal utility protection organization. In developed areas, additional measures should be taken to locate utilities not covered by the utility protection program. Before operating the drill rig, a pilot hole should be dug (with hand equipment) to a depth of three feet to check for undetected utilities or buried objects. Proceed with caution until a safe depth is reached where utilities normally would not be buried. The following safety requirements should be adhered to while performing drilling activities:

1. All drilling personnel should wear safety hats, safety glasses, and steel toed boots. Ear plugs are required and will be provided by the safety officer or driller.

2. Work gloves (cotton, leather, etc.) should be worn when working around or while handling drilling equipment.

3. All personnel directly involved with the drilling rig(s) should know where the kill switch(s) is located in case of emergencies.

4. All personnel should stay clear of the drill rods or augers while in motion, and should not grab or attempt to attach a tool to the drill rods or augers until they have completely stopped rotating. Rod wipers, rather than gloves or bare hands should be used to remove mud, or other material, from drill stem as it is withdrawn from the borehole.

5. Do not hold drill rods or any part of the safety hammer assembly while taking standard penetration tests or while the hammer is being operated.

6. Do not lean against the drill rig or place hands on or near moving parts at the rear of the rig while it is operating.

7. Keep the drilling area clear of any excess debris, tools, or drilling equipment.

8. The driller will direct all drilling activities. No work on the rig or work on the drill site will be conducted outside of the driller's direction. Overall drill site activities will be in consultation with the site geologist or engineer, if present.

9. Each drill rig will have a first-aid kit and a fire extinguisher located on the rig in a location quickly accessible for emergencies. All drilling personnel will be familiarized with their location.

10. Work clothes will be firm fitting, but comfortable and free of straps, loose ends, strings etc., that might catch on some moving part of the drill rig.

11. Rings, watches, or other jewelry will not be worn while working around the drill rig.

12. The drill rig should not be operated within a minimum distance of 20 feet of overhead electrical power lines and/or buried utilities that might cause a safety hazard. In addition, the drill rig should not be operated while there is lightening in the area of the drilling site. If an electrical storm moves in during drilling activities, the area will be vacated until it is safe to return.

## 2.7 Well Development

A newly completed monitoring well should not be developed for at least 24 hours after the surface pad and outer protective casing are installed. This will allow sufficient time for the well materials to cure before development procedures are initiated. The main purpose of developing new monitoring wells is to remove the residual materials remaining in the wells after installation has been completed, and to try to re-establish the natural hydraulic flow

conditions of the formations which may have been disturbed by well construction, around the immediate vicinity of each well. A new monitoring well should be developed until the column of water in the well is free of visible sediment, and the pH, temperature, turbidity, and specific conductivity have stabilized. In most cases the above requirements can be satisfied; however, in some cases the pH, temperature, and specific conductivity may stabilize but the water remains turbid. In this case the well may still contain well construction materials, such as drilling mud in the form of a mud cake and/or formation soils that have not been washed out of the borehole. Excessive or thick drilling mud cannot be flushed out of a borehole with one or two well volumes of flushing. Continuous flushing over a period of several days may be necessary to complete the well development. If the well is pumped to dryness or near dryness, the water table should be allowed to sufficiently recover (to the static water level) before the next development period is initiated. Caution should be taken when using high rate pumps and/or large volume air compressors during well development because excessive high rate pumping and high air pressures can damage or destroy the well screen and filter pack. The onsite geologist should make the decision as to the development completion of each well. All field decisions should be documented in the field log book.

The following development procedures, listed in approximate increasing order of the energy applied to the formation materials, are generally used to develop wells:

1. Bailing
2. Pumping/overpumping
3. Surging
4. Backwashing ("rawhiding")
5. Jetting
6. Compressed air (with appropriate filtering): airlift pumping and air surging

These development procedures can be used, individually or in combination, in order to achieve the most effective well development. In most cases, over-pumping and surging will adequately develop the well without imparting undue forces on the formation or well materials. Because of the danger of introducing contaminants with the airstream, the possibility of entraining air in the aquifer, and the violent forces imparted to the formation, air surging is the least desired method of development and should only be used where there is a specific need for the procedure. Air-lift pumping is permissible where an eductor pipe is used and several well volumes of water are removed from the well by other pumping means after air-lift pumping. Additional time before the first sampling event should be allowed when using air development methods, particularly airlift. The selected development method(s) should be approved by a senior field geologist before any well installation activities are initiated.

Wells can require a considerable length of time to equilibrate with the aquifer after construction and development. The length of time between development and the first sampling event should be as long as possible with times from 1 to 14 days recommended. The possibility of the first sampling event’s results being non-representative should always be considered.

## 2.8 Well Decommissioning (Abandonment)

When a decision is made to decommission (abandon) a monitoring well, the borehole should be sealed in such a manner that the well cannot act as a conduit for migration of contaminants from the ground surface to the water table or between aquifers. To properly decommission a well, the preferred method is to completely remove the well casing and screen from the borehole, clean out the borehole, and backfill with a cement or bentonite grout, neat cement, or concrete. In order to comply with state well decommissioning requirements, the appropriate state agency should be notified (if applicable) of monitoring well decommissioning. However, some state requirements are not explicit, so a technically sound well abandonment method should be designed based on the site geology, well casing materials, and general condition of the well(s).

### *2.8.1 Decommissioning Procedures*

As previously stated, the preferred method should be to completely remove the well casing and screen from the borehole. This may be accomplished by augering with a hollow-stem auger over the well casing down to the bottom of the borehole, thereby removing the grout and filter pack materials from the hole. The well casing should then be removed from the hole with the drill rig. The clean borehole can then be backfilled with the appropriate grout material. The backfill material should be placed into the borehole from the bottom to the top by pressure grouting with the positive displacement method (tremie method). This abandonment method can be accomplished on small diameter (1-inch to 4-inch) wells without too much difficulty. With wells having 6-inch or larger diameters, the use of hollow-stem augers for casing removal is very difficult or almost impossible. Instead of trying to ream the borehole with a hollow-stem auger, it is more practical to force a drill stem with a tapered wedge assembly or a solid-stem auger into the well casing and extract it out of the borehole. Wells with little or no grouted annular space and/or sound well casings can be removed in this manner. However, old wells with badly corroded casings and/or thickly grouted annular space have a tendency to twist and/or break-off in the borehole. When this occurs, the well will have to be grouted with the remaining casing left in the borehole. The preferred method in this case should be to pressure grout the borehole by placing the tremie tube to the bottom of the well casing, which will be the well screen or the bottom sump area below the well screen. The pressurized grout will be forced out through the well screen into the filter material and up the inside of the well casing sealing holes and breaks that are present.

A PVC well casing may be more difficult to remove from the borehole than a metal casing, because of its brittleness. If the PVC well casing breaks during removal, the borehole should be cleaned out by using a drag bit or roller cone bit with the wet rotary method to grind the casing into small cuttings that will be flushed out of the borehole by water or drilling mud. Another method is to use a solid-stem auger with a carbide tooth pilot bit to grind the PVC casing into small cuttings that will be brought to the surface on the rotating flights. After the casing materials have been removed from the borehole, the borehole should be cleaned out and pressure grouted with the approved grouting materials.

Where state regulations and conditions permit, it may be permissible to grout the casing in place. This decision should be based on confidence in the original well construction practice, protection of drinking water aquifers, and anticipated future property uses. The pad should be demolished and the area around the casing excavated. The casing should be sawn off at a depth of three feet below ground surface. The screen and riser should be tremie grouted with a 30% solids bentonite grout. Pouring bentonite chips into the well will be acceptable with wells large enough for the chips to fall to the bottom (generally 4" or larger).

# 3 Temporary Monitoring Well Installation

## 3.1 Introduction

Five types of temporary monitoring well installation techniques have been demonstrated as acceptable. The type selected for a particular site is dependent upon site conditions. The project leader and site geologist should be prepared to test temporary well installations on site and select the best solution. Temporary wells are cost effective, may be installed quickly, and can provide a rapid assessment of ground water quality.

Temporary monitoring well locations are not permanently marked, nor are their elevations normally determined. Sand pack materials may or may not be used, but typically there is no bentonite seal, grout, surface completion, or extensive development (as it normally applies to permanent monitoring wells). Temporary wells are generally installed, purged, sampled, removed, and backfilled in a matter of hours.

Due to the nature of construction, turbidity levels may initially be high. However, these levels may be reduced by low flow purging and sampling techniques as described in SESD Operating Procedure for Groundwater Sampling, SESDPROC-301.

Temporary wells may be left overnight, for sampling the following day, but the well must be secured, both against tampering and against the fall hazard of the open annulus. If the well is not sampled immediately after construction, the well should be purged prior to sampling as specified in SESD Operating Procedure for Groundwater Sampling, SESDPROC-301.

## 3.2 Data Limitation

Temporary wells described in this section are best used for delineation of contaminant plumes at a point in time, for some site screening purposes, or for determination of groundwater elevations and gradients. They are not intended to replace permanent monitoring wells. Temporary wells can be used in conjunction with a mobile laboratory, where quick-turnaround analytical results can be used to rapidly delineate contaminant plumes.

## 3.3 Temporary Well Materials

Materials used in construction of temporary monitoring wells are the same standard materials used in the construction of permanent monitoring wells. Sand used for the filter pack (if any) should be as specified in Section 2.5.3, Filter Pack Materials. The well screen and casing should be stainless steel for ruggedness and suitability for steam cleaning and solvent rinsing. Other materials may be acceptable, on a case by case basis. Some commercially available temporary well materials, pre-packed riser, screen and filter pack assemblies are available commercially; however, these pre-assembled materials cannot be

cleaned. Appropriate QA/QC must be performed to assure there will be no introduction of contamination.

## 3.4 Temporary Monitoring Well Borehole Construction

Borehole construction for temporary wells is as specified in Section 2.3, using a drill rig. Alternatively, boreholes may be constructed using hand augers or portable powered augers (generally limited to depths of ten feet or less). If a drill rig is used to advance the borehole, the augers must be pulled back the length of the well screen (or removed completely) prior to sampling. When hand augers are used, the borehole is advanced to the desired depth (or to the point where borehole collapse occurs). In situations where borehole collapse occurs, the auger bucket is typically left in the hole at the point of collapse while the temporary well is assembled. When the well is completely assembled, a final auger bucket of material is quickly removed and the well is immediately inserted into the borehole, pushing, as needed, to achieve maximum penetration into the saturated materials.

## 3.5 Temporary Monitoring Well Types

Five types of monitoring wells which have been shown to be acceptable are presented in the order of increasing difficulty to install and increasing cost:

### *3.5.1 No Filter Pack*

This is the most common temporary well and is effective in many situations. After the borehole is completed, the casing and screen are simply inserted. This is the least expensive and fastest well to install. This type of well is extremely sensitive to turbidity fluctuations because there is no filter pack. Care should be taken to not disturb the casing during purging and sampling.

### *3.5.2 Inner Filter Pack*

This type differs from the "No Filter Pack" well in that a filter pack is placed inside the screen to a level approximately 6 inches above the well screen. This ensures that all water within the casing has passed through the filter pack. For this type well to function properly, the static water level must be at least 6-12 inches above the filter pack. The screen slots may plug with this construction method.

### *3.5.3 Traditional Filter Pack*

For this type of well, the screen and casing are inserted into the borehole, and the sand is poured into the annular space surrounding the screen and casing. It may be difficult to effectively place a filter pack in open boreholes, due to collapse.

### *3.5.4 Double Filter Pack*

The borehole is advanced to the desired depth. As with the "inner filter pack" the well screen is filled with filter pack material and the well screen and casing inserted

until the top of the filter pack is at least 6 inches below the water table. Filter pack material is poured into the annular space around the well screen. This type temporary well construction can be effective in aquifers where fine silts or clays predominate.

#### *3.5.5 Well-in-a-Well*

The borehole is advanced to the desired depth. At this point, a 1-inch well screen and sufficient riser is inserted into a 2-inch well screen with sufficient riser, and centered. Filter pack material is then placed into the annular space surrounding the 1-inch well screen, to approximately 6 inches above the screen. The well is then inserted into the borehole.

This system requires twice as much well screen and riser, with attendant increases in assembly and installation time. The increased amount of well construction materials results in a corresponding increase in decontamination time and costs. The use of pre-packed well screens in this application will require rinse blanks of each batch of screens. Pre-pack Screen assemblies cannot be decontaminated for reuse.

### 3.6 Decommissioning

Temporary well boreholes must be decommissioned after sampling and removal of the screen and riser. Use of cuttings for backfilling holes will not be acceptable practice.

# 4 Direct-Push Technology in Groundwater Investigations

## 4.1 Screen Point Samplers

Screen Point samplers allow temporary wells to be established quickly and can return high quality samples. The sampler consists of a stainless steel or PVC screen housed in a hollow steel sheath and topped with a drive cap to adapt to the drive rods in use. A disposable point is inserted in the bottom of the sheath and serves to prevent soil from entering the sheath and damaging the screen during driving.

After driving the sampler to the target depth, an inner rod is inserted to hold the screen down at the bottom of the borehole while the sheath and rods are withdrawn to expose the screen. The disposable point stays at the bottom of the borehole. The inner rod system is withdrawn and sampling can commence immediately.

O-rings are commonly used on the disposable point. The additional friction from the O-ring can prevent the point from being driven off of the sampler in loose material or when encountering a hollow space such as during redriving.

Screen point samplers are deployed to a specified interval. If a greater sampling depth is desired after deployment, the sampler must be withdrawn, reassembled with a new point, and redriven to the greater depth. The standard screens can be withdrawn to a shallower interval if needed, but the sampler would still be accessing the deeper aquifer to some extent.

### *4.1.1 Special Considerations for Screen Point Samplers*

Decommissioning (Abandonment)

Like other wells, temporary screen points should be properly decommissioned. The most common means of decommissioning at SESD is to withdraw the screen point sampler, remove the screen, install a new disposable point, and redrive the sheath to the previously screened interval. A grouting head is attached to the probe rods, and grout pressure applied while withdrawing the rods to pull the disposable point free. The grout volume pumped is carefully managed to match the volume grouted during rod withdrawal.

Where preventing cross-connection of aquifers is critical or potential caving would prevent re-entry, a disposable screen can be used with some systems. The disposable screen is not linked to the sheath and will pull out and be left in the borehole. After sampling, the grouting head is attached to the rods, the rods pumped full of grout, and the sampler sheath is pulled off of the screen. Grouting proceeds as with re-entry grouting.

Geoprobe® Screen Points samplers have a feature available to knock a plug out of the bottom of the screen and thread a small diameter high-pressure grouting tube to

the bottom of the borehole. Grout is pumped through the tubing while rods are withdrawn and left threaded over the tubing aboveground. As this system is unwieldy and cannot reliably pump grout over 20% solids, it is not used at SESD.

SESD pressure-grouts soil sampling boreholes by reentry grouting or tremie grouting when depths exceed 10 ft, or groundwater is encountered. Shallower boreholes can be decommissioned by pouring pellets in short lifts and hydrating each lift with water, or by pouring a pourable grout.

Screen Material Selection

The screen point screens are available in stainless steel and PVC. Because of stainless steel's durability, ability to be cleaned and re-used, and overall inertness and compatibility with most contaminants, it is the material most used for SESD investigations. When stainless steel screens are stowed wet, they should be segregated from carbon steel components. Contact of the stainless screens with carbon steel when wet will cause galvanic corrosion that will shed chrome-bearing material when first flushed.

## 4.2 Groundwater Profiling

Rapid investigations can be facilitated by the use of groundwater profiling systems. A groundwater profiler allows a sampler to be advanced from one area of interest to the next with a discrete groundwater sample collected at each. The system may allow soil samples to be collected during advancement. As some sampler components are common for all samples, the groundwater profiler does not offer the same protection from cross-contamination that separate screen point samples would.

## 4.3 Small-Diameter Well Installation

With some limitations, direct push technology can be used to install permanent monitoring wells of quality commensurate with other drilling systems. The use of small diameter wells limits the possibilities for the pumps to be used in sampling. For shallow groundwater with water levels higher than 25 ft below ground surface, peristaltic pumps can be used with no limitation on minimum well diameter. For water levels deeper than 25 feet below ground surface, bladder pumps may be the only pumping option and well diameters should be 1" nominal diameter with an absolute minimum of ¾" nominal diameter.

Well materials are difficult to place with DPT systems and best results will be achieved with total depths less than 50 ft. It is also difficult or impossible to place bentonite seals, and caution should be used when aquifer isolation is particularly

important. Grout should be placed in the annular space by tremie pipe, as with conventional drilling installation. Grout placement by tremie will likely rule out the use of the smaller diameter tool strings such as 2.125" and 2.25" outside diameter (od). A 3.5" tool string with 2.75" inside diameter (id) will allow room for a 1" nom. diam. casing with grout pumped through ½" nom. dia. tremie. Pre-pack screens are available to install 2" nom. dia. wells in 3.5" od tool string, but grout cannot be placed by tremie with these systems and they should not be used.

Pre-packed screens are typically used, consisting of a slotted well screen surrounded by a sand filter pack wrapped in stainless steel screen wire. Sand packs wrapped by textile materials capable of or intended to filter fines or lower turbidity are unacceptable. Above the pre-packed screen standard well casing matching the slotted screen diameter is used.

Installation involves driving a tool string with disposable point to depth, placing the screen and casing inside, and withdrawing the tool string to dislodge the disposable point. The drive casing is withdrawn to fully expose the screen. Filter pack sand is then added during drive casing withdrawal until sand is placed to 2 ft above the screen. There is a narrow annular space between the pre-pack screen and borehole walls that the added sand may not fully fill. The placement of 2 ft of sand above the screen allows for settling.

Bentonite grout mixed to 30% solids content is then installed by tremie pipe while withdrawing the remaining drive casing. Care must be taken to not jet out the placed filter sand by resting the tremie on the bottom.

Alternate systems are available that use a polyethylene and foam skirt to isolate a bentonite seal wrapped in kraft paper from the screened interval. These systems result in natural development of the entire annular space around the pre-pack screen and introduce several materials that may have compatibility, contaminant leaching, or long-term stability issues. Although the placement of a bentonite seal is desirable, SESD does not use these systems due to concern over the other issues.

| Operating Procedure | |
| Title: Pore Water Sampling | ID: LSASDPROC-513-R5 |
| Issuing Authority: Field Services Branch Supervisor | |
| Effective Date: April 22, 2023 | Review Due Date: May 12, 2024 |
| Method Reference: N/A | SOP Author: Mel Parsons |

**Purpose**

The purpose of this operating procedure is to describe the methods and considerations to be used when obtaining a pore water sample from soil or sediment.

**Scope/Application**

This document describes procedures generic to all pore water sampling methods to be used by field personnel when collecting and handling samples in the field. On the occasion that Laboratory Services and Applied Science Division (LSASD) personnel determine that any of the procedures described in this section are inappropriate, inadequate or impractical and that another procedure must be used to obtain a pore water sample, the variant procedure will be documented in the field logbook, along with a description of the circumstances requiring its use. Mention of trade names or commercial products in this operating procedure does not constitute endorsement or recommendation for use.

# 1 General Information

## 1.1 Documentation/Verification

This procedure was prepared by persons deemed technically competent by LSASD management, based on their knowledge, skills and abilities and has been tested in practice and reviewed in print by a subject matter expert. The official copy of this procedure resides on the LSASD local area network (LAN). The Document Control Coordinator is responsible for ensuring the most recent version of the procedure is placed on the LAN and for maintaining records of review conducted prior to its issuance.

## 1.2 General Precautions

### 1.2.1 Safety

Proper safety precautions must be observed when collecting pore water samples. Refer to the LSASD Safety, Health and Environmental Management Program Procedures and Policy Manual (most recent version) and any pertinent site-specific Health and Safety Plans (HASP) for guidelines on safety precautions. These guidelines, however, should only be used to complement the judgment of an experienced professional. When using this procedure, minimize exposure to potential health hazards through the use of protective clothing, eye wear and gloves. Address chemicals that pose specific toxicity or safety concerns and follow any other relevant requirements, as appropriate.

### 1.2.2 Procedural Precautions

The following precautions should be considered when collecting pore water samples:

- Special care must be taken not to contaminate samples. This includes storing samples in a secure location to preclude conditions which could alter the properties of the sample. Samples shall be custody sealed during long-term storage or shipment.
- Collected samples are in the custody of the sampler or sample custodian until the samples are relinquished to another party.
- If samples are transported by the sampler, they will remain under his/her custody or be secured until they are relinquished.
- Shipped samples shall conform to all U.S. Department of Transportation (DOT) rules of shipment found in Title 49 of the Code of Federal Regulations (49 CFR parts 171 to 179), and/or International Air Transportation Association (IATA) hazardous materials shipping requirements found in the current edition of IATA's Dangerous Goods Regulations.
- Documentation of field sampling is done in a bound logbook. Chain-of-custody documents shall be filled out and remain with the samples until custody is relinquished.

- All shipping documents, such as bills of lading, will be retained by the project leader and stored in a secure place.

### 1.2.3 Records

Information generated or obtained by LSASD personnel will be organized and accounted for in accordance with LSASD records management procedures found in LSASD Operating Procedure for Control of Records, LSASDPROC-002 (most recent version). Field notes, recorded in a bound field logbook, will be generated, as well as chain-of-custody documentation, in accordance with LSASD Operating Procedure for Logbooks, LSASDPROC-010 (most recent version), and LSASD Operating Procedure for Sample and Evidence Management, LSASDPROC-005 (most recent version).

# 2 Sampling Methodology

## 2.1 General

The pore water sampling techniques and equipment described in this procedure are designed to minimize effects on the chemical and physical integrity of the sample. If the procedures in this section are followed, a representative sample of the pore water should be obtained.

## 2.2 Collection Considerations

The physical location of the investigator when collecting a sample may dictate the equipment to be used. Wading is the preferred method for reaching the sampling location, particularly if the stream has a noticeable current (i.e., is not impounded). However, wading may disrupt bottom sediments causing biased results; therefore, the sampler should enter the area downstream of the sampling location and collect the sample facing upstream. If the stream is too deep to wade, the pore water sample may be collected from a platform such as a boat or by SCUBA diving. If sampling from a boat or in water deeper than the length of the sampler, extensions may be utilized. If SCUBA diving, all diving activity must be conducted in accordance with EPA's Diving Safety Manual, current version.

## 2.3 Summary of Procedure

Pore water is collected using a pore water extracting device (Figure 1). The most common type used by LSASD is the PushPoint™ sampler (M.H.E. Products 2003), made out of stainless-steel tubing. The sampling end of the pore water device is inserted into the sediment to the desired depth, and pore water is extracted using a syringe or peristaltic pump. The device is suitable for use only in fine-grained material (no gravel or cobble). Other similar devices may be used providing that the integrity of the sample is maintained, and no ambient surface water is allowed in contact with the sample.

## 2.4 Sampling Equipment

A PushPoint™ or similar sampler typically consists of a pointed tubular stainless-steel tube with a screened zone at one end and a sampling port at the other. The pointed end with the screened zone consists of a series of very fine interlaced machined slots to allow pore water to enter the sampler.

A removable guard rod adds rigidity to the sampler during sediment insertion. The length of the screened zone will depend on the site-specific study design. Depending on the data quality objectives (DQO) of the study, filters may be placed over the screened zone if additional screening is needed. Pore water is collected through the opposite end of the device by connecting flexible tubing and using a syringe or peristaltic pump to extract the sample. Teflon® tubing is the preferred tubing to be used for collecting pore water samples. However, other tubing may be used, depending upon the DQOs for the specific application.

There are many modifications that can be incorporated into the procedure to satisfy data quality objectives for a specific application. The procedures discussed in the following sections provide guidance on the basic operation of pore water sampling devices and issues to consider when collecting pore water.

An alternative system is available in LSASD inventory for use in soft sediments in water deeper than wading depth. A well screen and short riser approximately ¾" in diameter are threaded to fasten to the bottom of a custom flange. Internal threads on the screen accept a tubing adapter. The accompanying rimmed flange has a coupling with both top and bottom threads. The well screen is screwed into the bottom of the flange and Teflon® tubing is attached to the tubing adapter threaded into the well screen. For deployment, the tubing is then inserted through a PVC pipe or well casing which is then screwed into the upper threads of the flange. The entire assembly can be deployed in water up to ten feet of depth from a well anchored boat.

## 2.5 Pore Water Sampler Deployment Considerations

It is critical in the collection of pore water to avoid surface water intrusion. Water will flow in a path of least resistance. If space is created around the sides of the sampling end of the pore water device during deployment, surface water may flow down the outside of the device to the screened area and into the intended sample. Therefore, the pore water device should be used with a sampling flange (Figure 2), especially when collecting pore water near the sediment-surface water interface. If pore water is collected from deep in sediments, a flange may not be necessary. When inserted though the flange, the body of the pore water device should form a watertight seal to eliminate surface water intrusion during sample collection. Flanges should include an outer vertical cutting ring to enhance sealing. Flange systems can be augmented by flexible plastic sheeting of appropriate material. The sheeting can be weighted to conform to a stream bottom by objects obtained from other areas of the stream away from the sampling location. Several of the flanges in LSASD inventory have a threaded nut and washer to facilitate sealing the flange to a polyethylene sheet.

The flange can be made of any material that will not cross contaminate the intended sample. If both inorganic and organic analyses are required, the flange should be made of inert material such as stainless steel or Teflon®. The size of the flange depends on the volume of pore water to be collected. If large volumes of pore water are to be collected, use a large flange size. A useful estimate can be made for planning by taking the required water volume, tripling it to assume 33% porosity, and then calculating the dimensions of a cylinder of this volume, based upon the penetration depth of the sampler. The flange should cover at least this estimated volume. If it is not practical to use a large flange, then multiple devices may be deployed, and smaller volumes can be collected from several devices for a composite sample. If multiple devices are deployed, they should be spaced an appropriate distance apart so they will not interfere with one another.

In general, the volume of pore water that can be collected at a given location is limited. Collecting large volumes of pore water will ultimately result in the collection of water from the overlying water body. Often, minimum required volumes must be negotiated with the laboratory to limit the volumes withdrawn.

Where significant differences in parameters such as pH or conductivity exist between the surface water and pore water, a check can be made at the end of sampling to assess whether surface water intrusion has occurred by measuring the pore water parameters at the beginning and conclusion of sampling. Fluorescent dye tracing can also be used for this purpose.

## 2.6 Pore Water Collection

The flange is first placed at the desired sampling point with the push-point removed to allow any water to escape from under the flange. The flange rim should be carefully worked into the soil or sediment until the flange is flush with the surface. The pore water device should then be inserted through the compression adapter on the flange and into the soil or sediment as carefully as possible (Figure 2). When the sampler is inserted to the desired depth, the compression adapter should be tightened. The push-point's guard rod can then be withdrawn. Do not reinsert the guard rod into the sampler for any reason until the sampler has been cleaned (particles rolled between the two metal surfaces will lock the parts together and permanently damage the sampler.)

When deploying the pore water device, care must be taken not to disturb the sampling area. If the sampler is wading, the sampler should lean out and insert the pore water device as far as possible away from where the sampler is standing to reduce potential effects of the sampler on the integrity of the pore water sample. Depth of penetration of the pore water device depends on the objectives of the specific investigation.

After the pore water device has been successfully deployed, attach the sample tubing to the sampling port of the pore water device. Short pieces of Silastic® tubing can be used to splice Teflon® sample tubing to a push-point sampler, taking care to butt the tubing to the sampler at the center of the splice. Then attach the other end of the tubing to a sample withdrawing device, such as a syringe or a peristaltic pump (according to LSASD Operating Procedure for Pump Operation, LSASDPROC-203). Before collecting a pore water sample, be sure to purge out all air and surface water from the pore water sampler and sample tubing with the appropriate amount of pore water. This step can be accomplished by calculating the volume of the sampler and attached tubing and pumping this volume plus an additional 10 percent of pore water through the sampler and tubing prior to collecting the sample. If utilizing a syringe for collection, a three-way valve with a side syringe must be utilized for the surface water purge in order not to cross contaminate the sampling syringe.

### 2.6.1 Peristaltic Pump/Vacuum Jar Collection

The peristaltic pump/vacuum jug can be used for sample collection of organic or inorganic samples because it allows for the sample to be collected without coming in contact with the pump head tubing, maintaining the integrity of the sample. This is accomplished by placing a Teflon® transfer cap assembly onto the neck of a pre-cleaned standard 1-liter amber glass container (Figure 3). Teflon® tubing (¼-inch O.D.) connects the container to both the pump and the sample source. The

pump creates a vacuum in the container, thereby drawing the sample into the container without it coming into contact with the pump head tubing.

Because the sample is exposed to a vacuum and is agitated as it enters the vacuum jug, this method cannot be used for collection of samples for volatile organic compounds. An alternative method for collecting volatile organics involves filling the Teflon® tubing with sample by running the pump for a short period of time. Once the tubing is full of water, the tubing is removed from the pore water sampler and, then pinched off at the pump in order to maintain the vacuum while it is being disconnected from the pump head tubing. The water is then allowed to carefully drain, by gravity, into the sample vials. Alternatively, without disconnecting the tubing from the pump head, the contained sample can be pushed out of the tubing, into the sample vials, by reversing the peristaltic pump at very low speed. Great care must still be taken with this method in order not to agitate the sample during the transfer process or to transfer water that has been in contact with the Silastic® tubing into the vials.

Because pore water is typically collected from an anaerobic environment, it is preferable, especially when collecting samples for nutrient analysis, to maintain the integrity of the sample by minimizing exposure to air. This can be accomplished by purging the sample container with an inert gas such as nitrogen or argon prior to sampling. In addition, if analyzing for nutrients or metals, the container can be pre-preserved in order to minimize exposure of the sample to ambient conditions.

An alternative, when collecting samples for metals, nutrients, or other sample analyses not affected by Silastic® tubing and when exposure to air is not a concern, is to collect the sample directly from the discharge of the pump head tubing after an adequate purge has been demonstrated. When collecting samples in this manner, there are several considerations of which to be aware. The pump head tubing (Silastic®, etc.) must be changed after each sample and a rinsate blank must be collected from a representative piece of the pump head tubing (only one blank per investigation). Also, precautions must be taken to ensure that the end of the discharge tubing is not allowed to touch the ground or other surface to ensure the integrity of samples collected in this manner.

### 2.6.2 Syringe

An alternative to using the pump and vacuum container is to use a syringe as the mechanism to draw the pore water through the sampling device. The tubing from the sampling port of the pore water device can be directly attached to a syringe with a three-way valve and a side syringe and the pore water sample can be manually withdrawn. The valve is first switched to the side syringe, which is used for purging air and any ambient surface water in the system prior to sampling. The volume to be purged is determined by the length and diameter of the sampling device and attached tubing. Once the sampler has been purged, the valve is switched to the sampling syringe and the sample is drawn into the syringe. The syringe can be used as the final sample container or the pore water can be transferred to another container, depending on project objectives and analytical requirements. This is the best method to use if the sample is to be collected underwater by SCUBA diving.

## 2.7 Quality Control

If possible, a control or background sample should be collected from a location not affected by the possible contaminants of concern and submitted with the other samples. In streams or other bodies of moving water, the control sample should be collected upstream of the sampled area. For impounded bodies of water, particularly small lakes or ponds, it may be difficult or inappropriate to obtain an unbiased control from the same body of water from which the samples are collected. In these cases, it may be appropriate to collect a background sample from a similar impoundment located near the sampled body of water if there is a reasonable certainty that the background location has not been impacted. Equipment blanks should be collected if equipment is field cleaned and reused on-site or, if necessary, to document that low- level contaminants were not introduced by pumps, bailers or other sampling equipment.

### 2.8 Specific Sampling Equipment Quality Assurance Techniques

All equipment used to collect pore water samples shall be cleaned as outlined in the LSASD Operating Procedure for Field Equipment Cleaning and Decontamination, LSASDPROC-205 (most recent version) or LSASD Operating Procedure for Field Equipment Cleaning and Decontamination at the FEC, LSASDPROC-206 (most recent version) and repaired, if necessary, before being stored at the conclusion of field studies. Cleaning procedures utilized in the field or field repairs shall be thoroughly documented in field records.

## 3 Special Sampling Considerations

### 3.1 Volatile Organic Compounds (VOC)

Pore water samples for VOC analysis must be collected in 40 ml glass vials with Teflon® septa. The vial may be either preserved with concentrated hydrochloric acid or they may be unpreserved. Preserved samples have a two-week holding time, whereas, unpreserved samples have only a seven day holding time. During most sampling events, preserved vials are used due to their extended holding time. In some situations, however, it may be necessary to use unpreserved vials. For example, if the surface water sample contains a high concentration of dissolved calcium carbonate, there may be an effervescent reaction between the hydrochloric acid and the water, producing large numbers of fine bubbles. This will render the sample unacceptable. In this case, unpreserved vials should be used, and arrangements must be confirmed with the laboratory to ensure that they can accept the unpreserved vials and meet the shorter sample holding times.

Samples for VOC analysis must be collected using either stainless steel or Teflon® equipment. Samples should be collected with as little agitation or disturbance as possible. The vial should be filled so that there is a meniscus at the top of the vial and absolutely no bubbles or headspace should be present in the vial after it is capped. After the cap is securely tightened, the vial should be inverted and tapped on the palm of one hand to see if any undetected bubbles are dislodged. If a bubble or bubbles are present, the vial should be refilled. Care should be taken not to flush any preservative out of the vial during topping off. If, after attempting to refill and cap the vial, bubbles are still present, a new vial should be obtained, and the sample should be re-collected.

### 3.2 Dissolved Metals Sample Collection

If a dissolved metals pore water sample is to be collected, an in-line filtration should be used. The use of disposable, high-capacity filter cartridges (barrel-type) or membrane filters in an in-line filter

apparatus is preferred. The high-capacity, barrel-type filter is preferred due to the higher surface area associated with this configuration.

Potential differences could result from variations in filtration procedures used to process water samples for the determination of trace element concentrations. A number of factors associated with filtration can substantially alter "dissolved" trace element concentrations; these include filter pore size, filter type, filter diameter, filtration method, volume of sample processed, suspended sediment concentration, suspended sediment grain-size distribution, concentration of colloids and colloidally-associated trace elements, and concentration of organic matter. Therefore, consistency is critical in the comparison of short-term and long-term results. Further guidance on filtration may be obtained from Section 4.7.3 of the LSASD Groundwater Sampling Procedure (LSASDPROC-301).

## 3.3 Special Precautions for Pore Water Sampling

- A clean pair of new, non-powdered, disposable latex gloves will be worn each time a different location is sampled, and the gloves should be donned prior to handling sampling equipment. The gloves should not come in contact with the media being sampled and should be changed any time during sample collection when their cleanliness is compromised.
- All background or control samples shall be collected and placed in separate ice chests or shipping containers. Sample collection activities shall proceed progressively from the least suspected contaminated area to the most suspected contaminated area. Samples of waste or highly contaminated media must not be placed in the same ice chest as environmental (i.e., containing low contaminant levels) or background samples.
- If possible, one member of the field sampling team should take all the notes and photographs, fill out tags, etc., while the other members collect the samples.
- Samplers must use new, verified, certified clean disposable equipment, or pre-cleaned non-disposable equipment. Non-disposable equipment should be pre-cleaned according to procedures contained in LSASD Operating Procedure for Field Equipment Cleaning and Decontamination (LSASDPROC-205), for collection of samples for trace metals or organic compound analyses.

## 3.4 Sample Handling and Preservation Requirements

- Pore water will typically be collected using a peristaltic pump and placed directly into sampling containers. In some cases, a syringe may be used to collect the pore water and then either left in the syringe as the sample container or transferred into an appropriate container.
- During sample collection, if transferring the sample from a collection device, make sure that the device does not come in contact with the sample containers.
- Place the sample into appropriate, labeled containers. Samples collected for VOC analysis must not have any headspace (see Section 3.1).
- All samples requiring preservation must be preserved as soon as practically possible, soon after sample collection. If pre-preserved VOA vials are used, these will be preserved with concentrated hydrochloric acid prior to departure for the field investigation. For all other chemical preservatives, LSASD will use the appropriate chemical preservative generally stored in an individual single-use vial as described in the LSASD Operating Procedure for Field Sampling Quality Control (LSASDPROC-011). The adequacy of sample preservation will be checked after the addition of the preservative for all samples, except for the samples collected for VOC analysis. If it is determined that a sample is not acceptably preserved, additional preservative should be added to achieve adequate preservation. Preservation requirements for surface water samples are found in

the USEPA Laboratory Services Branch *Laboratory Operations and Quality Assurance Manual* (LOQAM).

# FT 1800. Field Measurement of Stage, Surface Water Velocity, and Discharge (Flow) and Computation of Streamflow

Use FT 1800 in conjunction with the following DEP Standard Operating Procedures (SOPs):

- FA 1000 Regulatory Scope and Administrative Procedures
- FD 1000 Documentation Procedures
- FM 1000 Field Planning and Mobilization
- FT 1400 Field Measurement of Temperature

## FT 1801. *Introduction*

Streamflow, or discharge, is defined as the volumetric rate of flow of water (volume per unit time) in a channel. This can include any sediment or other solids that move with the water. Use the procedures described and referenced in FT 1800 to measure and compute discharge of flowing surface waters. For purposes of this SOP, "surface waters" shall be those waters meeting the definition of surface water in subsection 62-302.200(38), F.A.C, and the definition of "waters" in Section 403.031(13), F.S. This SOP cites widely accepted procedures published by the United States Geological Survey (USGS), such as *Techniques in Water-Resource Investigation* (TWRI), Book 3, Chapters A1-A21; and, *Techniques and Methods* (TM), Book 3, Chapters A7, A8, A19, A22, and A23, for measurements of stage (water level) and velocity, and computation of flow for various environmental conditions and constructed water conveyances. These required procedures are incorporated by reference in rule 62-160.800, F.A.C. (Chapter 62-160, Quality Assurance), and are referenced throughout this SOP using abbreviations for the USGS books and chapters identified above (i.e., "TWRI 3-A21," "TM 3-A7").

## FT 1810. EQUIPMENT

Select equipment and necessary supplies according to directions provided in the USGS standard procedures cited in this SOP. Document measurement locations, equipment and supplies used for site measurements according to requirements in FT 1850, below. Staff must be trained to use selected equipment before conducting measurements. This section describes selected types of equipment typically used.

1. Selection of Current Meters and Profilers

Select the appropriate current meter and method identified below, taking into consideration the depth and velocity to determine discharge by direct measurements. Refer to Table 6 in TM 3-A8 as a guide in meter selection.

1.1. Mechanical meters measure point-velocities based on the principle of proportionality between the velocity of the water and the resulting angular velocity of the meter motor.

1.2. Electromagnetic meters measure point-velocities based on the principle that water moving through a magnetic field will produce an electrical current. Electromagnetic meters measure the electrical current to determine the velocity of flowing water.

1.3. Acoustic velocity meter (AVM) systems are non-mechanical devices that measure the velocity of flowing water by sonic signal and the acoustic travel time technique. AVMs can measure a wider range of velocities than mechanical meters and are deployed at a gaging station to provide continuous records in tidally affected areas or areas with variable backwater conditions.

1.4. Acoustic Doppler Velocity meters (ADVM) are non-mechanical devices that measure a volume of velocities in the water column based on the Doppler principle. Velocity of the

water is measured using transmitted and received signals from sound pulses reflecting off particles moving in the water column. Some models are used for discharge measurements while others are deployed at gages to compute discharge by the index-velocity method.

1.5. Acoustic Doppler Current Profilers (ADCP) measure velocity magnitude and direction using the Doppler shift of acoustic energy reflected by material suspended in the water column, providing a profile of velocity through the water column. Some models are used for discharge measurements while others are deployed at gages to compute discharge by the index-velocity method.

2. Maintenance of Current Meters and Profilers

Maintain meters and check performance to assure quality of measurements. Do not repair meters or profilers during a discharge measurement at a site. Do not change meters or profilers while conducting a discharge measurement at a site.

2.1. Mechanical and Electromagnetic Meters for point-velocity measurements.

2.1.1. Before using, check meter and repair or replace any broken parts.

2.1.2. Clean and oil meter to maintain optimum performance.

2.1.3. For mechanical meters, perform a spin test to ensure the meter is working properly before and after each event. Record results of the test.

2.1.4. For electromagnetic meters, calibrate in still water per manufacturer's instructions.

2.1.5. Follow directions provided in TM 3-A8 to conduct the test required for the specific meter types.

2.2. Acoustic velocity meters (AVM) for continuous measurements.

2.2.1. Enlist expert staff to install and maintain AVMs for peak performance in accordance with the meter manufacturer's manual.

2.2.2. Inspect the meter for cleanliness and signs of any damage from field use, and document any actions taken to clean or repair the instrument.

2.3. Acoustic Doppler Velocity meters (ADVM) for point-velocity measurements or for continuous measurements.

2.3.1. Review internal diagnostics during every field visit.

2.3.2. Visually inspect meter for signs of damage before and after field use.

2.3.3. Complete onboard quality control test with each measurement.

2.3.4. Perform beam checks under the following conditions:

- When instrument is received and installed;
- If damage has occurred or is suspected;
- After a firmware upgrade or repair was made;
- After any quality control test failures; and,
- During every field visit.

2.4. Acoustic Doppler Current Profilers (ADCP): Follow the steps below before, during and after use of ADCPs.

2.4.1. Ensure the ADCP is in working order with the latest approved firmware and there is sufficient space on the memory card.

2.4.2. Set ACDP onboard clock, perform diagnostic tests via software menus, and store test results on field computer. Document the ADCP diagnostic test results.

2.4.3. Compare ADCP temperature reading to an external, or separate, thermistor before each deployment. ADCP reading must be within 2° C of external thermistor that has been verified per DEP SOP FT 1400. If the temperature measured by the ADCP temperature sensor differs repeatedly from the independent temperature measurement by 2°C or more, or if the ADCP temperature sensor has failed, the ADCP should not be used to make discharge measurements until the temperature sensor is repaired and checked. If a discharge measurement is necessary and another ADCP is not readily available, it may be possible to enter a temperature manually for use in the speed-of-sound calculations. This action is not recommended as standard practice, however, and it may decrease the accuracy of the discharge measurement (see TM 3-A22).

2.4.4. Measure and document any other parameters required by the manufacturer's manual.

## FT 1820. DIRECT MEASUREMENT METHODS FOR DETERMINING DISCHARGE AT GAGING STATIONS AND OTHER LOCATIONS

Direct measurements are made at gaging stations to determine daily discharge, instantaneous stage and discharge, or annual extremes in stage and discharge. For instructions on how to establish a new gaging station, see TWRI 3-A6. Discharge may need to be determined at other locations for specific project requirements. The information below is used for the determination of discharge by direct measurements.

### FT 1821. *Stage Measurements at Gaging Stations*

1. Establish the stage, or gage, height of zero flow (GZF). Gage height of zero flow occurs at a constructed or natural control feature at which the flow ceases at a determined gage height. Measure and document the GZF during low or no flow. The characteristics of some waterbodies may prohibit the measurement of the GZF.
2. All stage measurement devices must have a measuring resolution of 0.01 ft.
3. A primary reference gage and auxiliary reference gage must be installed at each gaging station. The primary reference gage is a non-recording gage used to set and check the recording gage that automatically records the stage of the water body. The auxiliary reference gage is a second, non-recording gage used to verify the primary reference gage, and detect any elevational movement due to substrate settling or other disturbances. The auxiliary reference gage must be installed structurally independent of the recording and the primary reference gages.
4. Proceed with the following steps to take stage measurements at gaging stations.
   4.1. Before taking stage measurements, inspect the system for proper operation.
   4.2. Measure the stage at the primary reference gage and compare to the gage station recorder during each site visit. If the recorder and primary reference gage differ by more than 0.02 feet, investigate the possible causes of error and adjust according to TM 3-A7. If there is a known difference between the recorder and primary reference gage, apply a correction factor according to TM 3-A7. Document any adjustments or corrections.
   4.3. Record any deviation between the recorder and the reference gage as well as maintenance performed. Indicate personnel performing the maintenance.
   4.4. If the stage at the gaging station fluctuates ≥ 0.1 ft during the measurement period, report gage heights to the nearest 0.1 ft and note the conditions.

5. See procedures in TM 3-A7 for instructions on maintaining gaging stations and obtaining stage measurements.

## FT 1822. *Midsection method for the determination of discharge*

1. Discharge measurements are commonly made by direct current-meter measurements at gaging stations or project defined locations. Methods of computation and determination may vary depending on how the measurements are taken in the field. Refer to the following procedures and references to determine discharge by direct measurements at a gaging station and project defined locations**.**
2. Select the site with as many qualities listed below, which allow for the highest level of accuracy of measurements for determining flow:
    - Reasonably straight channel with streamlines parallel to each other;
    - Stable streambed free of large rocks, weeds, and other obstructions that would create eddies, slack water, or turbulence; and
    - For measurements associated with a gaging station, locate the cross-section as close to the gaging station as possible.
3. If a moving boat is to be used with current meters, refer to TWRI 3-A11.
4. If a cableway is to be installed and used, refer to TM 3-A21.
5. Select current meter and velocity measurement methods based on site conditions and project requirements, including data quality objectives, according to TM 3-A8**.**
6. Determine the width of the cross section with tapes and taglines, surveying methods, or research grade Global Positioning System (GPS).
7. Estimate the number of subsections within a cross-section at which velocity will be measured so that each subsection will contribute approximately 5% and no more than 10% of the total calculated discharge, using historical transect data for the site, if available. Increase or decrease width of subsections during the measurement procedure, as needed, throughout the cross section to meet the 5% target. Resulting flow measurement accuracy is highest if the 5% target is achieved for all subsections, but the 5% target may not be achievable at some sites (narrow streams, for example). The number of subsections that do not meet the 5% target or 10% limit is a component of the quality evaluation of the discharge measurement in FT 1824. See TM 3-A8 for further instruction.
8. Measure depth of the vertical (i.e., the waterbody depth) using equipment applicable to the site and the flow measurement method (i.e., wading, bridge, cableway, or boat) according to TM 3-A8 descriptions.
9. Conduct velocity measurements in each subsection per the requirements of the method selected in section 5, above.
    9.1. Inspect the current meter and check operation prior to, during and after the measurement event as described in FT 1810.
    9.2. Hold the meter in the measurement location for the time described in the instrument manual (typically 40-70 seconds) before recording a reading**.** Reduce stabilization time if the stream is large with rapidly changing stage.
    9.3. Record the velocity at each measurement point.
10. If the discharge measurement is at a gaged site, compute discharge as soon as possible based on equations found in TM 3-A8. Check all calculations after computation for correctness.
11. Compare computed discharge to chosen or established rating curve, if a rating curve for the site exists, and determine the difference. If different by 10% or more, repeat measurement

under the same conditions. If the computed discharge from the second measurement is within 5% of the first, consult an experienced hydrographer to evaluate the discharge results and rating curve.

**FT 1823.** *Determination of Discharge from a Moving Boat Using Acoustic Doppler Profilers (ADCP)*

1. Acoustic Doppler Current Profilers (ADCP) are commonly used to determine discharge in large rivers and estuarine water. This technology differs from that used in traditional discharge measurements and requires practiced techniques for accurate measurement as well as expert knowledge to conduct with accuracy. Wading is not recommended with ADCPs. Use the following procedures and TM 3-A22 to determine discharge with ADCPs in a moving boat.
2. Site selection: Consider the following for ADCP use, in addition to conditions listed in FT 1822, section 2.1:
   - Left and right edges of the transect should be deep enough for measurement of velocity within two or more depth cells, or bins, as defined by the instrument's software, while being close enough to minimize the amount of discharge that must be estimated at the edges of the waterbody. A transect is a straight line from one bank of a waterway to the opposing bank, perpendicular to the flow, along which ADCP measurements are taken.
   - Avoid measurement sections having local magnetic fields (e.g., underwater cable crossings) due to overhead truss bridges, low steel beam spans, power lines and other sources of magnetism to minimize interference with the internal compass.
   - Avoid asymmetric channel geometries and cross sections with abrupt changes in channel-bottom slope. The streambed should be as uniform as possible and free of obstructions, such as debris and rooted vegetation.
3. Set up and configure the ADCP according to the manufacturer's specifications for the model.
4. Prepare for the discharge measurement by completing the following as described in TM3-A8:
   4.1. Perform diagnostic test and log results according to the instrument's manual.
   4.2. Conduct and record a moving bed test as described in TM 3-A22. If a moving bed is present, it is optimal to use GPS for bottom location; however, another method of compensation may be needed (see TM 3-A22).
   4.3. Establish start and stop points.
5. Measure discharge of a transect.
   5.1. Position boat at the start point. Measure and record the distance from start point to the shore. Use the profiler to estimate the shape of the edge areas by moving the ADCP as close as possible to the river edges, even if the velocity cannot be measured.
   5.2. Measure depth to the transducer below water surface before ADCP measurements are taken and record the depth in the measurement notes.
   5.3. Begin measurements. Hold position at the start point for a minimum of 10 ensembles, or profiles, of the water velocity.
   5.4. Drive boat across the river at a speed no greater than the water's speed, if possible.
   5.5. Approach ending shore slowly and hold position at the end point for 10 ensembles. Stop recording and measure the distance from the end point to the shore and record the distance in the measurement notes.

6. Conduct two discharge measurement transects, composed of one transect in one direction and one in the opposite direction back to the starting point identified in 5.1 above (i.e., one transect pair). If the transect pair is completed in less than 12 minutes, conduct discharge measurements for a second transect pair. Calculate the mean of the transects.
7. If the discharge for any of the transects differs by greater than 5% from the mean, and cannot be explained, conduct two additional transects and use the mean of all transect measurements as the discharge.
8. Deviations from the procedures in 6 and 7 above may be necessary (e.g., low water velocity, non-steady flow), and must be documented as described in TM 3-A22.
9. Evaluate data in the field, looking for potential problems in the data.
10. Make temporary backups of measurements per manufacturer's manual before leaving the site.

### FT 1824. *Qualitative Evaluation of Direct Measurements*

Data collected for the determination and calculation of discharge should be evaluated for accuracy using qualitative methods directly after making the measurement. Measurements should be rated based on the hydrographer's professional opinion of the measurement, not on how well or how poorly it plots in relation to an established rating curve. The experience and training of the hydrographer will affect the results of the qualitative evaluation. Refer to TM 3-A8 for more information on qualitative evaluation of measurements taken by the midsection method; for qualitative evaluation for measurements by ADCP, refer to TM 3-A22.

Consider the following factors in evaluating direct measurements:

- Conditions of the measuring section and the ability to accurately measure the depth.
- Conditions upstream and the presence or absence of structures.
- Uniform velocity distribution across the stream, including its smoothness, presence or absence of turbulence, obstructions, and abnormally high or low velocities.
- Condition and type of equipment.
- Spacing of observation subsections.
- Number of subsections that exceeded 5% or 10% of total discharge, and site conditions that may have required fewer than 20 subsections to be assessed.
- Rapidly changing stage and how thoroughly the parameters could be measured.
- Wind and weather conditions at the time of measurement.

### FT 1830. RATING CURVES AND COMPUTATIONAL DETERMINATION OF DISCHARGE

A rating curve is a plot or graph of variables associated with stream hydrology and discharge determination. The type of curve developed depends on the variables that are measured at the site. A simple rating only relates discharge to gage height, or stage. However, a discharge rating can include other variables, if required by the circumstances, and then is considered a complex rating. The following parts of this SOP discuss the two most common types of rating curves. See TWRI 3-A10 for theory and considerations associated with both simple and complex ratings. Information about the rating curve must be maintained according to FT 1850, section 6, such that the status of the curve is known.

## FT 1831. *Stage-Discharge Rating Curves at Gaging Stations*

Stage-discharge rating is the relation of the discharge at a gaging station to stage. See TWRI 3-A10 for information regarding plotting, formatting, shaping and analysis of the stage-discharge curves.

1. Identify the control for the gaging station. Measure and document the GZF during low or no flow. The characteristics of some waterbodies may prohibit the measurement of the GZF.
2. Develop a stage-discharge rating curve over various stages and a range of conditions for the waterway. Do not use a rating curve until there are measurements over the range of stage and flows for the waterway well distributed throughout the curve. Ratings should not be extended beyond two times the highest measured discharge except for extreme events, and then only under the guidance of an experienced hydrographer. Every effort should be made to measure and document such extreme events to prevent having to extend beyond the specified factor.
3. After establishing a rating curve for a site, it is recommended that staff measure discharge at the site every 2 months as well as during unusual flow conditions to improve or develop the rating curve. If direct discharge measurements consistently exhibit a difference greater than 5% from the discharge predicted by the established rating curve for a prolonged period, evaluate whether a change in the rating curve is warranted.

## FT 1832. *Using the Index-Velocity Method to Determine Discharge Rating Curves*

The index-velocity method is used to compute a continuous record of discharge when backwater due to a control structure or tidal control prevents the use of a stage as the unique predictor for discharge. Discharge computed by the index velocity method differs from traditional stage-discharge calculations by separating velocity and area into two ratings (index-velocity rating and stage-area rating). An index-velocity rating is developed after sufficient measurements have been made to cover the range of velocity measured by the index-velocity sensor and the mean channel velocity at the station, and a stage-area rating is developed from a relationship between stage and the cross-sectional area for the channel. During gage operation and after the two ratings have been created, the index-velocity instrument measures the index-velocity concurrently with stage, and the results of the two ratings are then multiplied together to calculate discharge. See TM 3-A23 for additional information. Proceed with the following for the use of Acoustic Velocity Meters (AVM) or Acoustic Doppler Velocity Meters (ADVM) for the development of index-velocity rating curves:

1. Carefully evaluate the candidate index velocity gage site prior to selection.
   1.1. Locate a site suitable for accurate flow measurements, as described in FT 1822 and FT 1823.
   1.2. Select a location at the site best suited for an AVM or an ADVM, as described in TM 2-A23.
   1.3. Measure the cross-section with an ADCP based on procedures described in FT 1823 and TM 3-A22 to evaluate the site for suitability as an index-velocity station, if possible.
2. Select the appropriate type of index-velocity instrument after site reconnaissance and evaluation of the site conditions have been documented.
3. Install and configure the AVM or ADVM.
   3.1. Consider the following for instrument installation.
      3.1.1. Mount the instrument to maximize the downstream velocity reading and minimize the cross-stream velocity reading.

3.1.2. Mount instrument so that servicing can occur at all stages, when possible.
3.1.3. Mount instrument so that it is oriented to avoid impeding acoustic beams.
3.1.4. Mount instrument with index marks to monitor instrument movement from initial placement.

3.2. Configure the meter for the specific characteristics of the site. Refer to the manufacturer's manual for configuration recommendations. At a minimum, the meter should be configured for the following as determined for the site conditions:

- Measurement volume not impinging on an obstruction, channel, or water surface.
- Measurement interval sufficient to reduce the standard error.
- Averaging period.

4. Establish and conduct routine field processes as described in TM 3-A23 for maintenance of meter. Keep records of these procedures.
5. Refer to TM 3-A23 for specific detail in the development of a velocity index-rating curve using AVM or ADVM data.

## FT 1833. *Computation of Continuous Records of streamflow*

Continuous records can be computed from point discharge measurements and corresponding sensors deployed at gaging stations. Data quality of stream flow records will vary depending upon the level of care and precision taken during the measurement of parameters, as well as site conditions at the time of measurement. Data used for computation of stream flow records should be thoroughly reviewed by an experienced hydrographer. Clearly indicate that extrapolated data for missing records used for the computation of continuous records are estimated values. Refer to TWRI 3-A13 for information on how parameters are corrected, data are reviewed, and how continuous discharge records are computed. These actions must all be documented per FT 1850.

## FT 1840. INDIRECT MEASUREMENT METHODS OF DISCHARGE

At some sites, direct measurements for the determination of discharge may not be possible or may be impractical. Indirect measurements allow for the determination of discharge when there is no physical access to a site, such as during floods and high flows or at control structures. An indirect method may be the most reliable means of determining peak flows.

1. Measurement of Discharge by Slope-Area Method

The slope-area method is nationally the most common indirect determination of discharge, but is not frequently used in low slope areas like Florida because of the very long distances required between sections to get ½ foot fall. Discharge is computed based on the uniform flow equation accounting for channel characteristics, water surface profiles and a roughness, or retardation, coefficient. This method requires the review of a selection of reaches and cross-sections for the computation of discharge. Refer to TWRI 3-A2 for equations and site selection information used to compute discharge by the slope-area method.

2. Measurement of Discharge at Confinement Structures by Indirect Methods

Control structure sites are often not ideal for direct measurements because the current is impeded, so indirect methods have been developed for various types of confinement structures.

See descriptions below to determine the best indirect methods for the site conditions or project requirements. Document all measurements and calculations for discharge at confinement structures according to applicable requirements in part FT 1850. A person or entity may choose to use direct measurement methods to determine discharge at confinement structures.

2.1. Measurement of Discharge at Width Contractions and Culverts by Indirect Methods: To determine the peak discharge in culverts, use equations based on continuity and energy. Best results are achieved when the difference between the upstream and downstream water levels is at least ½ foot. Culverts are often put in place due to roadways and can change the flow of a stream channel. Peak discharge can be determined through culverts by indirect methods based on high-water marks that define the headwater and tail-water elevations. For direction in the examination of culverts, explanation of equations, roughness coefficient determination, and discharge computations based on specific conditions and material types, see TWRI 3-A3 and TWRI 3-A4.

2.2. Measurement of Discharge at Dams by Indirect Methods: Control sections are typically formed at structures like weirs, dams, or embankments. Peak discharge at control sections can be determined from a field survey, from records of high-water marks, and from knowledge of the geometry of the structure. The geometry of the structure and channel, along with the ratio of head to crest, should be assessed before determining the structure type and choosing the discharge equation and coefficient. Extensive field notes must be kept of water marks, reference marks, and tail-water height. For techniques and calculations to determine discharge at control structures, see TWRI 3-A5.

2.3. Using Flumes for the Measurement of Discharge: Flumes have a limited use in measurement of discharge, but are useful when channel characteristics that affect gage height are subject to shift or when stream rises are unpredictable. Discharge is determined only by the configuration of the flume. Discharge determined by this method can be confirmed with current meter measurements. See TWRI 3-A14 for information about determining discharge based on flume design, construction, and operation.

## FT 1850. MINIMUM DOCUMENTATION REQUIREMENTS

Documentation specified in the TWRI and TM references cited in this SOP must be included in the records for all measurements and calculations performed according to this SOP. Record information and retain documentation for all stage, velocity and discharge determinations in a manner that allows unequivocal reconstruction of the essential details of field measurement events, discharge calculations, and any other treatments or manipulations of data. The following documentation shall be provided, if applicable to the site:

1. Site Information
    - Source and location of the measurement (e.g., identification number, station number or other description);
    - Latitude and longitude of cross-section(s) measurement location (if required for the project, monitoring program, etc.);
    - Number of channels measured and observed;
    - Length of reach measured (if applicable);

- Date and time site was measured;
- Personnel who visited the site and their duties;
- Description or name of project, or monitoring program, associated with the measurements; and
- Description of site conditions during visit.

2. Instrumentation
    - Vendor certificates of all factory-calibrated instrumentation;
    - Manufacturers' instrumentation manual and specifications;
    - Identity of specific instrumentation in the documentation with a unique description or code for each instrument unit used;
    - Date and time of all quality control activities prescribed by manufacturers' instructions based on instrument type;
    - Identity of the quality control activities performed;
    - Description of the performance of instrumentation during quality control activities (e.g., spin test results or on-board quality control of ADCP);
    - Date and time of corrective actions taken to correct instrument performance according to records requirements of FD 3000; and
    - Names of personnel performing corrective actions.
3. Field measurements
    - Method used for determination of discharge;
    - Analyst(s) performing measurements;
    - Date and time of measurements; and
    - Measurement value and unit for each measurement.
4. Describe and document the rationale for any modifications made to the standard reference procedures cited in this SOP that are used for the project. Include specific listings and descriptions of modifications made and link the modifications to the applicable sections of the standard reference procedures cited in this SOP.
5. Calculations
    - Raw information used for calculations;
    - Analyst(s) who conducted all calculations;
    - Method by which discharge was calculated;
    - Result and units of calculated discharge;
    - Rating curve to which calculated discharge is compared;
    - Reasoning for deviating from prescribed calculation methods indicated in the applicable sections of the standard reference procedures cited in this SOP; and
    - Provide enough information so that the discharge can be recalculated by an independent party and obtain the same result for verification purposes.
6. Rating Curves
    - Status of the rating curve as determined by a hydrographer (e.g., under development, established);
    - Date the curve was last reviewed;
    - Hydrographer(s) responsible for latest review of the rating curve;

- Entity responsible for the maintenance of the rating curve;
- Location associated with the rating curve; and
- All notes associated with the quality of the rating curve and its status.

Designation: D2488 – 09a

# Standard Practice for Description and Identification of Soils (Visual-Manual Procedure)[1]

This standard is issued under the fixed designation D2488; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

*This standard has been approved for use by agencies of the U.S. Department of Defense.*

## 1. Scope*

1.1 This practice covers procedures for the description of soils for engineering purposes.

1.2 This practice also describes a procedure for identifying soils, at the option of the user, based on the classification system described in Test Method D2487. The identification is based on visual examination and manual tests. It must be clearly stated in reporting an identification that it is based on visual-manual procedures.

1.2.1 When precise classification of soils for engineering purposes is required, the procedures prescribed in Test Method D2487 shall be used.

1.2.2 In this practice, the identification portion assigning a group symbol and name is limited to soil particles smaller than 3 in. (75 mm).

1.2.3 The identification portion of this practice is limited to naturally occurring soils (either intact or disturbed).

NOTE 1—This practice may be used as a descriptive system applied to such materials as shale, claystone, shells, crushed rock, etc. (see Appendix X2).

1.3 The descriptive information in this practice may be used with other soil classification systems or for materials other than naturally occurring soils.

1.4 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.5 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific precautionary statements see Section 8.

1.6 *This practice offers a set of instructions for performing one or more specific operations. This document cannot replace education or experience and should be used in conjunction with professional judgment. Not all aspects of this practice may be applicable in all circumstances. This ASTM standard is not intended to represent or replace the standard of care by which the adequacy of a given professional service must be judged, nor should this document be applied without consideration of a project's many unique aspects. The word "Standard" in the title of this document means only that the document has been approved through the ASTM consensus process.*

## 2. Referenced Documents

2.1 *ASTM Standards:*[2]

D653 Terminology Relating to Soil, Rock, and Contained Fluids

D1452 Practice for Soil Exploration and Sampling by Auger Borings

D1586 Test Method for Penetration Test (SPT) and Split-Barrel Sampling of Soils

D1587 Practice for Thin-Walled Tube Sampling of Soils for Geotechnical Purposes

D2113 Practice for Rock Core Drilling and Sampling of Rock for Site Investigation

D2487 Practice for Classification of Soils for Engineering Purposes (Unified Soil Classification System)

D3740 Practice for Minimum Requirements for Agencies Engaged in Testing and/or Inspection of Soil and Rock as Used in Engineering Design and Construction

D4083 Practice for Description of Frozen Soils (Visual-Manual Procedure)

## 3. Terminology

3.1 *Definitions:*

3.1.1 Except as listed below, all definitions are in accordance with Terminology D653.

[1] This practice is under the jurisdiction of ASTM Committee D18 on Soil and Rock and is the direct responsibility of Subcommittee D18.07 on Identification and Classification of Soils.

Current edition approved June 15, 2009. Published July 2009. Originally approved in 1966. Last previous edition approved in 2009 as D2488 – 09. DOI: 10.1520/D2488-09A.

NOTE 2—For particles retained on a 3-in. (75-mm) US standard sieve, the following definitions are suggested:
*Cobbles*—particles of rock that will pass a 12-in. (300-mm) square opening and be retained on a 3-in. (75-mm) sieve, and
*Boulders*—particles of rock that will not pass a 12-in. (300-mm) square opening.

3.1.2 *clay*—soil passing a No. 200 (75-µm) sieve that can be made to exhibit plasticity (putty-like properties) within a range of water contents, and that exhibits considerable strength when air-dry. For classification, a clay is a fine-grained soil, or the fine-grained portion of a soil, with a plasticity index equal to or greater than 4, and the plot of plasticity index versus liquid limit falls on or above the "A" line (see Fig. 3 of Test Method D2487).

3.1.3 *gravel*—particles of rock that will pass a 3-in. (75-mm) sieve and be retained on a No. 4 (4.75-mm) sieve with the following subdivisions:

*coarse*—passes a 3-in. (75-mm) sieve and is retained on a ¾-in. (19-mm) sieve.

*fine*—passes a ¾-in. (19-mm) sieve and is retained on a No. 4 (4.75-mm) sieve.

3.1.4 *organic clay*—a clay with sufficient organic content to influence the soil properties. For classification, an organic clay is a soil that would be classified as a clay, except that its liquid limit value after oven drying is less than 75 % of its liquid limit value before oven drying.

3.1.5 *organic silt*—a silt with sufficient organic content to influence the soil properties. For classification, an organic silt is a soil that would be classified as a silt except that its liquid limit value after oven drying is less than 75 % of its liquid limit value before oven drying.

3.1.6 *peat*—a soil composed primarily of vegetable tissue in various stages of decomposition usually with an organic odor, a dark brown to black color, a spongy consistency, and a texture ranging from fibrous to amorphous.

3.1.7 *sand*—particles of rock that will pass a No. 4 (4.75-mm) sieve and be retained on a No. 200 (75-µm) sieve with the following subdivisions:

*coarse*—passes a No. 4 (4.75-mm) sieve and is retained on a No. 10 (2.00-mm) sieve.

*medium*—passes a No. 10 (2.00-mm) sieve and is retained on a No. 40 (425-µm) sieve.

*fine*—passes a No. 40 (425-µm) sieve and is retained on a No. 200 (75-µm) sieve.

3.1.8 *silt*—soil passing a No. 200 (75-µm) sieve that is nonplastic or very slightly plastic and that exhibits little or no strength when air dry. For classification, a silt is a fine-grained soil, or the fine-grained portion of a soil, with a plasticity index less than 4, or the plot of plasticity index versus liquid limit falls below the "A" line (see Fig. 3 of Test Method D2487).

## 4. Summary of Practice

4.1 Using visual examination and simple manual tests, this practice gives standardized criteria and procedures for describing and identifying soils.

4.2 The soil can be given an identification by assigning a group symbol(s) and name. The flow charts, Fig. 1a and Fig. 1b for fine-grained soils, and Fig. 2, for coarse-grained soils, can be used to assign the appropriate group symbol(s) and name. If the soil has properties which do not distinctly place it into a specific group, borderline symbols may be used, see Appendix X3.

NOTE 3—It is suggested that a distinction be made between *dual symbols* and *borderline symbols.*

*Dual Symbol*—A dual symbol is two symbols separated by a hyphen, for example, GP-GM, SW-SC, CL-ML used to indicate that the soil has been identified as having the properties of a classification in accordance with Test Method D2487 where two symbols are required. Two symbols are required when the soil has between 5 and 12 % fines or when the liquid limit and plasticity index values plot in the CL-ML area of the plasticity chart.
*Borderline Symbol*—A borderline symbol is two symbols separated by a slash, for example, CL/CH, GM/SM, CL/ML. A borderline symbol should be used to indicate that the soil has been identified as having properties that do not distinctly place the soil into a specific group (see Appendix X3).

## 5. Significance and Use

5.1 The descriptive information required in this practice can be used to describe a soil to aid in the evaluation of its significant properties for engineering use.

5.2 The descriptive information required in this practice should be used to supplement the classification of a soil as determined by Test Method D2487.

5.3 This practice may be used in identifying soils using the classification group symbols and names as prescribed in Test Method D2487. Since the names and symbols used in this practice to identify the soils are the same as those used in Test Method D2487, it shall be clearly stated in reports and all other appropriate documents, that the classification symbol and name are based on visual-manual procedures.

5.4 This practice is to be used not only for identification of soils in the field, but also in the office, laboratory, or wherever soil samples are inspected and described.

5.5 This practice has particular value in grouping similar soil samples so that only a minimum number of laboratory tests need be run for positive soil classification.

NOTE 4—The ability to describe and identify soils correctly is learned more readily under the guidance of experienced personnel, but it may also be acquired systematically by comparing numerical laboratory test results for typical soils of each type with their visual and manual characteristics.

5.6 When describing and identifying soil samples from a given boring, test pit, or group of borings or pits, it is not necessary to follow all of the procedures in this practice for every sample. Soils which appear to be similar can be grouped together; one sample completely described and identified with the others referred to as similar based on performing only a few of the descriptive and identification procedures described in this practice.

5.7 This practice may be used in combination with Practice D4083 when working with frozen soils.

NOTE 5—Notwithstanding the statements on precision and bias contained in this standard: The precision of this test method is dependent on the competence of the personnel performing it and the suitability of the equipment and facilities used. Agencies that meet the criteria of Practice D3740 are generally considered capable of competent and objective testing. Users of this test method are cautioned that compliance with Practice D3740 does not in itself assure reliable testing. Reliable testing

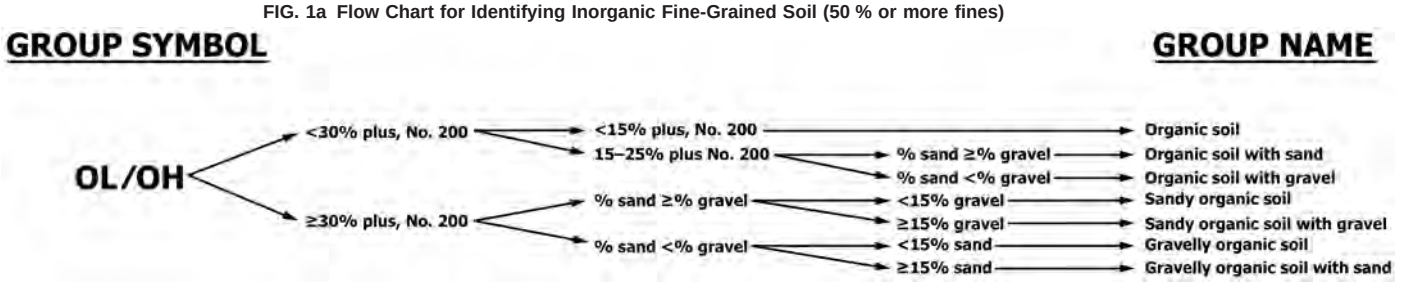
NOTE 1—Percentages are based on estimating amounts of fines, sand, and gravel to the nearest 5 %.

**FIG. 1a Flow Chart for Identifying Inorganic Fine-Grained Soil (50 % or more fines)**



NOTE 1—Percentages are based on estimating amounts of fines, sand, and gravel to the nearest 5 %.

**FIG. 1 b Flow Chart for Identifying Organic Fine-Grained Soil (50 % or more fines)**

depends on several factors; Practice D3740 provides a means for evaluating some of those factors.

## 6. Apparatus

6.1 *Required Apparatus:*

6.1.1 *Pocket Knife or Small Spatula.*

6.2 *Useful Auxiliary Apparatus:*

6.2.1 *Test Tube and Stopper* (or jar with a lid).

6.2.2 *Hand Lens.*

## 7. Reagents

7.1 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean water from a city water supply or natural source, including non-potable water.

7.2 *Hydrochloric Acid*—A small bottle of dilute hydrochloric acid, HCl, one part HCl (10 *N*) to three parts water (This reagent is optional for use with this practice). See Section 8.

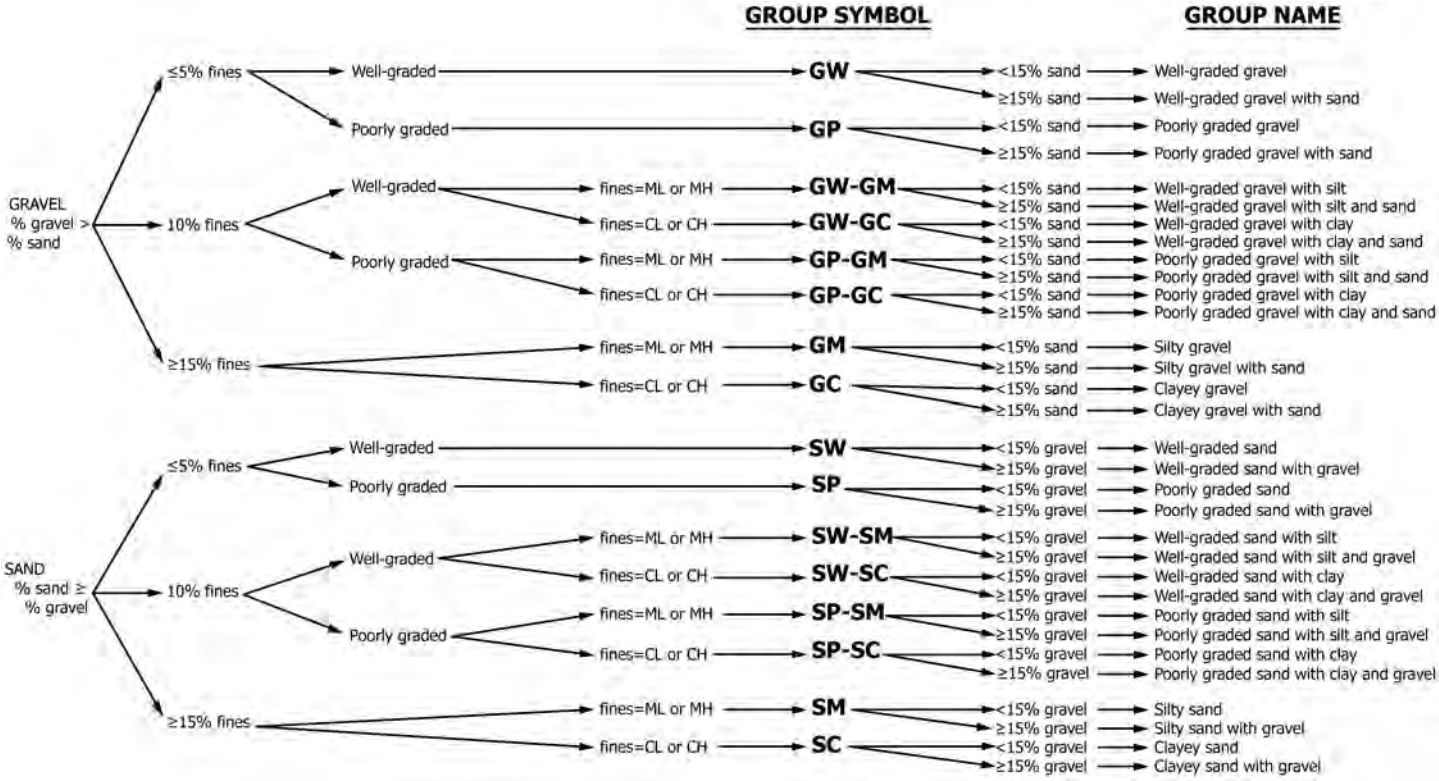
Downloaded/printed by
USDA - Natural Resources Conservation Service (USDA - Natural Resources Conservation Service) pursuant to License Agreement. No further reproductions authorized.



NOTE 1—Percentages are based on estimating amounts of fines, sand, and gravel to the nearest 5 %.

**FIG. 2 Flow Chart for Identifying Coarse-Grained Soils (less than 50 % fines)**

## 8. Safety Precautions

8.1 When preparing the dilute HCl solution of one part concentrated hydrochloric acid (10 *N*) to three parts of distilled water, slowly add acid into water following necessary safety precautions. Handle with caution and store safely. If solution comes into contact with the skin, rinse thoroughly with water.

8.2 **Caution**—Do not add water to acid.

## 9. Sampling

9.1 The sample shall be considered to be representative of the stratum from which it was obtained by an appropriate, accepted, or standard procedure.

NOTE 6—Preferably, the sampling procedure should be identified as having been conducted in accordance with Practices D1452, D1587, or D2113, or Test Method D1586.

9.2 The sample shall be carefully identified as to origin.

NOTE 7—Remarks as to the origin may take the form of a boring number and sample number in conjunction with a job number, a geologic stratum, a pedologic horizon or a location description with respect to a permanent monument, a grid system or a station number and offset with respect to a stated centerline and a depth or elevation.

9.3 For accurate description and identification, the minimum amount of the specimen to be examined shall be in accordance with the following schedule:

| Maximum Particle Size, Sieve Opening | Minimum Specimen Size, Dry Weight |
|---|---|
| 4.75 mm (No. 4) | 100 g (0.25 lb) |
| 9.5 mm (⅜ in.) | 200 g (0.5 lb) |
| 19.0 mm (¾ in.) | 1.0 kg (2.2 lb) |
| 38.1 mm (1½ in.) | 8.0 kg (18 lb) |
| 75.0 mm (3 in.) | 60.0 kg (132 lb) |

NOTE 8—If random isolated particles are encountered that are significantly larger than the particles in the soil matrix, the soil matrix can be accurately described and identified in accordance with the preceeding schedule.

9.4 If the field sample or specimen being examined is smaller than the minimum recommended amount, the report shall include an appropriate remark.

## 10. Descriptive Information for Soils

10.1 *Angularity*—Describe the angularity of the sand (coarse sizes only), gravel, cobbles, and boulders, as angular, subangular, subrounded, or rounded in accordance with the criteria in Table 1 and Fig. 3. A range of angularity may be stated, such as: subrounded to rounded.

10.2 *Shape*—Describe the shape of the gravel, cobbles, and boulders as flat, elongated, or flat and elongated if they meet the criteria in Table 2 and Fig. 4. Otherwise, do not mention the shape. Indicate the fraction of the particles that have the shape, such as: one-third of the gravel particles are flat.

Copyright by ASTM Int'l (all rights reserved); Fri Sep 30 13:07:21 EDT 2016
Downloaded/printed by
USDA - Natural Resources Conservation Service (USDA - Natural Resources Conservation Service) pursuant to License Agreement. No further reproductions authorized.

**TABLE 1 Criteria for Describing Angularity of Coarse-Grained Particles (see Fig. 3)**

| Description | Criteria |
|---|---|
| Angular | Particles have sharp edges and relatively plane sides with unpolished surfaces |
| Subangular | Particles are similar to angular description but have rounded edges |
| Subrounded | Particles have nearly plane sides but have well-rounded corners and edges |
| Rounded | Particles have smoothly curved sides and no edges |

10.3 *Color*—Describe the color. Color is an important property in identifying organic soils, and within a given locality it may also be useful in identifying materials of similar geologic origin. If the sample contains layers or patches of varying colors, this shall be noted and all representative colors shall be described. The color shall be described for moist samples. If the color represents a dry condition, this shall be stated in the report.

10.4 *Odor*—Describe the odor if organic or unusual. Soils containing a significant amount of organic material usually have a distinctive odor of decaying vegetation. This is especially apparent in fresh samples, but if the samples are dried, the odor may often be revived by heating a moistened sample. If the odor is unusual (petroleum product, chemical, and the like), it shall be described.

10.5 *Moisture Condition*—Describe the moisture condition as dry, moist, or wet, in accordance with the criteria in Table 3.

10.6 *HCl Reaction*—Describe the reaction with HCl as none, weak, or strong, in accordance with the critera in Table 4. Since calcium carbonate is a common cementing agent, a report of its presence on the basis of the reaction with dilute hydrochloric acid is important.

10.7 *Consistency*—For intact fine-grained soil, describe the consistency as very soft, soft, firm, hard, or very hard, in accordance with the criteria in Table 5. This observation is inappropriate for soils with significant amounts of gravel.

10.8 *Cementation*—Describe the cementation of intact coarse-grained soils as weak, moderate, or strong, in accordance with the criteria in Table 6.

10.9 *Structure*—Describe the structure of intact soils in accordance with the criteria in Table 7.

10.10 *Range of Particle Sizes*—For gravel and sand components, describe the range of particle sizes within each component as defined in 3.1.2 and 3.1.6. For example, about 20 % fine to coarse gravel, about 40 % fine to coarse sand.

10.11 *Maximum Particle Size*—Describe the maximum particle size found in the sample in accordance with the following information:

10.11.1 *Sand Size*—If the maximum particle size is a sand size, describe as fine, medium, or coarse as defined in 3.1.6. For example: maximum particle size, medium sand.

10.11.2 *Gravel Size*—If the maximum particle size is a gravel size, describe the maximum particle size as the smallest sieve opening that the particle will pass. For example, maximum particle size, 1½ in. (will pass a 1½-in. square opening but not a ¾-in. square opening).

10.11.3 *Cobble or Boulder Size*—If the maximum particle size is a cobble or boulder size, describe the maximum dimension of the largest particle. For example: maximum dimension, 18 in. (450 mm).

10.12 *Hardness*—Describe the hardness of coarse sand and larger particles as hard, or state what happens when the particles are hit by a hammer, for example, gravel-size particles fracture with considerable hammer blow, some gravel-size particles crumble with hammer blow. “Hard” means particles do not crack, fracture, or crumble under a hammer blow.

10.13 Additional comments shall be noted, such as the presence of roots or root holes, difficulty in drilling or augering hole, caving of trench or hole, or the presence of mica.

10.14 A local or commercial name or a geologic interpretation of the soil, or both, may be added if identified as such.

10.15 A classification or identification of the soil in accordance with other classification systems may be added if identified as such.

## 11. Identification of Peat

11.1 A sample composed primarily of vegetable tissue in various stages of decomposition that has a fibrous to amorphous texture, usually a dark brown to black color, and an organic odor, shall be designated as a highly organic soil and shall be identified as peat, PT, and not subjected to the identification procedures described hereafter.

## 12. Preparation for Identification

12.1 The soil identification portion of this practice is based on the portion of the soil sample that will pass a 3-in. (75-mm) sieve. The larger than 3-in. (75-mm) particles must be removed, manually, for a loose sample, or mentally, for an intact sample before classifying the soil.

12.2 Estimate and note the percentage of cobbles and the percentage of boulders. Performed visually, these estimates will be on the basis of volume percentage.

NOTE 9—Since the percentages of the particle-size distribution in Test Method D2487 are by dry weight, and the estimates of percentages for gravel, sand, and fines in this practice are by dry weight, it is recommended that the report state that the percentages of cobbles and boulders are by volume.

12.3 Of the fraction of the soil smaller than 3 in. (75 mm), estimate and note the percentage, by dry weight, of the gravel, sand, and fines (see Appendix X4 for suggested procedures).

NOTE 10—Since the particle-size components appear visually on the basis of volume, considerable experience is required to estimate the percentages on the basis of dry weight. Frequent comparisons with laboratory particle-size analyses should be made.

12.3.1 The percentages shall be estimated to the closest 5 %. The percentages of gravel, sand, and fines must add up to 100 %.

12.3.2 If one of the components is present but not in sufficient quantity to be considered 5 % of the smaller than 3-in. (75-mm) portion, indicate its presence by the term *trace*,

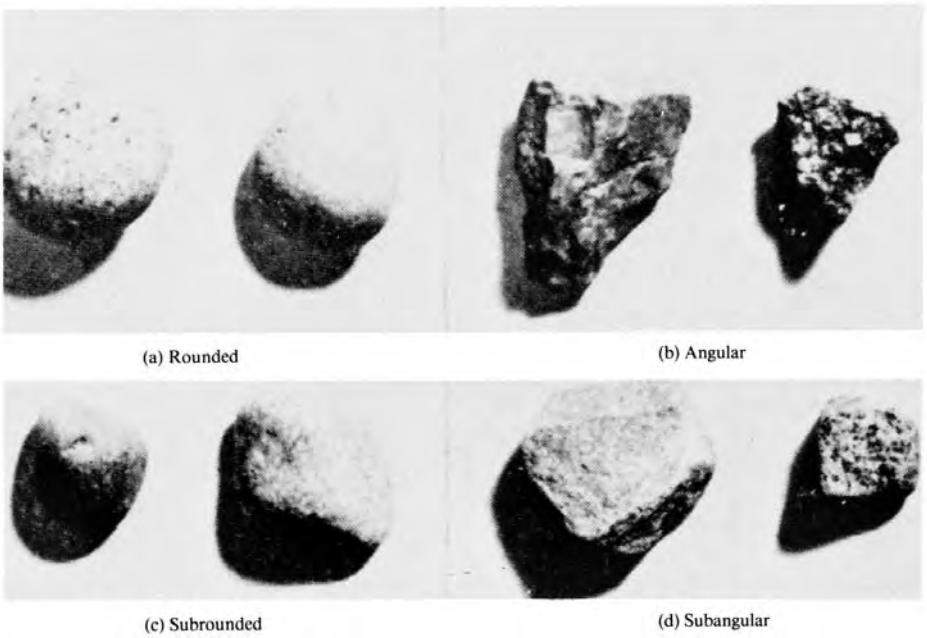

**FIG. 3 Typical Angularity of Bulky Grains**

**TABLE 2 Criteria for Describing Particle Shape (see Fig. 4)**

The particle shape shall be described as follows where length, width, and thickness refer to the greatest, intermediate, and least dimensions of a particle, respectively.

| | |
|---|---|
| Flat | Particles with width/thickness > 3 |
| Elongated | Particles with length/width > 3 |
| Flat and elongated | Particles meet criteria for both flat and elongated |

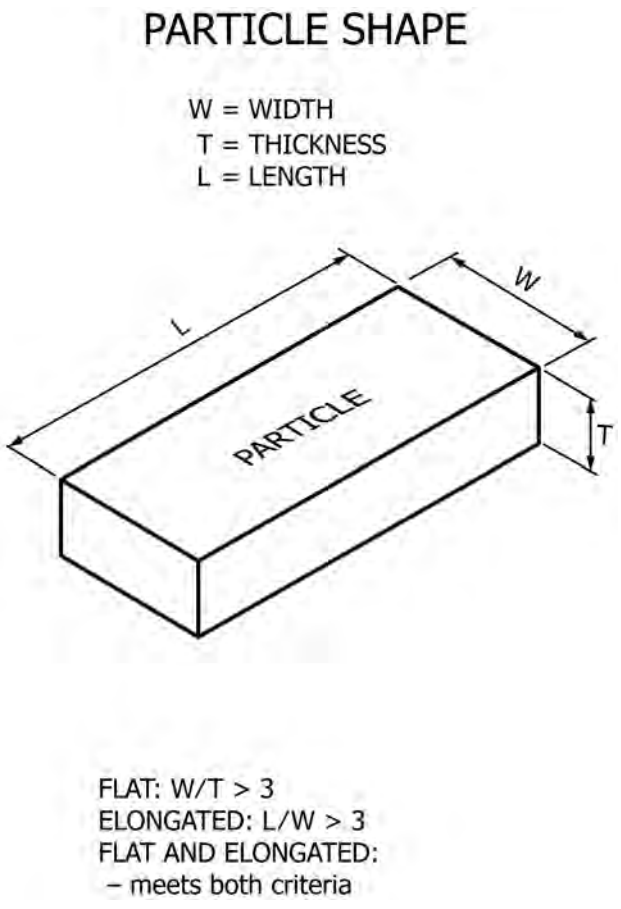

**FIG. 4 Criteria for Particle Shape**

for example, trace of fines. A trace is not to be considered in the total of 100 % for the components.

## 13. Preliminary Identification

13.1 The soil is *fine grained* if it contains 50 % or more fines. Follow the procedures for identifying fine-grained soils of Section 14.

13.2 The soil is *coarse grained* if it contains less than 50 % fines. Follow the procedures for identifying coarse-grained soils of Section 15.

## 14. Procedure for Identifying Fine-Grained Soils

14.1 Select a representative sample of the material for examination. Remove particles larger than the No. 40 sieve (medium sand and larger) until a specimen equivalent to about a handful of material is available. Use this specimen for performing the dry strength, dilatancy, and toughness tests.

14.2 *Dry Strength:*

14.2.1 From the specimen, select enough material to mold into a ball about 1 in. (25 mm) in diameter. Mold the material until it has the consistency of putty, adding water if necessary.

14.2.2 From the molded material, make at least three test specimens. A test specimen shall be a ball of material about ½

USDA - Natural Resources Conservation Service (USDA - Natural Resources Conservation Service) pursuant to License Agreement. No further reproductions authorized.

**TABLE 3 Criteria for Describing Moisture Condition**

| Description | Criteria |
|---|---|
| Dry | Absence of moisture, dusty, dry to the touch |
| Moist | Damp but no visible water |
| Wet | Visible free water, usually soil is below water table |

**TABLE 4 Criteria for Describing the Reaction With HCl**

| Description | Criteria |
|---|---|
| None | No visible reaction |
| Weak | Some reaction, with bubbles forming slowly |
| Strong | Violent reaction, with bubbles forming immediately |

**TABLE 5 Criteria for Describing Consistency**

| Description | Criteria |
|---|---|
| Very soft | Thumb will penetrate soil more than 1 in. (25 mm) |
| Soft | Thumb will penetrate soil about 1 in. (25 mm) |
| Firm | Thumb will indent soil about ¼ in. (6 mm) |
| Hard | Thumb will not indent soil but readily indented with thumbnail |
| Very hard | Thumbnail will not indent soil |

**TABLE 6 Criteria for Describing Cementation**

| Description | Criteria |
|---|---|
| Weak | Crumbles or breaks with handling or little finger pressure |
| Moderate | Crumbles or breaks with considerable finger pressure |
| Strong | Will not crumble or break with finger pressure |

**TABLE 7 Criteria for Describing Structure**

| Description | Criteria |
|---|---|
| Stratified | Alternating layers of varying material or color with layers at least 6 mm thick; note thickness |
| Laminated | Alternating layers of varying material or color with the layers less than 6 mm thick; note thickness |
| Fissured | Breaks along definite planes of fracture with little resistance to fracturing |
| Slickensided | Fracture planes appear polished or glossy, sometimes striated |
| Blocky | Cohesive soil that can be broken down into small angular lumps which resist further breakdown |
| Lensed | Inclusion of small pockets of different soils, such as small lenses of sand scattered through a mass of clay; note thickness |
| Homogeneous | Same color and appearance throughout |

in. (12 mm) in diameter. Allow the test specimens to dry in air, or sun, or by artificial means, as long as the temperature does not exceed 60°C.

14.2.3 If the test specimen contains natural dry lumps, those that are about ½ in. (12 mm) in diameter may be used in place of the molded balls.

NOTE 11—The process of molding and drying usually produces higher strengths than are found in natural dry lumps of soil.

14.2.4 Test the strength of the dry balls or lumps by crushing between the fingers. Note the strength as none, low, medium, high, or very high in accorance with the criteria in Table 8. If natural dry lumps are used, do not use the results of any of the lumps that are found to contain particles of coarse sand.

14.2.5 The presence of high-strength water-soluble cementing materials, such as calcium carbonate, may cause exceptionally high dry strengths. The presence of calcium carbonate can usually be detected from the intensity of the reaction with dilute hydrochloric acid (see 10.6).

**TABLE 8 Criteria for Describing Dry Strength**

| Description | Criteria |
|---|---|
| None | The dry specimen crumbles into powder with mere pressure of handling |
| Low | The dry specimen crumbles into powder with some finger pressure |
| Medium | The dry specimen breaks into pieces or crumbles with considerable finger pressure |
| High | The dry specimen cannot be broken with finger pressure. Specimen will break into pieces between thumb and a hard surface |
| Very high | The dry specimen cannot be broken between the thumb and a hard surface |

14.3 *Dilatancy:*

14.3.1 From the specimen, select enough material to mold into a ball about ½ in. (12 mm) in diameter. Mold the material, adding water if necessary, until it has a soft, but not sticky, consistency.

14.3.2 Smooth the soil ball in the palm of one hand with the blade of a knife or small spatula. Shake horizontally, striking the side of the hand vigorously against the other hand several times. Note the reaction of water appearing on the surface of the soil. Squeeze the sample by closing the hand or pinching the soil between the fingers, and note the reaction as none, slow, or rapid in accordance with the criteria in Table 9. The reaction is the speed with which water appears while shaking, and disappears while squeezing.

14.4 *Toughness:*

14.4.1 Following the completion of the dilatancy test, the test specimen is shaped into an elongated pat and rolled by hand on a smooth surface or between the palms into a thread about ⅛ in. (3 mm) in diameter. (If the sample is too wet to roll easily, it should be spread into a thin layer and allowed to lose some water by evaporation.) Fold the sample threads and reroll repeatedly until the thread crumbles at a diameter of about ⅛ in. The thread will crumble at a diameter of ⅛ in. when the soil is near the plastic limit. Note the pressure required to roll the thread near the plastic limit. Also, note the strength of the thread. After the thread crumbles, the pieces should be lumped together and kneaded until the lump crumbles. Note the toughness of the material during kneading.

14.4.2 Describe the toughness of the thread and lump as low, medium, or high in accordance with the criteria in Table 10.

**TABLE 9 Criteria for Describing Dilatancy**

| Description | Criteria |
|---|---|
| None | No visible change in the specimen |
| Slow | Water appears slowly on the surface of the specimen during shaking and does not disappear or disappears slowly upon squeezing |
| Rapid | Water appears quickly on the surface of the specimen during shaking and disappears quickly upon squeezing |

Copyright by ASTM Int'l (all rights reserved); Fri Sep 30 13:07:21 EDT 2016
Downloaded/printed by
USDA - Natural Resources Conservation Service (USDA - Natural Resources Conservation Service) pursuant to License Agreement. No further reproductions authorized.

**TABLE 10 Criteria for Describing Toughness**

| Description | Criteria |
|---|---|
| Low | Only slight pressure is required to roll the thread near the plastic limit. The thread and the lump are weak and soft |
| Medium | Medium pressure is required to roll the thread to near the plastic limit. The thread and the lump have medium stiffness |
| High | Considerable pressure is required to roll the thread to near the plastic limit. The thread and the lump have very high stiffness |

14.5 *Plasticity*—On the basis of observations made during the toughness test, describe the plasticity of the material in accordance with the criteria given in Table 11.

14.6 Decide whether the soil is an *inorganic* or an *organic* fine-grained soil (see 14.8). If inorganic, follow the steps given in 14.7.

14.7 *Identification of Inorganic Fine-Grained Soils:*

14.7.1 Identify the soil as a *lean clay*, CL, if the soil has medium to high dry strength, no or slow dilatancy, and medium toughness and plasticity (see Table 12).

14.7.2 Identify the soil as a *fat clay*, CH, if the soil has high to very high dry strength, no dilatancy, and high toughness and plasticity (see Table 12).

14.7.3 Identify the soil as a *silt*, ML, if the soil has no to low dry strength, slow to rapid dilatancy, and low toughness and plasticity, or is nonplastic (see Table 12).

14.7.4 Identify the soil as an *elastic silt*, MH, if the soil has low to medium dry strength, no to slow dilatancy, and low to medium toughness and plasticity (see Table 12).

NOTE 12—These properties are similar to those for a lean clay. However, the silt will dry quickly on the hand and have a smooth, silky feel when dry. Some soils that would classify as MH in accordance with the criteria in Test Method D2487 are visually difficult to distinguish from lean clays, CL. It may be necessary to perform laboratory testing for proper identification.

14.8 *Identification of Organic Fine-Grained Soils:*

14.8.1 Identify the soil as an *organic soil*, OL/OH, if the soil contains enough organic particles to influence the soil properties. Organic soils usually have a dark brown to black color and may have an organic odor. Often, organic soils will change color, for example, black to brown, when exposed to the air. Some organic soils will lighten in color significantly when air dried. Organic soils normally will not have a high toughness or plasticity. The thread for the toughness test will be spongy.

NOTE 13—In some cases, through practice and experience, it may be possible to further identify the organic soils as organic silts or organic clays, OL or OH. Correlations between the dilatancy, dry strength, toughness tests, and laboratory tests can be made to identify organic soils in certain deposits of similar materials of known geologic origin.

**TABLE 11 Criteria for Describing Plasticity**

| Description | Criteria |
|---|---|
| Nonplastic | A ⅛-in. (3-mm) thread cannot be rolled at any water content |
| Low | The thread can barely be rolled and the lump cannot be formed when drier than the plastic limit |
| Medium | The thread is easy to roll and not much time is required to reach the plastic limit. The thread cannot be rerolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit |
| High | It takes considerable time rolling and kneading to reach the plastic limit. The thread can be rerolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier than the plastic limit |

**TABLE 12 Identification of Inorganic Fine-Grained Soils from Manual Tests**

| Soil Symbol | Dry Strength | Dilatancy | Toughness and Plasticity |
|---|---|---|---|
| ML | None to low | Slow to rapid | Low or thread cannot be formed |
| CL | Medium to high | None to slow | Medium |
| MH | Low to medium | None to slow | Low to medium |
| CH | High to very high | None | High |

14.9 If the soil is estimated to have 15 to 25 % sand or gravel, or both, the words “with sand” or “with gravel” (whichever is more predominant) shall be added to the group name. For example: “lean clay with sand, CL” or “silt with gravel, ML” (see Fig. 1a and Fig. 1b). If the percentage of sand is equal to the percentage of gravel, use “with sand.”

14.10 If the soil is estimated to have 30 % or more sand or gravel, or both, the words “sandy” or “gravelly” shall be added to the group name. Add the word “sandy” if there appears to be more sand than gravel. Add the word “gravelly” if there appears to be more gravel than sand. For example: “sandy lean clay, CL”, “gravelly fat clay, CH”, or “sandy silt, ML” (see Fig. 1a and Fig. 1b). If the percentage of sand is equal to the percent of gravel, use “sandy.”

## 15. Procedure for Identifying Coarse-Grained Soils

(Contains less than 50 % fines)

15.1 The soil is a *gravel* if the percentage of gravel is estimated to be more than the percentage of sand.

15.2 The soil is a *sand* if the percentage of gravel is estimated to be equal to or less than the percentage of sand.

15.3 The soil is a *clean gravel* or *clean sand* if the percentage of fines is estimated to be 5 % or less.

15.3.1 Identify the soil as a *well-graded gravel*, GW, or as a *well-graded sand*, SW, if it has a wide range of particle sizes and substantial amounts of the intermediate particle sizes.

15.3.2 Identify the soil as a *poorly graded gravel*, GP, or as a *poorly graded sand*, SP, if it consists predominantly of one size (uniformly graded), or it has a wide range of sizes with some intermediate sizes obviously missing (gap or skip graded).

15.4 The soil is either a *gravel with fines* or a *sand with fines* if the percentage of fines is estimated to be 15 % or more.

15.4.1 Identify the soil as a *clayey gravel*, GC, or a *clayey sand*, SC, if the fines are clayey as determined by the procedures in Section 14.

15.4.2 Identify the soil as a *silty gravel*, GM, or a *silty sand*, SM, if the fines are silty as determined by the procedures in Section 14.

15.5 If the soil is estimated to contain 10 % fines, give the soil a dual identification using two group symbols.

15.5.1 The first group symbol shall correspond to a clean gravel or sand (GW, GP, SW, SP) and the second symbol shall correspond to a gravel or sand with fines (GC, GM, SC, SM).

Copyright by ASTM Int'l (all rights reserved); Fri Sep 30 13:07:21 EDT 2016
Downloaded/printed by
USDA - Natural Resources Conservation Service (USDA - Natural Resources Conservation Service) pursuant to License Agreement. No further reproductions authorized.

15.5.2 The group name shall correspond to the first group symbol plus the words “with clay” or “with silt” to indicate the plasticity characteristics of the fines. For example: “well-graded gravel with clay, GW-GC” or “poorly graded sand with silt, SP-SM” (see Fig. 2).

15.6 If the specimen is predominantly sand or gravel but contains an estimated 15 % or more of the other coarse-grained constituent, the words “with gravel” or “with sand” shall be added to the group name. For example: “poorly graded gravel with sand, GP” or “clayey sand with gravel, SC” (see Fig. 2).

15.7 If the field sample contains any cobbles or boulders, or both, the words “with cobbles” or “with cobbles and boulders” shall be added to the group name. For example: “silty gravel with cobbles, GM.”

## 16. Report

16.1 The report shall include the information as to origin, and the items indicated in Table 13.

NOTE 14—*Example: Clayey Gravel with Sand and Cobbles, GC*—About 50 % fine to coarse, subrounded to subangular gravel; about 30 % fine to coarse, subrounded sand; about 20 % fines with medium plasticity, high dry strength, no dilatancy, medium toughness; weak reaction with HCl; original field sample had about 5 % (by volume) subrounded cobbles, maximum dimension, 150 mm.
In-Place Conditions—Firm, homogeneous, dry, brown
Geologic Interpretation—Alluvial fan

NOTE 15—Other examples of soil descriptions and identification are given in Appendix X1 and Appendix X2.

NOTE 16—If desired, the percentages of gravel, sand, and fines may be stated in terms indicating a range of percentages, as follows:
*Trace*—Particles are present but estimated to be less than 5 %
*Few*—5 to 10 %
*Little*—15 to 25 %
*Some*—30 to 45 %
*Mostly*—50 to 100 %

16.2 If, in the soil description, the soil is identified using a classification group symbol and name as described in Test Method D2487, it must be distinctly and clearly stated in log forms, summary tables, reports, and the like, that the symbol and name are based on visual-manual procedures.

**TABLE 13 Checklist for Description of Soils**

1. Group name
2. Group symbol
3. Percent of cobbles or boulders, or both (by volume)
4. Percent of gravel, sand, or fines, or all three (by dry weight)
5. Particle-size range:
   Gravel—fine, coarse
   Sand—fine, medium, coarse
6. Particle angularity: angular, subangular, subrounded, rounded
7. Particle shape: (if appropriate) flat, elongated, flat and elongated
8. Maximum particle size or dimension
9. Hardness of coarse sand and larger particles
10. Plasticity of fines: nonplastic, low, medium, high
11. Dry strength: none, low, medium, high, very high
12. Dilatancy: none, slow, rapid
13. Toughness: low, medium, high
14. Color (in moist condition)
15. Odor (mention only if organic or unusual)
16. Moisture: dry, moist, wet
17. Reaction with HCl: none, weak, strong

*For intact samples:*

18. Consistency (fine-grained soils only): very soft, soft, firm, hard, very hard
19. Structure: stratified, laminated, fissured, slickensided, lensed, homogeneous
20. Cementation: weak, moderate, strong
21. Local name
22. Geologic interpretation
23. Additional comments: presence of roots or root holes, presence of mica, gypsum, etc., surface coatings on coarse-grained particles, caving or sloughing of auger hole or trench sides, difficulty in augering or excavating, etc.

## 17. Precision and Bias

17.1 This practice provides qualitative information only, therefore, a precision and bias statement is not applicable.

## 18. Keywords

18.1 classification; clay; gravel; organic soils; sand; silt; soil classification; soil description; visual classification

# APPENDIXES

**(Nonmandatory Information)**

## X1. EXAMPLES OF VISUAL SOIL DESCRIPTIONS

X1.1 The following examples show how the information required in 16.1 can be reported. The information that is included in descriptions should be based on individual circumstances and need.

X1.1.1 *Well-Graded Gravel with Sand (GW)*—About 75 % fine to coarse, hard, subangular gravel; about 25 % fine to coarse, hard, subangular sand; trace of fines; maximum size, 75 mm, brown, dry; no reaction with HCl.

X1.1.2 *Silty Sand with Gravel (SM)*—About 60 % predominantly fine sand; about 25 % silty fines with low plasticity, low dry strength, rapid dilatancy, and low toughness; about 15 % fine, hard, subrounded gravel, a few gravel-size particles fractured with hammer blow; maximum size, 25 mm; no reaction with HCl (Note—Field sample size smaller than recommended).

*In-Place Conditions*—Firm, stratified and contains lenses of silt 1 to 2 in. (25 to 50 mm) thick, moist, brown to gray; in-place density 106 lb/ft$^3$; in-place moisture 9 %.

X1.1.3 *Organic Soil (OL/OH)*—About 100 % fines with low plasticity, slow dilatancy, low dry strength, and low toughness; wet, dark brown, organic odor; weak reaction with HCl.

X1.1.4 *Silty Sand with Organic Fines (SM)*—About 75 % fine to coarse, hard, subangular reddish sand; about 25 % organic and silty dark brown nonplastic fines with no dry

Copyright by ASTM Int'l (all rights reserved); Fri Sep 30 13:07:21 EDT 2016
Downloaded/printed by
USDA - Natural Resources Conservation Service (USDA - Natural Resources Conservation Service) pursuant to License Agreement. No further reproductions authorized.

strength and slow dilatancy; wet; maximum size, coarse sand; weak reaction with HCl.

X1.1.5 *Poorly Graded Gravel with Silt, Sand, Cobbles and Boulders (GP-GM)*—About 75 % fine to coarse, hard, subrounded to subangular gravel; about 15 % fine, hard, subrounded to subangular sand; about 10 % silty nonplastic fines; moist, brown; no reaction with HCl; original field sample had about 5 % (by volume) hard, subrounded cobbles and a trace of hard, subrounded boulders, with a maximum dimension of 18 in. (450 mm).

## X2. USING THE IDENTIFICATION PROCEDURE AS A DESCRIPTIVE SYSTEM FOR SHALE, CLAYSTONE, SHELLS, SLAG, CRUSHED ROCK, AND THE LIKE

X2.1 The identification procedure may be used as a descriptive system applied to materials that exist in-situ as shale, claystone, sandstone, siltstone, mudstone, etc., but convert to soils after field or laboratory processing (crushing, slaking, and the like).

X2.2 Materials such as shells, crushed rock, slag, and the like, should be identified as such. However, the procedures used in this practice for describing the particle size and plasticity characteristics may be used in the description of the material. If desired, an identification using a group name and symbol according to this practice may be assigned to aid in describing the material.

X2.3 The group symbol(s) and group names should be placed in quotation marks or noted with some type of distinguishing symbol. See examples.

X2.4 Examples of how group names and symbols can be incororated into a descriptive system for materials that are not naturally occurring soils are as follows:

X2.4.1 *Shale Chunks*—Retrieved as 2 to 4-in. (50 to 100-mm) pieces of shale from power auger hole, dry, brown, no reaction with HCl. After slaking in water for 24 h, material identified as “Sandy Lean Clay (CL)”; about 60 % fines with medium plasticity, high dry strength, no dilatancy, and medium toughness; about 35 % fine to medium, hard sand; about 5 % gravel-size pieces of shale.

X2.4.2 *Crushed Sandstone*—Product of commercial crushing operation; “Poorly Graded Sand with Silt (SP-SM)”; about 90 % fine to medium sand; about 10 % nonplastic fines; dry, reddish-brown.

X2.4.3 *Broken Shells*—About 60 % uniformly graded gravel-size broken shells; about 30 % sand and sand-size shell pieces; about 10 % nonplastic fines; “Poorly Graded Gravel with Silt and Sand (GP-GM).”

X2.4.4 *Crushed Rock*—Processed from gravel and cobbles in Pit No. 7; “Poorly Graded Gravel (GP)”; about 90 % fine, hard, angular gravel-size particles; about 10 % coarse, hard, angular sand-size particles; dry, tan; no reaction with HCl.

## X3. SUGGESTED PROCEDURE FOR USING A BORDERLINE SYMBOL FOR SOILS WITH TWO POSSIBLE IDENTIFICATIONS.

X3.1 Since this practice is based on estimates of particle size distribution and plasticity characteristics, it may be difficult to clearly identify the soil as belonging to one category. To indicate that the soil may fall into one of two possible basic groups, a borderline symbol may be used with the two symbols separated by a slash. For example: SC/CL or CL/CH.

X3.1.1 A borderline symbol may be used when the percentage of fines is estimated to be between 45 and 55 %. One symbol should be for a coarse-grained soil with fines and the other for a fine-grained soil. For example: GM/ML or CL/SC.

X3.1.2 A borderline symbol may be used when the percentage of sand and the percentage of gravel are estimated to be about the same. For example: GP/SP, SC/GC, GM/SM. It is practically impossible to have a soil that would have a borderline symbol of GW/SW.

X3.1.3 A borderline symbol may be used when the soil could be either well graded or poorly graded. For example: GW/GP, SW/SP.

X3.1.4 A borderline symbol may be used when the soil could either be a silt or a clay. For example: CL/ML, CH/MH, SC/SM.

X3.1.5 A borderline symbol may be used when a fine-grained soil has properties that indicate that it is at the boundary between a soil of low compressibility and a soil of high compressibility. For example: CL/CH, MH/ML.

X3.2 The order of the borderline symbols should reflect similarity to surrounding or adjacent soils. For example: soils in a borrow area have been identified as CH. One sample is considered to have a borderline symbol of CL and CH. To show similarity, the borderline symbol should be CH/CL.

X3.3 The group name for a soil with a borderline symbol should be the group name for the first symbol, except for:

CL/CH lean to fat clay
ML/CL clayey silt
CL/ML silty clay

X3.4 The use of a borderline symbol should not be used indiscriminately. Every effort shall be made to first place the soil into a single group.

USDA - Natural Resources Conservation Service (USDA - Natural Resources Conservation Service) pursuant to License Agreement. No further reproductions authorized.

## X4. SUGGESTED PROCEDURES FOR ESTIMATING THE PERCENTAGES OF GRAVEL, SAND, AND FINES IN A SOIL SAMPLE

X4.1 *Jar Method*—The relative percentage of coarse- and fine-grained material may be estimated by thoroughly shaking a mixture of soil and water in a test tube or jar, and then allowing the mixture to settle. The coarse particles will fall to the bottom and successively finer particles will be deposited with increasing time; the sand sizes will fall out of suspension in 20 to 30 s. The relative proportions can be estimated from the relative volume of each size separate. This method should be correlated to particle-size laboratory determinations.

X4.2 *Visual Method*—Mentally visualize the gravel size particles placed in a sack (or other container) or sacks. Then, do the same with the sand size particles and the fines. Then, mentally compare the number of sacks to estimate the percentage of plus No. 4 sieve size and minus No. 4 sieve size present. The percentages of sand and fines in the minus sieve size No. 4 material can then be estimated from the wash test (X4.3).

X4.3 *Wash Test (for relative percentages of sand and fines)*—Select and moisten enough minus No. 4 sieve size material to form a 1-in (25-mm) cube of soil. Cut the cube in half, set one-half to the side, and place the other half in a small dish. Wash and decant the fines out of the material in the dish until the wash water is clear and then compare the two samples and estimate the percentage of sand and fines. Remember that the percentage is based on weight, not volume. However, the volume comparison will provide a reasonable indication of grain size percentages.

X4.3.1 While washing, it may be necessary to break down lumps of fines with the finger to get the correct percentages.

## X5. ABBREVIATED SOIL CLASSIFICATION SYMBOLS

X5.1 In some cases, because of lack of space, an abbreviated system may be useful to indicate the soil classification symbol and name. Examples of such cases would be graphical logs, databases, tables, etc.

X5.2 This abbreviated system is not a substitute for the full name and descriptive information but can be used in supplementary presentations when the complete description is referenced.

X5.3 The abbreviated system should consist of the soil classification symbol based on this standard with appropriate lower case letter prefixes and suffixes as:

| *Prefix:* | Suffix: |
|---|---|
| s = sandy | s = with sand |
| g = gravelly | g = with gravel |
| | c = with cobbles |
| | b = with boulders |

X5.4 The soil classification symbol is to be enclosed in parenthesis. Some examples would be:

| *Group Symbol and Full Name* | Abbreviated |
|---|---|
| CL, Sandy lean clay | s(CL) |
| SP-SM, Poorly graded sand with silt and gravel | (SP-SM)g |
| GP, poorly graded gravel with sand, cobbles, and boulders | (GP)scb |
| ML, gravelly silt with sand and cobbles | g(ML)sc |

## SUMMARY OF CHANGES

Committee D18 has identified the location of selected changes to this standard since the last issue (D2488 – 09) that may impact the use of this standard. (Approved June 15, 2009.)

*(1)* Revised Section 1.2.3.

# STANDARD OPERATING PROCEDURE FOR LOW-STRESS (Low Flow) / MINIMAL DRAWDOWN GROUND-WATER SAMPLE COLLECTION

## INTRODUCTION

The collection of "representative" water samples from wells is neither straightforward nor easily accomplished. Ground-water sample collection can be a source of variability through differences in sample personnel and their individual sampling procedures, the equipment used, and ambient temporal variability in subsurface and environmental conditions. Many site inspections and remedial investigations require the sampling at ground-water monitoring wells within a defined criterion of data confidence or data quality, which necessitates that the personnel collecting the samples are trained and aware of proper sample-collection procedures.

The purpose of this standard operating procedure (SOP) is to provide a method which minimize the amount of impact the purging process has on the ground water chemistry during sample collection and to minimize the volume of water that is being purged and disposed. This will take place by placing the pump intake within the screen interval and by keeping the drawdown at a minimal level (0.33 feet) ( Puls and Barcelona, 1996) until the water quality parameters have stabilized and sample collection is complete. The flow rate at which the pump will be operating will be depended upon both hydraulic conductivity of the aquifer and the drawdown with the goal of minimizing the drawdown. The flow rate from the pump during purging and sampling will be at a rate that will not compromise the integrity of the analyte that is being sampled. This sampling procedure may or may not provide a discrete ground water sample at the location of the pump intake. The flow of ground-water to the pump intake will be dependent on the distribution of the hydraulic conductivity (K) of the aquifer within the screen interval. In order to minimize the drawdown in the monitoring well a low-flow rate must be utilized. Low-flow refers to the velocity with which water enters the pump intake from the surrounding formation in the

immediate vicinity of the well screen. It does not necessarily refer to the flow rate of water discharged at the surface, which can be affected by flow regulators or restrictions (Puls and Barcelona, 1996). This SOP was developed by the Superfund/RCRA Ground Water Forum and draws from an USEPA's Ground Water Issue Paper, Low-Flow (Minimal Drawdown) Ground-Water Sampling Procedure, by Robert W. Puls and Michael J. Barcelona. Also, available USEPA Regional SOPs regarding Low-Stress(Low Flow)Purging and Sampling were used for this SOP.

## SCOPE AND APPLICATION

This SOP should be used primarily at monitoring wells which have a screen or an open interval with a length of ten feet or less and can accept a sampling device which minimizes the disturbance to the aquifer or the water column in the well casing. The screen or open interval should have been optimally located to intercept an existing contaminant plume(s) or along flowpaths of potential contaminant releases. Knowledge of the contaminant distribution within the screen interval is highly recommended and is essential for the success of this sampling procedure. The ground-water samples which are collected using this procedure are acceptable for the analyses of ground-water contaminants which may be found at Superfund and RCRA contamination sites. The analytes may be volatile, semi-volatile organic compounds, pesticides, PCBs, metals and other inorganic compounds. The screened interval should be located within the contaminant plume(s) and the pump intake should be placed at or near the known source of the contamination within the screened interval. It is critical to place the pump intake in the exact location or depth for each sampling event. This argues for the use of dedicated, permanently installed sampling devices whenever possible. If this is not possible then the placement of the pump intake should be positioned with a calibrated sampling pump hose sounded with a weighted-tape or using a pre-measured hose. The pump intake should not be placed near the bottom of the screened interval to avoid disturbing any sediment that may have settled at the bottom of the well.

Water-quality indicator parameters and water levels must be measured during purging, prior to sample collection. Stabilization of the water quality parameters as well as

monitoring water levels are a prerequisite to sample collection. The water-quality indicator parameters which are recommended include the following: specific electrical conductance, dissolved oxygen, turbidity, oxidation-reduction potential, pH, and temperature. The latter two parameters are useful data, but are generally insensitive as purging parameters. Oxidation-reduction potential may not always be appropriate stabilization parameter, and will depend on site-specific conditions. However, readings should be recorded because of its value as a double check for oxidation conditions, and for fate and transport issues. Also, when samples are collected for metals, semi-volatile organic compounds, and pesticides every effort must be made to reduce turbidity to 10 NTUs or less (not just the stabilization of turbidity) prior to the collection of the water sample. In addition to the measurement of the above parameters, depth to water must be measured during purging (U.S. Environmental Protection Agency, 1995).

Proper well construction, development and maintenance are essential for any ground-water sampling procedure. Prior to conducting the field work, information on the construction of the well and well development should be obtained and that information factored into the site specific sampling procedure. The attached Sampling Checklist is an example of the type of information that is useful.

Stabilization of the water-quality indicator parameters is the criterion for sample collection. But if stabilization is not occurring and the procedure has been strictly followed, then sample collection can take place once three (minimum) to six (maximum) casing volumes have been removed (Schuller et al., 1981 and U.S. Environmental Protection Agency., 1986; Wilde et al., 1998; Gibs and Imbrigiotta., 1990). The specific information on what took place during purging must be recorded in the field notebook or in the ground-water sampling log.

This SOP is not to be used where non-aqueous phase liquids (immiscible fluids) are present in the monitoring well.

**EQUIPMENT**

- Depth-to-water measuring device - An electronic water-level indicator or steel tape and chalk, with marked intervals of

0.01 foot. Interface probe for determination of liquid products (NAPL) presence, if needed.

- Steel tape and weight – Used for measuring total depth of well. Lead weight should not be used.
- Sampling pump – Submersible or bladder pumps with adjustable rate controls are preferred. Pumps are to be constructed of inert materials, such as stainless steel and teflon®. Pump types that are acceptable include gear and helical driven, centrifugal (low-flow type) and air-activated piston. Adjustable rate, peristaltic pump can be used when the depth to water is 20 feet or less.
- Tubing – Teflon® or Teflon® lined polyethylene tubing is preferred when sampling for organic compounds. Polyethylene tubing can be used when sampling inorganics.
- Power Source – If a combustion type (gasoline or diesel-driven) generator is used, it must be placed downwind of the sampling area.
- Flow measurement supplies – flow meter, graduated cylinder and a stop watch.
- Multi-Parameter meter with flow-through-cell – This can be one instrument or more contained in a flow-through cell. The water-quality indicator parameters which must be monitored are pH, ORP/EH, dissolved oxygen (DO), turbidity, specific conductance, and temperature. Turbidity readings must be collected before the flow cell because of the potential for sediment buildup which can bias the turbidity measurements. Calibration fluids for all instruments should be NIST-traceable and there should be enough for daily calibration through-out the sampling event. The inlet of the flow cell must be located near the bottom of the flow cell and the outlet near the top. The size of the flow cell should be kept to a minimum and a closed cell is preferred. The flow cell must not contain any air or gas bubbles when monitoring for the water-quality indicator parameters.
- Decontamination Supplies – Including a reliable and documented source of distilled water and any solvents (if used). Pressure sprayers, buckets or decontamination tubes for pumps, brushes and non-phosphate soap will also be needed.
- Sample bottles, sample preservation supplies, sample tags or labels and chain of custody forms.
- Approved Field Sampling and Quality Assurance Project Plan.
- Well construction data, field and water quality data from the previous sampling event.
- Well keys and map of well locations.

- Field notebook, ground-water sampling logs and calculator. A suggested field data sheet (ground-water sampling record or ground-water sampling log) are provided in the attachment.
- Filtration equipment, if needed. An in-line disposable filter is recommended.
- Polyethylene sheeting which will be placed on ground around the well head.
- Personal protective equipment specified in the site Health and Safety Plan.
- Air monitoring equipment as specified in the Site Health and Safety Plan.
- Tool box -All needed tools for all site equipment used.
- A 55-gallon drum or container to contain the purged water.

Materials of construction of the sampling equipment (bladders, pumps, tubing, and other equipment that comes in contact with the sample) should be limited to stainless steel, Teflon®, glass and other inert material. This will reduce the chance of the sampling materials to alter the ground-water where concentrations of the site contaminants are expected to be near the detection limits. The sample tubing diameter thickness should be maximized and the tubing length should be minimized so that the loss of contaminants into and through the tubing walls may be reduced and the rate of stabilization of ground-water parameters is maximized. The tendency of organics to sorb into and out of material makes the appropriate selection of sample tubing material critical for trace analyses (Pohlmann and Alduino, 1992; Parker and Ranney, 1998).

## PURGING AND SAMPLING PROCEDURES

The following describes the purging and sampling procedures for the Low-Stress (Low Flow)/ Minimal Drawdown method for the collection of ground-water samples. These procedures also describe steps for dedicated and non-dedicated systems.

Pre-Sampling Activities (Non-dedicated and dedicated system)

1. Sampling locations must begin at the monitoring well with the least contamination, generally up-gradient or furthest from the site or suspected source. Then proceed systematically to the monitoring wells with the most contaminated ground water.

2. Check and record the condition of the monitoring well for damage or evidence of tampering. Lay out polyethylene sheeting around the well to minimize the likelihood of contamination of sampling/purging equipment from the soil. Place monitoring, purging and sampling equipment on the sheeting.

3. Unlock well head. Record location, time, date and appropriate information in a field logbook or on the ground-water sampling log (See attached ground-water sampling record and ground-water sampling log as examples).

4. Remove inner casing cap.

5. Monitor the headspace of the monitoring well at the rim of the casing for volatile organic compounds (VOC) with a Photo-ionization detector (PID) or Flame ionization detector (FID), and record in the logbook. If the existing monitoring well has a history of positive readings of the headspace, then the sampling must be conducted in accordance with the Health and Safety Plan.

6. Measure the depth to water (water level must be measured to nearest 0.01 feet) relative to a reference measuring point on the well casing with an electronic water level indicator or steel tape and record in logbook or ground-water sampling log. If no reference point is found, measure relative to the top of the inner casing, then mark that reference point and note that location in the field logbook. Record information on depth to ground water in the field logbook or ground water sampling log. Measure the depth to water a second time to confirm initial measurement; measurement should agree within 0.01 feet or re-measure.

7. Check the available well information or field information for the total depth of the monitoring well. Use the information from the depth of water in step six and the total depth of the monitoring well to calculate the volume of the water in the monitoring well or the volume of one casing. Record information in field logbook or ground-water sampling log.

<u>Purging and Sampling Activities</u>

8A. Non-dedicated system - Place the pump and support equipment at the wellhead and slowly lower the pump and tubing down into the monitoring well until the location of the pump intake is set

at a pre-determined location within the screen interval. The placement of the pump intake should be positioned with a calibrated sampling pump hose, sounded with a weighted-tape, or using a pre-measured hose. Refer to the available monitoring well information to determine the depth and length of the screen interval. Measure the depth of the pump intake while lowering the pump into location. Record pump location in field logbook or groundwater sampling log.

8B. Dedicated system - Pump has already been installed, refer to the available monitoring well information and record the depth of the pump intake in the field logbook or ground-water sampling log.

9. Non-dedicated system and dedicated system - Measure the water level (water level must be measured to nearest 0.01 feet) and record information on the ground-water sampling log, leave water level indicator probe in the monitoring well.

10. Non-dedicated and dedicated system - Connect the discharge line from the pump to a flow-through cell. A "T" connection is needed prior to the flow cell to allow for the collection of water for the turbidity measurements. The discharge line from the flow-through cell must be directed to a container to contain the purge water during the purging and sampling of the monitoring well.

11. Non-dedicated and dedicated system - Start pumping the well at a low flow rate (0.2 to 0.5 liter per minute) and slowly increase the speed. Check water level. Maintain a steady flow rate while maintaining a drawdown of less than 0.33 feet (Puls and Barcelona, 1996). If drawdown is greater than 0.33 feet lower the flow rate. 0.33 feet is a goal to help guide with the flow rate adjustment. It should be noted that this goal may be difficult to achieve under some circumstances due to geologic heterogeneities within the screened interval, and may require adjustment based on site-specific conditions and personal experience (Puls and Barcelona, 1996).

12. Non-dedicated and dedicated system - Measure the discharge rate of the pump with a graduated cylinder and a stop watch. Also, measure the water level and record both flow rate and water level on the groundwater sampling log. Continue purging, monitor and record water level and pump rate every three to five minutes during purging. Pumping rates should be kept at minimal flow to

ensure minimal drawdown in the monitoring well.

13. Non-dedicated and dedicated system - During the purging, a minimum of one tubing volume (including the volume of water in the pump and flow cell) must be purged prior to recording the water-quality indicator parameters. Then monitor and record the water-quality indicator parameters every three to five minutes. The water-quality indicator field parameters are turbidity, dissolved oxygen, specific electrical conductance, pH, redox-potential and temperature. Oxidation-reduction potential may not always be an appropriate stabilization parameter, and will depend on site-specific conditions. However, readings should be recorded because of its value as a double check for oxidizing conditions. Also, for the final dissolved oxygen measurement, if the readings are less than 1 milligram per liter, it should be collected and analyze with the spectrophotometric method (Wilde et al., 1998 Wilkin et al., 2001), colorimetric or Winkler titration (Wilkin et al., 2001). The stabilization criterion is based on three successive readings of the water quality field parameters; the following are the criteria which must be used:

| **Parameter** | **Stabilization Criteria** | **Reference** |
|---|---|---|
| pH | ± 0.1 pH units | Puls and Barcelona, 1996; Wilde et al., |
| Specific electrical conductance (SEC) | ± 3% FS/cm | Puls and Barcelona, 1996 |
| oxidation-reduction potential (ORP) | ± 10 millivolts | Puls and Barcelona 1996 |
| turbidity | ± 10 % NTUs (when turbidity is greater than 10 NTUs) | Puls and Barcelona, 1996 Wilde et al., 1998 |
| dissolved oxygen | ± 0.3 milligrams per liter | Wilde et al., 1998 |

Once the criteria have been successfully met indicating that the water quality indicator parameters have stabilized, then sample collection can take place.

14. If a stabilized drawdown in the well can't be maintained at 0.33 feet and the water level is approaching the top of the screened interval, reduce the flow rate or turn the pump off (for 15 minutes) and allow for recovery. It should be noted whether or not the pump has a check valve. A check valve is required if the pump is shut off. Under no circumstances should the well be

pumped dry. Begin pumping at a lower flow rate, if the water draws-down to the top of the screened interval again turn pump off and allow for recovery. If two tubing volumes (including the volume of water in the pump and flow cell) have been removed during purging then sampling can proceed next time the pump is turned on. This information should be noted in the field notebook or ground-water sampling log with a recommendation for a different purging and sampling procedure.

15. Non-dedicated and dedicated system - Maintain the same pumping rate or reduce slightly for sampling (0.2 to 0.5 liter per minute) in order to minimize disturbance of the water column. Samples should be collected directly from the discharge port of the pump tubing prior to passing through the flow-through cell. Disconnect the pump's tubing from the flow-through-cell so that the samples are collected from the pump's discharge tubing. For samples collected for dissolved gases or Volatile Organic Compounds (VOCs) analyses, the pump's tubing needs to be completely full of ground water to prevent the ground water from being aerated as the ground water flows through the tubing. The sequence of the samples is immaterial unless filtered (dissolved) samples are collected and they must be collected last (Puls and Barcelona, 1996). All sample containers should be filled with minimal turbulence by allowing the ground water to flow from the tubing gently down the inside of the container. When filling the VOC samples a meniscus must be formed over the mouth of the vial to eliminate the formation of air bubbles and head space prior to capping. In the event that the ground water is turbid,(greater then 10 NTUs), a filtered metal (dissolved) sample also should be collected.

If filtered metal sample is to be collected, then an in-line filter is fitted at the end of the discharge tubing and the sample is collected after the filter. The in-line filter must be pre-rinsed following manufacturer's recommendations and if there are no recommendations for rinsing, a minimum of 0.5 to 1 liter of ground water from the monitoring well must pass through the filter prior to sampling.

16A. Non-dedicated system - Remove the pump from the monitoring well. Decontaminate the pump and dispose of the tubing if it is non-dedicated.

16B Dedicated system - Disconnect the tubing that extends from the plate at the wellhead (or cap) and discard after use.

17. Non-dedicated system - Before locking the monitoring well, measure and record the well depth (to 0.1 feet).
Measure the total depth a second time to confirm initial measurement; measurement should agree within 0.01 feet or re-measure.

18. Non-dedicated and dedicated system - Close and lock the well.

## DECONTAMINATION PROCEDURES

Decontamination procedures for the water level meter and the water quality field parameter sensors.
The electronic water level indicator probe/steel tape and the water-quality field parameter sensors will be decontaminated by the following procedures:
1. The water level meter will be hand washed with phosphate free detergent and a scrubber, then thoroughly rinsed with distilled water.

2. Water quality field parameter sensors and flow-through cell will be rinsed with distilled water between sampling locations. No other decontamination procedures are necessary or recommended for these probes since they are sensitive. After the sampling event, the flow cell and sensors must be cleaned and maintained per the manufacturer's requirements.

Decontamination Procedure for the Sampling Pump

Upon completion of the ground water sample collection the sampling pump must be properly decontaminated between monitoring wells. The pump and discharge line including support cable and electrical wires which were in contact with the ground water in the well casing must be decontaminated by the following procedure:

1. The outside of the pump, tubing, support cable and electrical wires must be pressured sprayed with soapy water, tap water and distilled water. Spray outside of tubing and pump until water is flowing off of tubing after each rinse. Use bristle brush to help remove visible dirt and contaminants.
2.Place the sampling pump in a bucket or in a short PVC casing (4-in. diameter) with one end capped. The pump placed in this device must be completely submerged in the water. A small amount of phosphate free detergent must be added to the potable water

(tap water).
3. Remove the pump from the bucket or 4-in. casing and scrub the outside of the pump housing and cable.
4. Place pump and discharge line back in the 4-in. casing or bucket, start pump and re-circulate this soapy water for 2 minutes (wash).
5. Re-direct discharge line to a 55-gallon drum, continue to add 5 gallons of potable water (tap water)or until soapy water is no longer visible.
6. Turn pump off and place pump into a second bucket or 4-in. Casing which contains tap water, continue to add 5-gallons of tap water (rinse).
7. Turn pump off and place pump into a third bucket or 4-in. casing which contains distilled/deionized water, continue to add three to five gallons of distilled/deionized water (final rinse).
8. If a hydrophobic contaminant is present (such as separate phase, high levels of PCB's, etc.) An additional decon step, or steps, may be added. For example, an organic solvent, such as reagent-grade isopropanol alcool may be added as a first spraying/bucket prior to the soapy water rinse/bucket.

## FIELD QUALITY CONTROL

Quality control (QC) samples must be collected to verify that sample collection and handling procedures were performed adequately and that they have not compromised the quality of the ground water samples. The appropriate EPA program guidance must be consulted in preparing the field QC sample requirements for the site-specific Quality Assurance Project Plan (QAPP).

There are five primary areas of concern for quality assurance (QA) in the collection of representative ground-water samples:

1. Obtaining a ground-water sample that is representative of the aquifer or zone of interest in the aquifer. Verification is based on the field log documenting that the field water-quality parameters stabilized during the purging of the well, prior to sample collection.
2. Ensuring that the purging and sampling devices are made of materials, and utilized in a manner, which will not interact with or alter the analyses.
3. Ensuring that results generated by these procedures are reproducible; therefore, the sampling scheme should incorporate co-located samples (duplicates).

4. Preventing cross-contamination. Sampling should proceed from least to most contaminated wells, if known. Field equipment blanks should be incorporated for all sampling and purging equipment, and decontamination of the equipment is therefore required.
5. Properly preserving, packaging, and shipping samples.

All field quality control samples must be prepared the same as regular investigation samples with regard to sample volume, containers, and preservation. The chain of custody procedures for the QC samples will be identical to the field ground water samples. The following are quality control samples which must be collected during the sampling event:

| Sample Type | Frequency |
|---|---|
| ● Field duplicates | 1 per 20 samples |
| ● Matrix spike | 1 per 20 samples |
| ● Matrix spike duplicate | 1 per 20 samples |
| ● Equipment blank | Per Regional requirements or policy |
| ● Trip blank (VOCs) | 1 per sample cooler |
| ● Temperature blank | 1 per sample cooler |

## HEALTH AND SAFETY CONSIDERATIONS

Depending on the site-specific contaminants, various protective programs must be implemented prior to sampling the first well. The site Health and Safety Plan should be reviewed with specific emphasis placed on the protection program planned for the sampling tasks. Standard safe operating practices should be followed, such as minimizing contact with potential contaminants in both the liquid and vapor phase through the use of appropriate personal protective equipment.

Depending on the type of contaminants expected or determined in previous sampling efforts, the following safe work practices will be employed:

Particulate or metals contaminants

1. Avoid skin contact with, and incidental ingestion of, purge water.
2. Use protective gloves and splash protection.

Volatile organic contaminants

1. Avoid breathing constituents venting from well.
2. Pre-survey the well head space with an appropriate device as specified in the Site Health and Safety Plan.
3. If monitoring results indicate elevated organic constituents, sampling activities may be conducted in level C protection. At a minimum, skin protection will be afforded by disposable protective clothing, such as Tyvek®.

General, common practices should include avoiding skin contact with water from preserved sample bottles, as this water will have pH less than 2 or greater than 10. Also, when filling pre-acidified VOA bottles, hydrochloric acid fumes may be released and should not be inhaled.

**POST-SAMPLING ACTIVITIES**

Several activities need to be completed and documented once ground-water sampling has been completed. These activities include, but are not limited to:

1. Ensure that all field equipment has been decontaminated and returned to proper storage location. Once the individual field equipment has been decontaminated, tag it with date of cleaning, site name, and name of individual responsible.
2. All sample paperwork should be processed, including copies provided to the Regional Laboratory, Sample Management Office, or other appropriate sample handling and tracking facility.
3. All field data should be complied for site records.
4. All analytical data when processed by the analytical laboratory, should be verified against field sheets to ensure all data has been returned to sampler.

Slide 2

Welcome. Here you will learn how to conduct and analyze low flow data to determine hydraulic conductivity (K). The short course is designed to take about 4 hours but take your time to conduct the simulations and to perform the required analyses. If you are seeking professional CEUs, you will be instructed at the end of the course on information you must submit.

Slide 3

# Introducing Your Instructor

- Professor of Geology at the University of Connecticut
  - Specializing in hydrogeology
  - Conducted research for over 25 years on improving site assessments at contamination sites
  - Authored over a hundred articles, reports and presentations
  - Developed patented PEBS method for field screening for volatile organics
  - Helped establish mobile site characterization group at CT DEEP (SASU)
  - Consultant to EPA, state regulators, industry, localities throughout US
  - Registered Geologist and Engineering Geologist in California
  - AIPG CPG
  - Recipient of the U. Connecticut Chancellor's Information Technology Award
- Senior Project Hydrogeologist with Woodward-Clyde Consultants
- Project Geologist with Nuclear Regulatory Commission
- Author of ***Expedited Site Assessment: The CD***
- Author and Instructor of online and mortar and brick continuing education courses for environmental professionals
- Manager, Robbins Consulting Services, LLC

Hi, I am Gary Robbins your instructor. I have spent a good portion of my professional career working on ways to improve site characterization methods at contamination sites and teaching lessons learned to students and professionals. Although I prefer to provide field based instruction, I have developed this short course as a mechanism to outreach to a larger audience of professionals. However, to maintain the sense of hands-on field experience, I have developed the test simulations in the short course. If along the way, you need some assistance, just click on the **Contact Instructor** link and send me an email with contact information. I will try to get back to you in short order. Enjoy learning.

Slide 4

# Special Thanks

- Special thanks to Steve Bartlett and Alexandra Aragon-Jose who assisted the author in the field in verifying the usefulness of the low flow K testing method.
- The author appreciates the assistance from all the professionals that conducted beta testing of this short course material.

Special thanks to my former students and coauthors who helped develop the approaches included in the short course.

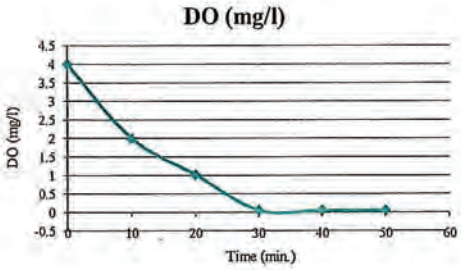
# 1. Low Flow Purging and Sampling Overview

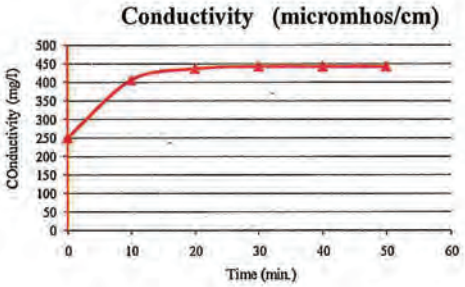
Low flow purging and sampling has become the norm for collecting ground water samples from monitoring wells. Typically, it entails purging a well by pumping at a relatively low discharge rate (<1 L/min) to minimize the amount of drawdown in the well. Once the drawdown is at steady state, water quality parameters are monitored until they are stable. Then a water quality sample is taken. Low flow sampling permits purging a well of "stale" water while minimizing drawdown which helps to promote radial flow to the well. Radial flow reduces complex mixing of water from difference levels in a formation that could result in complicated and inconsistent concentration averaging from sampling round to sampling round. It also reduces turbidity generation and the need for filtering.

Slide 7

# Low Flow Sampling Parameters

| Time (min) | DTW (ft) | Q(ml.min) | DO (mg/l) | ORP (mv) | T (oC) | EC (Mmhos/cm) | pH | Turbidity ( NTU) |
|---|---|---|---|---|---|---|---|---|
| 0 | 7.01 | 250 | 4 | 156 | 18 | 250 | 6.07 | 102 |
| 10 | 6.67 | 250 | 2 | 45 | 16 | 406 | 6.1 | 45 |
| 20 | 6.55 | 250 | 1.02 | -20 | 14 | 436 | 6.15 | 19 |
| 30 | 6.55 | 250 | 0.056 | -41 | 14 | 442 | 6.15 | 11 |
| 40 | 6.55 | 250 | 0.055 | -50 | 14 | 442 | 6.15 | 9 |
| 50 | 6.55 | 250 | 0.055 | -50 | 14 | 442 | 6.15 | 9 |





Data collected during low flow sampling includes, static depth to water, drawdown, flow rate, dissolved oxygen, temperature, conductivity, oxidation –reduction potential, pH and turbidity. Although the data collect during low flow sampling is used to determine when to sample, it is also very revealing of contaminant and hydrogeologic related conditions. It can provide direct and indirect information on the presence of contamination, on levels of biodegradation, and what ionic species may be stable and mobile. As will be shown in this course, the steady state discharge and drawdown achieved during low flow purging and sampling can be used to compute hydraulic conductivity.

Slide 8

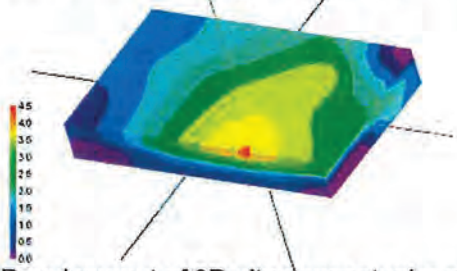
## Hydraulic Conductivity Has a Critical Influence on…

Ground water discharge and velocity
Contaminant velocity and flux

Direction of contaminant transport

Extent of investigation and magnitude of risk

Choice of remediation method

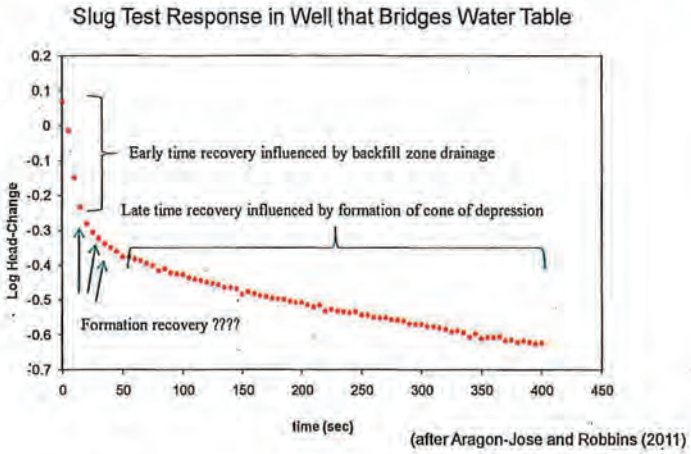


Development of 3D site conceptual model

Determining the magnitude and spatial variability of hydraulic conductivity at a contamination site is critical in performing site assessments, given the many factors that it influences as shown here. Hydraulic conductivity values collected while low flow sampling can also help monitor formation dynamics--whether a well needs development because fines have been mobilized during sampling or whether a remediation method may influence formation permeability over time

Slide 9

# Why Use the Low Flow Method to Determine K?



(after Aragon-Jose and Robbins (2011)

- Avoid backfill zone drainage and resaturation that makes determining K from slug tests in wells that have screens that bridge the water table dubious

At most contamination sites, the hydraulic conductivity is determined by slug testing. The main advantages of slug testing include: little, if any contaminated water is generated; equipment needs and test procedures are simple, and test analyses are straight forward. However, there are times when slug testing is problematic. In monitoring wells that bridge the water, slug test drawdown (head change) vs. time recovery curves are not log linear as predicted by the models used to analyze the tests (e.g., Hvorslev or Bouwer and Rice). The water level recovery is strongly influenced by backfill zone drainage in early time as shown on the figure. Backfill zone drainage results in an initial rapid recovery. The late time data is influenced by the formation of a cone of depression or ever decreasing recovery. These influences result in a multisegmented recovery curve. The hydraulic conductivity depends on

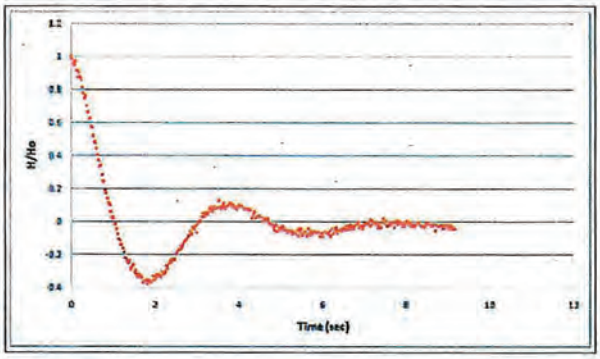
the slope of the recovery curve. One is left having to guess which part of the curve between the extremes represents only formation response. Of course this leads to a good deal of uncertainty in the analyses. The low flow method avoids these issues. At steady state, there is no backfill zone drainage or further development of a cone of depression influencing the near-field of the well.

Slide 10

# Why Use the Low Flow Method to Determine K?

Pneumatic Slug Test

Slug Test Response in High K Formation



•Avoid having to conduct pneumatic testing and use of complex analysis associated with slug tests in high K formations that exhibit oscillatory response

In highly permeable formations, slug test responses can be oscillatory (underdamped) and very short lived (seconds). To conduct slug tests in highly permeable formations requires using pneumatic equipment with a high frequency pressure transducer. It requires a considerable more effort than a typical slug test. Also, to determine hydraulic conductivity from oscillatory data requires using complex analyses. Furthermore, these tests are only valid if the well screen is fully submerged. Determining hydraulic conductivity from low flow sampling avoids the oscillatory response and allows for simplified analysis.

Slide 11

## Why Use the Low Flow Method to Determine K?

- Avoid another phase of investigation to conduct slug testing

- Monitor changes in formation water quality and permeability simultaneously to evaluate remediation method impact on both
  - oxygenates
  - iron filligs

Of course, conducting hydraulic testing while low flow sampling can avoid the need and cost associated with another phase of investigation. There are situations where remediation methods can impact a formation hydraulic conductivity which in turn will influence the ground water flow velocity and direction. Adding oxygenates to the groundwater can cause metals to precipitate which can clog pores. Iron walls made by injecting iron filings could also have similar impact. Determining the hydraulic conductivity while low flow sampling can be used to monitor these possible effects.

Slide 12

# 2. Test Parameters

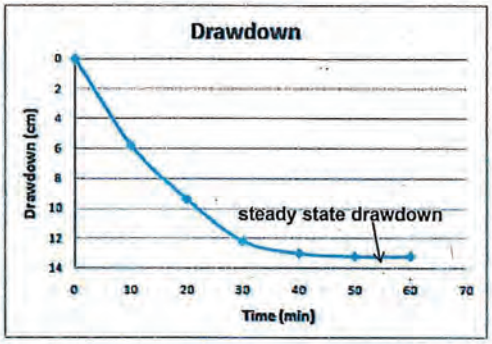
Steady State Drawdown

Steady State Flow Rate

In this section we will cover the ins and outs of field testing for hydraulic conductivity while low flow sampling. While the parameters needed are simple to measure, they must be measured as accurately as possible because only a limited amount of data is used in calculations.

Slide 13

# Steady State Drawdown



s = DTW(t) – DTWo
where:
s = drawdown
DTW(t) = depth to water while pumping
DTWo = depth to water before pumping

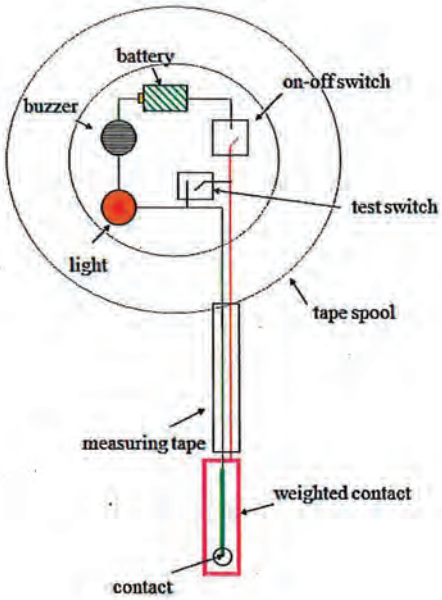
Water level meter

Pressure transducer

In low flow sampling, the drawdown is typically measured with a water level sounder. Drawdown is defined as the difference between the depth to water during pumping and the prepumping static water level. You can also determine the drawdown more accurately using a pressure transducer.

Slide 14

# Water Level Meter

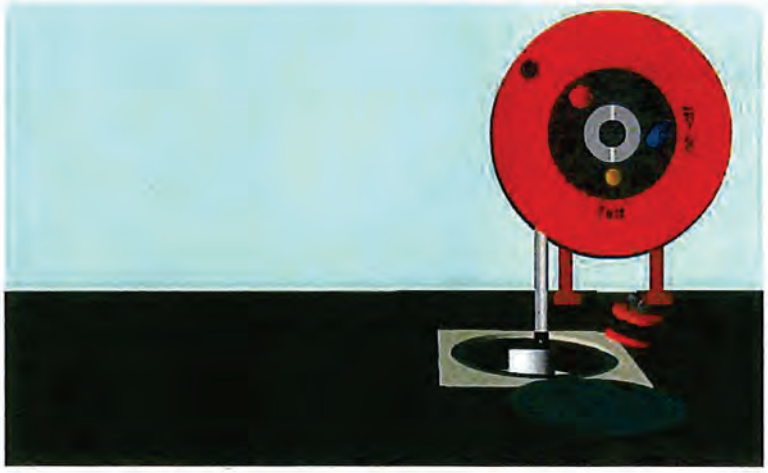


This is what a water level meter (sounder) looks like. It consists of a reel of Teflon® measuring tape in which two wires have been embedded. At the end of the wires is a weight. The outside of the weight is an electrical contact. Within the weight is another contact insulated from the outer contact. When the weight makes contact with water, the water completes an electrical circuit that consists of a battery, buzzer, light, on-off switch and circuit test switch. When the weight enters the water the buzzer sounds and the light turns on. One then reads the measuring tape length from a mark, such as the top of casing or ground surface. To get an accurate depth to water reading, be sure the tape is as straight as possible. Make several measurements to check on your readings. Also, avoid submerging the sound weight

as much as possible. Not only does submerging the sounder weight influence the water level (which rises) but it induces a transient head change (like a slug in test).

Slide 15

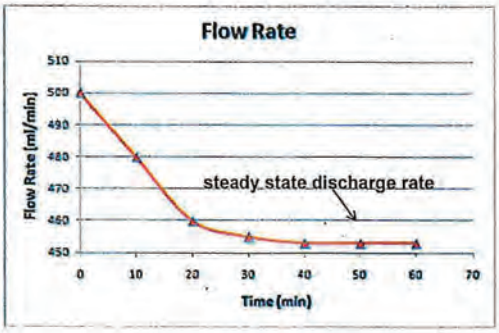
# Try the Water Level Sounder Simulation



Try the water level sounder simulation. What is the depth to water from the top of casing? If you going to use the one pair of measurements of discharge and drawdown to compute the hydraulic conductivity, be sure you can accurately read the meter. It is best to make several measurements of the same depth to water and average them.

Slide 16

# Steady State Discharge



Q = V/dt
where:
Q= Flow rate (discharge)
V = volume of water
dt = duration of collection

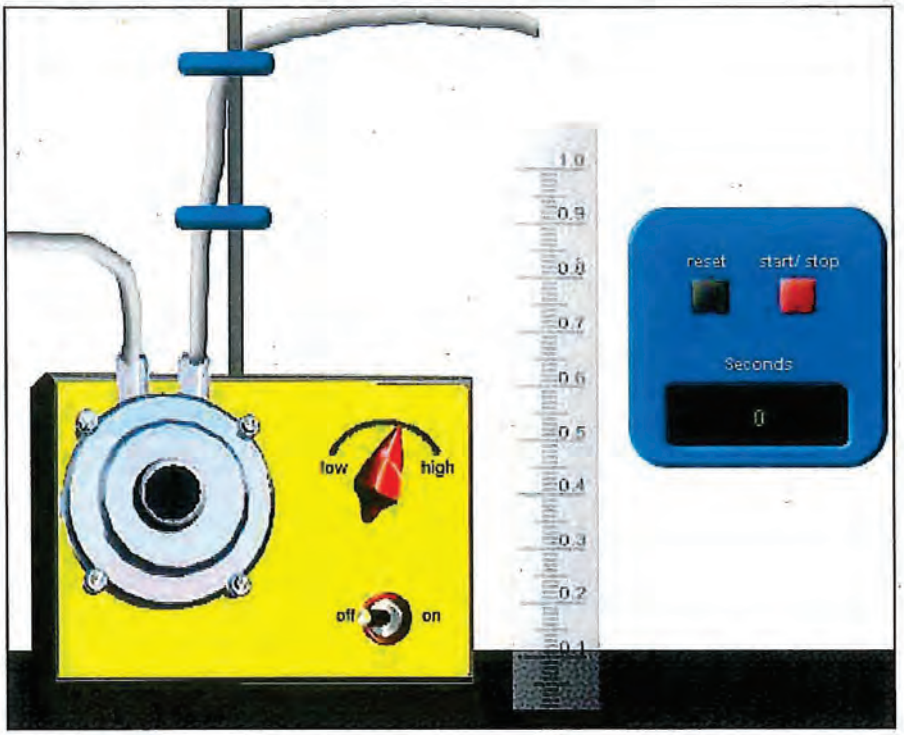
Graduated cylinders

Did you get 6.88 ft for the depth to water in the water level simulation? If not, be sure to reread the instructions on how to read the tape. In addition to the steady state depth to water, we need to know the steady state discharge. The steady state discharge can be readily determined using a stopwatch to time the collection of water in jugs or graduated cylinders. The flow rate is equal to the volume of water collected divided by the duration of collection. How much water and over what duration should you be collecting you ask? This depends on the flow rate and the gradations of the graduated cylinder you are using. I suggest you collect water for at least two minutes. That will pretty much negate a few seconds of error in measuring time. Collect at least enough water to fill 50% of the graduated cylinder. More is better than less. The more water you collect the more accurate you will be. In

addition to measuring the discharge using graduate cylinders, it can also be determined using an inline flow meter. Just be sure you meter is well calibrated.

Slide 17

# Try the Discharge Measurement Simulation

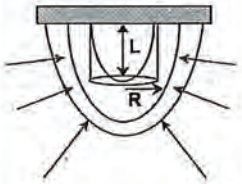


Try the discharge measurement simulation. You will be practicing how to determine the discharge using a graduated cylinder and stopwatch.

Slide 18

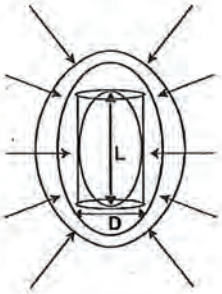
# 3. Steady State Models

**HALF ELLIPSOID**
**Dachler (1936)**



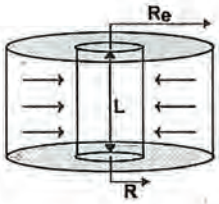
$$Q = \frac{2\pi LKH}{2.303\log\left[\frac{L}{R} + \sqrt{1+\left(\frac{L}{R}\right)^2}\right]}$$

**FULL ELLIPSOID**
**Hvorslev (1951)**



$$Q = \frac{2\pi LKH}{2.303\log\left[\frac{L}{D} + \sqrt{1+\left(\frac{L}{D}\right)^2}\right]}$$

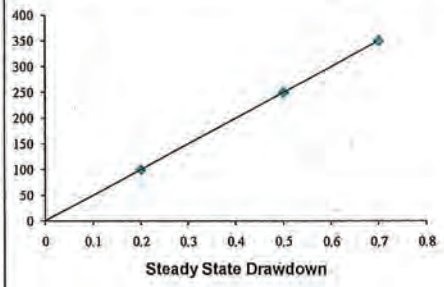
**RADIAL FLOW**
**Muskat (1937)**



$$Q = \frac{2\pi LKH}{2.303\log[R_e/R]}$$

Where:
Q = steady state flow rate
L = intake length
K = hydraulic Conductivity
H = steady state drawdown
R = intake radius
D = intake diameter
$R_e$ = radius of influence

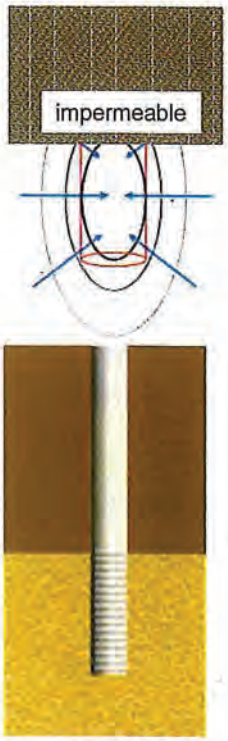
Q = slope*H
slope = f (well and formation geometry, K)



Did you get about 0.5 L/min for the steady state discharge in the simulation? The steady state discharge and drawdown can be substituted into steady state flow models to determine the hydraulic conductivity. The three models shown here are the foundation models for common slug test solutions. They are forms of Darcy's Law and take into account the well intake and formation geometry. As shown on the graph to the right, the models predict that the steady state drawdown and discharge are directly proportional (i.e., double one you double the other, half one you half the other). If you plotted the discharge (Q) vs. steady state drawdown (H), in theory the data would fit a straight line with a zero intercept and slope that is proportional to K. Let's look at the models more closely.

Slide 19

# Half Ellipsoid Model



*Formula*

$$Q = \frac{2\pi LKH}{2.303 \log\left[\frac{L}{R} + \sqrt{1+\left(\frac{L}{R}\right)^2}\right]}$$

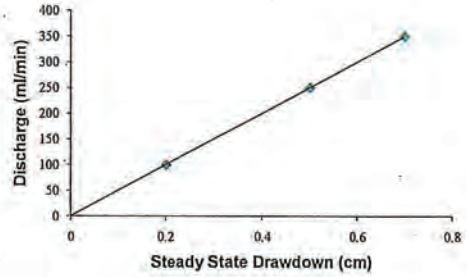
*Single O/H*

$$K = \frac{Q * 2.303 \log\left[\frac{L}{R} + \sqrt{1+\left(\frac{L}{R}\right)^2}\right]}{2\pi LH}$$

*Regression*

$Q = slope * H$

$$K = \frac{slope * 2.303 \log\left[\frac{L}{R} + \sqrt{1+\left(\frac{L}{R}\right)^2}\right]}{2\pi L}$$

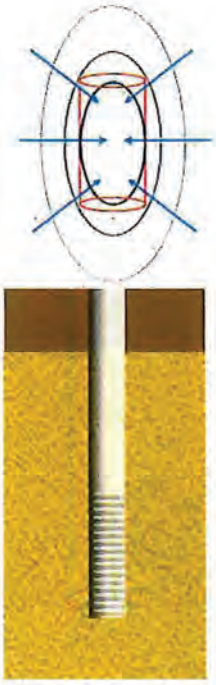


Where:
Q = steady state flow rate
L = intake length
K = Hydraulic Conductivity
H = steady state drawdown
R =intake radius

This is the half ellipsoid model. It is based on steady state flow to a line source that is truncated on one end, either the top or the bottom (Dachler, 1936). It would be applicable to a situation where there was a no flow boundary at one end of the well screen (e.g., low hydraulic conductivity layer, the water table). For a single pair of Q and H values, you can calculate the hydraulic conductivity by direct substitution. For three or more pairs of Q and H values the formula predicts a straight line that can be regressed to determine the slope. The hydraulic conductivity can be computed from the slope. This model is the basis for the Hvorslev slug test half ellipsoid model (Hvorslev, 1951).

Slide 20

# Full Ellipsoid Model



*Formula*

$$Q = \frac{2\pi LKH}{2.303 \log\left[\frac{L}{D} + \sqrt{1 + \left(\frac{L}{D}\right)^2}\right]}$$

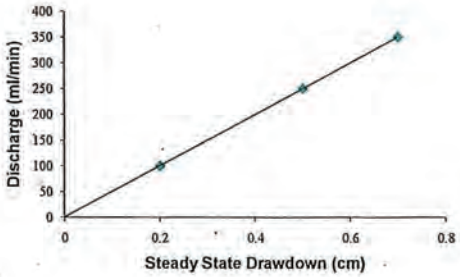
*Single O/H*

$$K = \frac{Q * 2.303 \log\left[\frac{L}{D} + \sqrt{1 + \left(\frac{L}{D}\right)^2}\right]}{2\pi LH}$$

*Regression*

$$Q = slope * H$$

$$K = \frac{slope * 2.303 \log\left[\frac{L}{D} + \sqrt{1 + \left(\frac{L}{D}\right)^2}\right]}{2\pi L}$$

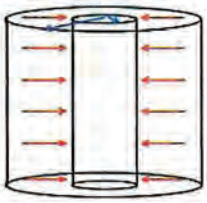


Where:
Q = steady state flow rate
L = intake length
K = Hydraulic Conductivity
H = steady state drawdown
D =intake diameter

This is the full ellipsoid model. It is based on steady state flow to a line source (Hvorslev, 1951). It is applicable to a situation where the well screen is installed in a uniform formation. For a single pair of Q and H values, you can calculate the hydraulic conductivity by direct substitution. For three or more pairs of Q and H values the formula predicts a straight line that can be regressed to determine the slope. The hydraulic conductivity can be computed from the slope. This model is the basis for the Hvorslev slug test full ellipsoid model.

Slide 21

# Radial Flow Model



***Formula***

$$Q = \frac{2\pi LKH}{2.303 \log(R_e / R)}$$

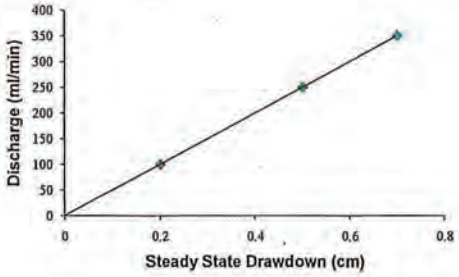
***Single Q/H***

$$K = \frac{Q * 2.303 \log(R_e / R)}{2\pi LH}$$

***Regression***

$$Q = slope * H$$

$$K = \frac{slope * 2.303 \log(R_e / R)}{2\pi L}$$



Where:
Q = steady state flow rate
L = intake length
K = Hydraulic Conductivity
H = steady state drawdown
R =intake radius
$R_e$ = radius of influence

How to find Re?

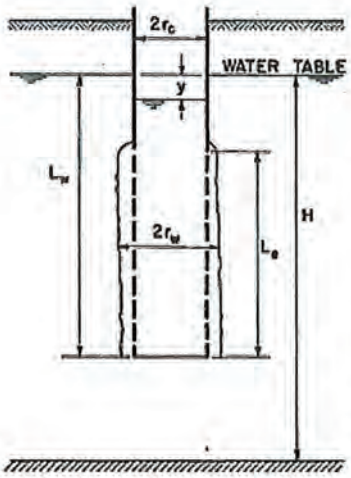
- 50 x hole radius
- 200 x hole radius (NAVY)
- Bouwer and Rice formulas based on electric analog modeling\

This model is the radial flow model (Muskrat 1937). The steady state radial flow model is based on integrating between two boundaries. One boundary is the well intake radius and the other is taken as the "radius of influence" ($R_e$) where the drawdown = 0. The model is a special case of the Thiem equation. It is applicable to a fully penetrating well in a confined aquifer, a well in a formation that is highly anisotropic (horizontal K >> vertical K), or a well that is screened from the water table to the bottom of a formation (low hydraulic conductivity layer). To use this model, one needs to define $R_e$. It is common to use a value = 50 * hole radius. Since the $R_e$ term is in a log, the hydraulic conductivity value is rather insensitive to the value chosen. For example, a ratio of $R_e/R$ in the model of 100 only changes the hydraulic conductivity value by a factor of 2. The model is the basis for the Bouwer and Rice

slug test solution. Using an electric analog model they determined values for $R_e$ based on the degree of well penetration in a formation.

Slide 22

# Bouwer and Rice Method to Determine $R_e$



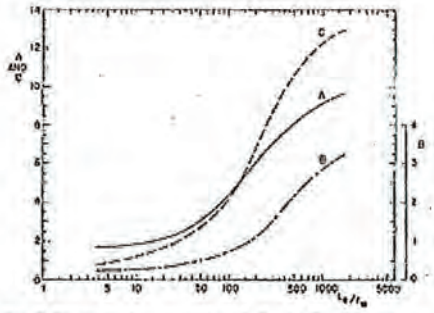


Fig. 2. Dimensionless parameters A, B, and C as a function of $L_e/r_w$ for calculation of $\ln(R_e/r_w)$.

$$\ln\frac{R_e}{r_w}=\left[\frac{1.1}{\ln(L_w/r_w)}+\frac{A+B\ln[(H-L_w)/r_w]}{L_e/r_w}\right]^{-1} \quad (4) \qquad L_w<H$$

$$\ln\frac{R_e}{r_w}=\left[\frac{1.1}{\ln(L_w/r_w)}+\frac{C}{L_e/r_w}\right]^{-1} \quad (5) \qquad L_w=H$$

From Bouwer, 1989, Ground Water, v. 27, n. 3, p. 304-309

Bouwer and Rice using an electrical analog model developed empirical equations to calculate $R_e$. These are shown here. They modeled steady state flow to a well by applying a voltage (analogous to head change) to a physical model of wires, resistors and capacitors. Their empirical equations define $R_e$ as 85% dissipation of the initial voltage (analogous to the initial head change). Although the model equation was developed for a fully penetrating well, they determined $R_e$ for both fully and partially penetrating well intakes. The equations shown depend on the thickness of the aquifer (H), the depth to the bottom of the screen ($L_w$), and the length of the screen ($L_e$). If the screen is partially penetrating ($L_w < H$), determine constants A and B from the graph for $L_e/r_w$. If the well is fully penetrating ($L_w = H$), determine constant C. Then use equation (4) for a partially penetrating well or (5) for a fully penetrating well

to determine $R_e/r_w$. Instead of using the graphs to find A, B or C, you can fit the graphs with polynomial functions and incorporate them into a spreadsheet for analysis. I did just that and incorporated the functions into the Radial Flow Analysis Spreadsheet which we will use to do some analysis later.

Slide 23

## Choosing the Correct Model and Input Parameters

- Check boring and construction logs for key parameters and for choosing model
- Set Intake length (L) = sand pack length if sand pack remains fully saturated during testing
- Set Intake length (L) = length from static water level to bottom of screen if screen bridges the water table
- Set Intake radius or diameter (R or D) = hole radius or diameter
- Use the Bouwer and Rice model if confined aquifer is fully screened or if you can justify that K in horizontal direction >> K in vertical direction
- Use the full ellipsoid model if screen is fully submerged and no upper or lower boundaries.
- Use the half ellipsoid model if screen bridges water table but does not bottom on a boundary

The K value you obtain will only be as good as the extent to which the well and formation geometry match the mathematical model. If you calculated the K value using each of the three models presented here, you will get different answers. Try choosing the model that best matches each wells geometry and formation conditions. I cannot overemphasize the need to examine the boring and construction logs for the wells you are testing. Listed on the slide are some guidelines I follow in choosing well parameters and models. Although you can use the Bouwer and Rice model for situations involving partial penetration, I try not to because the model assumes radial flow. This is not the case for the ellipsoidal models.

Slide 24

# 4. Test Procedures

Single pair of discharge and drawdown values

(1) Periodically measure the drawdown with a water level sounded or continuously monitor the water level with a pressure transducer until steady state is achieved.

(2) Once at steady state, measure the flow rate.

(3) Substitute the flow rate and steady state drawdown into the appropriate flow model and compute the hydraulic conductivity.

(4) For QA purposes, measure the flow rate and steady state drawdown three times to assess reproducibility.

Three or more pairs of discharge and drawdown values

(1) Repeat steps (1) and (2) above at three different flow rates but keep the drawdown small relative to the wetted thickness of the formation (< 10-15%)

(2) Plot Q vs. H. The data should lie on a straight line. Regress the line and determine the slope.

(3) Substitute the slope into the appropriate flow model and compute the hydraulic conductivity.

Here are the test procedures for computing K. If you are monitoring the same well periodically, after some initial measurements, you can use the single pair of discharge and drawdown measurements with confidence. The three or more pairs approach provides more confidence in your results if you get a straight line with a high correlation coefficient. It also indicates the theory is sound.

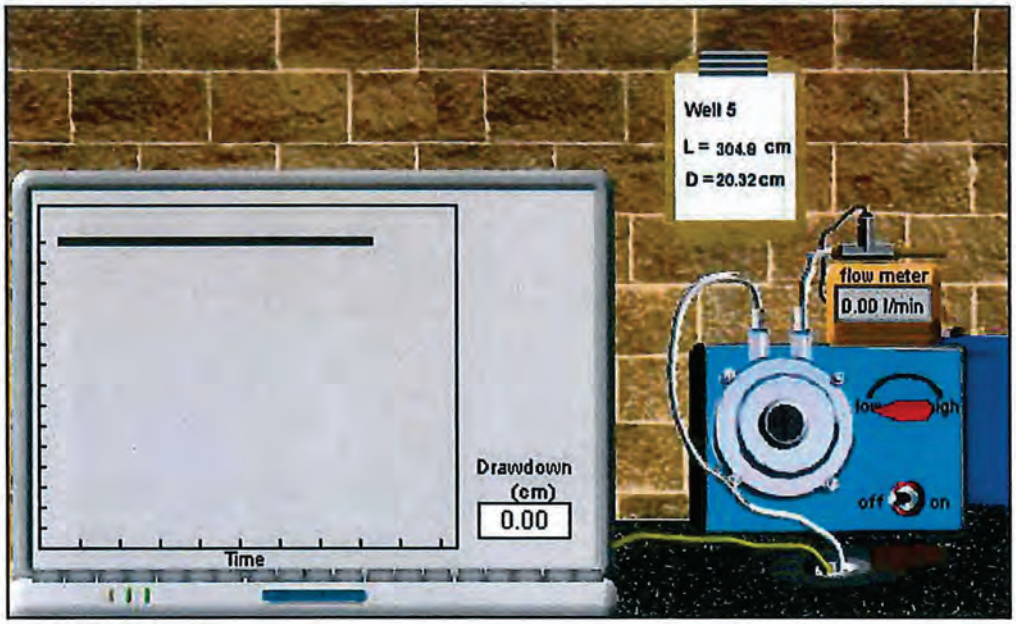
Slide 25

# View the Constant Head Test Video

View the constant head test video. Here we conducted testing at Port Hueneme, CA in a high permeable formation. The procedures would be the same for lower hydraulic conductivity environments but the flow rate would be much less.

Slide 26

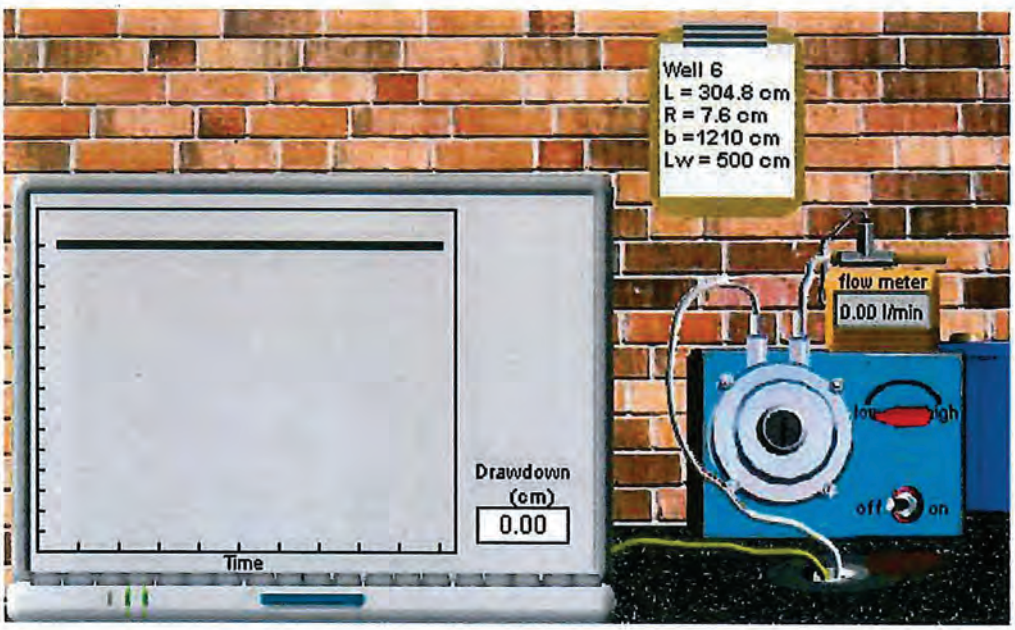
# 5. Conduct the Low Flow Simulation



Let's try a Low Flow Test Simulation. First open the Ellipsoidal Flow Steady State Model Analysis Excel Workbook. One worksheet can be used to analyze a single pair of Q and H data. The other can be used to analyze three pairs of data. In the simulation, flow is measured using an inline flow meter and drawdown is measured using a pressure transducer. Open the simulation and follow the directions. If you are an environmental professional seeking CEUs, save your work with your name in the title. You will have to submit a pdf copy of the workbook for credits.

Slide 27

# Conduct the Low Flow Simulation Using the Radial Flow Model



In this simulation, we have a partially penetrating well in an unconfined sandy aquifer. We will assume radial flow to the well and analyze the problem using the Radial Flow Steady State Model Excel Workbook. Open the workbook to the Single Q and H analysis worksheet. To computer Re ("radius of influence") the worksheet uses polynomial fits to the Bouwer and Rice graphs for A, B and C. The worksheet determines which parameters to use depending on the values of L, LW and b. If they are all equal, then the well is fully penetrating and parameter C is used. If not, parameters A and B are used. Open the Radial Flow Simulation and follow the directions in the simulation. If you are an environmental professional seeking CEUs, save your work with your name in the title. You will have to submit a pdf copy of the workbook for credits.

Slide 28

# 6. Sensitivity Analysis

- What Q or range of Q should I use?
- What pump should I use?
- What should I use to collect water to determine Q?
- How much drawdown will I get for a given Q?
- Do I have to pump at a rate > low flow (about 1 LPM)?
- How much water will I have to discharge and dispose of?

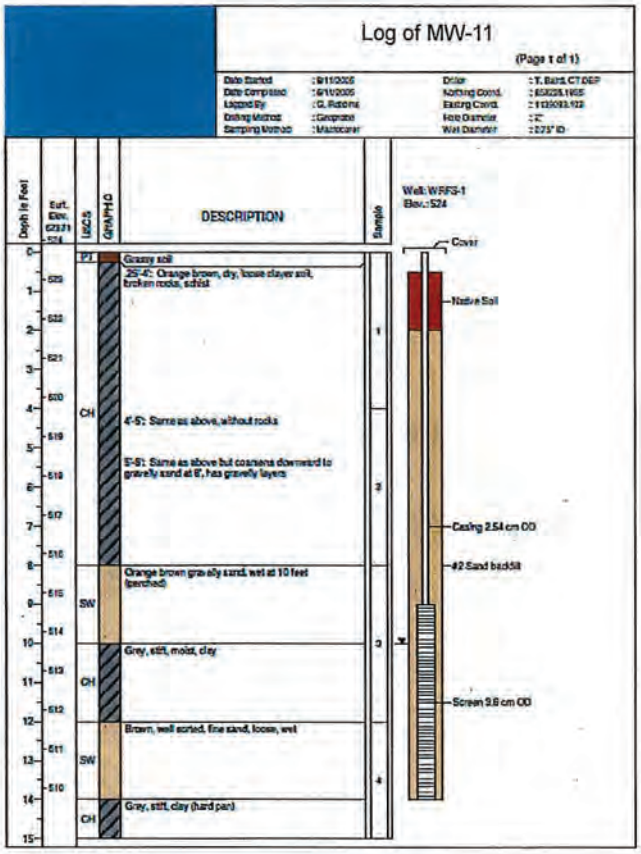
The flow rates (Q) and drawdowns were very different in the two simulations. In the first simulation, measureable drawdown was obtained within a range below 1 LPM. In the second simulation, because the formation had high permeability, you had to pump at a higher discharge to obtain measureable drawdown. In this case, you might collect your water quality samples within the range of parameters acceptable to regulatory authorities and then increase the flow rate to obtain the hydraulic conductivity. The questions listed here can best be addressed by conducting a sensitivity analysis prior to conducting a test. Set up a spreadsheet with an appropriate model and plug in the input parameters. Take an educated guess at the hydraulic conductivity based on the formation description. Then plug in Q values or drawdown values to determine drawdown or Q. Open the sensitivity workbook and

try the problems. If you are an environmental professional seeking CEUs, save your work with your name in the title. You will have to submit a pdf copy of the workbook for credits.

Slide 29

# 7. QA/QC Considerations

- Must accurately determine discharge and drawdown, especially if a single pair of values is being determined
- Review the boring log to determine the appropriate steady state flow model and the well parameters
- Wells need to be developed prior to testing



These three bullets cover where the major sources of error lie in determining K using the method. Be sure to accurately measure the discharge and steady state flow rate. Look over the boring log for the well to determine the appropriate model and input parameters. For the well intake radius, I use the radius of the hole. This assumes the backfill K is much greater than the formation K. If the well screen or sand pack around the screen are clogged with fines this will impact the test results. I recommend you develop a well prior to conducting a K test by plunging and pumping. If you use a well that will be monitored quarterly, you would only develop it the first time out. Keep in mind that the test only is measuring conditions in the near-field of the well and will be influenced by the presence of a disturbed or clogged zone ("Skin effect") around the well intake.

Slide 30

# Method Limitations

- For high K situations, you may have to exceed low flow pumping maximums to get appreciable drawdown
- For low K situations, you may have to exceed low flow drawdown maximums even at low pumping rates
- Generate contaminated water for disposal
- Near-field method subject to influence by drilling disturbance and intake clogging
- Relative to slug testing requires more equipment and resolution of logistical issues (e.g., water storage, power)

I have found empirically that the working range of the method extends from a hydraulic conductivity value greater than about $5 \times 10^{-6}$ to one that is less than $10^{-2}$ cm/s. Of course, the working range depends on formation conditions and the well design. Hence, the usefulness of performing a sensitivity analysis for a given set of conditions. In addressing the first issue, it may be best to collect your samples then increase the flow rate beyond regulatory low flow parameter guidance to obtain data to compute hydraulic conductivity values. Although the second issue may be resolved using a very low pumping rate, this solution might not be practical given time constraints. In terms of water needing proper storage and disposal, if a single pair of steady state discharge and drawdown is used, than no additional water may be generated beyond what would normally be generated during low flow sampling.

Again conduct a sensitivity analysis to get some sense as to how much water might be generated. The method measures the hydraulic conductivity in the near-field and like slug tests, depends on formation conditions in the immediate vicinity of the well. Although you might need more equipment then a slug test, and logistically it is more complex, the equipment needs and logistics are about the same as that for low flow sampling.

Slide 31

# 8. Case Histories

A. Analysis of Quarterly Monitoring Reports

B. Comparison of Pumping and Slug Tests, High K Environment

C. Comparison of Pumping and Low Flow Tests, Low K Environment

D Wells that Bridge the Water Table

Let's look at 4 case histories where the hydraulic conductivity was determined using the method.

Slide 32

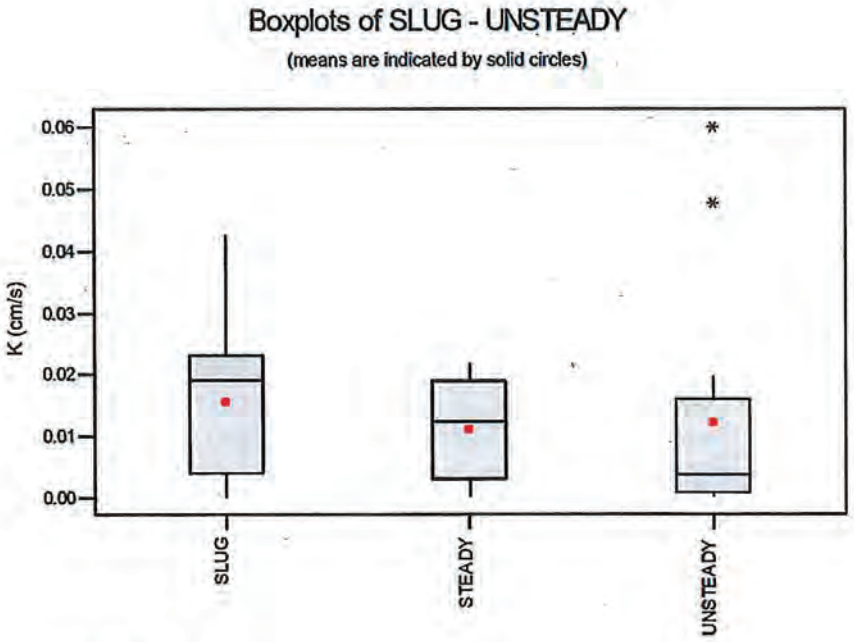
SDTW = starting depth to water
SSDTW = steady state depth to water
H = SSDTW-SDTW
SSL = saturated screen length
%RSD = 100*Std. Dev/Mean

After Robbins et al (2009)

I compiled the data in this table from consultant reports for three rounds of quarterly monitoring at three monitoring wells at a contamination site in Connecticut. The data were collected by 4 different field technicians (see the Tech column). I used the low flow data to calculate the hydraulic conductivity values based on single pairs of discharge and drawdown. Note the high degree of reproducibility in hydraulic conductivity values from sampling round to sampling round. This is exemplified by the low %RSD values (percent relative standard deviation). The %RSD is a measure of reproducibility. A %RSD of 50 represents a variation on the order of a factor of 2. Obviously, the technicians in this case are well trained in taking careful measurements.

Slide 33

## B. Comparison of Pumping and Slug Tests, High K Environment

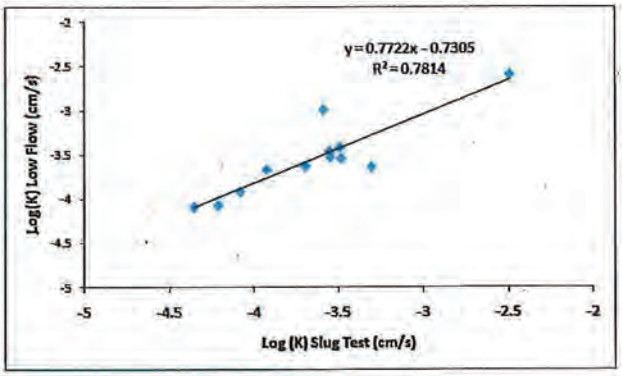


(After Bartlett et al 2004)

Bartlett et al. 2004 conducted a comprehensive study of the method at the Naval Facility in Port Hueneme, California. The study entailed testing wells installed by different methods and of different designs. They compared the results of 109 slug tests with 14 steady state (three pairs of discharge and steady state drawdown) pumping tests and 14 unsteady steady pumping tests. The tests were conducted in a high K formation ($10^{-2}$ cm/s). All the wells had fully submerged screens. They conducted ANOVA statistical comparisons and found there was no statistical difference in hydraulic conductivity values amongst the sets of tests as shown by the box plot comparisons.

Slide 34

## C. Comparison of Pumping and Low Flow Tests, Low K Environment



Water Resources Field Station

- 11 wells
  - 9 direct push
    - 7 wells ¾" ID
    - 3 wells 1" ID
  - 2 wells HSA
    - 1 well 2" ID
    - 1 well 4" ID

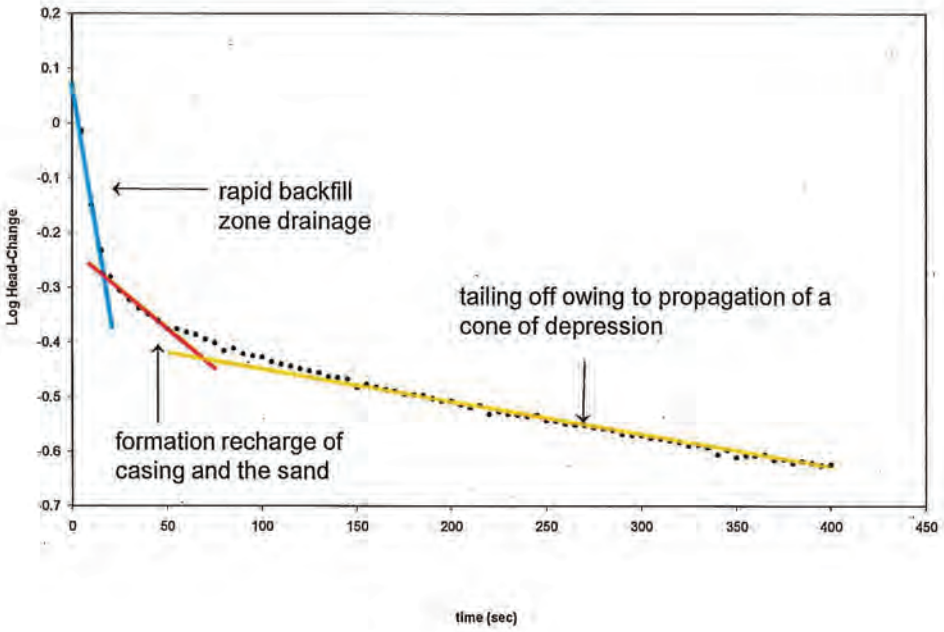
10 wells K values within a factor of 2
1 well K values within a factor of 3 to 4

After Robbins et al (2009)

Robbins et al (2009) compared hydraulic conductivity determinations from low flow tests and slug tests in glacial till and glacial lake sediments in Connecticut. Here the formation permeability was relatively low ($10^{-4}$ - $10^{-3}$ cm/s). All of the 11 wells tested had fully submerged screens. Most of the wells were installed by direct push. Two of the wells were installed by a hollow stem auger. The low flow and slug test results were in relatively good agreement as shown on the graph. Most of the wells yielded hydraulic conductivity values by low flow and slug testing that were well within a factor of 2.

Slide 35

## D. Wells that Bridge (Cross) the Water Table



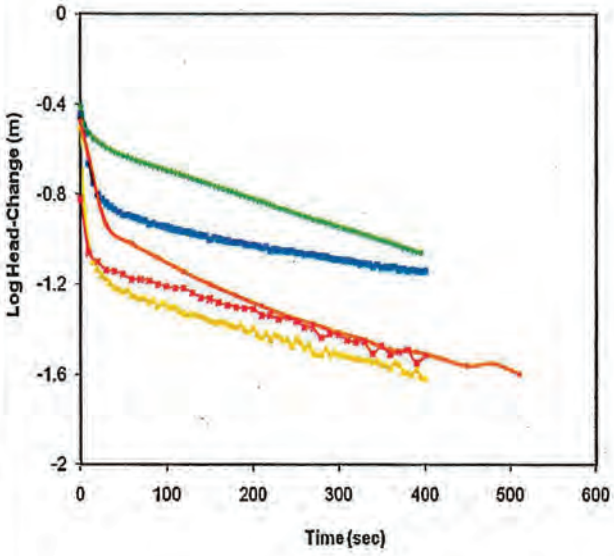
(After Aragon-Jose and Robbins (2011)

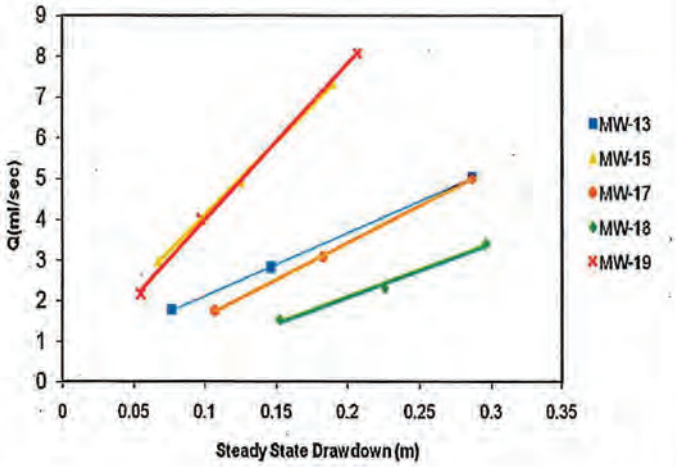
As noted earlier slug tests in wells that bridge the water table typically exhibit rapid early time recovery owing to backfill zone drainage and resaturation and late time asymptotic tailing due to the formation of a cone of depression. These recovery effects are not incorporated into slug test models used to analyze the data. It has been suggested that the intermediate period (shown here in red) be used to analyze the tests. However, the recovery even in this period is not free of backfill zone influence. As such, hydraulic conductivity values obtained from these test will likely over estimate the formation conductivity. Aragon-Jose and Robbins (2011) showed that the steady state method overcomes these problems. This is because once steady state drawdown is achieved the backfill zone has stopped draining and has no influence on flow to the well. Also, as long as the drawdown is small relative to

the saturated screen length, the cone of depression is small and should also not significantly influence flow to the well.

Slide 36

## Slug Tests vs. Steady State Tests





After Aragon-Jose and Robbins (2011)

These figures are from Aragon-Jose and Robbins (2011). The figure on the left illustrates the slug test response curves for 5 wells whose screens bridge (cross) the water table. Note that all the slug test responses exhibit early time rapid backfill zone drainage and late time asymptotic tailing. The intermediate responses occur only over very short periods. Slug test theory for wells with overdamped response would predict the curves on the left should plot as straight lines which of course they do not. The figure on the right shows the steady state discharge and drawdown curves for the same wells tested by the low flow method. Each curve is based on three pairs of data. Note how all the curves are straight lines as would be predicted by the theoretical flow models.

Slide 37

## Comparison of Slug Tests with Steady State Tests

**Ratios between Slug Test and Constant Head Test Hydraulic Conductivity Determinations**

| Well | Constant Porosity (36.7%) | Constant Specific Yield (28.7%) | Computed Specific Yield (variable) |
|---|---|---|---|
| MW13 | 6.2 | 5.2 | 2.9 |
| MW15 | 4.8 | 4.0 | 4.3 |
| MW17 | 3.9 | 3.3 | 2.4 |
| MW18 | 5.7 | 4.8 | 1.5 |
| MW19 | 3.2 | 2.6 | 2.9 |

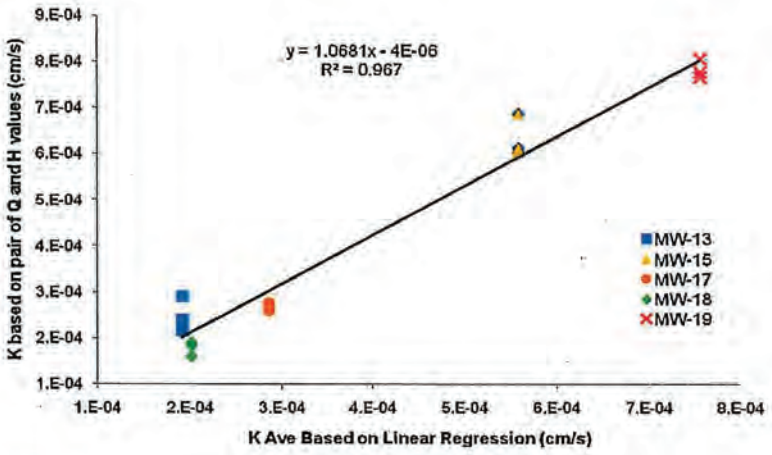
*K* determinations from the constant head test are the regressed values.

After Aragon-Jose and Robbins (2011)

This table from Aragon-Jose and Robbins (2011) compares values of hydraulic conductivity computed using the two different test methods. Because slug testing results in backfill zone drainage, the recovery curve is influenced by the pore space in the backfill zone that must be refilled. The amount of pore space in effect influences the effective radius of the well intake. The columns on the table are for three different assumptions regarding the backfill zone. The first column assumes a constant porosity. The second column assumes a constant specific yield as better representing the water drained. The third column is based on computing specific yields for each test. Of course the steady test avoids the need to consider backfill zone drainage. In all cases the slug tests overestimated the conductivity relative to the steady state tests.

Slide 38

## Single vs. Multiple Pairs of Discharge and Drawdown Data



After Aragon-Jose and Robbins (2011)

This graph compares hydraulic conductivity values based on single pairs of steady state flow and drawdown values with those based on linear regression of three pairs of steady state flow and drawdown values for the 5 wells. It shows that when care is used you can obtain the same value of hydraulic conductivity from analyzing just one pair of values as you would using multiple values of flow and drawdown. Although you can determined the hydraulic conductivity using a single pair or discharge and drawdown values, having multiple pairs helps confirm your results.

Slide 39

# 9. Some Last Words by the Author

I hope you have enjoyed the course. I am always looking to improve the material. I would appreciate any ideas you may have on improvements to this course or suggestions for new courses when you submit the required course evaluation.

I suggest you might review the references for additional material on the subject.

Thanks for taking the course.

Your author,

Gary Robbins

# 10. How to Obtain CEUs

If you are a professional and are seeking continuing education credits for taking the course you will have to submit certain material. Please click on the **How to Obtain CEUs** link to learn what states have approved the course, for instructions on what material you must submit for credits and how to submit the material.

# 11. Select References

Interested in more information on this subject? Click on the **references** link. You will find references (many of which you can download) on the subjects covered, the models used, well development and test related issues.

## Ellipsoidal Flow Steady State Model
## Single Pair of Discharge and Drawdown

| | | | |
|---|---|---|---|

## 1.0 Introduction

This Investigation-Derived Waste (IDW) Plan describes procedures for managing waste generated during the Phase 2 Remedial Investigation (RI) at the former New York Ordnance Works (NYOW) Formerly Used Defense Site (FUDS) Property ID: C02NY0290, Baldwinsville, New York. The work is being performed in accordance with the Uniform Federal Policy for Quality Assurance Project Plan (UFP-QAPP).

This IDW Plan provides procedures for characterizing, accumulating, storing, tracking, transporting, and disposing of waste originating from work performed as part of the investigations. The Joint Venture (JV) (Environmental Assessment Services, LLC [EAS] and WSP USA Solutions, Inc., [WSP]) has prepared this document under United States Army Corps of Engineers (USACE), Contract No. W912WJ23D0007, Task Order Number W912WJ23F0130.

Anticipated IDW that will be generated from the Phase 2 RI activities include the following:

- soil cuttings from borings.
- purge water from well development and groundwater/porewater sampling; and
- decontamination fluids.

Other waste that will be generated and considered as municipal waste generated from the Phase 2 RI activities include the following:

- Used personal protective equipment (PPE) and used disposable sampling equipment.
- General debris and refuse (e.g., water bottles, food wrappers, empty cement and bentonite bags).

Site contaminants of potential concern (COPCs) were identified during the Phase 1 RI and documented in the *Phase 1 Risk Screening and Data Gap Analysis* (USACE, 2023a). The following COPCs by site (i.e., area of concern [AOC]) have been identified:

- AOC 1 – 2,4-dinitrochlorobenzene (2,4-DNCB), 2,4-dinitrophenol (2,4-DNP), picric acid, and target analyte list (TAL) metals;
- AOC 3 – volatile organic compounds (VOCs), semi-VOCs (SVOCs), polyaromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs) aroclors, picric acid, and TAL metals;
- AOC 4 – 2,4-DNCB, 2,4-DNP, and picric acid; and
- AOC 5 – PAHs, TAL metals.

Waste generated from these activities will be managed and disposed of in accordance with New York State Department of Environmental Conservation (NYSDEC) and federal hazardous and solid waste regulations. Based on previous site investigation work and waste characterization data, it is anticipated that the waste generated will be nonhazardous.

## 2.0 Roles, Responsibilities, and Training

The project manager (PM) and Field Team Lead (FTL) have primary responsibility for ensuring compliance with guidelines and requirements for waste management provided under this plan. However, all members of the field team are responsible for compliance at all times.

Field staff are responsible for the implementation of the work associated with waste management, including ensuring that containers are appropriately labeled, waste is sampled properly and on time, required inspections are performed and documented, and proper notifications are provided to USACE New England and the disposal facilities. Field staff will provide all necessary documentation to the PM, FTL, and other appropriate individuals for proper waste management.

The senior technical lead or FTL will be responsible for completing all associated analytical data, waste documentation (profiles, land disposal restrictions [LDRs], etc.) and final classification of waste. All waste documentation (profiles, manifests, LDRs, etc.) will be reviewed for accuracy before submitting to the USACE PM for signature.

Field staff who will manage hazardous waste will meet the training requirements of Title 40 *Code of Federal Regulations* (CFR) 262.34(a)(4) and 265.16 through the following:

- Hazardous Waste Operations and Emergency Response (HAZWOPER) training required bythe Occupational Safety and Health Administration (OSHA) in 29 CFR 1910.120.
- Classroom or online training on remediation waste management; classroom training provided as a module inthe 40-hour initial HAZWOPER course and 8-hour HAZWOPER training refresher courses.
- Dangerous goods shipping (Department of Transportation [DOT], and International Air Transport Association.
- On-the-job training, which includes project-specific health and safety plan review (requires each site worker and guests to review and sign the plan), activity hazard analysis, daily “tailgate” safety meetings, and project-specific work plan review (e.g., this IDW plan).

DOT training per 49 CFR 172, Subpart H, as appropriate, is also required for those staff who are involved in the following activities:

- Selecting and marking packaging or container for hauling.
- Preparing hazardous materials for transportation.
- Loading, unloading, or handling hazardous materials.
- Operating a vehicle used to transport hazardous materials.
- Preparing or reviewing hazardous materials shipping papers, including hazardous waste manifests.

This page intentionally left blank.

Table 1 **Typical Bottle and Preservation Requirements for Soil Waste Characterization Samples**

| Parameter | Analytical Method | Bottle Requirement | Preservative |
|---|---|---|---|
| TCLP VOCs | SW8260D | 4 oz glass jar with Teflon lid | Ice |
| TCLP SVOCs | SW8270E | 4 oz glass jar with Teflon lid | Ice |
| TCLP RCRA Metals | SW846 6020B | 1 x 4 oz Jar | Ice |
| Reactivity | 9034/SW846 9012B | 1 x 4oz jar | Ice |
| Flashpoint | EPA 261.21 | 1 x 8 oz jar | Ice |
| pH/ Corrosivity | SW846-9045D | 1 x 8 oz jar | none |

Table 2 **Typical Bottle and Preservation Requirements for Liquid Waste Characterization Samples**

| Parameter | Analytical Method | Bottle Requirement | Preservative |
|---|---|---|---|
| TCLP VOCs | SW8260D | 2 x 40mL VOAs | Ice<br>HCL to pH < 2, Ice |
| TCLP SVOCs | SW8270E | 2 x 1L amber glass bottle | Ice |
| TCLP RCRA Metals | SW846 6020B | 1 x 120 poly bottle w/ HNO3 | HNO3 to pH<2, Ice |
| Reactivity | 9034/SW846 9012B | 2 x 1L amber glass bottle | HNO3 to pH<2, Ice |
| Flashpoint | EPA 261.21 | 1 x 250 ml plastic | Ice |
| pH/ Corrosivity | SW846-9045D | 1 x 250 ml plastic | Ice |

Notes:
TCLP = toxicity characteristic leaching procedure
HCl = hydrochloric acid
L = liter(s)
$HNO_3$ = nitric acid
mL = milliliters
RCRA = Resource Conservation and Recovery Act

## 3.0 General Waste Management Requirements

The following section discusses general requirements for placing waste in accumulation and storage areas.

### 3.1 Waste Collection and Accumulation

Generally, waste will be managed as hazardous at the point of generation until analytical results are received, and the waste is characterized as nonhazardous. All waste will be managed in accordance with the requirements outlined in this IDW plan, unless otherwise specified. The RCRA hazardous waste management requirements apply the moment a waste is generated. The date or point of generation is the day that a waste is first placed in a container (e.g., drum, tank, etc.), or placed in a stockpile outside of an area of concern.

Waste will be staged inside temporary fencing located in the parking lot of the NYSDEC office located in the Three Rivers Wildlife Management Area near AOC 4. Signs will be posted identifying responsible personnel and emergency contact phone numbers. Good housekeeping practices will be maintained at the waste accumulation area. A secured chain-link fenced area will be constructed for the staging of investigation-derived wastes (IDW) and municipal 20-yard or equivalent dumpster for municipal trash. Due to most of the AOCs being within public areas with high visibility, all IDW generated will be brought to this staging area and drums generated for each AOC will be grouped separately. A fire extinguisher and eye wash station will be placed within the secured fence. During transport from the AOC to the waste accumulation area, the appropriate placards will be displayed.

Dangerous or hazardous waste, if generated, will be segregated from nonhazardous waste. Additionally, incompatible waste (e.g., flammable and corrosive wastes) will be segregated. Solids and liquid drums will be segregated within the designated IDW staging area by AOC. However, sites (i.e., AOCs) where there are similar waste streams (i.e., solids vs. liquids) and COPCs (AOC 1 soil and AOC 4 soil) can be grouped together. Waste from a given site should be placed into as few drums as possible to facilitate record keeping and characterization sampling. Specifically:

- Spoils from AOC 1 and AOC 4 may be combined in drums, if needed, since similar COPCs (e.g., 2,4-DNCB, 2,4-DNP, and picric acid) were identified.
- Spoils from AOC 3 will be kept containerized and separate from the other AOCs.
- Spoils from AOC 5 will be kept containerized and separate from the other AOCs.
- Aqueous fluids (purge water, decon fluid) from AOC 1 will be kept separate and not combined with aqueous fluids from any other AOC.
- Aqueous fluids (purge water, decon fluid) from AOC 3 may be combined with Background purge water generated from porewater samples.
- Aqueous fluids (purge water, decon fluid) from AOC 5 may be combined with Background purge water from Background monitoring wells since similar COPCs (i.e., PAHs, TAL metals) have been identified in groundwater.

All waste will be contained or otherwise managed to prevent the spread of contamination, as follows:

- All liquids, including decontamination water, will be contained in tightly sealed (leak- proof) compatible drums or portable tanks.
- Solid waste, including contaminated environmental media, will be contained in drums.
- Wastes from each AOC may be combined, if needed. Waste from a given site should be placed into as few drums as possible to facilitate record keeping and characterization sampling.

### 3.2 Waste Storage Time Limit

If hazardous waste is generated, it will be removed from the site within 90 days from date of generation. Based on previous sampling during the Phase 1 RI (USACE, 2021), waste is expected to be nonhazardous and will be removed from the site as soon as possible. The date of generation is the day that a waste is first placed in a container (e.g., drum, tank, etc.) or stockpile.

### 3.3 Container Labelling

Waste containers will be labeled in accordance with 49 CFR 172, 173, and 178. Waste containers must have visible labels and the labels will always include the type of waste, location from which the waste was generated, and accumulation start date. Until a waste is characterized, it will be handled as if it is hazardous, and an analysis-pending label will be placed on the container. Once the waste has been characterized as hazardous or nonhazardous, the "analysis pending" label will be removed and replaced with the appropriate "Hazardous" or "Nonhazardous" waste label.

A description of the different labels anticipated for use at the site are as follows:

- **"Analysis Pending" or "Investigation Derived Waste"** – This is a temporary label used until analytical results are received and reviewed, and the waste is characterized as hazardous or nonhazardous. Once the waste is characterized, this label will be replaced with one of the following labels. The accumulation start date must be included on this label.
- **"Hazardous Waste":** Preprinted or handwritten labels with the following information:
- Accumulation start date.
- Generator name, address and phone number (USACE New England PM).
- U.S. Environmental Protection Agency (EPA) ID number .
- Proper DOT shipping name.
- Prior to transport, the manifest number must be added (for containers of less than 110-gallon capacity).
- **"Nonhazardous Waste":** Preprinted waterproof labels with the following information will be attached to the container:
- Generator name, address and phone number (USACE New England PM).
- Drum/container/tank accumulation start date.
- Waste-specific information (composition, origin of waste/boring ID, and other information necessary to identify the waste).
- **"Waste Inventory Labels":** The PM and FTL will ensure that all wastes from generation to final disposition are tracked. Waste stored at central storage areas, or stored away from the site of generation, will be labeled for inventory purposes and logged onto a waste inventory sheet. A weather-proof label, in addition to the labels mentioned above, will be applied to each of these containers. At a minimum, this label will contain the following information:
  - ID number unique to each container.
  - Name of the site that the waste is from.
  - Contents of the container, including the project-specific location, boring, or well.

- Accumulation start date.
- Name and telephone number of generator contact (USACE New England PM).

Where applicable, labels showing the major hazards (e.g., flammable, oxidizer, and carcinogen) also will be included on the container prior to shipment.

### 3.4 Inspections

IDW accumulation areas will be inspected at least weekly for malfunctions, deterioration, discharges, and leaks that could result in a release. Secondary containment (if utilized) will also be inspected at least weekly for liner and berm integrity and for signs of erosion. Examples of inspection parameters include:

- Drummed waste and remnant material containers will be inspected for leaks, signs of corrosion, or signs of general deterioration.
- Areas will be inspected to ensure that good housekeeping practices are maintained.
- Verification of emergency response equipment and spill equipment appropriate to the waste's hazards. Signage will be included that provides emergency response contact(s) and telephone number(s).

Any deficiencies observed or noted during inspection will be corrected immediately. Appropriate measures may include transfer of waste from a leaking container to a new container, replacement of liner or cover, or repair of containment berm.

Inspections will be recorded. Any deficiency and corrective action will be documented. A follow-up inspection will be performed and recorded on the inspection form immediately after any noted deficiencies have been corrected. Copies of the report will be maintained onsite and available for review. Example inspection forms are provided in **Attachment 1**.

### 3.5 Security/Emergency Response

Waste accumulation areas and temporary waste staging at the work area will contain emergency response equipment and spill equipment appropriate to the waste's hazards. Signage will be included that provides 24-hour emergency response contact and phone number. The Health and Safety Plan (a separate document from this one) identifies the project emergency response procedures and equipment, including emergency response contacts and phone numbers.

In addition to the Health and Safety Plan procedures, hazardous waste accumulation areas, if needed, will be provided with (1) fire extinguishers if waste known or suspected to be flammable or ignitable are present, and (2) decontamination equipment. Spill control equipment (e.g., sorbent pads, etc.) will be available in the waste accumulation areas and where liquids are transferred from one vessel/container to another.

### 3.6 Employee Training

Field staff who will manage hazardous or potentially hazardous IDW, including the preparation of shipping documents (for example, manifests), will meet the hazardous waste generator training requirements of 40 CFR 265.16 and DOT (49 CFR 171 – 179) through the following:

- OSHA 1910.120 HAZWOPER training.
- On-the-job training including the following:
  - Project-specific Health and Safety Plan review, which requires each site worker and guest to review and sign the plan.

  - Activity hazard analysis and daily safety meetings.
  - Project-specific Work Plan review; for example, this project-specific IDW plan.
- DOT training per 49 CFR 172, Subpart H, as appropriate, for those performing the following functions:
  - Selecting and marking packaging or container for hauling.
  - Preparing hazardous materials for transportation.
  - Loading, unloading, or handling hazardous materials.
  - Operating a vehicle used to transport hazardous materials.
  - Preparing or reviewing hazardous materials shipping papers, including hazardous waste manifests.

### 3.7 Spills During Waste Handling

All spills will be reported internally as indicated in the Health and Safety Plan. Refer to this plan for emergency response procedures and additional reporting requirements. The definition of a release includes any spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping, or disposing into the environment (including the abandonment or discarding of barrels, containers, and other closed containers) of any potentially hazardous chemical, substance, and/or material.

It is important that the USACE New England PM along with the JV PM also be notified immediately of spills/releases and other environmental compliance-related incidents (e.g., permit exceedance, notice of violation, regulatory violation) or near-loss environmental incidents. The USACE New England PM along with the JV PM will evaluate the spill or release to determine agency reporting requirements (e.g., National Response Center or state agency). Immediate internal spill reporting is critical to assure compliance applicable agency spill reporting requirements since EPA requires certain spills/releases be reported within 15 minutes.

Spill control equipment (e.g., sorbent pads) will be available in the waste accumulation areas and where liquids are transferred from one vessel to another. Sorbent used on spills of ignitable waste/materials should not be used past their capacity, and will be either containerized with additional sorbent, or overpacked to prevent draining of liquid. Any fire protection provisions outlined in the Health and Safety Plan must be adhered to.

### 3.8 Waste Tracking Log

A Waste Tracking Log (**Attachment 2**) will be used to track waste from generation to final disposition. Waste will be logged on this form the day the waste is generated and placed into containers. Transportation of waste will be inventoried the day of transportation from the site using the Waste Tracking Log.

## 4.0 Waste Characterization Procedures

Waste will be characterized in accordance with 40 CFR Part 261, Subpart C, and analyzed in accordance with this IDW plan. Additional guidelines related to field documentation, sample nomenclature, chain of custody, and sample handling is in the main body of the UFP-QAPP.

### 4.1 Municipal Trash

Municipal trash, such as empty cement, bentonite and sandbags, pallets, water bottles, and food wrappers, will be placed into the dumpster located at the accumulation area for local municipal trash landfill disposal. Also disposed of as municipal trash will be nitrile gloves, Tyvek® suits (if used), empty single-use sampling supplies (e.g., tubing, scoops), and wipes/paper towels.

### 4.2 Waste Sampling Guidelines

General instructions for collecting and characterizing samples for solid and liquid wastes are in the sections below. Sample containers, holding-time requirements, and preservation requirements for typical waste characterization analyses are summarized in **Table 1** (solids) and **Table 2** (liquids). The IDW disposal facility, once selected, may have additional analytical requirements. Field handling and storage of samples and sample containers are described in the main body of the UFP-QAPP.

#### 4.2.1 General Soil Sampling Guidelines

Analytical requirements for soil IDW are shown in **Table 1**. Offsite treatment or disposal facilities may have different sampling requirements and a higher sampling frequency may be required. Collection of soil samples for waste characterization typically include the following:

- Collect one sample for each 55-gallon drum from each AOC, keeping samples segregated by AOC. For example, if there are 10 drums for AOC 1, then collect one sample from each of the 10 drums, composite using cone and quarter techniques, and submit for analyses for AOC 1. Repeat, for the other AOCs. A hand user will be used to collect the sample.

Soil aliquots for VOC analyses should be collected using the following general procedure:

- Using a hand auger or other device, retrieve a core from one waste container.
- Remove the core from the auger or other device and place the sample into the 4-ounce (oz.) glass jar. The transfer operation should ideally be completed in 1 minute to minimize loss of volatile components.

Soil samples for all other analyses can be collected as follows:

- Collect one sample from each of the drums into a stainless-steel bowl.
- Homogenize the grab samples by the quartering techniques using a stainless-steel spoon until a uniform texture and color is achieved.
- Fill the appropriate sample jars completely full with the homogenized sample.
- Close the jar, label, and package the sample for shipment to the laboratory.

#### 4.2.2 General Liquid Waste Sampling Guidelines

Analytical requirements for liquid IDW are shown in **Table 2**. Offsite treatment or disposal facilities may have different sampling requirements and a higher sampling frequency may be required. The following sampling procedures maybe used for liquids waste analysis:

- Using a bailer, or peristaltic pumping methods, collect and combine an aliquot of water from each 55-gallon liquid drum present at the time of sampling. Note, the combined volume needs to be greater than the required total sample volume (4,820 milliliters [mL]) needed.
- Transfer the combined volume and fill sample containers for the appropriate analyses. Note, collect the VOC analysis first. The 40-mL vials for VOC analyses must be filled so that there is no headspace in any of the vials.
- Label and package the samples for shipment to the laboratory.
- Evaluate analytical results against discharge criteria.
- Non-hazardous waste will be disposed of off-Site at a non-hazardous waste RCRA Subtitle D landfill.

### 4.3 Waste Screening Criteria

Waste analytical results will be compared to the toxicity characteristic criteria provided in 40 CFR 261.24. Waste characterized as RCRA hazardous will be evaluated to determine whether the waste meets the RCRA LDR standards. Specifically, a generator of hazardous waste must determine if the waste must be treated before land disposal.

The classification of a waste is important for proper selection of the disposal facility, manifesting, and record keeping. Based on Phase 1 RI results, Phase 2 RI IDW is not anticipated to be hazardous.

### 4.4 Municipal Solid Waste

Municipal solid waste (MSW) that has not come into contact with site contaminants will generally be characterized using generator knowledge only. No analytical testing is required for characterization of these wastes. Potential MSW includes nonrecyclable office/field materials, single-use sampling equipment, and debris. MSW will be placed in a receptacle and disposed of as municipal waste.

### 4.5 Recyclable Material

Potential recyclable materials include office/field materials such as paper, cardboard, glass, and plastic generated from shipping sample containers and equipment or performing general record keeping. These wastes will be recycled where practical.

## 5.0 Container-Specific Handling Guidelines

This section provides guidance for the management and handling of different containers commonly used to store and transport IDW. All containers will be inspected upon arrival at the site for equipment in disrepair and any contamination or residual contents. If a container is in disrepair, is contaminated, or already contains a waste, it will be immediately rejected and documented. A container inventory log will be maintained in a logbook to facilitate identification and tracking of waste and containers.

### 5.1 Small Containers and Drums

The following guidelines relate to drums and small containers:

- Containers will be inspected and accepted by the JV prior to the driver leaving the site.
- Only new, water-tight drums and containers will be used. Do not use reconditioned drums purchased from an outside source. It is acceptable to reuse new drums from the site that are in good condition and have been steam cleaned.
- The insides and outsides of the drums must be free of any residues.
- No penetrating dents are allowed that could affect the integrity of the drum. Special attention to any dents at the drum seams should be made to ensure a seal. Use the highest level of integrity standards for drums intended to contain liquids.
- If containers are rusted or have creases, they must be replaced so the drums will not have the opportunity to leak.
- Drums will have United Nations approval numbers embossed on the bottom or stenciled on the side, “1A2/Y1.7/150” for liquids and “1A2/X425/S” for solids.
- Containers must be compatible with the type of waste being stored in them.
- Drums should be removable-head-type drums without bungs. Bung holes in the lid are acceptable for special applications, but bung holes in the side of the drum are never acceptable.
- All bungs must be tight.
- Each drum will be provided with its own label, and the labels will be visible.
- Waste will be properly contained, labeled, covered, and placed on pallets. The pallets will be arranged to allow access between them for container inspection.
- Adequate aisle space shall be provided between containers to allow the unobstructed movement of personnel and equipment. A row of drums should be no more than two drums wide. Drums are not to be stacked on top of each other.
- Drums will remain closed and lid rings tightened down except when removing or adding waste to the drum. Lids should fit correctly, and the gasket must be in good condition. Lids will be properly secured at the end of each workday.
- Drums will be disposed of with the contents. If the contents are removed from the drums for offsite transportation and treatment or disposal, the drums will be decontaminated prior to reuse or before leaving the site.
- Drums containing liquids must be provided with secondary containment (lined, bermed area) and may not be located near a storm water inlet or conveyance.

The following guidelines should be followed when placing hazardous waste in drums:

- Only one waste stream type per drum is allowed.
- Drums must be on an intact pallet and must be provided with secondary containment (lined, bermed area) and may not be located near a storm water inlet or conveyance.
- Drums must not be filled greater than 90 percent full; leave a minimum of 3 inches of headspace.
- Lids must be securely tightened with a good gasket in place, as required by DOT shipping regulations. Would the drum be leak free if it were turned upside down? If not, the drum is not securely tightened with a good gasket.
- Make sure that the drum ring bolt is below the top of the drum and that the nut is tightened, as required by DOT shipping regulations.

## 6.0 Waste Transportation and Disposal

In general, once IDW soil and aqueous sample results have been received by the JV, the following steps will occur:

- The JV will coordinate with the disposal company, to generate a waste profile. Once waste profile is filled out, the waste profile along with analytical results will be sent to the disposal company;
- The waste profile sheet including laboratory results that show the material does not meet any DOT hazard class (i.e., such as hazardous waste, hazardous substance, or marine pollutant) will be submitted to USACE no later than two (2) weeks prior to shipment. The names of the licensed transportation and disposal facilities will also be provided to USACE. The JV signs the waste profile
- The disposal company approves the signed waste profile.
- The JV schedule a date for off-site disposal and requests a copy of the waste manifest prior to off-site disposal to ensure that the shipping document is called a Non-Hazardous Waste Manifest, and materials must be described as, and meet the requirements of, "Non-RCRA and Non-DOT Regulated.
- Once the transporter is on-site to remove the IDW, the JV FTL signs the manifest as the “Offeror of the Non-RCRA, Non-DOT Regulated Material.”
- Waste profile sheets and shipping documents will be included in the Final Field Report.

### 6.1 Waste Profile

Waste characterization information will be used to complete the waste profile form(s) provided by the designated offsite treatment or disposal facility as part of the waste acceptance process. A separate waste profile will be generated for each media (i.e., solids and aqueous). As previously mentioned in Section 3.1, spoils from each AOC will be separate and not combined with aqueous fluids. Like media that also contains similar COPCs may be combined. For example, spoils from AOC 1 and AOC 4 may be combined in drums, if needed, since similar COPCs (e.g., 2,4-DNCB, 2,4-DNP, and picric acid) were identified. AOC 3 and AOC 5 spoils will be kept separate. Refer to Section 3.2 for additional details.

The profile typically requires the following information:

- Generator information, including name, address, contact, and phone number.
- Site name, including street and mailing address.
- Process generating waste (e.g., soil borings, well purge water, decontamination fluids).
- Source of contamination and historical use (i.e., historical releases).
- Waste composition (e.g., 95 percent soil, 5 percent debris).
- Physical state of waste (e.g., solid, liquid).
- Applicable hazardous waste codes

### 6.2 Shipping Documentation

#### 6.2.1 Manifests and Bills of Lading

Each load of waste (solids, or aqueous) material will be manifested separately and will be shipped using either a nonhazardous (based on Phase 1 RI) waste manifest and bill of lading. At a minimum, the manifest

form will include the following information:

- Generator information including name, address, contact and phone number, and EPA ID number.
- Transporter information including name, address, contact and phone number, and EPA ID number.
- Designated facility information including name, address, phone number, and EPA ID number.
- Site name including street/mailing address.
- DOT Proper Shipping Name.
- Type and number of containers.
- Quantity of waste (volumetric estimate).
- Task order or job number.
- Profile number.
- 24-hour Emergency phone number.

The generator and the transporter must sign the manifest prior to the load leaving the site. Prior to the waste pick up, the JV FTL will review the manifest(s) and confirm the transporter listed on the manifest identifies the transporter removing the waste and that all signatures are completed. The original facility-signed manifest will be returned to the address of the generator.

## 6.3 Waste Transport

### 6.3.1 Department of Transportation Requirements

Requirements under 49 CFR 171 through 180 will apply to all offsite shipments of hazardous materials and waste. The information contained in this section is provided as a general guide. Requirements specific to each hazardous material will be determined in the field. It is the responsibility of a DOT- trained individual to ensure that the requirements of 49 CFR 171 through 180 are met.

#### 6.3.1.1 Shipping Name

Material that exhibits one of the nine DOT hazard class characteristics (explosives, gases, flammable liquids, flammable solids, oxidizing substances, toxics/poisons, radioactive materials, corrosive substances, or miscellaneous hazards) is regulated under DOT rules for the transportation of hazardous material. If material is suspected to be a hazardous material, it will be shipped under the suspected hazard class. Each shipment of a suspected hazardous material will be provided with a proper shipping name using the Hazardous Materials Table in 49 CFR 172.101. All determinations will be made by DOT-trained personnel. Based on the Phase 1 RI, the IDW generated during the Phase 2 RI is anticipated to be nonhazardous.

#### 6.3.1.2 Packaging, Marking, and Labelling

The shipping name, hazard class, identification number, technical names (if applicable), EPA markings and waste code numbers, and consignee/consignor designations will be marked on packages for shipment (49 CFR 172.301). Once a waste is characterized, reference will be made to the Hazardous Materials Table in 49 CFR 172.101 to determine the appropriate label.

#### 6.3.1.3 Placards

Appropriate placards will be determined by DOT-trained personnel. Specific placard descriptions are found starting at 49 CFR 172.521. If a placard is required, it will be affixed on each side and each end of the transport vehicle.

#### 6.3.1.4 Waste Transporter Requirements

Each transport vehicle and load of waste will be inspected before leaving the site and documented. The quantities of waste leaving the site will be recorded on a transportation and disposal log (**Attachment 1**). A contractor licensed for commercial transportation will transport nonhazardous waste. If the waste is hazardous or dangerous, the transporter will have an EPA Identification number, and will comply with transportation requirements outlined in 49 CFR 171-180 (DOT), and Delaware Solid Waste Management rules and regulations. If waste is determined to be hazardous, additional Delaware requirements (Hazardous Waste Management) and 40 CFR 263.11 and 263.31 (Hazardous Waste Transportation) are also applicable.

Drivers of offsite disposal trucks must not come in physical contact with the contaminated material while covering the load or preparing it for transport. The JV and the transport driver will ensure that there is no visible soil/waste material on the sides or tires of any trucks leaving the staging area, or vehicle leaving the site. The JV will use proper decontamination procedures to remove soil or debris from the outsides of the vehicles if necessary, to ensure soil is not tracked beyond designated work areas.

Trucks used for offsite disposal will be equipped with appropriate liners and tarps in acceptable working condition and all loads will be lined and covered prior to departure. Liners and covers will be properly secured to assure that the vehicles do not leak or release any waste constituents at any time during the transport process. Waste materials will be loaded in an area designated during mobilization.

The transporter will be responsible for weighing loads at a certified scale. For each load of material, weight measurements will be obtained for each full and empty container, dump truck, or tanker truck. Disposal quantities will be based on the difference of weight measurements between the full and empty container, or dump truck. Weights will be recorded on the waste manifest and weight ticket.

The transporter will observe the following practices when hauling and transporting waste offsite:

- Minimize impacts to general public traffic.
- Repair road damage caused by construction and/or hauling traffic.
- Line and cover trucks/trailers used for hauling hazardous or regulated waste to prevent spills or releases.
- Decontaminate vehicles prior to re-use, other than hauling contaminated waste.
- Ensure seals on trucks transporting liquids are in good condition.
- Waste or materials from other sites may not be combined with waste generated during this project.
- All personnel involved in offsite disposal activities will follow safety and spill response procedures outlined in the Health and Safety Plan. All loads will be covered, and the trucks inspected by KGS and the transport driver to ensure the loads are secure, proper placarding is in place, and shipping documentation is accurate.

#### 6.3.1.5 Shipment Methods

All waste shipments offsite will comply with procedures specified in the Hazardous Materials Transportation Act, 49 CFR 171. Hazardous materials will be properly classified, described, packaged, marked, and labeled for shipment as required by 49 CFR. For example, a bulk package for solids is defined as having a maximum net mass of 882 pounds or more and a maximum capacity of 119 gallons or more. All packaging and labeling of waste will be performed by staff trained to meet the DOT requirements (for example, hazardous materials employee training requirements under 49 CFR 172 Subpart H).

### 6.3.2 Spill Reporting and Response

In the event of a spill or release of waste, the transporter will immediately notify JV personnel, in accordance with the Health and Safety Plan**.** The following information about the spill will be reported and recorded by the transport driver and the JV:

- Organization, name, and phone number of point-of-contact at spill site.
- Date and time of spill.
- Type of waste material (e.g., soil, water) and contaminant, and/or product (e.g., soil cuttings).
- Location, environment (e.g., confined within building, outside buildings, concrete, asphalt, soil or grass).
- Estimated volume.
- Media affected (e.g., spilled on concrete pad or soil).
- Weather conditions at time of spill.
- Detailed description of source and cause of spill.
- Any storm drains, waterways, or water bodies affected.
- Any injuries or property damage.
- Actions taken to correct situation.
- Final disposition of spilled material.

The transporter will also report a spill or release of hazardous waste or hazardous material, as required, to the following entities:

- National Response Center: (800) 424-8802 or (202) 426-2675.
- Spill Reporting Hotline: (800) 522-0206.

Transporters that report spills/releases to the National Response Center will also report in writing, as required by 49 CFR 171.16, to the Director, Office of Hazardous Materials Regulations, Materials Transportation Bureau, Department of Transportation, Washington DC. 20590.

## 6.4 Transportation Security Plans

Anyone offering or transporting a DOT hazardous material that requires placarding is required to have a Transportation Security Plan under 49 CFR 172 Subpart I. Each Transporter must also have a Transportation Security Plan since they may be packaging DOT hazardous materials for shipment. The Transporter's Transportation Security Plan can be a program-wide or company-wide plan and does not need to be project- or site-specific. The plan should address only those aspects of transportation for which

the Transporter might be responsible.

### 6.5 Disposal of Waste Streams

Offsite treatment, disposal, or recycling facilities will use the waste profile analytical results and supporting documentation (e.g., generator knowledge) to determine whether a waste will be accepted. Most environmental waste from the site is expected to be classified as nonhazardous waste and will be transported and disposed of offsite at a permitted Subtitle D landfill with approval under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Off-site Rule (40 CFR 300.400). Hazardous waste, although not expected, will be disposed of or treated accordingly. The designated offsite facility will be responsible for providing a copy of the fully executed waste manifest and a certificate of treatment or disposal to the USACE PM and JV PM for each load of waste received.

## 7.0 Record Keeping

The JV will retain copies of transporter-signed, fully executed waste manifests and waste analysis records discussed in this IDW plan for the disposal of all removed material in the project records for 3 years, as required by RCRA.

The following transportation and offsite disposal records and documents will be maintained in the project files:

- Copies of the waste profiles and associated characterization data
- Transportation and offsite disposal records, including:
  - The transporter signed manifest as well as the fully executed manifests, and copies of the following: Land Disposal Restriction notifications/certifications, and weight tickets.
  - Designated offsite facility waste receipts, certificates of disposal/destruction.
- Training records.
- Inspection records.

| Inspections completed weekly and documented | | |
| If any of these questions were marked NO, please add comment and corrective actions: | | |

## Incoming Drum Inspection Form

Project: _____ Drum arrival date: _____ Number of number: _____ Inspector/company:_____ Inspection date: _____

| | Yes | No |
|---|---|---|
| Drum is in good condition, no rust, holes, or unacceptable dents | | |
| Residual contamination/waste/material in or on drum (look under liner if installed): | | |
| Drum has UN Code | | |
| Drum lid fits and seals, gasket is in acceptable condition | | |
| Drum ring and bolt are in place and function | | |

Example of UN code: 1A1/Y1.4/150/10 USA/M1234 3 mm *Include photos of any unsatisfactory items.*

- 1A1 = Packaging identification code
- /Y1.4 Y = performance code
- 1.4 =maximum specific gravity
- 150 = hydrostatic test pressure
- 10= year manufactured
- USA = country of origin
- M1234 = manufacturers registered symbol
- mm = minimum thickness for reuse

Comments (if rejected include why):

Drums accepted: signature of inspector _____ Drums rejected: signature of inspector _____

## Scope

This method is useful for identifying and quantitating the following polychlorinated biphenyls (PCBs) as Aroclors in aqueous matrices:

| Compound | LOQ (µg/L) |
|---|---|
| Aroclor 1016 | 0.5 |
| Aroclor 1221 | 0.5 |
| Aroclor 1232 | 0.5 |
| Aroclor 1242 | 0.5 |
| Aroclor 1248 | 0.5 |
| Aroclor 1254 | 0.5 |
| Aroclor 1260 | 0.5 |

The following aroclors can also be analyzed for upon request by the client, usually on a project basis. Since aroclors 1262 and 1268 contain peaks that elute much later than 1260, the GC run time needs to be extended to ensure the entire pattern has eluted.

| Compound | LOQ (µg/L) |
|---|---|
| Aroclor 1262 | 0.5 |
| Aroclor 1268 | 0.5 |
| Aroclor 5422 | 1.0 |
| Aroclor 5432 | 1.0 |
| Aroclor 5460 | 1.0 |

See Appendix I for GC operating conditions and calibration information when analyzing for Aroclor 5422, 5432, and/or 5460.

Limits of Quantitiation (LOQs) are based on annual statistical evaluation of laboratory data and are subject to change. The current Method Detection Limits (MDLs) and LOQs are maintained in the LIMS.

## Basic Principles

A portion of an aqueous sample is extracted serially with methylene chloride. The volume of sample extracted can be adjusted depending on the physical appearance of the sample and the amount sent for analysis. The extract is dried, concentrated, and exchanged into hexane. The PCBs are then identified and quantitated using gas chromatography (GC) with an electron capture detector (ECD). The extract may require further cleanup (by florisil, sulfuric acid, or copper) to reduce matrix interferences that introduce large, unresolvable peaks in the chromatogram (due to interferents such as phthalates, oxygenated organics, unsaturated organics, or elemental sulfur).

Uncontrolled Copy

## Reference Modifications

Gas Chromatography conditions are different than those listed in Method 8082A however, all QC criteria are met.

## Interferences

1. Avoid contact with any plastic material during the extraction and analysis procedures to minimize interferences from phthalate esters.

2. Scrupulously clean all glassware to minimize interferences caused by laboratory contaminants.

3. An electron capture detector (ECD) is very sensitive to compounds that contain halogens and will also respond to many other compounds and materials including oxygenated organics, unsaturated organics, and elemental sulfur.

4. Extracts may require further cleanup if interferents are present. Refer to *T-OE-PEST-WI10281* for details on each cleanup procedure. Interfering materials can introduce large, unresolvable peaks into the chromatogram.

   a. Use Florisil cleanup to reduce organics that can interfere (polar compounds).

   b. Use GPC to remove sulfur and higher molecular weight organics.

   c. Use copper or TBA cleanup to remove elemental sulfur.

5. Common single component pesicides such as DDT, DDD, and DDE may cause interference with the aroclor pattern. To ensure that the analyst is aware of this, a standard containing DDE/DDD/DDT will be run with each initial calibration.

## Safety Precautions and Waste Handling

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

Gloves, lab coats, and safety glasses must be worn when preparing standards. Safety glasses must be worn around the GC where solvents and sample extracts are handled.

GC vials are disposed of in the designated lab container and subsequently lab packed for final disposal. All solvent waste is placed in designated containers in the laboratory then taken to the lab-wide facility by personnel trained in hazardous waste disposal.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each analyst performing instrumental analysis must work with an experienced analyst for a period of time until they can independently calibrate the instrument, use the chromatography data system to set up sequences, perform the calculations, interpret chromatograms, perform instrument maintenance, and enter data into the LIMS. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an Initial Demonstration of Capability (IDOC).

The IDOC consists of four laboratory control samples (LCS) that are carried through all steps of the analysis and meet the LCS acceptance criteria, per EPA 8000D section 9.3.3.2. The criteria include the

Uncontrolled Copy

calculation of mean accuracy and standard deviation. Various options are available for a DOC and can include four LCSs, one blind sample, or one ICAL with 4 ICVs and/or CCVs.

## Sample Collection, Preservation, and Handling

Samples are collected in 1 L or 250 mL amber glass containers with Teflon-lined caps and kept cool at 0° to 6°C, not frozen.

PCBs have no maximum recommended holding time for the extraction. Some agencies or projects may require a specific hold time for the extraction. If the hold time is specified in the project, this hold time must be followed. Sample analysis must be performed with 40 days of extraction. Extracts are stored in the freezer at ≤-10°C.

## Apparatus and Equipment

1. HP 7890 gas chromatograph equipped with an electron capture detector, or equivalent

2. Columns:

   a. Phenomonex MultiRes I – 30 m × 0.32 mm × 0.5 µm, or equivalent

   b. Phenomonex MultiRes II – 30 m × 0.32 mm × 0.25 µm, or equivalent

3. Integrating system such as Chrom Perfect® by Justice Laboratory Software, or equivalent. Chrom Perfect® is a data system capable of storing and reintegrating chromatographic data and determining peak areas using a forced baseline, area summation, baseline projection, and performing baseline compensation as required.

4. Various sizes of Class A volumetric flasks, pipettes, and syringes

## Reagents and Standards

A. Reagents

   1. Follow manufacturer's guidelines for storage conditions.

   2. Hexane for autosampler rinse vials. Stored at room temperature up to 1 year.

   3. UPC (Ultra Pure Carrier) helium for carrier gas.

   4. UPC nitrogen for detector make-up gas.

   5. UPC hydrogen carrier gas, either bottled or from a generator.

B. Standards

   1. All standards are prepared using Class A volumetric pipettes, syringes, and flasks.

   2. All weights are made on an analytical balance.

   3. Unopened ampules are stored according to the manufacturer's instructions and are stable until the expiration date provided by the manufacturer.

   4. All prepared standard solutions are stored at <-10° C in labeled containers for up to 6 months. If comparison with check standards indicates a problem prior to expiration date, the standards must be replaced.

   5. Aroclor 1016 stock – Restek 32006 at 1,000,000 ppb in hexane. Prepare an intermediate by diluting 1 to 10 mL of hexane.

   6. Aroclor 1016/1260 stock – Restek 32039 at 1,000,000 ppb in hexane. Prepare an intermediate by diluting 1 to 10 mL of hexane.

Uncontrolled COPY

7. Aroclor 1221 stock – Restek 32007 at 100,000 ppb in hexane. Two separate lots are kept on hand to provide a second source.

8. Aroclor 1232 stock – Restek 32008 at 100,000 ppb in hexane. Two separate lots are kept on hand to provide a second source.

9. Aroclor 1242 stock – Restek 32009 at 100,000 ppb in hexane. Two separate lots are kept on hand to provide a second source.

10. Aroclor 1248 stock – Restek 32010 at 1,000,000 ppb in hexane. Prepare an intermediate by diluting 1 to 10 mL of hexane. Two separate lots are kept on hand to provide a second source.

11. Aroclor 1254 stock – Restek 32011 at 1,000,000 ppb in hexane. Prepare an intermediate by diluting 1 to 10 mL of hexane. Two separate lots are kept on hand to provide a second source.

12. Initial calibration Verification standard (ICV) Stocks:

a. Aroclor 1016 - Accustandard cat # C-216S-H-10X at 1,000,000 ppb

Aroclor 1260 Accustandard Cat# C-260S-H-10x at 1,000,000 ppb

Prepare an intermediate by diluting 1mL of each to 10 mL of hexane.

b. Aroclor 1248 - Accustandard cat# C-248S-H-10X at 1,000,000 ppb.

Prepare an intermediate by diluting 0.5 mL to 5 mL of hexane

c. Aroclor 1254 – Accustandard cat#C-254S-H-10X at 1,000,000 ppb.

Prepare an intermediate by diluting 0.5 mL to 5mL of hexane.

13. Surrogate stock (SS) – Supelco 861284 containing DCB/TCX at 200,000 ppb in acetone.

14. 1016/1260 Matrix spike (MS) stock: Restek 32039. Each at 1,000,000 ppb in hexane. Also used as a second source stock. Prepare an intermediate by diluting 1 mL to 10 mL of hexane.

15. Aroclor 1262 stock – Restek #32409 at 1,000,000 ppb in hexane. Prepare an intermediate by diluting 1 mL to 10 mL of hexane.

16. Aroclor 1268 stock – Restek #32410 at 1,000,000 ppb in hexane. Prepare an intermediate by diluting 1 mL to 10 mL of hexane.

17. Instrument Blank (IBLK) – Surrogate Stock (SS) – Supelco #861284 containing Decachlorobiphenyl (DCB) and Tetrachlorometaxylene (TCX) at 200,000 ppb each in acetone.

18. Prepare working standards using the reagent module in the LIMS as a guide.

a. In the reagent module, first enter the reagents in this section as 'source' reagents.

b. Then select 'intermediate' reagent and load the most recent version of the working standard you wish to create for editing, or create a new standard if the working standard has not yet been prepared in TALS.

c. The module contains the following information: reagent description (ex. AR161), source reagent code, amount used, final amount, solvent used and solvent lot, concentration of each compound in solution, and expiration date. The working standards have an expiration date of 6 months.

d. The calibration scheme begins at or below the reporting limit through a 20 fold of the initial calibration level:

| **Calibration Standard** | **INT standard 10,000 ug/L Vol. (mL)** | **Surrogate GCS_ARpestssr Vol. (mL)** | **Final Vol. (mL)** | **Aroclor conc. (ug/L)** | **DCB/TCX Conc. (ug/L)** |
|---|---|---|---|---|---|
| GCS_AR161 (1016/1260) | 0.025 | 0.025 | 100 | 25 | 2.0 |
| GCS_AR162 (1016/1260) | 0.05 | 0.05 | 100 | 50 | 4.0 |
| GCS_AR163 (1016/1260) | 0.1 | 0.25 | 100 | 100 | 20 |

| | | | | | |
|---|---|---|---|---|---|
| GCS_AR164 (1016/1260) | 0.2 | 0.5 | 100 | 200 | 40 |
| GCS_AR165 (1016/1260) | 0.5 | 0.76 | 100 | 500 | 61 |
| GCS_AR166 (1016/1260) | 1.0 | 1.0 | 100 | 1000 | 80 |

| Standard Name | Parent Solution | Aliquot (mL) | Final Vol. (mL) | Final Conc. (ug/L) | Solvent | Description |
|---|---|---|---|---|---|---|
| GCS_MD16 | GCS_AR1660ING | 0.01 | 200 | 5.0 | Hexane | 1016/1260 MDL Standard |
| | GCSARpestssr | 0.01 | | 0.4 | | |
| GCS_IC16 | GCS_IC16INT | 1.0 | 200 | 200 | Hexane | Second Source ICV Check Standard |
| | GCS_ARpestssr | 0.4 | | 40 | | |
| GCS_IBLKpcb | GCS_PESTSUR | 0.05 mL | 500 | 20 | Hexane | SW-846 Water Surrogate - identical to that prepared for the Pesticides/PCBs analysis |

e. For 1L preps (3510C):

| Standard Name | Parent Solution | Aliquot (mL) | Final Vol. (mL) | Final Conc. (ug/L) | Solvent | Description |
|---|---|---|---|---|---|---|
| OP_PCB_MS | Aroclor 1016/1260 stock | 1.25 | 250 | 5000 | Acetone or methanol | PCB Spike used for extraction |
| OP_SW_SS | Pest Surr mix | 3 | 2000 | 300 | Acetone or methanol | SW846 surrogate standard used for extraction |

f. For 250mL preps (3510C_LVI)

| Standard Name | Parent Solution | Aliquot (mL) | Final Vol. (mL) | Final Conc. (ug/L) | Solvent | Description |
|---|---|---|---|---|---|---|
| OP_MINIPCB_MS | OP_PCB_MS | 12.5 | 50 | 1250 | Acetone or methanol | PCB Spike used for extraction |
| OP_SW_SS | Pest Surr mix | 0.375 | 1000 | 75 | Acetone or methanol | SW846 surrogate standard used for extraction |

The MS and SS working solutions are stored <-10°C.

19. An initial calibration verification standard must also be prepared at a concentration at the mid-point of the calibration for 1016, 1260, 1248, 1254 using a stock solution purchased from a different vendor or different lot than that used for the calibration standards.

20. Additional standards and preparations are listed in Appendix I for Aroclor 5442, 5432, and 5460 (PCT analysis).

## Extraction

See organic extraction procedure *T-OE-PEST-WI10920*.

## Gas Chromatographic Conditions

The conditions listed are usually the optimum operating conditions but can vary to improve the sensitivity, linearity, and overall chromatography or shorten run times on each GC system.

A Merlin microseal can be used in place of traditional septum.

| | |
|---|---|
| Detector | ECD |
| Detector Temperature | 330°C |

## Calibration

A. Fill the autosampler rinse vials with clean solvent or replace vials that appear dirty.

B. Prepare a sequence using the following order of injections:

1. Conditioner
2. IBLK
3. EVAL
4. AR161
5. AR162
6. AR163
7. AR164
8. AR165
9. AR166
10. AR481
11. AR482
12. AR483
13. AR484
14. AR485
15. AR486
16. AR541
17. AR542
18. AR543
19. AR544
20. AR545
21. AR546
22. AR214
23. AR324
24. AR424
25. AR624
26. AR684
27 AR16X
28. MD16 (MDL)
29. IC16X (ICV)
30. IC48X (ICV)
31. IC54X (ICV)
32. Blank
33. LCS
34. 1234567
35. 1234567ms
36. 1234567msd
37.- 47. Continue running samples
48. AR164 (CCV)
49. IBLK

1. Note for our routine PCBs: The AR21, AR32, and AR42 are level 4s in the ICAL and are entered as AR214 and AR424 in the ICAL. Also the AR62 and AR68 are both level 4s and are listed as AR624 and AR684 in the sequences.

Uncontrolled copy

2. A single point of Aroclor 1016 is analyzed with the calibration to aid in better pattern recognition in the samples. Aroclor 1016 and 1242 have similar patterns with the exception of the smaller trailing peaks at the end of the Aroclor 1242 pattern. This is identified in the sequence as AR16X.

3. A DDT/Endrin breakdown standard is run with each ICAL in order to provide the retention times of p,p-DDE, p,p-DDD, and p,p-DDT which may interfere with the pattern for aroclor 1254, 1248, and 1260.

4. See Appendix I for a sequence example when the analysis of PCTs (Aroclors 5442, 5432, and 5460) is requested.

D. Continue running groups of samples/injections. Each bracket must contain no more than 20 samples/injections and last no more than 12 hours for Method 8082A. Each bracket is followed by the continuing calibration check standard and an instrument blank (IBLK).

E. The conditioner injection is usually a standard or sample that has already been injected.

1. The conditioner is used to prime the system.

2. It is best utilized when the GC has not been running and there is a gap in time prior to starting a set of injections.

F. Hexane blanks can also be run to allow the GC to go through some temperature programs and/or to check the cleanliness of the system.

G. Instrument blanks (IBLK) may also be run with the continuing calibration standards. This is optional but frequently requested for projects.

1. The instrument blank (IBLK) is injected after the conditioners but before the initial calibration.

2. It is used to determine that the instrument is free of background noise or contamination.

H. For projects where a known aroclor is present and at the request of clients other aroclors can be run for the continuing check standard. For instance, a set of continuing standards can be AR484, AR164, and IBLK.

I. Aroclor 1262 and 1268 can be analyzed when requested. A full six point curve can also be run, depending on the project requirements.

J. Initial Calibration (ICAL)

1. Calibrate for the aroclors using the six levels of 1016, 1260, 1248, and 1254. Use the single point for 1221, 1232, 1242, 1262, and 1268 when needed. As an option, 1248 and 1254 can use a single point calibration.

2. An external standard calibration based on the average calibration factor (AVG CF) for all analytes is used for quantitation where the %RSD is ≤20%.

3. The surrogate standards are calibrated using the AR16 levels using AVGCF unless the %RSD is >20%.

4. If the RSD is > 20%, use a calibration curve.

   a. Use a linear fit.

   b. The correlation coefficient must be >0.99 to be a valid fit.

   c. Extrapolate or force to zero is not allowed. Set the zero to ignore.

When 8000D is referenced and curve fits are used in the initial calibration, percent error (%E) must be calculated for each calibration level. Standard levels at or below the LOQ must meet +/- 50%, standards above the LOQ must meet +/-30%. (%error = (true concentration - calculated concentration )/true concentration)*100). All individual peaks used to calculate the aroclor pattern must meet the %E criteria.

5. If the 0.99 curve coefficient cannot be met:

Uncontrolled copy

a. Inspect the data points to see if one or more calibration level became concentrated due to solvent evaporation or degraded over time.

b. Reinject or remake the standard if a specific calibration level has concentrated due to solvent evaporation, or degraded over time..

c. Perform instrument maintenance as needed. See *T-PEST-WI10007* for troubleshooting linearity problems.

6. The calibration range for the aroclors is 50ug/L to 1000 µg/L. Level 1 is equivalent to the Limit of Quantitation.

7. Set up the aroclor calibration data in LIMS. The retention times of the peaks to use for identifying and quantifying the aroclors are entered into the calibration file along with the corresponding peak heights and concentrations.

8. Ensure the peaks in the standards are labeled properly, including the surrogates in all injections that contain them.

9. Set the scaling of chromatograms and peak integration parameters so that the size of the peaks for each compound of interest are approximately 2 to 3 mm in height at the concentration of the method detection limit (MDL).

a. Ensure all peaks in the MDL standard are integrated.

b. By running the 1016/1260 MDL standard, the majority of peaks of all aroclors are represented.

K. Initial Calibration Verification (ICV)

1. Verify the calibration curves using the ICV mixtures injected directly after the full ICAL.

2. The % difference of the concentrations for these must be within 20% difference of the nominal concentration. All the individual peaks used in the ICAL for the PCB pattern must meet this criteria.

a. If this criteria is not met, reinject the ICV.

b. If the criteria is not met again, then prepare a new standard.

c. If the criteria is not met after analyzing the new ICV standard, then a recalibration is performed.

L. Continuing Calibration Verification (CCV)

1. Calibration verification is performed after each set of twenty injections (samples, QC, blanks, etc.) or 12 hours, whichever comes first.

2. Use AR16 to evaluate the calibration of the aroclors (or other aroclors as requested for particular clients or projects).

3. Other aroclors can also be used along with AR16. This must be done if a site has prior history of containing a specific aroclor, or as requested for client projects or to meet other regulatory requirements.

4. The concentration quantitated for the continuing calibration check standards must be within 20% difference (%D) of the nominal concentration for each compound. All the individual peaks used in the ICAL for the PCB pattern must meet this criteria.

5. Samples must be bracketed with compliant standards.

a. Exception: If the standard following a sample is outside the ±20% but exhibits increasing response, the samples before it do not have to be reinjected if the target analytes are not detected. A comment must be added to the analytical report.

b. If two consecutive/sequential CCVs fail, corrective action must be taken, which can include performing injection port maintenance, baking the instrument or other types of maintenance. Two consecutive/sequential CCVs must meet the criteria or an initial calibration must be performed before sample analysis can continue.

Uncontrolled Copy

c. If confirmation of target analytes is needed, then the second column should meet the 20% continuing calibration criteria, as well as all initial calibration criteria. if either of these are not met, a comment must be added to the analytical report.

6. The instrument blank (IBLK) is injected after each set of continuing calibration verifications when requested.

a. It must be evaluated as a water matrix against the water MDL/LOQs.

b. The IBLK must not have any target compounds above the reporting limits.

(1) If a target analyte is detected in the IBLK, any associated samples with a detection for that same target must be evaluated.

(2) Unless the concentration in the sample is more than 10x the IBLK value, the sample must be reinjected after another compliant IBLK.

(3) Instrument maintenance, like baking the system or injection port maintenance is usually necessary to clean up instrument.

7. Retention time (RT) windows

a. Established as 3× the standard deviation determined over 72 hours or at no less than ±0.02 min, applied to the mid-point initial calibration standard.

b. If the RTs for a CCV fall outside the RT window, update the mid-point RT using that standard.

(1) Save this under the appropriate name to indicate an update has occurred.

(2) RTs cannot be updated more than once per day. All subsequent standards run within a 24-hour period must be within this window.

(3) If RTs are not consistent, the cause must be investigated and corrective action taken.

## Procedure

1. Make injections via an auto sampler.

2. Samples are analyzed according to the sequence in the calibration section above, along with the appropriate check standards.

3. Retention times of peaks in the samples are compared to the standard RT windows.

Peaks present on both columns that are also in the correct ratios to represent an aroclor are quantitated and the high value is reported unless chromatographic anomalies are observed. See *T-PEST-WI9954*.

4. Use a minimum of three to six peaks for quantitation, with the exception of certain mixes where it can be more accurate to use less peaks to avoid excessive overlap of patterns.

5. If significant interference is present, schedule florisil and/or sulfuric acid cleanup. If elemental sulfur is present, copper treat the extract. If these techniques do not reduce the matrix problems, dilute the extract with hexane, analyze, and adjust the LOQs accordingly. Also, the reporting limit for individual aroclors may be raised in instances where matrix interference hinders the recognition of an aroclor pattern in the specified retention time window. The reporting limit is calculated by averaging the concentration of at least 3 peaks in the pattern.

6. Report the results for the least dilute sample where the concentration measured is within the acceptable calibration range.

## Calculations

A. See *T-PEST-WI9847* for details on all calculations/equations used to evaluate the initial and continuing calibration.

Uncontrolled Copy

B. Calculation of results is performed according to the following procedures:

1. The peak heights generated by the integration system are used to calculate the calibration factors (CF) for peaks of interest for each aroclor. Usually, the six major peaks that are unique to each aroclor are chosen for quantitation with the exception of 1221 where only three peaks are available.

2. Sample concentrations are calculated per peak using average calibration factor (AVG CF) from the initial calibration for 1016, 1260, 1248, and 1254 where a multi-point calibration is run, single point CF for 1221, 1232, 1242, (a multi-point calibration can also be run for these as requested or necessary to meet client or regulatory agency requirements). Do not use individual peaks that have values <MDL in quantitation.

3.

$$\frac{Sample\ Height}{AVG\ CF\ (CF)} \times \frac{FV}{IV} \times DF = \mu g/L\ as\ received$$

**Where:**

FV = Final volume – 2 or 10 mL

IV = Initial volume – 250 or 1000 mL

DF = Dilution factor, as needed

The final result that is reported is determined as the average of the result for each peak chosen for quantitation:

4. The surrogate results are determined using either AVGRF or linear curve:

$$(Result\ 1 + Result\ 2 + \ldots + Result\ n) / n = Average\ Result$$

a. Using AVGCF from the initial calibration:

$$\frac{Sample\ Height}{AVG\ CF\ (CF)} \times \frac{FV}{IV} \times DF = \mu g/L\ as\ received$$

b. Using linear curve from the initial calibration:

$$[(Sample\ Height - Y - intercept)/Slope] \times \frac{FV}{IV} \times DF = \mu g/L\ as\ received$$

**Where:**
FV = Final volume – 2 or 10 mL
IV = Initial volume – 250 or 1000 mL
DF = Dilution factor, as needed

## Statistical Information/Method Performance

LCS, MS, and RPD are compared to the limits stored in the LIMS. The limits for LCS and MS are statistically derived. Historical data for MS/Ds, LCS/Ds, measurement of uncertainty, is reviewed at least annually. Reporting limits including method detection limits (MDLs) and limits of quantitation (LOQs) are set according to EPA method requirements, are analyzed quarterly, and are evaluated annually. Refer to *QA-SOP11892* for specific guidelines and procedures. Updates to the LIMS are made as needed by the QA Department and only as directed by the manager. The department database is updated via a download from the LIMS.

## Quality Assurance/Quality Control

Uncontrolled Copy

A reagent water blank and a reagent water spike (LCS) are analyzed each day with every batch of samples (batch size is 20). An MS/MSD is performed per batch as long as there is ample volume of a sample in the batch. If an MS/MSD cannot be performed, an LCSD must be extracted.

Aroclor 1016 and 1260 are routinely spiked, however, other aroclors can be spiked as requested by clients.

DCB and TCX are added as surrogates to each sample and QC to monitor the efficiency of the extraction, the operation of the autosampler, and to monitor retention times throughout the GC run.

If any client, agency, or state has more stringent QC or batch requirements, these must be followed.

See *T-PEST-WI10011* for details on QC acceptance criteria and corrective action.

## Appendix I

### PCT Analysis ( Aroclor 5442, 5432, and 5460)

A. Standards:

PCT-Stocks - Aroclor 5432 (Accustandard T-4325), 5442, and 5460(Accustandard T-460S) purchased as individually ampulated solutions from Accustandard at 35,000ug/L.

MS stock of Aroclor 5442 - Absolute Cat. #71791. 1000ug/mL in Methanol.

Prepare working standards using the reagent module of the LIMS as a guide.

1. In the reagents module, first enter the reagents in this section as 'source' reagents.

2. Then select 'intermediate' reagent and load the most recent version of the working standard you wish to create for editing or create a new standard if the working standard has not yet been prepared in TALS.

3. The module contains the following information: reagent description (ex. AR161), source reagent code, amount used, final amount, solvent used and solvent lot, concentration of each compound in solution, and expiration date. The working standards have an expiration date of 6 months.

4. The calibration scheme begins at or near the reporting limit through a 20 fold of the initial calibration level.

5. The scheme for preparing the matrix and surrogate spiking solutions used in the extraction process are listed below. The MS and SS working solutions are stored at <-10° C.

| Standard Name | Parent Solution | Aliquot (mL) | Final Volume (mL) | Solvent | Description |
|---|---|---|---|---|---|
| MS | 5422 MS Stock | 0.625 | 125 | Acetone or methanol | PCT Water Spike |
| SS | SS Stock | 3 | 2000 | Acetone or methanol | PCB surrogate |

B. GC Chromatographic Conditions

Detector: ECD
Detector temp: 300°C
Oven Temp: 110°C to 250°C at 40°C/min, 280ºC to 330°C at 30°C/min, hold 9 min.
Carrier: Hydrogen at 5.0 mL/min
Makeup gas: N2 at 80mL/min or equivalent
Injection size: 1-uL, direct injection
Injection temp: 225°C

The conditions listed serve as a guideline only and are typically the optimum operating conditions. The analyst may make any changes to the chromatographic conditions to improve the speed of analysis,

Uncontrolled Copy

linearity, sensitivity, and/or improve separation if initial and continuing calibration criteria and quality assurance criteria listed within this analysis document are met.

**Scope**
This method is used for determination of mercury in aqueous and solid samples. The optimum concentration range for this method is 0.2 to 5.0 ppb.

Matrices - EPA 7470A and EPA 245.1 are applicable to water analysis. EPA 7471A and EPA 7471B are applicable to soil and tissue analysis. EPA 245.1 is applicable to drinking water analysis.

Method Detection Limits (MDLs) are based on annual statistical evaluation of laboratory data and are subject to change. The current MDLs and RLs are maintained in the LIMS, and are subject to change without notification.

**Basic Principles**
The Leeman Labs Mercury Analyzer utilizes continuous flow technology with drying of the sample vapor for the analysis of mercury by automated vapor generation. The reaction for the mercury analysis is a simple reduction reaction. The mercury is reduced with stannous chloride to liberate mercury metal and Tin (IV) chloride. An inert gas is used to sweep the volatile mercury into the absorption cell in the optical path of the atomic absorption spectrophotometer. The dry vapor enters one path of the optical cell, which has been optimized for fast response (small diameter), and sensitivity (long length).

Mercury is measured using a solid state detector with a wide dynamic range and a mercury source that delivers a stable source of emission at 254 nm. The signal is referenced to the simultaneous absorbance of air through direct view of the lamp. The system adds Stannous chloride to the samples via a "Y" connection in the pump tubing. The peristaltic pump then carries the sample/stannous mix to the liquid gas separator. Argon gas is bubbled through the liquid and used to transport the volatile mercury into the detector. The mercury is reduced with stannous chloride to liberate mercury metal and Tin (IV) chloride.

**Definitions**

1. CRA - Low Level Check Standard
2. MSA – Method of Standard Additions
3. SPLP - Synthetic Precipitation Leaching Procedure
4. TCLP – Toxicity Characteristic Leaching Procedure
5. QC Type Designators:
    a. BKG – unspiked background sample
    b. DUP – Sample Duplicate
    c. MS – sample spike
    d. MSD – Sample spike duplicate
    e. MB –Preparation Blank (Water/ Solid). Equivalent to a Method Blank (MB)
    f. LCS/LCSD - Laboratory Control Sample/Laboratory Control Sample Duplicate

**Interferences**
Potassium permanganate is added to samples to eliminate possible interference from sulfide. Concentrations as high as 20 mg/L of sulfide as sodium sulfide do not interfere with the recovery of added inorganic mercury from reagent water.

Samples high in chlorides require additional permanganate (as much as 25 mL) because, during the oxidation step, chlorides are converted to free chlorine, which also absorbs radiation of 253.7 nm. Take care to ensure that free chlorine is absent before the mercury is reduced and swept into the cell by using an excess of hydroxylamine sulfate (or chloride) reagent.

Copper has been reported to interfere; however, copper concentrations as high as 10 mg/kg had no effect on recovery of mercury from spiked samples.

**Safety Precautions and Waste Handling**
All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Preparing samples for inorganic analysis involves working with concentrated acids and other chemicals which are dangerous if not handled carefully:

**Nitric acid (HNO3)** – This acid can cause skin burns. Add nitric acid to samples in a hood to avoid exposure to toxic fumes.

**Sulfuric acid (H2SO4)** – This acid is a strong oxidizing agent and can cause severe burns. Sulfuric acid spills are extremely slippery, adding to the danger. Always use in a fume hood. Never mix with concentrated HCl or concentrated KMNO4 to avoid a violent reaction (explosive splattering and extreme heat).

**Hydrochloric acid (HCl)** – This acid can cause skin burns. Never mix HCl with concentrated H2SO4 to avoid a violent reaction. Always use in a fume hood.

When diluting strong acids, never add water to acid; always add acid to water.

Store concentrated acids in the prep room acid lockers. Only acids are to be stored in these lockers. (Store solvents in the flammable liquid storage cabinet.) Some concentrated acids are kept in the acid reagent bottles on prep room counters. Fill reagent bottles in an operating fume hood using caution to avoid spills.

Perform acid digestions in hoods that are turned on and have active alarms. Notify a supervisor immediately if the hood is malfunctioning or the alarm sounds. Samples that contain dust may be hazardous. Open in a fume hood.

Samples that may contain cyanide require special precautions to avoid exposure to hydrogen cyanide gas. Contact your supervisor prior to adding acid. Always open these samples and add the acid in a hood.

Use spill pillows to absorb large acid spills (small spills are cleaned with wet paper towels.) Use SPILL-X-A powder or equivalent to neutralize any remaining acid and then rinse the area thoroughly with water.

Dispose of acid waste properly. Collect all acid digestions, waste solutions, and expired reagent solutions in waste containers. When the acid waste containers are full, a designated acid waste handler transfers the waste to the acid neutralization tank.

Uncontrolled Copy

**Personnel Training and Qualifications**
All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each analyst performing the instrumental analysis must work with an experienced analyst for a period of time until they can independently calibrate the instrument, use the system to set up sequences, perform the calculations, interpret raw data, and enter data into the LIMS. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an Initial Demonstration of Capability (IDOC).

The IDOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation. Various options are available for a DOC and can include four laboratory control samples or one blind sample. Refer to *QA-SOP11178* for more guidance on these options.

**Sample Collection, Preservation, and Handling**
Aqueous samples are collected in plastic or glass containers, preserved to a pH of <2 with nitric acid. Samples must be analyzed within 28 days of collection.
**NOTE:** Regulatory Drinking Water samples (EW) are collected in 1-L plastic or glass containers and must be analyzed by EPA 245.1. Drinking water samples are not analyzed for dissolved mercury.

Solid samples are collected in glass containers and stored at 0° to 6°C not frozen. Samples must be analyzed within 28 days of collection.

Dissolved Mercury: Samples to be analyzed for soluble mercury requiring filtration at the lab must be submitted unpreserved. The sample is run through a 0.45 micron filter within 5 days of receipt and are collected in plastic containers and preserved to a pH of <2 with HNO3.

Samples must be held for 16 hours following preservation and checked again prior to processing.

Store sample digestates in plastic bottles at room temperature. Store standards and digestates separately.

**Apparatus and Equipment**

1. Hydra II Mercury Analyzer
2. Leeman Labs Envoy software – a windows based program to help navigate the software.
3. 15-mL graduated polypropylene screw cap tubes (certified ± 1%)
4. 10-mL sterile disposable syringes
5. 25-mm syringe filters, PTFE, 0.45-µm
6. 40-mL clear glass VOA vials and lids
7. 50-mL polypropylene containers and covers (digestion vessels for block digestion) - certified clean and Class A equivalent

**Reagents and Standards**
A. Store all standards and reagents in polyethylene or glass containers at room temperature. Label the container with the solution name, lot number, date prepared, the expiration date, the initials of the person preparing the solution, and the storage conditions.

**NOTE:** Standard/ spiking concentration and reagent vendors are subject to change without notification.

B. Reagents use the following or equivalent:

1. Nitric acid, 70.0% to 71.0% HNO3, Fisher Trace Metal Grade reagent, 1.428 g/mL; Store in glass container at room temperature. Follow manufacturer's expiration date.
2. Sodium chloride, NaCl, J.T. Baker, Certified ACS. Store in plastic container at room temperature. Follow manufacturer's expiration date.
3. Hydroxylamine hydrochloride, NH2OH·HCl, J.T. Baker, Certified ACS. Store in plastic container at room temperature. Follow manufacturer's expiration date.
4. Reagent Water
5. Stannous chloride solution, 10% SnCl, Baker Analyzed reagent, ACS. Store in plastic container at room temperature. Follow manufacturer's expiration date.
6. Hydrochloric acid, HCl, 36.5% to 38.0%, Fisher Trace Metal Grade reagent, 1.194 g/mL or equivalent. Store in glass container at room temperature. Follow manufacturer's expiration date.

C. For the preparation of calibration blanks, ICBs, CCBs, calibration standards, ICVs, CCVs, CRAs, Method Blanks, LCSs and Matrix Spikes solutions, see Form *T-MET-WI9084*.

D. General solutions - See Form *T-MET-WI9084*.

NOTE: Method states to use Sulfuric acid when making Stannous Chloride, however, manufacture requires HCl. The lab practices this deviation in order to maintain instrument performance.

**Calibration**
Leeman Labs Hydra II Mercury Analyzer

1. The software program has been developed to check the correlation coefficient of the curve, run appropriate ICV and CCVs at proper intervals, and check the percent recoveries of the ICV and CCVs.
2. Due to the instrument software limitations, the calibration blank is included in the correlation coefficient calculation.
3. A recalibration and reread of any associated samples is required for any checks that fall outside the windows.
4. For the frequency, acceptance criteria and corrective action see SOP *T-MET-WI35797*
5. For the preparation of calibration standards, see *T-MET-WI9084*.
6. The calibration is part of each run shown in the LIMs system

Uncontrolled Copy

**Procedure**

A. Sample Digestion

1. Aqueous samples are digested by EPA 7471A/B according to SOP *T-MET-WI11924*.

2. Aqueous samples are digested by EPA 245.1 according to SOP *T-MET-WI26740*.

3. Solid samples are digested according to SOP *T-MET-WI11948*.

B. Leeman Labs Hydra II Mercury Analyzer Operation

1. Instrument Setup

a. If needed, turn ON the power to the instrument (switch in the back) and computer.

b. Ensure that Argon supply is set to 15 psi.

c. Double click the Envoy icon on the desktop to initialize the instrument software.

d. Put on the peristaltic pump cassettes. Do not over tighten.

e. Check to see that the lamp, peristaltic pump and gas are on. If necessary, open the Method/Instrument Control Panel and turn them on and set appropriate parameters.

f. Check that the rinse bottle is full. Place tubing into bottle with a 2.0% Hydrochloric Acid (HCl) solution. For preparation of 2.0% HCl solution, see *T-MET-WI9084*.

g. Check that the 10% stannous chloride bottle is full and place tubing into bottle. For preparation of 10% stannous chloride, see *T-MET-WI9084*.

h. Click the start icon on the Tool Bar to turn on the peristaltic pump and press the green play button.

i. Allow 20 minutes for lamp and pump equilibration.
a) There is an option to use Chart Recorder which displays when the instrument is optimized. To utilize this feature follow these steps
i. Observe Instrument
ii. Stabilization Tools
iii. Chart Recorder : resize window to ~1200 seconds or 10mins.

j. Inspect all system connections for leaks.

k. The system is now ready to be optimized for automated analysis.

2. Autosampler and Run Setup

a. Clear previous analyses
i. Analysis Tab
ii. Tools
iii. Database Manger
iv. Create Archive

b. Scan the samples from their label that is on the sample itself into the Envoy program under the Sequence Tab
i. Select Sequence
ii. New
iii. Select correct rack size
iv. Scan samples in order

c. Check QC
i. Method Tab
ii. QC control checks tab
iii. Modify QC as needed to set pass/fail flags

d. Press Run Sequence (Test tube rack icon): The calibration and sequence will run automatically with CCV and CCB every 10 analyses.

e. The results of the calibration and samples can be observed in the Analysis Tab.

**Sample Analysis**

1. Filtering Samples

a. Samples that are cloudy or have particulate suspended in solution must be filtered prior to analysis.

b. Difficult matrix samples or samples with limited volume may be filtered using a 10-mL sterile disposable syringe fitted with a 0.45 um PTFE syringe filter.

c. If any samples are filtered, the MB and the LCS on the batch must be filtered.

d. Document all filtrations on the run cover sheet.

2. Dilutions

a. Dilute samples with appropriate matrix matching solution when necessary to yield a response that falls within the calibration range.

b. Stop run if sample is above 4.5ppb. Rinse system and dilute sample immediately. Reanalyze. If the subsequent sample analyzed after an over range sample has a detection, reanalyze the subsequent sample as well.

c. Report the results for the least dilute sample where the concentration measured is within the acceptable calibration range.

3. Data Export: follow the below step by step instructions
On the instrument
a. Analysis Tab

Uncontrolled copy

b. Report Tab
c. Select Statisics
d. Select Load
e. Select TALS Export
f. Select OK
g. Check all data on this run
h. Select Report
i. Select CSV File
1.Name CSV file (2034301MO7)
j. Select Save to desktop
k. Drop CSV to IDAT sequence shortcut on desktop
l. Drop CCV to LIMS import shortcut on desktop

4. Attach raw data to run: follow the step by step instructions
On the instrument
a. Analysis Tab
b. Report Tab
c. Select Detailed
d. Select Load
e. Select Detailed TALS
f. Select OK
g. Check all data on this run
h. Select report
i. Select CSV file
1.Name CSV file (2034301MO7)
j. Select Save
k. Drop CSV Raw file to IDAT sequence shortcut on desktop

**NOTE:** Do not paste this report into the TALS import file.

5. See Data Review section for when data is in LIMs system. See SOP *T-MET-WI35797* for final data review.

6. Shutdown

a. Place Stannous Chloride and rinse tubing into 10% HCl for minimum of 5 minutes.

b. Place tubing into reagent water for a minimum of 5 minutes

c. Remove tubing from reagent water to allow the aspirating of air for a minimum of 5 minutes.

Never leave bottle of Stannous Chloride and rinse connected to the instrument if the pump clamps are released because siphoning can occur and cause damage to the instrument.

**NOTE:** Do not turn off power switch to instrument on a daily basis.

**Calculations**
1. Final Result

a. Water sample (ug/L)

$$\text{Instrument Reading} \times \frac{\text{Dilution Volume}}{\text{Aliquot Volume}} \times \frac{\text{Final Volume}}{\text{Sample Volume}}$$

b. Solid sample (mg/kg)

$$\text{Instrument Reading} \times \frac{\text{Dilution Volume}}{\text{Aliquot Volume}} \times \frac{\text{Final Volume}}{\text{Sample Weight (grams)}}$$

2. Relative percent different (RPD)

$$RPD = \frac{S - D}{(S + D)/2} \times 100$$

**Where:**

S = first sample value

D = duplicate sample value

3. Spike recovery

$$\%\,Recovery = \frac{SSR - SR}{SA} \times 100$$

**Where:**

SSR = spiked sample result

SR = sample result

Uncontrolled copy

SA = spike added

4. Correlation Coefficient

$$r = \frac{\sum XY - \frac{\sum X \sum Y}{N}}{\sqrt{\left(\sum X^2 - \frac{(\sum X)^2}{N}\right)\left(\sum Y^2 - \frac{(\sum Y)^2}{N}\right)}}$$

**Where :**

X = the known concentration

Y = the instrument response

N = the total number of data points

5. Serial Dilution

$$\%\ Difference = \frac{(5 \times SDR) - SR}{SR} \times 100$$

**Where:**

SDR = serial dilution result

SR = sample result

6. Methods of standard additions (MSA)

Take 4 identical aliquots of the same sample. Leave one unspiked. Spike the other 3 aliquots with different levels of a standard solution. Add blank solution to sample aliquots so that the final volume is the same for all. Use small volumes of spiking solution to avoid diluting the sample more than 10%. Analyze the 4 aliquots and record the instrument readings in absorbance. Use the readings and spike values to find the slope and x- and y- intercepts. The x- intercept is the result.

$$\text{Slope} = m = \frac{\sum x_i y_i - (\sum x_i \sum y_i)/n}{\sum x_i^2 - (\sum x_i)^2/n}$$

$$\text{Y-Intercept} = b = \bar{y} - m\bar{x}$$

$$\text{Result} = -\frac{b}{m}$$

$$\text{Correlation Coefficient} = r = \frac{\sum \{(x_i - \bar{x})(y_i - \bar{y})\}}{\sqrt{\left[\sum (x_i - \bar{x})^2\right]\left[\sum (y_i - \bar{y})^2\right]}}$$

The correlation coefficient (r) for the least squares fit must be ³0.995. If the r value is <0.995, the MSA must be repeated at the same dilution. If the r value is again low, the result with the higher r value is verified and both are flagged with a "+" in the data package. If the r value is <0.990, the sample is run at an interference dilution to overcome matrix effects. This usually requires a raised limit of quantitation. If a client requests a particular limit of quantitation that prohibits further dilution, then the sample is repeated at the same dilution and the best of the two results is verified.

**Statistical Information/Method Performance**
Generate MDLs and LOQs according to *QA-SOP11892*. The department supervisor maintains annual study data.

QC limits for MS/MSD, and LCS/LCSD are established through statistical analysis of historical data. The limits are maintained in the LIMS for the relevant analysis numbers.

The department supervisor requests that a Quality Assurance Specialist update to the LIMS as needed. Update the department database via a download from the LIMS.

**Quality Assurance/Quality Control**
Batch Quality Control

1. For the preparation and concentrations of Batch Quality Control see *T-MET-WI9084*.
2. For the frequency, acceptance criteria and corrective action see *T-MET-WI35797*.

Uncontrolled Copy

3. For EPA 7470A, 7471A, and 7471B, a digestion batch is up to 20 samples. Each batch must contain a MB, LCS, BKG, DUP, MS and MSD (an LCSD is used if there is insufficient sample for an MSD).

4. For EPA 245.1 Rev 3, a digestion batch is up to 10 samples. Each batch must contain a MB, LCS, BKG, DUP, and MS (an LCSD is used if there is insufficient sample for an MSD).

**Data Review**

1. To view imported analytical batch in the LIMS, follow these steps:
    a. Go to Analyst
    b. Choose Analyst Desktop II
    c. Select the instrument where the data is pulled from on the left hand side by expanding the Instrument option
    d. Data will be listed with a designated analytical batch number given by the LIMs system under the instrument where it was analyzed.
    e. Record this designated analytical batch number on prep batch paperwork.

2. How to complete 1st level review of analytical batch
    a. Once analytical batch is located from following steps in #1 double click to open the batch
    b. Choose Edit button
    c. When asked if data should be processed choose No
    d. Edit Standards/Batch QC
        i. Scan calibration standards from prep batch sheet
    e. If PDS is on analytical run enter PDS data
        i. Go to the Reagents tab at the bottom
        ii. Scan lot number of spike used in PDS
        iii. Enter volume of spike used for PDS. Normally this would be 0.1mL to a final volume of 10mL
        iv. Go to Worksheet Tab and enter a final volume for the PDS. Normally, this would be 10mL
    f. Calculate Results
        i. Go to Samples Results Tab
        ii. Highlight all samples by using Ctrl + L
        iii. Right click and choose Identify
        iv. Once samples are and calibration and all identified it is always a good practice to recalculate by hitting F6

    g. Evaluate the Results
        i. Go to the Sample List tab
        ii. Either look at each line individually to ensure calibration and data are valid or filter by job number and evaluate data
        iii. Look for recoveries in the spiked calibration as well as the batch QC
        iv. Look for contamination in blanks
        v. Look for E flags for samples that need to be diluted. If they were diluted check that the dilution makes sense.

    h. Enter Batch Information
        i. Prior to saving batch right click and chose View Batch Information or press Ctrl + 1
            a. If you try to save batch without going to this screen the program will prompt you
        ii. Enter analyst
        iii. Enter Stannous Chloride ID lot #
        iv. Enter tube lot #s if dilutions were made, filtering of samples occurred, or PDS was used
        v. Enter lot number of filters used
        vi. Hit Ok to save

    i. Attach Raw Data
        i. Go to IDAT Sequence folder \\lldata\Env\IDAT-Sequences
        ii. Find the analytical run by searching the unique run number given to it by the analyst.
        iii. Double Click on file once located
        iv. Once file is open, Save As pdf file and name the file the analytical run number give to the data by the LIMs system.
        v. Open Sharefile in Google Chrome
        vi. Go into the Personal Folder and choose Browse Files
        vii. Find File and select Upload
        viii. Once uploaded into Sharefiles go into the analytical batch in the LIMs system and choose Docs button at top
        ix. Right click and select Add New Document
        x. Select the document in the Personal Folder in Sharefiles and hit Select
        xi. Hit OK and now the raw data file is attached into the analytical batch

    j. 1st level data
        i. Once data has been confirmed by analyst to be valid and the raw data is attached go to Sample List tab
        ii. Highlight calibration and samples that are valid (if all samples Ctrl +L to highlight)
        iii. Either do Ctrl + Shift + 1 to turn status to 1st Level or right click, Review Sample, Choose 1st Level Review

**Instrument Maintenance and Repair**

A. Routine Maintenance

1. Replace the pump tubing as needed under normal daily usage.
    a. Inspect tygon supply lines for discoloration and cloudiness
    b. Check peri-pump lines for flattening

2. As needed for foamy samples, replace liquid/gas separator
    a. Remove and rinse the clear front panel
    b. For severe foam replace entire gas box module

3. If liquid has entered the optical cell, check the optical cell and windows, and if needed, clean the optical cell.

    a. Wipe the optical cell with a soapy solution (one drop of liquid Ivory soap to 500 mL reagent water) and warm tap water.

    b. Rinse with reagent water and dry. To speed the drying of the optical cell, connect the heater plug to the optical cell with the windows off for several minutes.

    c. Clean the quartz windows with methanol and a piece of lens paper.

4. Document any maintenance in the Mercury maintenance logbook.

NOTE: Detailed instructions for the maintenance and troubleshooting of the Leeman Labs Mercury Analyzer can be found in the Leeman Labs Hydra II Mercury Analyzer Manual.

Uncontrolled copy

B. Taking an instrument/analysis out of service/returning an instrument/analysis to service.

NOTE: In the event of an equipment failure, perform the steps in SOP *QA-SOP11901*:

1. Document the nature of the failure in the maintenance logbook.

2. Document how and when the defect was discovered.

3. Notify a supervisor or experienced analyst to determine a person who can decide on appropriate action to take.

4. The instrument must be clearly tagged as Out of Service. The tag must be printed from Q-E*QA-FRM6871* contain the following information:

   a. Date taken out of service.

   b. Employee who took the instrument out of service.

   c. Reason for tagout.

5. The date taken out of service and the date returned to service must be documented in the logbook.

6. Document any corrective action that was taken and the result of that corrective action (i.e., system calibration within specifications, etc.) to bring the equipment back into service.

7. Supervisory personnel must perform a documented evaluation and review of instrumentation/equipment where a major or uncommon failure has occurred to assess the potential impact the failure could have on the calibration and/or qualification of the instrument.

8. After a repair, document whether the function has been fixed. Calibration or verification activities are to be performed before the instrumentation is put back into service.

## Scope

This procedure applies to analyses performed at Eurofins Lancaster Laboratories Environmental (ELLE) using ICP-MS for identification and quantitation of metallic constituents.

Aqueous undigested samples and digestates (aqueous and solid matrices) are analyzed via this SOP.

Limits of Quantitation (LOQs/RLs), Method Detection Limits (MDLs) and linear ranges are maintained in the LIMS. These are subject to change without notification.

This procedure is used for analysis and instrument operation for the Agilent 7700 and 7900 series ICPMS instruments.

## Basic Principles

ICP-MS is an analytical instrument that uses the energy of inductively coupled plasma to generate ions to be analyzed in the mass spectrometer.

The instruments use a discrete sampling system that first loads the sample into a Teflon sample loop. The sample is then pushed by a carrier solution using a computer controlled peristaltic pump that delivers the sample from the loop into the nebulizer attached to a cooled Scott double pass spray chamber.

The Agilent 7700 (E05) and 7900 (E07/E08/E09) can analyze samples in 3 different modes of operation, although typically analysis is done in 3 mode or No Gas mode only:

1. Mode 1 – no gas. This mode does not use a collision or reaction gas. Elements with a low atomic mass or that have no interferences can be analyzed using the "no gas" mode.

2. Mode 2 – Hydrogen ($H_2$) mode. This mode uses $H_2$ as a reaction gas, since it reacts quickly and efficiently with the Argon-based interfering species, but reacts slowly or not at all with the analyte(s) of interest. In this mode, interferences can be reduced to the level of baseline noise, allowing lower detection limits to be achieved for some difficult elements.

3. Mode 3 – Helium (He) mode. This mode uses He as a collision gas for reliable, predictable removal of unknown matrix interferences. No new interferences are formed in the cell, and no analytes are lost by a reaction.

## Interferences

ICP-MS interferences include isobaric elemental interferences and polyatomic ion interferences derived from the plasma gas, reagents, and/or sample matrix. The Agilent 7900 utilize helium as an inert collision gas to reduce or eliminate many types of polyatomic ion interferences.

Physical interferences caused by the change in sample matrix affecting sample transport and/or nebulization must be compensated for using internal standardization.

Memory interference is the contribution of analyte signal from a previous sample onto the next sample analysis. Adequate rinse time with an appropriate rinse solution of the sample introduction system overcomes any memory interference.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.
See the *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Preparing samples for inorganic analysis involves working with concentrated acids and other chemicals which are dangerous if not handled carefully:

Uncontrolled Copy

**Hydrochloric acid (HCl)** – This acid can cause skin burns. Only mix with approved solutions. Always use this chemical in a fume hood.

**Hydrofluoric acid (HF)** – This acid is very toxic and absorbs through the skin without pain. This acid is found at trace levels in standard solutions.
**Hydrogen Peroxide 30% (**H2O2) **-** This oxidizer can cause skin burns. Always use in a fume hood.

**Nitric acid (HNO3)** – This acid can cause skin burns and burning of the respiratory tract. Add nitric acid to samples in a fume hood to avoid exposure to toxic fumes.

When diluting strong acids, never add water to acid; always add acid to water.
Store concentrated acids in the prep room acid cabinets. Only acids are to be stored in these cabinets. Flammable solvents are stored in flammable liquid storage cabinets. Some concentrated acids are kept in the acid reagent bottles on prep room counters. Fill reagent bottles in an operating fume hood using caution to avoid spills.

Large spills are cleaned by HSE. For large spills of concentrated acid, immediately evacuate the area and dial 1-1-1. HSE will use spill pillows to absorb large acid spills (small spills are cleaned with wet paper towels.)

Dispose of acid waste properly. Collect all acid digestions, waste solutions, and expired reagent solutions in waste containers. When the acid waste containers are full, a designated acid waste handler transfers the waste to the acid neutralization tank.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each analyst performing the instrumental analysis must work with an experienced analyst for a period of time until they can independently calibrate the instrument, use the sequence editor to set up the run, perform calculations, interpret raw data, and enter/transfer data into the LIMS. Proficiency is measured through documented audits of the tasks listed, and checking of data as well as an IDOC (Initial Demonstration of Capability) and continued DOCs (Demonstration of Capability) as defined in *QA-SOP11178*.

The IDOC consists of four laboratory control samples (LCS) that are carried through all steps of the prep and analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation.

## Sample Collection, Preservation, and Handling

Aqueous undigested samples, aqueous digestates, and solid digestates are analyzed via this SOP. Samples must be analyzed within 6 months of collection for all methods in this SOP.

Aqueous samples are collected in plastic or glass containers. Drinking Water samples are collected in 1-L plastic or glass containers. Aqueous samples are preserved with nitric acid with a pH of < 2 and stored at 0° to 6°C, not frozen, or at room temperature.

Aqueous digestates are digested per the method in *T-MET-WI11938* (aqueous samples 200.8), *T-MET-WI8639* (aqueous samples 3005A). Aqueous non-digested samples are prepared per the method in SOP *T-MET-WI8732* (lab and field filtered waters and <1NTU Drinking water). Aqueous samples are stored in 50 ml plastic vials at room temperature.

Solid samples are collected in glass containers and stored at 0° to 6°C, not frozen. Digestates are digested per the method in SOP *T-MET-WI8636*. Solid samples are stored in 100 ml plastic vials at room temperature.

Store standards and digestates separately.

The general practice in the metals group is to discard the digestions after all the required metals from a batch of samples have been analyzed and lab completed in the LIMS. Samples which require the digestate to be held for long term storage are periodically evaluated for discard.

Uncontrolled Copy

## Apparatus and Equipment

A. The following is a list of the hardware used in the Agilent 7700 and 7900 ICP-MS systems.

1. Inductively Coupled Plasma Mass Spectrometers (ICP-MS)

a. The Agilent 7700 and 7900 - The sample introduction system consists of an ESI FAST discrete sampling system, Teflon nebulizer and cooled spray chamber attached to a concentric quartz tube plasma torch.

2. Autosampler

a. The Agilent 7700 and 7900 (E08) systems use an ESI SC-8 FAST autosampler. The Agilent 7900 (E07 & E09) systems use an ESI SC-14 FAST autosampler. The autosampler parameters for each automated run are entered into the Sample List in MassHunter software.

3. Coolflow

a. The Agilent 7700 and 7900 G3292A Recirculating Chillers are set up to deliver cooling liquid to the ICP-MS at a regulated pressure of ~40 psi.

4. Computer

a.The Agilent 7700 and 7900 are controlled by a Windows-based IBM compatible PC with MassHunter software installed.

5. Vacuum Pumps

a. The Agilent 7700 and 7900 both have a 2-stage vacuum system. A rotary pump evacuates the interface chamber; a turbo molecular pump evacuates the ion lens chamber and the analyzer chamber.

B. The following is a list of the apparatus necessary for the setup of an ICP-MS run for analysis:

1. ICP-MS prep batch sheets.

2. Test tube racks

3. Graduated 15-mL polypropylene tubes and caps

4. 50-mL polypropylene screw cap tubes

5. FilterMate 2 µm filters and plungers

6. 10-mL sterile disposable syringes

7. 25-mm syringe filters, PTFE, 0.45µm

8. 30-mL polypropylene medicine cups

9. Fixed volume hand-held pipettes (25 – 2000 µL) - Eppendorf or equivalent.

**NOTE:** For routine operation, calibration, and maintenance of fixed-volume, hand-held pipettes, see *QA-SOP11880*.

## Reagents and Standards

Refer to Form *T-MET-WI12065* for reagent and standard information and the preparation of the following standards and solutions

1. ICP-MS Calibration Standards and ICP-MS LOQ Check Standard Solution (CRI)

2. ICP-MS Initial and Continuing Calibration Verification Standards

Uncontrolled copy

3. Interference Check Solutions

4. Rinse/Carrier, Tuning, and Calibration Solutions

5. Internal Standard Solution

6. PDS Solutions

7. General Acids and Chemicals

## Calibration

Before calibration is performed, allow the instrument to warm up for the recommended time, usually at least 15 minutes, if the plasma has been off for 15 minutes or less, or at least 30 minutes if the plasma has been off for more than 15 minutes. Daily tuning requirements must be performed prior to calibration of the instrument and after warm up occurs. Full Tuning and Optimization is done as needed, or when required by the Group Leader or Manager.

Calibration is performed daily. Calibrations consist of a blank and one to three standards, followed by analysis of an ICV, ICB, CCV, CRI, ICSA/ICSAB, LRC, CCV, and CCB.

A single point calibration, consisting of a blank and one standard, is used for all analysis, except Non-TNI samples requiring a multi-point calibration (either MA MCP or CT RCP protocol or a lab note indicating a multi-point calibration is needed). For samples requiring a multi-point calibration the calibration consists of a blank, "S1", "S2", and "S3" standards. The concentrations of the calibration standards are defined in *T-MET-WI12065*.

For data review, acceptance criteria, and corrective action, see *T-MET-WI35797*.

## Procedure

A. Instrument Start Up

This procedure is the same for the Agilent 7700 (E05) and the 7900 (E07/E08/E09) instruments.

1. Power on the ESI autosampler and start the ESI software.

2. Make sure the instrument is powered on before starting the ICP-MS software – the light on the front of the instrument will be red (shutdown mode), orange (standby mode) or green (analysis mode).

3. If the instrument is powered down: flip the main power switch on the back of the instrument to the on position, and then make sure the Foreline Pump (red switch) is also in the on position.

4. Make sure the recirculating chiller power switch is in the on position. If the orange light on the front of the chiller is on, you will need to turn off the chiller and add coolant before turning the chiller back on.

5. Verify that the program is in Online mode – the Hardware tab will have a green check mark if it is online.

6. If the Hardware tab has a red x instead of the green check, click on the arrow down in the Hardware tab and select Communication. Select Online and click OK.

7.Check the Instrument Status pane. The instrument should be in one of three modes: Shutdown (plasma and vacuum off, red light on the front of instrument); Standby (plasma off but vacuum on, orange light on the front of instrument); Analysis (plasma and vacuum on, green light on the front of instrument).

8. If in Shutdown mode click on the Hardware tab arrow down and select Vacuum On – the Foreline pump will start and the instrument will transition to Standby mode.

9. Once Standby mode has been reached select Plasma On from the Plasma tab arrow down.

10. When asked if you want to "Run 'Startup' after plasma ignition?", select No.

11. The plasma will ignite and the instrument will transition to Analysis mode.

Uncontrolled Copy

12. Once Analysis mode is achieved you must allow the instrument to warm up for at least 20 minutes before running the EPA Daily Tune check sample.

B. Running the Daily Tune Check

1. To run the EPA Daily Tune check place both probes into the EPA Tune Solution and allow sufficient time for the solution to flush through both lines.

2. Make sure the FAST valve is in the LOAD position.

3. Once the EPA Tune Solution is aspirating into the spray chamber take the following steps to start the EPA Daily Tune check.

4. Click on the arrow down for the Batch tab.

5.Open the batch "~ICPMS.b" by clicking on the file in the drop down menu or the pop up menu if necessary.

6. In the Batch pane select the Acq Method tab then the Tune tab.

7. Right click in the Signal Monitor grid and select Report, then Generate Tune Report.

8. In the window that appears verify that the Report Template selected is as follows:

C:\Agilent\ICPMH\Report Templates\en\Letter\Tune Report\TuneCheckReport.xltx

9. Click Generate. The software will acquire the tune check data from the instrument and a report will be printed.

10. If the EPA Daily Tune fails any of the criteria rerun the tune a second time. If it fails a second time take corrective action before running the EPA Daily Tune check again (maintenance or optimization of tuning parameters).

C. Sample analysis

1. Once the EPA Daily Tune passes all criteria, place the internal standard probe in the internal standard solution and place the carrier probe into the carrier solution.

2. Once the carrier and internal standard solution have flushed through the tubing and are aspirating into the spray chamber, sample analysis can begin.

3. In MassHunter open the method batch file used for analysis. Use ~ICPMS.b for non-potable waters and solids analyses, and ~ICPMS_nogas.b for drinking water analysis.

4. Save the batch with a new name:

YYMDDR## where:

YY is the two digit year
M is the letter of the alphabet corresponding to the month (A for January, B for February, etc.)
DD is the two digit day of the month
R is the letter of the alphabet that changes for each attempted run sequence

Example: For the first run started on March 19 in the year 2012 the batch folder would be named 12C19A01.b

5. Enter the calibration standards and lot numbers in the order of:

ICV/ICB/CRI/ICSA/ICSAB/LRC(s)/Rinse(s)/CCV/CCB

6. Scan all samples into the sample list and add PDS/SD and/or dilutions as needed.

7. Add a CCV/CCB block after every 10 samples (or ending the run) as well as an ending CRI/ICSA/ICSAB as needed per method or project note.

Uncontrolled Copy

8. Enter the locations of the samples to match the rack in which they will loaded onto the auto-sampler. Ensure that the order of the samples on the batch paperwork/re-read sheet match the order in which they are loaded.

9. Right click on the sample list and print a copy.

10. Use the print out to confirm the sample ID(s) and locations of the samples on the auto-sampler.

11. Load the auto-sampler based off of the printed out sample list. Sign off on the sample list with your initials, employee number and the date.

12. Keep the sample list with the batch(es) paperwork until the batch is imported into the LIMS. Note the analytical and prep batch(es) numbers on the sample list and give to the Group Leader.

D. Pouring an ICP-MS run (Waters only in 50 mL digestion tubes):

**It is important to minimize any chance of contamination, to both yourself and the samples. Keep your hands and the work area clean at all times. Wear appropriate PPE at all times to prevent exposure to chemicals and samples including lab coat, gloves, and safety glasses, and additional PPE as required by project or health and safety.**

**NOTE:** See Form *T-MET-WI12065* for standards and solutions used during the analytical run.

1. Choose the appropriate prep batch sheet.

**NOTE:** When retrieving the batch from the shelf for the first time, record the batch location on the cap of the prep blank in black sharpie. This saves time when returning the batch to the proper location after analysis and shows that the batch has been poured before and verified to be in the correct order. To prevent more than one batch from being assigned to the same location, the digestion trays all have the location written on the foam holder.

2. Verify that each digestion tube is in the correct order according to the prep sheet. If anything is missing, correct the prep sheet and notify PREP or the Group Leader to correct the LIMS and put the sample back in for digestion. If the order is incorrect, reorder the sample digestion tubes to match the paperwork.

3. For batches prepared in hot blocks in 50-mL digestion tubes or prepared by the MTL_ND method:

a. The only tubes that typically need to be poured for the initial run are the post digestion spike (PDS) and serial dilution (SD)samples. These are prepared using the background sample (BKG) or the duplicate background sample (DUP) when limited sample volume is available.

b. All other samples remain in the 50-mL digestion tubes for analysis.

4. Samples that need to be poured into test tubes:

a. Obtain the appropriate number of tubes.

b. Write the last four digits of the sample number and the dilution factor if greater than 1 on each tube. If the MB or LCS must be in tubes, write MB/LCS and the prep batch number/location on the tubes.

c. Place tubes in test tube racks in the same order as the samples on the prep batch cover sheet and/or re-read.

d. The analyst must ensure that tubes are labeled correctly, that dilutions are performed accurately, and that the dilutions are recorded on the prep cover sheet and/or re-read.

5. Post-digest spike (PDS):

a. A PDS is required for each batch (sample volume permitting).

b. A PDS is prepared by pipetting 0.2 mL of the appropriate PDS solution into a 15-mL graduated test tube, and bringing it to a volume of 10 mL with the background sample, "BKG". If the PDS must be diluted, pipette 0.2 mL of the PDS solution into a 14 mL graduated test tube, add the appropriate amount of background sample, "BKG", and dilute to 10 mL using matrix rinse. If there is limited

Uncontrolled Copy

volume for the background sample, "BKG", then the "DUP" may be used for dilutions of the PDS or SD. If the duplicate is used for PDS or SD, make an internal NCM on the analytical batch after analysis.

c. Record the lot number of the PDS solution used on the prep batch cover sheet and/or re-read.

6. Serial dilution (SD)

a. Prepare the SD by diluting the background sample at a dilution that is equal to 5× the dilution factor of the PDS sample (i.e.if PDS= DF1, SD must = DF5; if PDS=DF5, SD must=DF25).

7. Filtering samples

a. Samples that are cloudy or have particulate suspended in solution must be filtered prior to analysis to prevent clogging of the sample introduction system, which causes run failures and instrument down time to correct the problem.

b. Samples that are in the 50-mL digestion tubes may be filtered using the FilterMate filtration devices and plunger or a syringe and syringe filter.

c. Attach a filtration device to the plunger and very carefully insert the filter into the digestion tube until the filter reaches the bottom of the digestion tube.

d. Remove and discard the plunger.

e. An alternative for samples in any type of vessel is to filter using a 10-mL sterile disposable syringe fitted with a 0.45µm PTFE syringe filter.

f. If any samples are filtered, the MB and LCS must also be filtered. If any QC sample is filtered (BKG, DUP, MS, or MSD), then all QC including the MB and LCS must be filtered.

g. Document all filtrations on the prep batch cover sheet.

**NOTE:** It is not necessary to filter all samples (in 50 mL digestion tubes only) that contain particulate, as long as all of the particulate is settled to the bottom of the tube below the 5-mL mark in 50-mL digestion vessels. The sampling depth of the autosampler probe is set such that the tip of the probe is approximately 100 mm above the bottom of the digestion tube. It is necessary to filter all solid samples and to dilute to DF2 prior to analysis.

8. Verify that all samples in the hotblock tray are in the correct position and/or pour each sample (or sample filtrate) into the appropriate tube. Usually, the order of the batch QC is MB, LCS, (LCSD), Bkg, PDS, DUP, MS, (MSD), and SD. Most importantly, the actual positions of the samples in the tray must match the autosampler table used for analysis.

**NOTE:** Immediately prior to beginning analysis, the analyst must visually verify that each sample is in the position indicated in the autosampler table used for the run.

9. If not being analyzed immediately, cap any poured tubes to prevent contamination of the samples (digestion tubes and dilutions prepared in graduated test tubes must be capped tightly except during pouring and/or analysis).

10. Return samples to sample storage, being sure to place the batch back into the location recorded on the prep batch sheet.

11. Record the following on the prep batch cover sheet: initials, employee number, and the date, and lot numbers for PDS, filters, test tubes, as used).

12. NOTES:

a. A PDS and a SD are performed on one sample in each digestion batch. Typically, the background sample is chosen. If the batch QC is split between two samples, the PDS is performed on the background sample accompanied by a matrix spike; the SD is performed on the background sample accompanied by a matrix duplicate. If sample volume is limited, it is acceptable to use the duplicate for the PDS and SD.

b. Batches with only field blanks or equipment blanks do not need a PDS or a SD.

c. Air filter batches need only a SD on one sample in the batch (a PDS is not required).

Uncontrolled Copy

d. "As Received" samples are analyzed with a blank and LCS, LCSD (prepared by the analyst).

e. Documentation is of utmost importance. Verify all entries.

E. Data analysis and Import

1. Once the sample run is complete you will switch to or open the Offline ICP-MS Data Analysis program to make any changes to internal standard selection and generate the file for import into LIMS. Note, the Attachment Internal Standard Reference includes the appropriate internal standards to reference for each metal.

2. Once in the Offline ICP-MS Data Analysis program open the batch that contains the run data you are going to process by clicking Open Analysis File (open folder icon or from the File drop down menu).

3. Evaluate appropriate internal standard selection based on the Quality Control section of this SOP and method requirements for the samples analyzed.

4. If it is appropriate to change internal standard selection from the defaults in the method used click the DA Method Editor button (skip to step e. if alternate internal standard selection is not needed).

a. Under Method Development Tasks (in the left pane of the DA Method Editor window) select "FullQuant" under item number 4 (Set up Analysis Parameters).

b. Under the analyte list that appears in the right hand pane of the DA Method Editor you will see a list of the analytes.

c. Change internal standards for any analytes where alternate internal standard selection is both necessary and appropriate.

d. Then click "Return to Batch-at-a-Glance" in the left hand pane.

e. When prompted to "Update Analysis Method?" select "Yes".

f. Click the "Process Batch" button to recalculate all concentration values in the batch folder using the internal standard selections you made while in the DA Method Editor.

5. To generate the file for import into LIMS you must first select all the data rows needed for your run, starting with the ICIS down to the last row in your run. If you restarted the run only select the most recent ICIS and all samples below it.

6. Once the appropriate rows of data are selected click on Tools and select "Upload to TALs" to run the script that compiles the file for import.

7. A pop up will appear once the script is complete stating that the file was created successfully. While the batch is still highlighted click on the Report tab. Generate the raw data PDF's and save them into the respective run's folder.

8. Open the ITUNE app and select the .rep file that was generated along with the tune file for that day. This will generate a new .rep file that will then be copied to the import folder. This will put the run into the LIMs system.

## Calculations

1. Final Result

a. Water sample

$$\text{Instrument Reading} \times \frac{\text{Dilution Volume}}{\text{Aliquot Volume}} \times \frac{\text{Final Volume}}{\text{Sample Volume}}$$

Uncontrolled Copy

b. Solid sample (mg/kg)

$$\text{Instrument Reading} \times \frac{\text{Dilution Volume}}{\text{Aliquot Volume}} \times \frac{\text{Final Volume}}{\text{Sample Weight (grams)}}$$

2. Relative percent different (RPD)

$$RPD = \frac{S - D}{(S + D)/2} \times 100$$

**Where:**

S = first sample value

D = duplicate sample value

3. Spike recovery

$$\%\ Recovery = \frac{SSR - SR}{SA} \times 100$$

**Where:**

SSR = spiked sample result

SR = sample result

SA = spike added

4. Correlation Coefficient

$$r = \frac{\sum XY - \frac{\sum X \sum Y}{N}}{\sqrt{(\sum X^2 - \frac{(\sum X)^2}{N})(\sum Y^2 - \frac{(\sum Y)^2}{N})}}$$

**Where :**

X = the known concentration

Y = the instrument response

N = the total number of data points

5. Serial Dilution

$$\%\ Difference = \frac{(5 \times SDR) - SR}{SR} \times 100$$

SR-controlled copy

**Where:**

SDR = serial dilution result

SR = sample result

6. Methods of standard additions (MSA)
Take either 4 identical aliquots (for 3 point MSA) or 2 identical aliquots (for one point MSA) of the same sample. Leave one unspiked. Spike the other 3 aliquots with different levels of a standard solution (for 3 point MSA) and spike the other aliquot at approximately the indigenous concentration of the sample (for one point MSA). Add blank solution to sample aliquots so that the final volume is the same for all. Use small volumes of spiking solution to avoid diluting the sample more than 10%. Analyze the 4 aliquots or 2 aliquots and record the instrument readings in absorbance. Use the readings and spike values to find the slope and x- and y- intercepts. The x- intercept is the result.

$$\text{Slope} = m = \frac{\sum x_i y_i - (\sum x_i \sum y_i)/n}{\sum x_i^2 - (\sum x_i)^2/n}$$

$$\text{Y-Intercept} = b = \bar{y} - m\bar{x}$$

$$\text{Result} = -\frac{b}{m}$$

$$\text{Correlation Coefficient} = r = \frac{\sum\{(x_i - \bar{x})(y_i - \bar{y})\}}{\sqrt{\left[\sum (x_i - \bar{x})^2\right]\left[\sum (y_i - \bar{y})^2\right]}}$$

The correlation coefficient (r) for the least squares fit must be ³0.995. If the r value is <0.995, the MSA must be repeated at the same dilution. If the r value is again low, the result with the higher r value is verified and both are flagged with a "+" in the data package. If the r value is <0.990, the sample is run at an interference dilution to overcome matrix effects. This usually requires a raised limit of quantitation. If a client requests a particular limit of quantitation that prohibits further dilution, then the sample is repeated at the same dilution and the best of the two results is verified.

7. Average, Standard Deviation and Relative Standard Deviation

The average result, $\bar{x}$, is calculated by summing the individual results and dividing this sum by the number (n) of individual values:

$$\bar{x} = \frac{x_1 + x_2 + x_3 + x_4 + \ldots x_n}{n}$$

Standard deviation is a measure of how precise the average is or how well the individual numbers agree with each other.

UNCONTROLLED COPY

$$\text{Standard deviation, } S = \sqrt{\frac{(x_1-\bar{x})^2+(x_2-\bar{x})^2+(x_3-\bar{x})^2+\ldots+(x_n-\bar{x})^2}{n-1}}$$

Relative standard deviation (RSD) is expressed in percent and is obtained by multiplying the standard deviation by 100 and dividing this product by the average.

$$\text{Relative standard deviation, RSD} = \frac{100\times S}{\bar{x}}$$

Uncontrolled copy

## Statistical Information/Method Performance

Generate MDLs and LOQs according to *QA-SOP11892*.

The department principal scientist and manager maintain annual study data. The department principal scientist, manager, and/or group leader requests that a Quality Assurance Specialist update to the LIMS as needed by department email.

Refer to *QA-SOP11896* for statistical information.

## Quality Assurance/Quality Control

A. For 6020, 6020A and 6020B, each digestion batch (up to 20 samples) must contain a method blank, LCS, and either an BKG, DUP, MS, MSD or an LCS/LCSD (limited volume or approved by manager and QA only).

B. For 200.8, each digestion batch (up to 10 samples) must contain a method blank, LCS, and either an BKG, DUP, MS or an LCS/LCSD (limited volume or approved by manager and QA only). An additional BKG and MS are added for batches over 10 samples up to 20 samples.

C. QC limits for MS/MSD, and LCS/LCSD are established through statistical analysis of historical data.

1. The limits are maintained in the LIMS in Method Limit Groups.

2. The limits are evaluated every 6 months and updated as needed.

3. The limits are subject to change without notification.

D. Batch Quality Control

1. For the preparation and concentrations of Quality Control samples see *T-MET-WI12065*.

2. For the frequency, acceptance criteria and corrective action see *T-MET-WI35797*.

E. Raw data quality checks

1. Make sure that the run is correctly labeled, and dated and that the corresponding prep sheet is attached to the run.

2. Verify that the appropriate Tuning Report is with the run.

3. For run and batch QC/Calibration frequency, acceptance criteria and corrective action, see *T-MET-WI35797* tables.

4. Spike levels of batch QC are available in the LIMS and on T-MET-WI9082.

5. LOQs (RLs), MDLs, and IDLs are available to analysts in the LIMS in Method Limit Groups and Equipment Limit Groups.

6. Check to make sure that all results are not> 90% of the Linear Range, according to LIMS Equipment Limit Groups. If a sample reading is above 90% of the linear range, then reread the sample at a dilution sufficient to bring the sample concentration to approximately the middle of the calibration range.

7. Check that the **absolute** value of all non-detected analytes is less than the RL. A technical decision must be made as to whether a reread is warranted for readings <|RL|.

8. Check for carryover between samples. Sample RSD >20%, with a concentration > the LOQ decreasing progressively over time (i.e., Reading 3<2<1). Flag any suspect samples for reread.

**NOTE:** Whenever a sample is encountered that exceeds the calibration range, the following sample must be checked for carryover for the over range analyte (s) and any suspect results must be deselected and reanalyzed. During reanalysis the sample order must be modified as needed to avoid carryover from any over range sample(s).

9. For all EW (samples from public drinking water sources), highlighted mint green in the LIMS, check the results against the MCL (maximum contaminant level) by reviewing the limits tab in analyst desktop II. If an analyte **exceeds** the MCL, is a certified analyte for the SDWA method, and is associated with a mint green compliance drinking water sample, notify the verification group at once by NCM or email. An automated email is sent to the Client Service Representative and the state for the analytes listed below with the exception of Pb and Cu which follow the 90$^{th}$ percentile rule (the CSR tracks the lead and copper and notifies the supplier when necessary). Suppliers must be notified within the required time limit as stated in QA-SOP11886.

10. To avoid the risks associated with polyatomic interferences in wastewater and soil matrices all analytes must be analyzed on the collision cell ICP-MS instruments which include Agilent 7900, Equipment E07 - 27813, Equipment E08 - 30647, Equipment E09 - 30921).

a. Because EPA 200.8 rev. 5.4 does not currently allow the analysis of drinking water samples using collision cell ICP-MS all drinking water samples must be analyzed using a method with no gas mode for all analytes on the Agilent 7700, which includes Equipment E05 - 19204.

11. Check the internal standard level for the entire run. Reference the Internal Standard Reference attachment in this SOP for the appropriate internal standards to use for each metal. If the internal standard reading for any sample is out of the acceptance range of the S0 reading, evaluate whether this is a result of the sample matrix or drift from other samples in the run. Only reread the sample at a dilution if the internal standard appears to be out of range due to the sample matrix. For samples where an internal standard is above the acceptance range it is acceptable to reprocess the data using an alternate internal standard. This is the preferred approach in order to avoid raised reporting limits. The acceptance criteria differ based on the method being used. Refer to *T-MET-WI35797* for the method acceptance criteria.

**NOTE:** The internal standard is added in equal concentration to all of the samples and standards via a dedicated line on the peristaltic pump. The analytical lines referenced to an internal standard report a corrected concentration value based on the ratio of analyte to internal standard intensities. All the calculations for determining concentration are based on Intensity Ratio (IR). The IR is defined as the background corrected intensity signal of the

Uncontrolled Copy

analyte line (Ia) divided by the internal standard value (Iis). IR= Ia/Iis.

12. For TCLP and SPLP samples, an MSA (method of standard additions) is required if:

a. The sample concentration falls between 80% and 100% of the regulatory limit.

b. If the TCLP or SPLP matrix spike (QA) recovers <20%, all samples in the leachate batch must be reanalyzed using the method of standard additions for that analyte.

13. When items 1 – 12 are complete, check the following:

a. All samples requiring reread/redigestion are listed on the reread paperwork, and redigestions are communicated to the verification group by email.

b. The data are uploaded to LIMS via data transfer to TALS.

| *T-WC-WI11519* | pH Probes and Meters |

## Scope

This SOP provides the guidelines for analysts performing pH on solid, soil, and solvent samples. This procedure is applicable to solid/soil/solvent samples.

The sensitivity limit for this technique is 0.01 pH units.

## Basic Principles

A 1:1 slurry is prepared and the activity of hydrogen ions in the supernatant is measured using a combination pH electrode.

Determination of corrosivity is based on the pH value of the sample.

## Reference Modifications

Method 9045C/D has been modified for the analysis of solid, soil, and solvent samples in the following ways:

1. An Automatic Temperature Compensator is used for all samples instead of manually performing calculations to correct measured pH values if the sample and buffer solution temperatures differ by more than 2°C.

2. 25 g of soil to 25 g reagent water is used instead of the 20 g: 20 mL ratio.

3. The samples are tumbled for approximately 30 minutes instead of being stirred with a stir bar for 5 minutes. Samples that are analyzed for both ORP and pH are stirred with a sir bar for 5 minutes and analyzed immediately for both analyses. Both are shown to have acceptable precision according to a duplicate analysis study.

These modifications are performed in order to allow for adequate agitation and to provide sufficient supernatant to immerse the pH electrode during analysis.

Uncontrolled Copy

## Interferences
Interferences occur when oily or particulate matter adheres to the electrodes and reduces the response. Gentle wiping or rinsing with reagent water usually corrects this problem. Temperature effects are compensated for by calibrating the pH meter at the temperature of the sample or using a pH meter equipped with temperature compensators. There are no means of controlling temperature effects caused by shifts in ionic equilibria of the sample.

## Safety Precautions and Waste Handling
All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention. Standard safe laboratory procedure must be followed as outlined in the Chemical Hygiene Plan.

## Personnel Training and Qualifications
All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each technician performing these techniques must work with an experienced technician for a period of time until they can independently perform the procedure. Proficiency is measured through an Initial Demonstration of Capability (IDOC).

The IDOC and the DOC consists of four pH readings of the 7.00 pH buffer (which is used as the laboratory control standard) that are carried through all steps of the procedure and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation.

## Sample Collection, Preservation, and Handling
Sample must be collected in an unpreserved container and stored at 0° to 6°C; not frozen, until the time of analysis. There is no published holding time for pH analysis on soil; analysis is performed as soon as possible after sample is received in the laboratory.

## Apparatus and Equipment
1. Analytical balance capable of weighing 0.0001 g

2. pH meter equipped with an ATC probe (Automatic Temperature Compensator)

3. Combination electrode or equivalent

4. Stir bar and stir plate

## Reagents and Standards
1. 7.00 pH Buffer (ISO 17034 certified standard) – Control Company (Fisher Scientific Catalog 15-078-281) or equivalent, purchased; see container for shelf life information.

2. Appropriate pH electrode filling solution for electrode, purchased. Store at room temperature. See label for expiration date.

## Calibration
Balances must be calibrated each day before use.

Calibrate pH meter as described in *T-WC-WI11519*.

Uncontrolled copy

## Procedure

1. Make sure the pH meter has been calibrated within the last 24 hours.

2. Weigh 25 ± 0.5 g of sample into a clean specimen cup and add 25 ± 0.5 mL of reagent water (makes a 1:1 slurry).

If the sample absorbs the water, add an additional 25 ± 0.5 mL of reagent water (makes a 1:2 slurry). If a 1:2 slurry does not provide sufficient supernatant to immerse the pH electrode, use less sample and add reagent water in proportion to the weight selected. Enter a comment in LIMS indicating the dilution.

3. Tightly place the screw-cap lid on the sample and mix the slurry in the tumbler for approximately 30 minutes. If ORP is also analyzed, stir the samples with a stir bar for 5 minutes and proceed to step 5.

4. Remove the sample from the tumbler and allow the sample to settle for about 1 hour.

5. Rinse and shake off any water on the electrodes.

6. Dip the electrodes into the supernatant (aqueous layer) of the sample and allow to equilibrate. If necessary, decant or pipette this layer into another container.

7. Using the calibrated, pH meter note the pH value of the sample after the meter equilibrates, and enter the value in the LIMS.

**NOTE**: If pH reading is < 4.00 or >10.00, then the pH result will be reported with a qualifying flag.

8. Note the temperature of the sample and record the value in LIMS.

9. Rinse and clean the electrodes before proceeding to the next sample.

10. If corrosivity is to be reported, read the pH 2 and 12 standards and record the pH value.

11. Corrosivity is determined from the sample's pH reading. A "Yes" or "No" response is entered for the corrosivity result, depending on the pH value. A sample is considered corrosive if the pH is <2 or >12, warranting a "Yes" result. A sample with a pH value from 2 to 12 has a corrosivity result of "No".

## Calculations

Not applicable.

## Statistical Information/Method Performance

Not applicable to this procedure

## Quality Assurance/Quality Control

1. Batch size - a batch contains up to 20 samples, analyzed within a 24 hour period

2. See Table I for QC acceptance criteria. If acceptable results cannot be obtained and the client requests that the data be reported, the data must be qualified to note that the method criteria were not met.

3. For every batch, a LCS, and two DU must be analyzed. When there is not enough sample to perform a DU, a LCSD must be performed. If 10 or fewer samples are on a batch then only one DU is required.

4. Every ten samples analyzed must be bracketed by CCVs.

5. When analyzing for Corrosivity, a pH check using buffers 2 and 12 must be analyzed.

6. If the meter must be re-calibrated during the analysis, a LCS must be analyzed after the calibration is performed.

Uncontrolled Copy

5. Follow Project Notes in the LIMS for any additional unique client requirements.

6. See LIMS for current quality control acceptance windows.

Table I – QC Frequency and Acceptance Criteria

| QC Check | Minimum Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|---|
| CCV (7.00 S.U. pH solution) | After every 10 samples and at the end of a batch | 90 – 110% | Re-analyze samples bracketed by failing CCVs |
| LCS (7.00 S.U. pH solution) | 1 per batch at the beginning of each batch | Per statistical evaluation, see LIMS for current limits | If reanalysis cannot be performed, data must have an NCM explaining the LCS qualification. |
| LCSD (7.00 S.U. pH solution) | Per Client or regulatory requirement | Per statistical evaluation, see LIMS for current limits | If reanalysis cannot be performed, data must have an NCM explaining the LCS qualification. |
| Sample Duplicate (DU) | 1 per 10 samples analyzed (2 per batch of 20) | Per statistical evaluation, see LIMS for current limits | Data are qualified |

## Scope

This method is used for identifying and quantitating the following PCBs in solid samples and wipes using SW846 8082A:

| Compound | Soil LOQ (µg/kg) | Wipes LOQ (µg) | Tissue LOQ (µg/kg) |
|---|---|---|---|
| Aroclor 1016 | 17 | 0.5 | 34 |
| Aroclor 1221 | 17 | 0.5 | 34 |
| Aroclor 1232 | 17 | 0.5 | 34 |
| Aroclor 1242 | 17 | 0.5 | 34 |
| Aroclor 1248 | 17 | 0.5 | 34 |
| Aroclor 1254 | 17 | 0.5 | 34 |
| Aroclor 1260 | 17 | 0.5 | 34 |
| Aroclor 1262 | 17 | 0.5 | 34 |
| Aroclor 1268 | 17 | 0.5 | 34 |

Aroclors 5422, 5432, and 5460 can be analyzed upon request of the client. See Appendix I for GC operating conditions and calibration information.

| Compound | Soil LOQ (µg/kg) |
|---|---|
| Aroclor 5422 | 33 |
| Aroclor 5432 | 33 |
| Aroclor 5460 | 33 |

Limits of Quantitiation (LOQs) are based on statistical evaluation of laboratory data and are subject to change. The current Method Detection Limits (MDLs) and LOQs are maintained in the LIMS.

## Basic Principles

A solid sample or entire wipe is extracted using sonic probe with 1:1 methylene chloride:acetone, or microwave extraction with hexane. The extract is dried, concentrated, and exchanged to hexane. A florisil and sulfuric acid cleanup is utilized to reduce any matrix interferences. The PCBs are then identified and quantitated using gas chromatography (GC) with electron capture detector (ECD). Copper cleanup may also be employed to reduce elemental sulfur or other matrix interferences which introduce large, unresolvable peaks into the chromatogram. Refer to *T-OE-PEST-WI10281* for details on each cleanup procedure.

Solid matrices other than soil can also be analyzed as long as the sample can be handled through the extraction technique. Typically solids are reduced to small pieces for extracting (concrete, wood, other plant material etc). Tissue samples are ground and homogenized prior to extracting. Tissue samples may be whole fish, filets, or other miscellaneous species (usually aquatic but not necessarily). Wipe samples are analyzed by taking the entire wipe sample and any solvent in the sample container.

## Reference Modifications

Gas Chromatography conditions are different than those listed in Method 8082A, however, all QC criteria are met.

## Interferences

Avoid contact with any plastic material during the extraction and analysis procedures to minimize interferences from phthalate esters.

Scrupulously clean all glassware to minimize interferences caused by laboratory contaminants.

An electron capture detector (ECD) is very sensitive to compounds that contain halogens and will also respond to many other compounds and materials including oxygenated organics, unsaturated organics, and elemental sulfur.

Extracts may require further cleanup by sulfuric acid, florisil, or copper if interferents such as oxygenated organics, unsaturated organics, and elemental sulfur are present. Refer to *T-OE-PEST-WI10281*

Uncontrolled Copy

for details on each cleanup procedure.

Common single component pesicides such as DDT, DDD, and DDE may cause interference with the aroclor pattern. To ensure that the analyst is aware of this, a standard containing DDE/DDD/DDT will be run with each initial calibration.

## Safety Precautions and Waste Handling

See *Chemical Hygiene Plan* for generalinformation regarding employee safety, waste management, and pollution prevention.

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

Gloves, lab coats, and safety glasses must be worn when preparing standards. Safety glasses must be worn around the GC where solvents and sample extracts are handled.

GC vials are disposed of in the designated lab container and subsequently lab packed for final disposal. All solvent waste is placed in designated containers in the laboratory then taken to the lab-wide facility by personnel trained in hazardous waste disposal.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each analyst performing instrumental analysis must work with an experienced analyst for a period of time until they can independently calibrate the instrument, use the chromatography data system to set up sequences, perform the calculations, interpret chromatograms, perform instrument maintenance, and enter data into the LIMS. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an Initial Demonstration of Capability (IDOC).

The IDOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation (per EPA 8000D the criteria are the statistical LCS window, and RPD </= 20%). Various options are available for a DOC and can include four laboratory control samples or one blind sample.

## Sample Collection, Preservation, and Handling

Samples are collected in wide-mouth glass containers with Teflon™-lined caps and kept cool at 0° to 6°C, not frozen.

PCBs have no maximum recommended holding time for the extraction. Some agencies or projects may require a specific hold time for the extraction. If the hold time is specified in the project, this hold time must be followed. Sample analysis must be performed within 40 days of extraction. Extracts are stored in the freezer at ≤-10°C

## Apparatus and Equipment

1. HP 7890 gas chromatograph equipped with an electron capture detector or equivalent
2. Columns:
    a. Phenomonex MultiRes I – 30 m × 0.32 mm × 0.5 µm or equivalent
    b. Phenomonex MultiRes II – 30 m × 0.32 mm × .25 µm or equivalent
    c. Alternatively, Restek columns can be used.
3. Integrating system such as Chrom Perfect® by Justice Laboratory Software, or equivalent. Chrom Perfect® is a data system capable of storing and reintegrating chromatographic data and determining peak areas using a forced baseline, area summation, baseline projection, and performing baseline compensation as required.
4. Various sizes of Class A volumetric flasks, pipettes, and syringes

## Reagents and Standards

A. Reagents
    1. Hexane for autosampler rinse vials, stored at room temperature.
    2. UPC (Ultra pure carrier) helium for carrier gas
    3. UPC nitrogen for detector make-up gas
    4. UPC hydrogen for carrier, either bottled or from a generator

Uncontrolled Copy

B. Standards

1. All standards are prepared using Class A volumetric pipettes, syringes, and flasks.
2. An analytical balance is used to measure all weights.
3. Unopened ampules are stored according to the manufacturer's instructions and are stable until the expiration date provided by the manufacturer.
4. All prepared standard solutions are stored at ≤-10°C in labeled containers or vessels.
5. Aroclor 1016 & 1260 stock – Restek #32039 at 1,000,000 ppb in isooctane or equivalent. Prepare a ten-fold dilution for an intermediate.
6. Aroclor 1016 ICV Stock – Accustandard Cat# C-2165-H-10X at 1,000,000 ppb in Hexane.
7. Aroclor 1260 ICV Stock - Accustandard Cat# C-2605-H-10X at 1,000,000 ppb in Hexane.
8. Aroclor 1221 stock – Restek #32007 at 100,000 ppb in isooctane or equivalent. Two lots are kept on hand to provide a second source.
9. Aroclor 1232 stock – Restek #32008 at 100,000 ppb in isooctane or equivalent. Two lots are kept on hand to provide a second source.
10. Aroclor 1242 stock – Restek #32009 at 100,000 ppb in isooctane or equivalent. Two lots are kept on hand to provide a second source.
11. Aroclor 1248 stock – Restek #362010 at 1,000,000 ppb in isooctane or equivalent. Two lots are kept on hand to provide a second source. Prepare an intermediate by diluting 1 mL to 10 mL of hexane.
12. Aroclor 1254 stock – Restek #32011 at 1,000,000 ppb in isooctane or equivalent. Two lots are kept on hand to provide a second source. Prepare an intermediate by diluting 1 mL to 10 mL of hexane.
13. Surrogate stock (SS) – Supelco #861284 containing DCB/TCX at 200,000 ppb in acetone or equivalent. Prepare an intermediate by diluting 1.0 mL to 25 mL of hexane for AR1016/1260, AR1254, AR1248.
14. 1016/1260 Matrix spike (MS) stock – Restek #32039 at 1,000,000 ppb in hexane or equivalent.
15. Aroclor 1262 stock – Restek #32409 at 1,000,000 ppb in hexane or equivalent. Prepare an intermediate by diluting 1 mL to 10 mL of hexane.
16. Aroclor 1268 stock – Restek #32410 at 1,000,000 ppb in hexane or equivalent. Prepare an intermediate by diluting 1 mL to 10 mL of hexane.
17. Instrument Blank (IBLK) – Surrogate Stock (SS) – Restek #32000 containing Decachlorobiphenyl (DCB) and Tetrachlorometaxylene (TCX) at 2000,000 ppb in acetone or equivalent.
18. Prepare working standards using the reagents module of the LIMS as a guide.
    a. In the reagents module, first enter the reagents in this section as 'source' reagents.
    b. Then select 'intermediate' reagent and load the most recent version of the working standard you wish to create for editing, or create a new standard if the working standard has not yet been prepared in TALS.
    c. The module contains the following information: reagent description (ex. AR161), source reagent code, amount used, final amount, solvent used and solvent lot, concentration of each compound in solution, and expiration date. The working standards have an expiration date of 6 months.
    d. The calibration scheme begins at or near the reporting limit through a 20 fold of the initial calibration level.
    e. The scheme for preparing the matrix and surrogate spiking solutions used in the extraction process are listed below.

| Standard Name | Parent Solution | Aliquot (mL) | Final Volume (mL) | Solvent | Description |
|---|---|---|---|---|---|
| PCB Spike | Aroclor 1016/1260 MS Stock | 1.25 | 250 | Acetone | PCB Spike |
| SS | Pest Surr Stock | 1.5 | 1000 | Methanol | SW-846 Water surrogate – identical to that prepared for Pest/PCB analyses |

19. An initial calibration verification standard must also be prepared at a concentration at the mid-point of the calibration for 1016, 1260,1248 and 1254 using a stock solution purchased from a different source other than that used for the calibration standards.
20. Additional standards and preparations are listed in Appendix I for Aroclor 5442, 5432, and 5460 (PCT analysis).

**Extraction**

See organic extraction work instruction T-OE-Pest-WI10922 for sonication extraction and T-OE-Pest-WI10927 for microwave extraction.

Uncontrolled Copy

**Gas Chromatographic Conditions**

The conditions listed are usually the optimum operating conditions but can vary to improve the sensitivity, linearity, and overall chromatography or shorten run times on each GC system. A Merlin microseal may be used in place of a traditional septum.

| | |
|---|---|
| Detector | ECD |
| Detector Temperature | 330°C |
| Oven Temperature | 110°C<br>40°C/min to 250°C<br>20°C/min to 280°C<br>30°C/min. to 330°C<br>Hold until DCB elutes ~ 2 min. |
| Carrier | Hydrogen at 12 psi, 5ml/min constant flow<br>(Can be substituted with Helium) |
| Makeup gas | N2 at 30 mL/min. for Varian GCs<br>N2 at 55 mL/min. for HP GCs |
| Injection size | 1 µL, direct injection |
| Injection Temperature | 225°C |

**Calibration**

1. Fill the autosampler rinse vials with clean solvent or replace vials which appear dirty.
2. Prepare a sequence using the following suggested order of injections:

    1. Conditioner
    2. IBLK
    3. EVAL
    4. AR161
    5. AR162
    6. AR163
    7. AR164
    8. AR165
    9. AR166
    10. AR481
    11. AR482
    12. AR483
    13. AR484
    14. AR485
    15. AR486
    16. AR541
    17. AR542
    18. AR543
    19. AR544
    20. AR545
    21. AR546
    22. AR214
    23. AR324
    24. AR424
    25. AR624
    26. AR684
    27. AR16xx
    28. MD16 (MDL)
    29. IC16x (ICV)
    30. IC48x (ICV)
    31. IC54x (ICV)
    32. Blank
    33. LCS
    34. 1234567
    35. 1234567ms
    36. 1234567msd
    37-47. Continue running samples
    48. AR164(CCV)
    49. IBLK

    a. For routine PCBs:

        (1) The AR21, AR32, and AR42 are level 4 in the cal and are entered at AR214, AR324, and AR424 in the cal.

        (2) AR62 and AR68 are both level 4 and are listed as AR624 and AR684 in the sequences.

        (3) A single point of Aroclor 1016 is analyzed with the calibration to aid in better pattern recognition in the samples. Aroclor 1016 and 1242 have similar patterns with the exception of the smaller trailing peaks at the end of the Aroclor 1242 pattern. This is identified in the sequence as AR16xx.

Uncontrolled copy

(4) A DDT/Endrin breakdown standard is run with each ICAL in order to provide the retention times for p,p-DDE, p,p-DDD, and p,p-DDT which may interfere with the pattern for aroclor 1248, 1254, and 1260.

b. See Appendix I for a sequence example when the analysis of PCTs (Aroclors 5442, 5432, and 5460) is requested.

3. Inject conditioner to prime the system.

a. The conditioner injection is usually a standard or sample which has already been injected.

b. It is used to prime the system and is best utilized when the GC has not been running and there is a gap in time prior to starting a set of injections.

c. Hexane blanks may also be run to allow the GC to go through some temperature programs and/or to check the cleanliness of the system.

4. An instrument blank (IBLK) is always run prior to a new calibration to confirm that the instrument is free of background noise or contamination. IBLK may also be run with the continuing check standards - this is optional but frequently requested for projects.

5. Initial Calibration (ICAL)

a. Calibrate for the aroclors using the six levels of 1016, 1260, 1248, and 1254 (calibration range of 50 µg/L through 1000 µg/L) and using the single point for 1221, 1232, 1242, and 1262 and 1268 when needed (200 µg/L standard used).

b. As an option, 1248 and 1254 may use a single point calibration.

c. An external standard calibration based on the average calibration factor (AVG CF)for each individual peak chosen in the pattern is used for quantitation where the %RSD is ≤20%.

d. The surrogate standards are calibrated using the AR16 levels and the calibration is also performed using AVG CF unless the %RSD is >20%.

e. When the % RSD criteria is not met (i.e. >20%), a linear calibration curve is used.

(1) The curve must meet a correlation coefficient of 0.99 to be a valid fit.

(2) Extrapolate or force to zero is not allowed. Set the zero to ignore.

(3) North Carolina and 8000D requires calculation of % error for any linear fits. The criteria for % error of standard levels at or below the LOQ is +/- 50%. The criteria for % error of all other standard levels is +/-30%.

%error = ((true – calc)/true) x 100

f. If the %RSD criteria or 0.99 curve coefficient cannot be met:

(1) Inspect the data points to see if one or more calibration levels may have concentrated due to solvent evaporation or degraded over time.

(2) Reinject or remake the standard if this is the cause.

(3) Use a quadratic fit provided six points are used in the calibration and the curve meets a correlation coefficient of 0.99. The % error must be calculated and meet the criteria defined in e.4. **NOTE:** A quadratic fit may not be used for South Carolina samples.

(4) Perform instrument maintenance as needed.

(5) See *T-PEST-WI10007* for troubleshooting linearity problems.

g. Set up the aroclor calibration data in a custom program under Datalog. The retention times of the peaks to use for identifying and quantifying the aroclors are entered into the calibration file along with the corresponding peak heights and concentrations (in µg/L).

h. Ensure the surrogate peaks in the standards are labeled properly.

i. Set the scaling of chromatograms so that the size of the peaks of interest for each aroclor are approximately 2 to 3 mm in height at the concentration of the method detection limit (MDL).

(1) Ensure all peaks in the MDL standard are integrated.

(2) By running the 1016/1260 MDL standard, the majority of peaks for all aroclors should be represented.

6. Initial Calibration Verification (ICV)

a. Verify the calibration curves using the ICV mixtures injected directly after the full ICAL.

b. The % difference of the concentrations of each individual peak used to calculate the Aroclor must be within 20% difference of the nominal concentration.

7. Continuing Calibration Verification (CCV)

a. Calibration verification is performed after each set of twenty injections (samples, QC, blanks, etc.) or 12 hours, whichever comes first.

b. Use AR16 to evaluate the calibration of the aroclors (or other aroclors as requested for particular clients or projects).

Uncontrolled Copy

c. The concentration quantitated for each individual peak used to calculate the Aroclor in the continuing calibration verification standards must be within 20% difference (%D) of the nominal concentration for each peak/surrogate.

d. Samples must be bracketed by compliant standards.

(1) Exception: If standard following a sample is outside the ±20% but exhibits increasing response, the samples before it do not have to be reinjected if the target analytes are not detected. A comment must be added to the analytical report.

(2) If two consecutive/sequential CCVs fail, corrective action must be taken, which can include performing injection port maintenance, baking the instrument or other types of maintenance. Two consecutive/sequential CCVs must meet the criteria or an initial calibration must be performed before sample analysis can continue.

e. If confirmation of target analytes is needed, then the second column should meet the 20% continuing calibration criteria, as well as all initial calibration criteria. If either of these are not met, a comment must be added to the analytical report.

8. The instrument blank (IBLK), if requested for, is injected before or after each set of continuing calibration verification, depending on project specifications/project notes.

a. It must be evaluated as a water matrix against the water MDL/LOQs.

b. The IBLK must not have any target compounds above the reporting limits.

(1) If a target analyte is detected in the IBLK, any associated samples with a detection for that same target must be evaluated.

(2) Unless the concentration in the sample is more than 10x the IBLK value, the sample must be injected after another compliant IBLK.

(3) Instrument maintenance, i.e., baking the system or injection port maintenance is usually necessary to clean up the instrument.

9. Retention time (RT) windows

a. Established as 3× the standard deviation determined over 72 hours, or at no less than ±0.02 min, applied to the midpoint initial calibration standard.

b. If the RTs for a continuing calibration verification standard fall outside the RT window, update the midpoint RT using that standard.

(1) Save this under the appropriate name to indicate an update has occurred.

(2) RTs cannot be updated more than once per day. All subsequent standards run within a 24-hour period must be within this window.

(3) If RTs are not consistent, the cause must be investigated and corrective action taken.

**Procedure**

1. Prepare a sequence of injections as suggested in the Calibration Section, along with the appropriate check standards.

2. Retention times of peaks in the samples are compared to the standard RT windows.

a. Peaks present on both columns that are also in the correct ratios to represent an aroclor are quantitated, and the high value is reported unless chromatographic anomalies are observed. See *T-PEST-WI9954*.

b. Use a minimum of three to six peaks for quantitation, with the exception of certain mixes where it may be more accurate to use less peaks to avoid excessive overlap of patterns.

3. Continue running groups of samples/injections followed by check standards every 12 hours or 20 injections, whichever comes first.

a. For projects where a known aroclor is present and at the request of clients, other aroclors can be run for the continuing check standard. For instance, a set of continuing standards may be AR484, AR164, IBLK.

b. Aroclor 1262 and 1268 can be analyzed when requested. A full six point curve can also be run, depending on the project requirements.

4. If significant interference is present, schedule florisil and/or sulfuric acid cleanup. If elemental sulfur is present, TBA or copper the extract or have it put through GPC cleanup. If these techniques do not reduce the matrix problems, dilute the extract with hexane and adjust LOQs accordingly.

5. Report the results for the least dilute sample where the concentration measured is within the acceptable calibration range.

**Calculations**

1. The peak heights generated by the integration system are used to calculate the calibration factors (CF) for peaks of interest for each aroclor.

Usually, the six major peaks that are unique to each aroclor are chosen for quantitation, with the exception of 1221 where only three peaks are available.

Uncontrolled Copy

2. Sample concentrations are calculated per peak using average calibration factor (AVG CF) from the initial calibration.

$$\frac{Sample\ Height}{AVG\ CF\ (CF)} \times \frac{FV}{IW} \times DF = \mu g/kg\ as\ received\ per\ peak$$

**Where:**

FV = Final volume (mL)

IW = Initial weight (g)

DF = Dilution factor, as needed

The final result that is reported is determined as the average of the result for each peak chosen for quantitation:

$$(Result\ 1 + Result\ 2 + \ldots + Result\ n) / n = Average\ Result$$

3. The surrogate results are determined using either AVGRF or linear curve:

a. Using AVGCF from the initial calibration:

$$\frac{Sample\ Height}{AVCRF\ (CF)} \times \frac{FV}{IW} \times DF = \mu g/kg \quad as\ received$$

b. Using linear curve from the initial calibration:

$$[(Sample\ Height - Y - intercept)/Slope] \times \frac{FV}{IW} \times DF = \mu g/kg\ as\ received$$

**Where:**

FV = Final volume

IW = Initial weight

DF = Dilution factor, as needed

4. See *T-PEST-WI9847* for all other equations related to the analysis.

## Statistical Information/Method Performance

LCS,MS, and RPD are compared to the limits stored in the LIMS. The limits for LCS and MS are statistically derived. Historical data for MS/Ds, LCS/Ds, measurement of uncertainty, is reviewed at least annually. Acceptance limits are generated according to *T-PEST-WI9980*. Reporting limits including method detection limits (MDLs) and limits of quantitation (LOQs) are set according to EPA method requirements and are evaluated annually. Refer to *QA-SOP11892* for specific guidelines and procedures. Updates to the LIMS are made as needed by the QA Department and only as directed by the manager. The department database is updated via a download from the LIMS.

## Quality Assurance/Quality Control

QC Acceptance limits are established as statistical limits. See *T-PEST-WI9980* for further information on monitoring and establishing limits.

A sodium sulfate blank and a sodium sulfate spike (LCS) are analyzed with every group of samples up to a maximum of 20. An MS/MSD is performed per batch. For wipes and when an MS/MSD cannot be performed, an LCSD will be extracted.

Aroclor 1016 and 1260 are routinely spiked; however, other aroclors can be spiked as requested by clients.

DCB and TCX are added as surrogates to each sample and QC to monitor the efficiency of the extraction, the operation of the autosampler, and to monitor retention times throughout the GC run.

If any client, agency, or state has more stringent QC or batch requirements, these must be followed.

Uncontrolled Copy

See *T-PEST-WI10011* for details on QC acceptance criteria and corrective action.

## Appendix I

### PCT Analysis (Aroclor 5422, 5432, and 5460)

A. Standards:

1. PCT Stocks- Aroclor 5432, 5442, and 5460 are purchased as individually ampulated solutions from Accustandard at 35,000 ug/L.

2. Surrogate Stock- Ultra ISM-320 containing TCX/DCB at 200,000ppb in acetone. Prepare an intermediate by diluting 0.25mL to 25mL of hexane.

3. MS stock of Aroclor 5442 - Absolute cat# 71791, 1000ug/L in Methanol.

4. Prepare working standards using the reagents module of the LIMS as a guide.

   a. In the reagents module, first enter the reagents in this section as 'source' reagents.

   b. Then select 'intermediate' reagent and load the most recent version of the working standard you wish to create for editing, or create a new standard if the working standard has not yet been prepared in TALS.

   c. The module contains the following information: reagent description (ex. AR161), source reagent code, amount used, final amount, solvent used and solvent lot, concentration of each compound in solution, and expiration date. The working standards have an expiration date of 6 months.

   d. The calibration scheme begins at or near the reporting limit through a 20 fold of the initial calibration level.

   e. The scheme for preparing the matrix and surrogate spiking solutions used in the extraction process are listed below.

| Standard Name | Parent Solution | Aliquot (mL) | Final Volume (mL) | Solvent | Description |
|---|---|---|---|---|---|
| MS | Aroclor 5422 Stock | 0.75 | 100 | Acetone | Aroclor 5442 PCT Spike |
| SS | Pest Surr mix | 1.5 | 1000 | methanol | SW 846 surrogate |

B. GC Chromatographic Analysis:

The conditions listed serve as a guideline only and are typically the optimum operating conditions. The analyst may make any changes to the chromatographic conditions to improve the speed of analysis, linearity, sensitivity, and/or improve separation if initial and continuing calibration criteria and quality assurance criteria listed within this analysis document are met.

**Scope**

This method is suitable for the determination of the concentration of certain semivolatile organic compounds (priority pollutant list, target compound list, Appendix IX list, TCLP list, and CCW list) found in soils, tissues, waters, and leachates. Typical limits of quantitation (LOQ) achieved are 33 µg/kg for soils, 132 µg/kg for tissues, 1 µg/L for waters, and 0.002 mg/L for leachates. Specific compound lists and associated method detection limits (MDLs) and LOQs can be found in the Laboratory Information Management System (LIMS) under the analysis numbers listed in the header of this SOP.

**Basic Principles**

Water samples are extracted according to *T-OE-SVOA-WI11432*. Soil samples are extracted according to T-OE-SVOA-WI10925 or *T-OE-SVOA-WI10928*. Leachates are extracted according to *T-OE-SVOA-WI10935*. Non-water soluble matrices are extracted according to *T-OE-SVOA-WI10917*.

An environmental sample (soil, water, sludge, etc.) is solvent extracted and then analyzed by electron impact gas chromatography/mass spectrometry (EI GC/MS). A predetermined aliquot of an extract containing organic compounds in solvent is injected onto a fused silica capillary column coated with a relatively non-polar stationary phase, which is enclosed in a temperature controlled oven. A carrier gas, which is ultra-pure helium, passes continuously through the column. The GC oven is temperature programmed and the organic mixture separates into its individual components as it moves along the length of the column. This separation is the function of the polarity and boiling point of the individual compounds. This column empties into a mass selective detector. When a compound reaches the detector, it is bombarded by high-energy electrons (70eV). This causes the compounds to fragment, forming ions. By applying various voltages to the lens, the positive ions are thrust into a quadrupole mass analyzer, which selects for a given mass fragment at a given time. These selected fragments reach an electron multiplier that detects and generates a signal for each mass fragment. The signals are amplified and sent to a computer. Target compounds are identified on the basis of relative retention times and spectral match to standards that are injected every 12 hours on the same system.

Quantification is achieved via use of the internal standard calibration technique. The average relative response factor of a multi-point calibration is used for quantification when the appropriate criteria are met.

**Interferences**

Method interferences may be caused by impurities in solvents, reagents, glassware, or other hardware used in the processing of samples. All glassware is solvent rinsed before use and a method blank is performed with each extraction batch to demonstrate that the extraction system is free of contamination.

Sample matrices can have an effect on the ability of the GC/MS system to resolve the individual masses used for quantification. Samples may require dilutions, a reduction in the extraction volume/weight used, a raised final extraction volume, or extract clean-up using various techniques in order to achieve proper target separation and determination.

**Safety Precautions and Waste Handling**

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

The toxicity or carcinogenicity of each reagent used in this method has not been precisely defined; however, each chemical compound and reagent should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means are available such as fume hoods, safety glasses, lab coats, and gloves.

All solvent waste generated from this analysis must be collected for recycling (if applicable) or must be disposed of in designated containers. These are then transferred to a lab-wide disposal facility. Any solid waste material (disposable pipettes, broken glassware, pH paper) must be disposed of in the normal solid waste collection containers or sharps containers, as applicable.

**Personnel Training and Qualifications**

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each analyst performing instrumental analysis must work with an experienced analyst for a period of time until they can independently perform daily maintenance, calibrate the instrument, change the column, clean the source, interpret chromatograms, perform calculations, review

Uncontrolled Copy

data, and enter data into the LIMS. The analyst is also trained on the preparation of dilutions and calibration standards. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an Initial Demonstration of Capability (IDOC).

The IDOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation (per EPA 8000D, the statistical LCS window and RSD </= 20%)).

Various options are available for a DOC and can include four laboratory control samples or one blind sample. The RSD criteria is 20%.

Refer to *QA-SOP11178* for more guidance on these options.

**Sample Collection, Preservation, and Handling**
Water samples are collected in 250mL or 1L glass amber glass containers with PTFE-lined lids and may be preserved with sodium thiosulfate ($Na_2S_2O_3$). They are stored at 0ºC to 6ºC, not frozen, prior to extraction and must be extracted within 7 days of collection.

Solid samples are collected in glass wide-mouth jars with PTFE-lined lids and are not preserved. They are stored at 0ºC to 6ºC, not frozen, prior to extraction and must be extracted within 14 days of collection.

All sample extracts must be stored at ≤-10ºC (freezer) and protected from light using amber glass vials. All samples, sample extracts, and standards must be stored separately and in an area free from contamination. All extracts must be analyzed within 40 days of extraction.

**Apparatus and Equipment**

1. Hewlett-Packard Model 5890 (Series I and II) or Hewlett-Packard/Agilent 6890 or 7890 Gas Chromatograph or equivalent
2. Hewlett-Packard Models 5971, 5972, and Hewlett-Packard/Agilent 5973, 5975 Mass Selective Detector or equivalent
3. Hewlett-Packard ChemStation Software
4. Thru-Put Systems Target Acquisition Software/Oracle Database or equivalent
5. Column – 20 M × 0.18 mm ID × 0.18 µm, Agilent DB-5MS or equivalent
6. Column - 30M × 0.25 mm ID x 0.25 µm df, J&W Scientific DB-5MS or equivalent
7. Hamilton Gastight syringe, or equivalent – various volumes
8. Amber GC vials with crimp caps

**Reagents and Standards**

A. Reagents - All reagents are stored per manufacturer guidelines unless otherwise noted. Reagent vendors are subject to change without notification.

1. Helium carrier gas, UPC grade
2. Methylene chloride ($MeCl_2$ or $CH_2Cl_2$) – Baker Ultra Resi-Analyzed

B. Standards

1. Supelco Equity Semivolatile Internal Standard Mix, Part #46955-U or equivalent, 1000 µg/mL in methylene chloride. Ampulated solutions are maintained under refrigeration (0° to 6°C, not frozen) until consumed or manufacturer determined expiration date. Working solution is maintained at room temperature and is replenished daily from ampulated solutions. For 250 mL aqueous analyses Supelco Equity Semivolatile Internal Stanac Mix is diluted 4x to make a 250 µg/mL in methylene chloride solution. This solution is maintained under refrigeration (0° to 6°C, not frozen) for up 6 months.

2. Refer to *T-SVOA-WI11998* for the preparation and storage of tuning, calibration, and spiking solutions.

**Calibration**
See Procedure F for initial calibration processing and Procedure G for continuing calibration check processing.

**Procedure**

A. Standard preparation – Solutions are used to standardize the GC/MS system every 12 hours and are prepared approximately every 20-30 days or more frequently if needed based on consumption. See *T-SVOA-WI11998* for standard preparation. Calibration standard solutions may be used up to the labeled expiration date or until component degradation is observed. Degradation is determined by the inability to pass continuing calibration checks or by observations of unacceptable chromatography.

B. Internal standard mix is added to all standards and subsequent samples at a concentration of 20 µg/mL (5 µg/mL for 250 mL aqueous analyses). Using a 25-µL syringe, 20 µL of Supelco Equity Semivolatile Internal Standard Mix or equivalent, 1000 µg/mL (250 µg/mL for 250 mL aqueous analyses) in methylene chloride are added to 1 mL of standard or sample extract. If only 0.5 mL of sample is in the vial, 10 µL of internal spiking solution is added to the sample. See Table II for the list of compounds calibrated for and the internal standard that is assigned to each.

C. Daily maintenance – Refer to *T-SVOA-WI9598* for this procedure.

D. Instrument conditions

Equip a GC/MS (such as referenced under Apparatus and Equipment) in one of the two following manners:

1. For a 5890/5971 or 5972 and 6890/5973 or 5975
   a. Column – 30M × 0.25 mm ID x 0.25 µm df, J&W Scientific DB-5MS or equivalent
   b. Injector – Split/splitless operated in splitless mode
   c. Injector Temp – 275°C
   d. Detector Temp – 300°C
   e. Gas – Helium at approximately 1.5 mL/min, constant flow mode
   f. Oven Temp – 45°C for 3 minutes, ramp at 8°C/minute to 225°C, then ramp at 12°C/minute to 300°C and hold for 7.5 minutes.
2. For a 6890/5973 or 5975

Uncontrolled Copy

a. Column – 20M × 0.18 mm ID x 0.18 µm df, J&W Scientific DB-5MS or equivalent

b. Injector – Split/splitless operated in split mode, 20:1 split

c. Injector Temp – 275°C

d. Detector Temp – 280°C

e. Gas – Helium at approximately 1.0 mL/min, constant flow mode

f. Oven Temp – 40°C for 1 minute, ramp at 25°C/minute to 100°C, then ramp at 30°C/minute to 280°C, followed by another ramp at 25°C/minute to 320°C, hold for 2 minutes.

**NOTE:** It is not necessary to use the exact parameters listed above. Equivalent columns and conditions may be used to improve the linearity, sensitivity, overall chromatography, and performance required by the method on each GC/MS system.

E. Tuning

1. The DFTPP tune check standard is used to assess GC column performance and injection port inertness as well as mass spectrometer performance. The GC/MS system's tune is checked by inspecting the mass spectrum of the DFTPP peak and column performance and injection port inertness is evaluated with pentachlorophenol, benzidine, and DDT.

2. The GC/MS should be tuned using a predetermined aliquot of a 50 ng/µL or 12.5 ng/µL solution of DFTPP containing decafluorotriphenylphosphine, pentachlorophenol, benzidine, and DDT. This solution is prepared as indicated in *T-SVOA-WI11998*. See the tables below for acceptance criteria and corrective actions.

| DFTPP Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Prior to initial calibration and every 12 hours prior to continuing calibration standard | 1. Criteria in Table I<br><br>2. DDT breakdown ≤20%*<br><br>3. Tailing factors:<br>- Benzidine ≤ 2<br>- Pentachlorophenol ≤ 2 | 1. Re-tune. Analysis cannot proceed until tune meets criteria.<br><br>2. More aggressive injection port maintenance.<br><br>3. Clean the source.<br><br>4. Change the column. |

*__NOTE:__ DDT breakdown greater than 20% may be acceptable if you are calibrating for polynuclear aromatic hydrocarbon compounds only. Consult your supervisor when this situation occurs.

3. Use only the background-subtracted spectrum of the following when evaluating the DFTPP:

A three scan average of the apex of the scan, the apex of the scan −1 and the apex of the scan +1.

**NOTE**: All standards, samples, and associated quality control samples with a particular tune must use the identical conditions of the mass spectrometer.

F. Initial calibration (ICAL)

1. Perform standardization by analyzing at least five levels of calibration standards ranging from 0.5 µg/mL to 120 µg/mL or from 0.125 µg/mL to 30 µg/mL for mini-sep waters analysis. (Refer to *T-SVOA-WI11998* for the preparation of calibration standards.) Use the internal standard calibration technique to generate an average relative response factor for each target compound and surrogate. The relative standard deviation (%RSD) of the response factors determines the suitability of the average relative response factor for calculation of compound concentration. At the end of the calibration standard injections, inject a Method Detection Limit (MDL) standard and an initial calibration verification (ICV) standard. See the tables below for acceptance criteria and corrective actions.

| ICAL Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Initially and when the daily calibration standard fails criteria. | 1. Minimum response factors must be met in all levels of the calibration – especially in the lowest level of the calibration (see table IV).**<br><br>2. %RSD for each compound must be ≤20%. If more than 10% of the compounds in the ICAL exceed 20% RSD and/or also do not meet the minimum correlation coefficient for alternate fits (ie, the correlation coefficient is <0.990) then the analysis cannot proceed.<br><br>3. For any compound on a linear or quadratic fit the % error is measured between the calculated and expected amounts of the compound(s) at each calibration level to determine the calibration function acceptability for linear and non-linear curves. The % error must be ≤50% for the low calibration point. For calibration points above the LOQ the % error must be ≤30%.<br><br>4. The relative retention times of the target compounds must agree within 0.06 relative retention time units. | 1. Any target compound with a %RSD <20% will use the average RRF. For any compound in which the %RSD >20%, use a first degree (linear) fit provided the correlation coefficient (CC; r) is ≥0.995 or the coefficient of determination (COD;$r^2$) is ≥0.99. If the linear fit fails to meet this criteria, then a second order (quadratic) fit may be used*** provided the coefficient of determination is ≥0.99. If use of both the linear fit and the quadratic fit is acceptable using this criteria for any given compound, then use the fit with the smallest negative y-intercept. When using a quadratic fit, if the y-intercept quantifies to be greater than the MDL, consult your supervisor immediately or re-calibrate. See below for corrective action if the coefficient of determination for a quadratic fit is <0.99.*<br><br>2. Re-inject any levels that appear to be outliers due to an injection error.<br><br>3. If standard levels on the outside of the curve appear to be outliers for individual compounds and are throwing off the calibration curve, they |

Uncontrolled Copy

| | | |
|---|---|---|
| | 5. Structural isomers that produce very similar mass spectra are identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is <25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. | can be dropped from the calibration keeping the following in mind:<br>a. If a low calibration point is dropped, the analyst must ensure that the compound is still being calibrated to or below its LOQ.<br>b. If a high calibration point is dropped, any detections must recover below the new upper calibration limit.<br>4. Re-prep calibration standards.<br>5. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

*See USEPA Method 8000D for the calculations associated with non-linear fit types.
**Minimum response factors are not required to be met for method 8270E. They are provided for guidance.
***Quadratic fits are not permitted when analyzing samples from South Carolina.

| MDL Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Immediately following an initial calibration and before sample analysis | 1. The system must be able to detect all compounds in the MDL standard. | 1. If any compounds are not detected in the MDL standard, analysis can proceed if the compound is detected at or below its MDL in a higher concentration level.<br>2. If the system does not detect the compound(s), then the tuning and/or calibration procedure must be repeated under conditions that will yield a detection for the compound(s) or the MDL must be raised for the compound(s).<br>3. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

| ICV Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Immediately following an initial calibration and before sample analysis | 1. The ICV must be prepared using a second source standard.<br>2. %Drift for each compound must be ≤30%<br>3. The EICP area for each internal standard must fall within the window of -50% to +100% of the areas from the mid-level calibration standard produced during the initial calibration. | 1. Re-prep and re-analyze the ICV.<br>2. If the recovery for any compound fails these criteria low, the compound cannot be analyzed for under the calibration until a new calibration has been established or a passing ICV has been analyzed.<br>3. If the recovery for any compound fails these criteria high, the compound may be analyzed for but any samples with detections should be re-analyzed under a valid ICAL or will be reported with a qualifying comment.<br>4. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

With supervisory approval, the following problematic compounds can be allowed to fail the 0.99 coefficient of determination criteria for a quadratic fit. If the COD is less than 0.99 for any other compound, the system should be inspected for problems and re-calibrated. Supervisory approval is required for exceptions to these guidelines.

| |
|---|
| 1,4-Phenylenediamine |
| 4-Aminobiphenyl |
| 3,3′-Dimethylbenzidine |
| 4,4′-Methylenebis(2-chloroaniline) |
| 4-Nitroquinoline-1-oxide |
| 1,4-Naphthoquinone |
| methapyrilene |

**Note that this allowance is not to be used for compliance samples, and any data reported under the calibration must be qualified.**

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

3. Six levels of calibration standards must be used if a quadratic (second-order) type calibration fit is used.

4. One of the calibration standards must be at a concentration at or below the limit of quantitation (LOQ). The other concentrations correspond to the expected range of concentrations found in samples or should define the working range of the GC/MS system.

Uncontrolled Copy

5. The concentration of the MDL standard may require modification dependent upon the current MDL values.

G. Continuing Calibration Verification (CCV)

1. Perform a continuing calibration verification (CCV) by injecting a predetermined aliquot of a calibration standard at a concentration near the mid-point of the calibration, not to exceed ½ the highest level in the calibration.

| CCV Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| 1. Every 12 hours.<br><br>2. The CCV is analyzed each day a curve is not analyzed.<br><br>3. The CCV is analyzed after the DFTPP. | Target compounds must meet the minimum response factor criteria (see Table IV).*<br><br>1. The maximum % drift for all target compounds is 20%. No more than 20% of the target compounds can be greater than 20% drift. All target compounds that exceed 20% drift must be less than or equal to 50% drift.<br><br>2. The relative retention times of the internal standards must be within 10 seconds of the retention times from the mid-level calibration standard of the last initial calibration. The exception would be in the case of column maintenance.<br><br>3. The EICP area for each internal standard must fall within the window of -50% to +100% from the areas of the mid-level standard produced during the last initial calibration.<br><br>4. Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is <25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. The resolution should be verified on the mid-point concentration of the ICAL as well as the check standard. | 1. In cases where compound(s) recover >20%D low, they may still be reported as non-detects if it can be demonstrated that there was adequate sensitivity to detect the compound(s) at the applicable quantitation limit. For situations when the failed compound is present, the concentrations must be reported as estimated values.<br><br>2. In cases where compound(s) recover >20%D high, analysis may continue, but any samples with detections should be re-analyzed under a valid CCV or the results will be qualified.<br><br>3. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

*Minimum response factors are not required to be met for method 8270E. They are provided for guidance.

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

2. In the event that a CCV fails and the cause is not obvious such as in the case of a concentrated standard or a mis-injection, corrective action must be taken. The corrective action must be documented in the form of a non-conformance memo. If the CCV does not pass after corrective action, a new initial calibration must be established.

H. Analysis of Samples:

1. All sample extracts are stored at ≤-10°C and protected from light from the time of sample extraction.

2. Prior to sample analysis, add 20 µL of internal standard to each 1.0 mL of sample extract. Concentration of internal standards in extract is 20 ng/µL (5 ng/µL for 250 mL aqueous analyses).

3. Analyze a predetermined aliquot of each sample extract under the same conditions used for the initial and continuing calibrations.

4. At the conclusion of data acquisition, use the same software to tentatively identify peaks within the retention time window of interest. Examine the ion abundances of components in the chromatogram. If the ion abundance of the target ion used for quantitation exceeds the calibration range, dilute the aliquot and reanalyze. When preparing dilutions, add sufficient internal standard to maintain the same concentration as that of the ICAL.

Dilution criteria:

1) Initial dilutions are recommended in the following situations:

i. More than three internal standard recoveries are <-50%

ii. Either of the last two internal standard recoveries are <-80%.

iii. The analyst's judgment of a sample extract's color or viscosity indicates possible matrix interference.

2) Secondary dilutions are required to bring all target compounds into the calibration range of the GC/MS.

I. Qualitative analysis

A compound is identified by comparison of the following parameters with those of a standard of the suspected compound (standard reference spectra). The reference mass spectrum used for this comparison should be generated by the laboratory using the conditions of the method, but the laboratory may also use a certified reference library. In order to verify identification, the following criteria must be met:

Uncontrolled Copy

1. The intensities of the characteristic ions of the compound must maximize in the same scan or within one scan of each other. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 30% relative intensity if less than three such ions occur in the reference spectrum.

2. The RT should be within ±10 seconds of the RT for this analyte in the CCV run at the beginning of the 12-hour period (delta RT 0.17 minute) or within ±10 seconds relative to the shift of the associated IS (delta RT of the IS ± 10 seconds). If the RT for the IS has shifted, the sample should be inspected for similar shifts for the associated target analytes. If RT drift is significant, relative retention time (RRT) may be used as an alternative to delta RTs.

3. The relative intensities of the qualifier ion(s) should agree within 30% of the relative intensities of these ions in the reference spectrum.

**NOTE:** N-Nitrosodiphenylamine decomposes in the gas chromatographic inlet and cannot be separated from diphenylamine. For this reason, it is acceptable to report the combined result for both n-nitrosodiphenylamine and diphenylamine for either of these compounds as a combined concentration.

**NOTE:** 1,2-Diphenylhydrazine is unstable even at room temperature and readily converts to azobenzene. Given the stability problems, it would be acceptable to calibrate for 1,2-diphenylhydrazine using azobenzene. Under these poor compound separation circumstances the results for either of these compounds should be reported as a combined concentration.

J. Quantitative analysis

Once a compound has been identified, quantitation is based on the internal standard technique and the integrated abundance from the extracted ion current profile (EICP) of the primary characteristic ion. The list of primary characteristic ions and secondary ions can be found in Table III.

## Calculations

Refer to *T-SVOA-FRM9602* for all calculations.

## Statistical Information/Method Performance

LCS, MS, surrogate, and RPD recoveries are compared to the limits stored in the LIMS. LCS and surrogate limits are statistically derived every six months in accordance with *T-SVOA-WI9604*. All RPDs are set to a default value of 30%. MS limits are set equal to LCS limits.

Historical data for MS/Ds, LCS/Ds, surrogates, and measurement of uncertainty is reviewed at least annually.

Refer to the QA/QC section of this SOP and the criteria listed throughout this procedure for additional information on the performance of this method.

## Quality Assurance/Quality Control

A. Batch QC

1. Each extraction batch of ≤20 samples must contain a method blank, a laboratory control sample (LCS) and an unspiked background sample (US), a matrix spike (MS), and a matrix spike duplicate (MSD).

2. A laboratory control sample/laboratory control sample duplicate (LCS/LCSD) is prepared with the extraction batch if adequate sample volume is not provided to prepare a matrix spike and matrix spike duplicate.

3. Additional QC samples may be required to meet project or state certification requirements.

B. QC and sample spiking

1. The LCS/D and MS/D are spiked at a concentration of 50 µg/L with the exception of the following (in µg/L):

| | | | |
|---|---|---|---|
| Hexachlorocyclopentadiene | 100 | Benzoic acid | 100 |
| 2,4-Dinitrophenol | 100 | 1-Naphthylamine | 100 |
| 2-Naphthylamine | 100 | 3,3’-Dimethylbenzidine | 100 |
| Benzidine | 250 | 3-Methylphenol | 25 |
| 4-Methylphenol | 25 | | |

2. All samples are spiked with surrogates by the organic extraction group to evaluate the extraction process. Acid extractable surrogates are spiked at a concentration of 200 ng/µL and base/neutral extractable surrogates are spiked at a concentration of 100 ng/µL.

3. Prior to analysis each extract is spiked with an internal standard mix at a concentration of 20 ng/µL.

4. All spiking concentrations are 4x lower for 250 mL aqueous analyses.

C. QC items, acceptance criteria, and corrective actions.

**NOTE: If any client, state, or agency has more stringent QC, QC limits, or batch requirements, these must be followed instead.**

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Internal Standards | 1. Peak area within -50% to +100% of the area in the associated reference standard.<br>2. Retention time (RT) within 30 seconds of RT for associated reference standard. | 1. Check instrument for possible problems and then re-inject sample(s).<br>2. If re-injection meets the criteria, report this injection.<br>3. If re-injection still shows the same problem, report first injection.<br>4. If there is substantial matrix interference, the analyst may dilute the extract as outlined in Procedure H.4. |

Uncontrolled Copy

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Method Blank | 1. Must meet internal standard criteria.<br>2. Must meet surrogate criteria.<br>3. All target compounds must be less than the reporting limit for the associated samples. | 1. Inspect system for possible problems and reanalyze.<br>2. If the surrogates are out of spec high data can be used provided there aren't detections in the method blank.<br>3. If the surrogates are out of spec low and there aren't detections in the associated samples, the data can be used.*<br>4. If the method blank contains target compounds and the associated samples do not contain these compounds, no corrective action is required.<br>5. If the target compounds in the blank are also in the associated samples at a concentration <10x that in the blank, the samples are re-extracted unless the detection does not interfere with project data requirements.<br>6. If the target compounds in the blank are also in the associated samples at a concentration >10x than in the blank the data is usable. |
| Instrument Blank** | 1. Must run after the CCV if no clean method blank is analyzed at the beginning of a 12-hour analytical period.<br>2. Must meet internal standard criteria.<br>3. All target compounds must be less than the reporting limit for the associated samples. | 1. Inspect system for possible problems and reanalyze.<br>2. If the instrument blank contains target compounds and the associated samples do not contain these compounds, no corrective action is required. If the target compounds in the blank are also in the associated samples, the samples should be re-extracted unless it does not interfere with project data requirements or if sample detections are at a level 10x higher than the detections in the blank. |
| Laboratory Control Sample/Laboratory Control Sample Duplicate | 1. Must meet internal standard criteria.<br>2. Must meet surrogate criteria.<br>3. % Recoveries within QC limits. Refer to the analysis numbers in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis.<br>4. RPDs within QC limits. | 1. If non-compliant, check for calculation or preparation errors.<br>2. If no errors found, check system for problems and reanalyze.<br>3. If LCS/LCSD recoveries are still outside acceptance limits, one of the following actions must be taken:<br>a. if recoveries are outside acceptance limits low, the sample(s) must be re-extracted.<br>b. if recoveries are outside acceptance limits high, data may be usable if the compounds that recovered above QC limits are not detected in samples.<br>c. if recoveries are outside acceptance limits high and there are detections for the failing compounds, the sample(s) must be re-extracted.<br>4. If RPDs fail but recoveries are within QC limits, no further action is required.<br>5. If surrogates fail to meet criteria but all target compounds are within specification, data is usable.*<br>6. Marginal exceedance limits, as defined in the NELAC standards, may be used if the defined requirements have been met. |

Uncontrolled copy

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Matrix Spike/Matrix Spike Duplicate(MS/MSD) | 1. Must meet internal standard criteria.<br>2. Must meet surrogate criteria.<br>3. % Recoveries within LCS limits. Refer to the analysis number in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis.<br>4. RPDs within QC limits. | 1. If LCS within QC limits, proceed with sample analysis.<br>2. If most recoveries or RPDs out of spec, consult supervisor. BKG, MS, MSD may need to be re-extracted. |
| Surrogates | % Recoveries within QC limits. Refer to the analysis numbers in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis. | 1. If non-compliant, check for calculation or preparation errors.<br>2. If no errors found, check system for problems and reanalyze.<br>3. If no problem is found, re-extract and reanalyze.<br>4. If surrogates are out of spec high and no targets are detected in the sample no corrective action is required.<br>5. For samples analyzed only at a dilution ≥10x, no further action is required for surrogate failures. |

*Requires approval of supervisor
**Method blank or instrument blank in each 12-hour analytical period required for 8270E.

**NOTE:** Any failures without corrective action require approval of supervisor and completion of a non-conformance memo (NCM).

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

D. Lower Limit of Quantitation (LLOQ)

1. Refer to *QA-SOP11892* for initial and ongoing LLOQ requirements.

E. Method Detection Limit (MDL)

1. Refer to *QA-SOP11892* for initial and ongoing MDL requirements.

F. Limit of Quantitation (LOQ)

1. Refer to *QA-SOP11892* for initial and ongoing LOQ requirements.
2. Until the laboratory has sufficient data to determine the acceptance limits, the LLOQ criteria is ± 20% of the statistically determined LCS limits.

## Scope

This method is applicable for the determination of total organic carbon (TOC) in soils and other samples not easily analyzed by the TOC waters method. The limit of quantitation (LOQ) for this method can be found in the analysis information file. Quantitative TOC results up to 1,000,000 mg/kg may be obtained by this method.

## Basic Principles

TOC is determined by acidifying a sample and heating it to remove the TIC. An aliquot of sample (1 mg to 1 g) is weighed into a sample cup. The sample is then heated to 1100°C for combustion of the remaining TOC. The resulting carbon dioxide from the TOC is detected by a nondispersive infrared (NDIR) detector that has been calibrated to directly display the mass of carbon dioxide detected. The mass is proportional to the mass of TOC in the sample. Samples analyzed by this method include solids such as soils or sediments, slurries, sludges, brines, and corrosives.

The TC method is identical to the TOC method, with the exception that there is not an acidification and heating step to remove the TIC.

TIC is the calculation subtracting the TOC soil result from the result obtained when analyzing the TC.

## Reference Modifications

The calibration standards, QC standards, and LCS employed for this analysis are composed of only organic sources of carbon (Sucrose for the calibration and a purchased standard for the LCS and CCV standards). Therefore, the Total Organic Carbon content is equal to the Total Carbon content in these standards.

Uncontrolled Copy

Method SW-846 9060 is a quadruplicate analysis that is designed for water analysis, the lab does not run the solids in quadruplicate the analysis runs a single injection of all samples.

## Interferences

Carbon is ubiquitous in nature. Therefore, extra care must be taken to avoid contamination of reagents, glassware, and any other materials that come in contact with the sample. Samples which are light in weight may need to be analyzed at smaller aliquots to fit within a sample cup. These samples are reported with an elevated LOQ.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

1. Normal laboratory practices for safety must be followed.

2. Extreme caution must be used when handling sample cups after they have been analyzed.

3. Discard acid waste in acid waste containers.

4. See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each technician performing these techniques must work with an experienced technician for a period of time until they can independently perform the procedure. Proficiency is measured through an Initial Demonstration of Capability (IDOC).

The IDOC consists of four aliquots spiked with sucrose at 1-4X the RL that are carried through all steps of the procedure and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy of 50-150%, and relative standard deviation of less than or equal to 20%.

The DOC consists of four laboratory control samples (or alternatively, one blind sample) that are carried through all steps of the procedure. The DOC includes calculation of mean accuracy and standard deviation. The mean accuracy criteria are the LCS windows. The RSD criteria is 20%.

## Sample Collection, Preservation, and Handling

Samples must be collected and stored in glass containers unpreserved. Samples must be stored under refrigeration at 0° to 6°C, not frozen.

Because very small amounts (1 mg to 1 g) of sample are used for the analysis, the sample must be as homogeneous as possible.

The holding time for analysis by SW-846 9060/9060A is 28 days. The holding time for analysis by the Lloyd Kahn method is 14 days.

## Apparatus and Equipment

1. Skalar-Primacs SC100

2. PC and SNAccess software

3. 2-stage gas regulator (two required)

4. Sample cups

Uncontrolled Copy

5. Fiber quartz wool

6. Analytical balance, capable of accurately weighing to 1. mg

7. Glassware – General laboratory glassware as needed for preparing reagents and standards

8. Microliter syringe, various volumes

## Reagents and Standards

**NOTE:** All chemical used must be ACS reagent grade unless otherwise noted.
Different volumes or weights may be used provided the ratios remain equivalent.
See *QA-SOP11188*, for the appropriate labeling and documentation of reagent and standard preparation.

1. Ultra pure oxygen gas (60 psi)

2. Phosphoric acid. Store at room temperature. See label for expiration date.

3. 1+1 Phosphoric acid (WC_TOC_1:1PA)

| | |
|---|---|
| Phosphoric acid (H3PO4) | 50 mL |
| Reagent water | 50 mL |

Take 50 mL of H3PO4 and add slowly while swirling to a 100-mL volumetric flask containing 50 mL reagent water. Store at room temperature. Prepare fresh every 6 months.

4. TOC stock calibration standard (sucrose containing 30% carbon) (WC_TOC_30%SUC), purchased. See label for expiration date. Store at room temperature.

5. TOC LCS standard, purchased (WC_TOC_SLCSCC). Certified reference material, ISO-17034 certified. See label for expiration date, and the certified concentration. Store at room temperature.

## Sample Cup Preparation

Sample cups must be conditioned prior to analysis. This is achieved by heating the cups to at least 900°C for a period of 5 minutes.

## Calibration

1. Working standards for calibration

Pipette a volume of the Sucrose calibration standard into the sample cups as follows:

| Working Std. (mg C) | Vol. Sucrose (µL) |
|---|---|
| 0.30 | 1.0 |
| 0.90 | 3.0 |
| 3.0 | 10.0 |
| 6.0 | 20.0 |

2. Continuing calibration verification standard (CCV)

This is a purchased standard, and the acceptable range is specified by the manufacturer.

## Procedure

1. Turn on oxygen to 60 psig.

Uncontrolled copy

2. Measure the carrier gas (oxygen) flow rate and adjust to 200 mL/min.

3. Power up instrument.

4. Program in a sequence file.

5. Run the calibration sequence as follows: 0.30, 0.90, 3.0, and 6.0 mg C (Performed monthly).

6. The instrument automatically calculates the R and list the calibration data.

7. Samples are analyzed along with the appropriate laboratory control standard and preparation blank. A check standard (CCV) and a continuing calibration blank (CCB) must be run at the beginning of each run and after every ten samples.

8. Add sufficient glass wool to each cup to cover the bottom surface.

9. Weigh samples into sample cups (up to 1000 mg). Add 1+1 H3PO4 drop wise until effervescence stops. Heat at 75°C for 15 minutes. Record the oven ID, time and temperature of this step in the log book.

**NOTE:** This procedure will convert inorganic carbonates and bicarbonates to carbon dioxide and eliminate it from the sample. The addition of H3PO4 and the heating to 75°C is not performed for samples requesting Total Carbon analysis.

10. Analyze the residue according to the instrument manufacturer's instructions for the remaining TOC result.

## Calculations

1. To determine mg/kg TOC or TC

   mg/kg = (Raw result in mg C) x (1000/weight in mg) x (1000)

2. To determine LOQ/MDL factors

$$Factor = \frac{Maximum\ sample\ aliquot\ weight\ (1000.mg)}{weight\ of\ sample\ (mg)}$$

3. To determine Total Inorganic Carbon (TIC)

   TIC = Total Carbon (TC) - Total Organic Carbon (TOC)

4. Relative Error

   % Relative Error = $[(x'_i - x_i) / x_i]*100$

   where:
   $x_i$ = True value for the calibrated standard
   $x'_i$ = Measured concentration of the calibration standard

## Statistical Information/Method Performance

1. The method detection limit (MDL) is determined annually by following the procedure outlined in *QA-SOP11892*.

2. The quality control acceptance windows are based off the manufacture data. The lab evaluates these windows per CRM received.

## Quality Assurance/Quality Control

Uncontrolled copy

1. A calibration must be performed every 30 days. The acceptable range for the calibration is R = 0.995 or greater. Calculate the relative error (%RE) of the lowpoint and midpoint calibration standard. The low point must be less than or equal to 50% and the mid point must be less than or equal to 10%. If this criteria is not met, the instrument must be recalibrated.

2. A batch must contain no more than 20 field samples.

3. A batch blank (MB) must be analyzed with every batch (not to exceed 20 samples). An acceptable result is < the limit of quantitation. If the MB does not meet this criterion, it must be rerun twice. If either of the two additional trials do not meet the acceptance criterion, all samples in the batch must be repeated.

4. A laboratory control standard (LCS) must be analyzed with every batch (not to exceed 20 field samples). For TOC this is a purchased standard and the acceptable range is specified by the manufacturer. The LCS should undergo the same steps as the samples. If the LCS does not meet the acceptable criterion, it must be repeated twice. If either of the two additional trials do not meet the acceptance criterion, all samples in the batch must be reanalyzed.

5. Based upon client requirements, a laboratory control standard duplicate (LCSD) may need prepared and analyzed under the same conditions as the LCS. The acceptance criterion for the LCSD is the same as that of the LCS. The relative percent difference between the LCS and the LCSD is calculated statistically.

6. Lloyd Kahn - one sample is analyzed in quadruplicate every batch. The acceptable relative percent difference is statistically determined. The duplicate relative percent differences must be tracked to continually monitor method performance.

7. 9060- A matrix spike (MS) and matrix spike duplicate (MSD)must be analyzed for every 20 samples. The sample is spiked with 3 ul of the Sucrose standard. The acceptance range is determined statistically. The spike recoveries must be tracked to continually monitor method performance.

8. A check standard (CCV) and blank (CCB) must be run after every ten injections (including blanks and standards). The acceptable range for the CCV determined by the manufacturer. An acceptable CCB result is < the limit of quantitation. If either, or both, of these injections do not meet the acceptance criterion, the unacceptable original must be repeated twice. If either of the two additional trials do not meet the acceptance criterion, all samples since the last compliant CCV/CCB must be reanalyzed.

9. A CCV and CCB shall be analyzed at the beginning and the end of each run. At any time when the instrument has been idle for a period of 4 hours or more, a CCV and CCB must be analyzed. If either of these parameters cannot meet specifications, the instrument must be recalibrated.

| *QA-SOP11892* | Determining Method Detection Limits and Limits of Quantitation |
| *QA-SOP11896* | Establishing Control Limits |

## Scope:

This procedure is applicable for the determination of total organic carbon, Dissolved Organic Carbon, or Total Inorganic Carbon in water and wastewaters by SM 5310 C or EPA 415.1.

Swabs can be accepted and analyzed for TOC as a special request by the client.

The current limit of quantitation (LOQ) and method detection limit (MDL) for this analysis can be found in the laboratory information management system (LIMS).

## Basic Principles:

The procedure outlined in this method pertains to the O.I. Model 1030 analyzer. This model uses the persulfate oxidation technique.

A sample aliquot of water or wastewater is injected into a reaction vessel at 100°C where metered amounts of phosphoric acid are added. The sample is purged with ultrapure nitrogen gas to remove inorganic carbon as carbon dioxide and any purgeable organic carbon (POC). Following the purging of the inorganic fraction, a metered amount of sodium persulfate is added to the reaction vessel, and the sample is heated. The persulfate oxidizes any organic carbon to carbon dioxide. Following the completion of the persulfate digestion, the carbon dioxide is carried to the IR detector by the nitrogen stream.

Samples for DOC are passed through a 0.45-µ membrane filter prior to analysis. TIC can be determined by calculating the difference between total carbon and TOC.

Clients can send swabs for the determination of TOC. These samples are reported as mg/swab. Multiply the concentration of TOC found in the extract by the swab extract volume.

## Reference Modifications:

Uncontrolled Copy

There are no procedural differences between EPA 415.1 and SM 5310 C.

Syringe filters are not rinsed prior to sample filtration. All Method Blanks and LCS samples are filtered in the laboratory to show that there is no interference (positive or negative) that impacts DOC analysis. MB are evaluated to <1/2RL and LCS are evaluated to method criteria, showing acceptability of filters used in the laboratory.

## Interferences:

This method is generally free of interferences when normal wastewater and water samples are analyzed. However, high concentrations of chloride can interfere and several other problems can arise from certain sample matrices. These are listed below.

1. Chloride can react with the persulfate, which can cause erroneously low TOC results. Samples high in chloride may require that extra persulfate be added and the reaction time extended. The chlorine gas that is produced is also damaging to the molecular sieve. For these reasons, samples must not be preserved with hydrochloric acid.

2. Samples with high levels of inorganic carbon may require extra acid and longer purge time to ensure all the carbonates and bicarbonates are removed from the sample. A smaller sample volume may also be used.

3. Samples with high levels of organic carbon may require that extra sodium persulfate be added and that the reaction time is extended to ensure that all the organic carbon is oxidized by the persulfate. A smaller sample volume may also be used. Spiking the sample with a known amount of carbon and calculating recovery can be used to verify the oxidation efficiency.

4. When sequentially analyzing samples, carryover may occur when a sample high in carbon is followed by a sample low in carbon. This will produce erroneously high results for low-level TOC samples. This is caused by adsorption of organic carbon on the Teflon™ tubes and overloading of the molecular sieve. If an excessively high-level sample is accidentally introduced into the system, it may be necessary to clean the digestion vessel with reagent water before analyzing any more samples. This is accomplished by cycling reagent water and the reagents through the system until TOC values drop to less than 1/2 the RL.

## Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Normal laboratory safety practices must be followed when performing this method. Extra care must be taken when handling the persulfate reagent (which is a strong oxidant) and unknown samples that could contain toxic or carcinogenic chemicals. Inspect all glassware before use. Discard or send for repair any glassware that is chipped, flawed, or broken.

## Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each technician performing these techniques must work with an experienced technician for a period of time until they can independently perform the procedure. Proficiency is measured through an Initial Demonstration of Capability (IDOC).

The IDOC consists of four replicates of the LCS. The mean of the replicates must fall within ± 15% of the true value and have a RSD <10%.

Uncontrolled Copy

Various options are available for a DOC and can include four LCS's that meet the method acceptance criteria, or analysis of one blind sample.

## Sample Collection, Preservation, and Handling:

All samples must be collected in glass containers and stored at 0°to 6°C not frozen.

TOC samples must be acidified with concentrated phosphoric acid or sulfuric acid to a pH <2. The holding time for these samples is 28 days.

DOC samples are field or lab filtered within 48 hours, and then acidified with concentrated phosphoric acid or sulfuric acid to a pH <2. The holding time for these samples is 28 days after preservation.

## Apparatus and Equipment

1. O.I. Corporation Model 1030 TOC analyzer

2. O.I. Corporation Model 1088 Rotary Autosampler

3. 2-stage gas regulator

4. Analytical balance capable of accurately weighing to 0.0001 g

5. Automatic pipettes

6. Syringe filters - 0.45 µm pore size

## Reagents and Standards

A. All chemicals used must be ACS reagent grade unless otherwise noted.
B. Different volumes or weights may be used provided the ratios remain equivalent.

C. Reagents and Standards
1. Ultra-pure nitrogen gas (30 psi)

2. (WC_TOC_SodPer) Oxidizing reagent - Sodium persulfate (Na2S2O8)
   a. Dissolve 100 ± 1 g of sodium persulfate in approximately 500 mL of reagent water in a 1000-mL volumetric flask.

   b. Dilute to volume with reagent water.

   c. Purge with nitrogen gas for 1 hour to release inorganic carbon present in reagent.

   d. This solution is stable for 6 months and is stored at room temperature in a plastic container.

3. (WC_TOC_5%Phos) Phosphoric acid (5% w/w)

   a. Add 59 mL of 85% H3PO4 to about 500 mL of reagent water in a 1000-mL volumetric flask.

   b. Mix thoroughly and dilute to volume with reagent water.

   c. This solution is stable for 6 months and is stored at room temperature in a plastic container.

4. (WC_TIC_QC) Total Inorganic Standard (500 mg/L)

   Sodium bicarbonate (NaHCO3) 0.1750 g ±0.0005 g

Uncontrolled Copy

Sodium carbonate (Na2CO3) 0.2209 g ±0.0005 g

a. Dissolve above reagents in a 100-mL volumetric flask containing about 50 mL of reagent water.

b. Dilute to volume with reagent water.

c. Prepare monthly. Do not acidify. Store in the flask at 0°to 6°C not frozen.

5. ISO 17034 Certified Reference Material (CRM): Purchased. See certificate of analysis for true value supplied by the vendor.

## Calibration:

1. (WC_TOC_CALSTD) TOC stock calibration standard (1000 mg C/L)

    a. This is a purchased standard, ISO 17034 certified.

2. (WC_TOC_QC_STD) TOC stock QC standard (500 mg C/L)

    Phosphoric acid, concentrated (H3PO4) 20 drops

    a. Dissolve 1.063 ± 0.005 g of KHP a 1000-mL volumetric flask containing about 500 mL of reagent water.

    b. Add concentrated phosphoric acid (H3PO4) to the 1000-mL volumetric flask until the pH is <2.

    c. Bring to volume with reagent water

    d. Prepare every 30 days. Store in an amber glass bottle at 0º to 6º C, not

3. Working standards for calibration and QC

Pipette a volume of TOC stock standard into the appropriate volumetric flask that contains reagent water and three drops of concentrated phosphoric acid. Dilute to volume with reagent water. Prepare daily, as needed, according to the following table:

| Volume Stock CAL Standard (mL) | Standard Concentration (mg/L) | Final Volume (mL) |
|---|---|---|
| 10 | 100 | 100 |
| 5 | 50 | 100 |
| 5 | 25 | 200 |
| 1 | 10 | 100 |
| 3.0 | 7.5 | 100 |
| 0.1 | 1.0 | 100 |
| | | |
| Volume Stock QC Standard (mL) | Standard Concentration (mg/L) | Final Volume (mL) |
| 0.4 | 1.0 - CCVL | 200 |
| 10.0 | 25 - LCSW / ICV / CCV (Mid) | 200 |
| 10.0 | 50 - CCV (High) | 100 |

4. Instrument Calibration

Uncontrolled copy

a. The instrument must be calibrated at least every 30 days, or whenever acceptable check standards can no longer be obtained. Prepare a calibration sequence as follows:

Clean Up
Rinse
QC Blank
STD - 0mg/L
1.0 mg/L CAL
2.0 mg/L CAL
15 mg/L CAL
20 mg/L CAL
50 mg/L CAL
100 mg/L CAL
ICB
ICV

b. A calibration of 6 standards and a reagent water blank must be run monthly as the instrument calibration. The correlation coefficient of the curve must be ≥0.995.

c. Calibration is linear. The % Relative Error for the 1.0 mg/L and the 25 mg/L standard must be less than 15%.

d. Immediately after a calibration run, analyze the ICB. The ICB is reagent water brought to pH of <2 with phosphoric acid. The ICB must be < the MDL. If the result is higher, a new calibration must be prepared with lower concentrations.

e. After the ICB, analyze the ICV. The ICV must be within 15% of the true value.

**Procedure:**

1. General (more detailed instructions for each step can be found in the instrument manual)

2. Start up the instrument in the following manner:

a. Turn on the power switch located at the back of the instrument. The system loads the startup screen and User Login dialog box. Turn on the nitrogen gas flow.

b. Prime the syringe and all reagents by following the manufacturer's instructions located in the instrument manual.

3. Load the active sequence. The daily sequence must include:

100 mg/L CAL standard
CCB
CCV (High) - 50 mg/L
[bracket of 10 samples]
CCB
CCV (Mid) - 25 mg/L
[bracket of 10 samples]
CCB
CCVL - 1.0 mg/L

4. Each sample is injected in duplicate. The RPD of the duplicate injections must be< 10% when the concentrations are greater than five times the LOQ.

5. For DOC, the samples and all quality control samples are filtered through a 0.45 micron filter. There is no subtraction of the filter blank in the calculation for DOC.

6. For swab samples, add 20 to 50 mL of reagent water to the container holding the swab. Record the amount of reagent water added. Shake the sample for 5 minutes. Filter the extract through a 0.45 micron filter as described abouve in #5.

7. Load samples onto the autosampler trays.

Uncontrolled copy

8. Press Start.

## Calculations:

The TOC result (in mg/L) is performed as below using the average of the two injections:

*raw result (mg/L from instrument) x dilution factor = final TOC (mg/L)*

For swab samples report the TOC as mg per swab by the following:
*TOC, mg per swab = T x L*

***Where:***
T = the concentration of TOC found in the extract in mg/L.
L = swab extract volume (L) = (mL used for the extract/1000).

## Statistical Information/ Method Performance:

1. The method detection limit (MDL) is determined annually by following the procedure outlined in *QA-SOP11892*. The 7 replicates must be analyzed over a period of at least 3 days.

2. The quality control acceptance windows are generated annually by following the procedure outlined in *QA-SOP11896*.

## Quality Assurance/Quality Control:

A. Calibration QC Requirements

1. See the Calibration section for frequency of calibration, acceptance criteria, and corrective actions.

B. Analytical Batch QC Requirements

1. The Continuing Calibration Verification (CCV) alternates between high, mid, and low CCVs.

2. The Continuing Calibration Blank (CCB) and Method Blank (MB) is reagent water brought to a pH of <2 with phosphoric acid.

3. A batch contains no more than 20 samples and the appropriate QC. Each batch must have a Method Blank (MB), a Laboratory Control Standard (LCS), a sample duplicate (DU) for each 10 samples in the batch, a matrix spike (MS) for each 10 samples in the batch.

4. See Table: QC Frequency and Acceptance Criteria. If any of the QC does not meet acceptance criterion, see T-WC-WI11652 for handling outliers and the appropriate corrective action that must be taken.

5. Sample results may not exceed the concentration of the highest standard. If a sample result falls above this value, the sample must be diluted with reagent water and run again.
