# Executive Summary

This Uniform Federal Policy Quality Assurance Project Plan (UFP-QAPP) describes the technical approach and data quality objectives (DQOs) for conducting field investigations to support the Phase 2 Remedial Investigation (RI) at the New York Ordnance Works (NYOW) Formerly Used Defense Site (FUDS) (Property No. C02NY0290), New York State Department of Environmental Conservation (NYSDEC) Site Number 734003, located in Baldwinsville, New York. Environmental Assessment Services, LLC. (EAS) and WSP USA Solutions, Inc. (WSP) joint venture (JV) (herein known as the EAS WSP JV) has prepared this document under United States Army Corps of Engineers (USACE) New England District (CENAE), Contract No. W912WJ23D0007, Task Order W912WJ23F0130.

This document has been prepared in general accordance with the UFP-QAPP guidance manual (Intergovernmental Data Quality Task Force [IDQTF], 2005), optimized UFP-QAPP worksheets manual (IDQTF, 2012), and U.S. Environmental Protection Agency (EPA) QA/G4, Guidance for the Data Quality Objective Process (EPA, 2006). Project-specific DQOs are designed to ensure data of adequate quality are collected to support project decisions. DQOs have been developed in consensus with the project team and in accordance with the guidance documents (IDQTF, 2005; IDQTF, 2012; EPA, 2006/2012).

A Phase 1 RI was initiated and completed in 2021 at the former NYOW site. The Phase 1 RI investigated four (4) areas of concern (AOCs); AOC 1 – Former Ammonium Picrate Building Area; AOC 3 – Former Landfill Area; AOC 4 – Former Bunker Area; and AOC 5 – Former Power Plant (USACE, 2021, 2022). During the Phase 1 RI, soil and groundwater samples were collected in order to investigate possible releases associated with Department of Defense (DoD)-related activities at each AOC. In addition to performing soil and groundwater sampling at the specific AOCs, background soil and groundwater samples were collected in order to compare contaminants of potential concern (COPCs) to site-specific background concentrations. The results of the Phase 1 RI were documented in the *Remedial Investigation Phase 1 Field Report – AOC 4 and AOC 5* (USACE, 2021) and *Remedial Investigation Phase 1 Field Report – AOC 1, AOC 3, AOC 4 ISM, and Background* (USACE, 2022). Using the Phase 1 RI data, risk screening was performed, and data gaps were identified in the *Phase 1 Risk Screening and Data Gaps Analysis Report* (USACE, 2023a). The following COPCs by AOC were identified from the risk screening:

- AOC 1 – 2,4-dinitrochlorobenzene (2,4-DNCB), 2,4-dinitrophenol (2,4-DNP), picric acid, and metals.
- AOC 3 – volatile organic compounds (VOCs), semi-VOCs (SVOCs), polyaromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs) Aroclors, picric acid, and metals.
- AOC 4 – 2,4-DNCB, 2,4-DNP, and picric acid.
- AOC 5 – PAHs, PCBs, and metals.

The *Phase 1 Risk Screening and Data Gaps Analysis Report* (USACE, 2023a) is provided as **Appendix A** to this UFP-QAPP.

The AOC specific data gaps that were identified within the *Phase 1 Risk Screening and Data Gaps Analysis Report* (USACE, 2023a) will be used to guide the Phase 2 RI. In general, additional investigations into the nature and extent of contamination in soil and groundwater, along with investigations into potential impacts to additional media (i.e., surface water, porewater, and sediment), and an evaluation on site-hydrogeological conditions (e.g., groundwater flow, hydraulic conductivity) is needed to complete the RI phase.

Therefore, the project DQOs described within this UFP-QAPP include:

- Fully delineate the nature and extent of COPCs in soil, groundwater, surface water, porewater, and sediment.
- Update the conceptual site model (CSM), including contaminant migration pathways, fate and transport, geologic and hydrogeologic site conditions, and exposure pathways.

- Define and establish background concentrations for the appropriate media (e.g., soil, groundwater, surface water, porewater, and sediment).
- Conduct a quantitative baseline human health risk assessment (HHRA) and a screening level ecological risk assessment (SLERA), which will also incorporate site-specific Phase 1 and Phase 2 data and refinements in a refined SLERA (RLSERA). Note, throughout this UFP-QAPP, the term “SLERA” will be generally used to describe the combined assessment unless a distinction between the two components is necessary.

In general, the objectives will be accomplished by conducting additional sampling investigations geared to address AOC-specific data gaps, as detailed within this UFP-QAPP, in various media (e.g., soil, groundwater, surface water, porewater, and sediment). These AOC-specific DQOs are based on data gaps identified within the *Phase 1 Risk Screening and Data Gaps Analysis Report* (USACE, 2023a) and are summarized throughout this document. This UFP-QAPP discusses the overall approach and describes the means and methods of data collection. Additional details regarding the methods and approach to the HHRA and SLERA are provided in **Appendix B** and **Appendix C**, respectively. If additional data are needed to fulfill data gaps after the completion of collection of Phase 2 data, then additional investigations would be proposed as an addendum to this UFP-QAPP.

# Worksheet #6 – Project Communication Pathways

| Communication Drivers | Organization | Name | Contact Information | Procedure (Timing, Pathways, Documentation, etc.) |
|---|---|---|---|---|
| Project scope changes and approval of UFP-QAPP | USACE CENAE | Erin Bradley | 978.318.8195<br>erin.e.bradley@usace.army.mil | Contracting Officer (KO). Provides administrative direction to JV Contracts Manager and project team; authorizes real-time changes to plan and can stop work, if needed. The EAS WSP JV PM and USACE CENAE PM will work together to identify and agree to changes of scope and will communicate these changes to Ms. Bradley. Once all parties agree, the project can proceed. The project will not proceed until the necessary approvals of this UFP-QAPP have been received. If there are significant changes (e.g., laboratory limits and methods, and the laboratory itself, etc.), then a UFP-QAPP Addendum may be needed and approved. During the preparation of the UFP-QAPP, any changes will be documented in comment response matrices. If there are changes during field work (e.g., depths, drilling methods, etc.), those changes must be approved prior to initiating field activities. The changes will be documented on field forms and within the Phase 2 Field Report as a separate section titled “Deviations from UFP-QAPP”. Changes and/or clarifications related to the QAPP that do not rise to the level of a scope change will also be discussed with and agreed upon by the PDT prior to implementation and will be documented in the Field Change Form. The Field Change Form is provided with the Project-Specific Quality Management Plan (QMP). |
| Primary Point of Contact (POC) | USACE CENAE | Amanda Martin | 978.318.8152<br>amanda.k.martin@usace.army.mil | Primary POC for the EAS WSP JV. Coordinates management with USACE KO. Can delegate communication to other internal or external points of contact. Technical and scheduling scope modification items to be discussed with USACE POC for clarification and approved by KO as necessary. |
| Manage project tasks | EAS WSP JV | Russ McCormick, P.G.<br>Project Manager/QCM | 978.460.9603<br>rmccormick@easbio.com | Inform appropriate project staff (field and non-field) of tasks to complete and required completion date. Communicate potential scope issues with project team, task progress, and resources/information required to complete tasks. |

| Communication Drivers | Organization | Name | Contact Information | Procedure (Timing, Pathways, Documentation, etc.) |
|---|---|---|---|---|
| Delays/changes to field work and daily field reports | EAS WSP JV | Russ McCormick, P.G. Project Manager/QCM | 978.460.9603 mccormick@easbio.com | Project staff will inform the project manager of daily field progress and delays or changes to fieldwork. The project manager will inform the project team of field work progress. |
| Review and approve release of geologic data and upload to database | EAS WSP JV | Michael Shadle Project Chemist/Project Database Manager | 804.934.1792 michael.shadle@wsp.com | The EAS WSP JV database manager will coordinate with a KGS scientist to fill and upload FUDSChem locations/coordinates/elevations, boring logs, lithology, well construction information, water levels. The EAS WSP JV QCM will review submittals for accuracy prior to uploading. If Synectic's is involved with the uploading of all data, the EAS WSP JV Project Chemist will still be responsible as the final reviewer and approver of all data uploaded into the database. |
| Review and approve release of analytical data and upload to database | EAS WSP JV | Michael Shadle Project Chemist | 804.934.1792 michael.shadle@wsp.com | USACE CENAE will review data deliverables received from the laboratory for completeness and accuracy prior to uploading to database. Communication pathways will be between the USACE CENAE and the EAS WSP JV project chemist. If Synectic's is involved with the uploading of all data, the EAS WSP JV Project Chemist will still be responsible as the final reviewer and approver of all data uploaded into the database. |
| Reporting of laboratory data quality issues | EAS WSP JV | Michael Shadle Project Chemist | 804.934.1792 michael.shadle@wsp.com | The EAS WSP JV project chemist will communicate issues related to data quality upon receipt of samples or during analyses to the EAS WSP JV project manager. |
| Distribution of analytical data | EAS WSP JV | Michael Shadle Project Chemist | 804.934.1792 michael.shadle@wsp.com | The EAS WSP JV project chemist will receive all deliverables from the subcontracted laboratory and distribute data to the appropriate parties. Validated data will be made available in accordance with the timeframes specified unless these periods are extended by mutual agreement among the project team managers. If Synectic's is involved with the uploading of all data, the EAS WSP JV Project Chemist will still be responsible as the final reviewer and approver of all data uploaded into the database. |
| Regulatory agency interface | USACE CENAE | Amanda Martin | 978.318.8152 amanda.k.martin@usace.army.mil | Communicates with NYSDEC/NYSDOH; provides direction to the EAS WSP JV project manager and project team. |
| Site access, work coordination, health and safety | USACE CENAE | Amanda Martin | 978.318.8152 amanda.k.martin@usace.army.mil | Coordinates field activities with project team. Reviews technical deliverables. Reviews/audits/ assures compliance with health and safety procedures. |

| Communication Drivers | Organization | Name | Contact Information | Procedure (Timing, Pathways, Documentation, etc.) |
|---|---|---|---|---|
| | EAS WSP JV | Russ McCormick, P.G. Project Manager/QCM | 978.460.9603<br>rmccormick@easbio.com | Coordinates field activities with project team. Reviews technical deliverables. Reviews/audits/ assures compliance with health and safety procedures. |
| | | George Lukert, P.G./Technical Lead | 971.409.9302<br>george.lukert@wsp.com | |
| | | Erik Reinhart / FTL | 315.374.1773<br>erik.reinhart@wsp.com | |
| Field progress reports | EAS WSP JV | Erik Reinhart / FTL | 315.374.1773<br>erik.reinhart@wsp.com | Daily Quality Control Reports (DQCRs) will be prepared by the FTL and provided to the senior technical lead and EAS WSP JV PM for review and issuance to the project team. DQCRs will be provided daily via email and attached as an Appendix to the Phase 2 Field Report. Daily summary emails will be distributed to the project team by the EAS WSP JV PM. |
| | | George Lukert, P.G / Technical Lead | 971.409.9302<br>george.lukert@wsp.com | |
| | | Russ McCormick, P.G., PM/ QCM | 978.460.9603<br>rmccormick@easbio.com | |
| Stop work authorization and initiation of corrective actions | Project Team | Project Team | All team members | All team members are authorized to stop work and initiate corrective actions should there be a reason to do so. Whoever stops work or initiates corrective actions will inform all other interested parties immediately. The project team will be notified of any stop work order that creates an imminent and substantial endangerment to the health and welfare of personnel on site or in the surrounding area or to the environment. |
| Data review and interpretation; risk assessment | EAS WSP JV | Russ McCormick, P.G. PM primary POC | 978.460.9603<br>rmccormick@easbio.com | Responds to technical or field questions; reviews data and technical deliverables; provides verbal or written comments to the project manager on technical deliverables; develops and calibrates flow and geotechnical/geochemical models; performs model simulations. |

# Worksheet #9 – Project Planning Session Summary

A scoping meeting was held to review and discuss the technical approach for the project and the content of the UFP-QAPP. The meeting was held on 20 November 2023.

The project planning session/project scoping meeting included identification of the participants, their organizations, roles, and titles, a review of project goals, field activities and field methods, sampling locations, analyses to be performed on multi-media sampling.

**Location:** Teams Meeting.

**Meeting Date:** Monday, 20 November 2023.

**Start Time / End Time:** 1300 / 1500 EST.

**Attendees:**

- Amanda Martin (USACE CENAE – PM)
- Gina Romano (USACE CENAE – Geologist)
- Constance Lapite (USACE CENAE – Chemist)
- Grace Greenberg (USACE CENAE – HHRA)
- Cheryl Montgomery (USACE ERDC – ERA)
- Michelle Bourne (USACE ERDC – ERA)
- Cliff Opdyke (USACE CENAE – HHRA)
- Russ McCormick (EAS WSP JV – PM)
- George Lukert (EAS WSP JV – Senior Geologist/Technical Lead)
- Pamela Rodgers (EAS WSP JV – HHRA)
- Norman Richardson (EAS WSP JV -ERA)
- Laurie Ekes (KGS – Chemist/Database Manager)

During the 20 November 2023 scoping session, the background on each AOC, along with data gaps that were identified after the Phase 1 RI, along with proposed Phase 2 sampling locations were discussed with the USACE Project Delivery Team (PDT). In general, additional virtual meetings, held on a monthly basis with the same team members listed above, were needed to further discuss PDT recommendations. The following is a summary of key discussion points made per AOC:

**AOC 1:**

It was determined that three (3) soil borings were needed to surround each ammonium picrate building (APB). The PDT recommended that these would be needed for the risk assessment. The PDT also agreed to placing a monitoring well immediately downgradient/at the base of each APB (six (6) total). These wells will represent the source area. A monitoring well should also be placed downgradient of a source well. The PDT recommended that the wetland sample locations be placed using a discrete (statistically derived) approach. The EAS WSP JV agreed. Therefore, a summary of the proposed sampling scope of work (SOW) for AOC 1 is as follows:

- Twenty-two (22) soil borings.
- Twelve (12) surface soil (saturated [i.e., hydric]) only sample locations (within the wetlands).
- Ten (10) monitoring wells.

**AOC 3:**

It was determined that ten (10) additional soil boring only locations should be placed within a decision unit (DU) that surrounds the parking lot and landfill extents. The ten (10) discrete additional borings would be placed using a statistically derived approach. The EAS WSP JV agreed to this approach. The use of fertilizers at the golf course was also discussed and should be considered when evaluating certain metals concentrations at this site. Therefore, a summary of the proposed sampling SOW for AOC 3 is as follows:

- Seven (7) co-located soil borings/monitoring wells;
- Ten (10) soil only borings;
- Eight (8) co-located surface water, porewater, and sediment locations.

**AOC 4:**

A total of sixty (60) discrete surface soil samples (or five per bunker) are proposed within this UFP-QAPP. The purpose of these samples is to confirm the non-detect results for picric acid, 2,4- DCNB, and 2,4-DNP that were identified during the Phase 1 RI incremental sampling methodology (ISM) that was performed in 2021. 2,4-DNCB, 2,4-DNP and picric acid in ISM surface soil had low bias attributable to low surrogate recoveries for multiple samples and the uniformly low bias of results reported as non-detect was identified as a data gap (USACE, 2022). A discussion ensued regarding why surface soil samples were not collected at discrete locations along the drainage ditches or at the base of the floor drainage outlets located at outside each bunker. The PDT decided that additional surface soil samples are not needed in the drainage ditches because the DUs are intended to characterize surface conditions around the bunkers, including the surface of the swales. Additionally, AOC 4 will be treated as one exposure unit (EU) in the risk assessment, and therefore, there will be ample surface soil sample data that will be considered representative.

The NYSDEC maintains the drains exiting the bunkers and the roadside ditch along igloo road. NYSDEC staff at Three Rivers had been planning on performing some modifications to the drains that exit the bunkers. They were planning on cleaning drains and re-connecting them to the road-side ditches, which would require excavation. They were also considering placing stone over the apron area and installing culverts across the roadside ditches in certain locations. This was to prevent icing and improve vehicle access to the bunkers.

**AOC 5:**

As a result of the 18 December 2023 PDT call it was decided to group the following subareas into the four (4) DUs:

- Boiler House and Electric Substation
- Coal Storage Area (CSA)
- Drainage Ditch, and Coal Aggregate Bins (CABs)
- Possible Dump Area.

This results in eight (8) borings per DU or 32 soil borings for AOC 5. These 32 discrete soil borings are to be placed using a statistically derived approach. The hydric soil locations were to be placed in the drainage ditch to the west of AOC 5 and will be placed at discrete locations. Therefore, a summary of the proposed sampling SOW for AOC 5 is as follows:

- Thirty-two (32) soil boring only locations.
- Three (3) surface soil (saturated [i.e., hydric]) only sample locations (within the wetlands).
- Eleven (11) monitoring wells.

Additionally, the PDT recommended PCB Aroclors analysis be removed from groundwater sampling since it was not detected in soil during the Phase 1 RI (USACE, 2023a), and that there was no reason to believe there was a release (this decision was later reversed. See section 10.2.4 for additional discussion).

The decision to collect coal microscopy data to develop a line of evidence between the presence/absence of coal and the presence/absence of PAHs and metals was made in July 2025 based on the data gap recommendation made in the *Phase 1 Risk Screening and Data Gaps Analysis Report* (USACE, 2023a, **Appendix A**). The original intent was to exclude samples with heavy coal presence because the PAHs are assumed to be related to the presence of coal particulates and not from the leaching of coal into the surrounding soils. However, based on further discussion between USACE and the Environmental and Munitions Center of Expertise (EMCX), the PDT was informed that if there are Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) related contaminants identified in an exposure medium (soil intermingled with coal particulates in AOC 5) that pose an unacceptable risk, then the media would have to be remediated regardless of the presence of coal. Therefore, soil samples from AOC 5 will be collected for coal microscopy but the data (relative presence of coal) will be used to support the conceptual site model (CSM) in terms of nature and extent (source) and fate and transport related evaluations. The meeting minutes between the USACE and EMCX are attached as part of **Appendix A**.

**Background:**

The PDT recommended the background surface water/porewater/sediment sample locations should be placed near where the proposed background soil sample locations which are located west/upstream of AOC 3. The PDT recommended placing the samples in streams that are similar in size and type (i.e., substrate, flow, banks, vegetative in nature). The EAS WSP JV agreed. The PDT were ok with the presented background hydric soil locations pending rights-of-entry (ROE) are obtained prior to sampling. Therefore, a summary of the proposed sampling SOW for the Background locations is as follows:

- Eight (8) co-located surface water, porewater, and sediment locations.
- Eight (8) surface soil (saturated [i.e., hydric]) only sample locations (within wetlands).
- Six (6) monitoring wells.

The background surface water, porewater, and sediment sampling will initially be limited to PAHs, and target analyte list (TAL) metals/mercury. If review of the AOC 3 surface water, porewater, and sediment sampling results indicate the need to evaluate additional parameters upstream of AOC 3, then additional analysis will be considered during the second round of sampling at the background locations.

This page was intentionally left blank.

# Worksheet #10 – Conceptual Site Model

As defined in Engineer Manual 200-1-12 - Environmental Quality, Conceptual Site Models, a CSM describes sources of possible DoD-impacts, as well as complete, potentially complete, or incomplete human and ecological exposure pathways; current, determined, or reasonably anticipated future use of property; and human and ecological potential receptors (USACE, 2023b). A CSM is an iterative planning and communication tool that provides a structure to summarize and display information and to identify additional information needed to develop technically sound decisions.

This worksheet provides the current CSM for the NYOW project and was primarily developed based on the Phase 1 RI (2023a). The below sections describe the NYOW location and current use, history, previous investigations, physical characteristics, constituent fate and transport, and potential receptors and exposure pathways.

## 10.1 Former Facility Location and Current Use

As shown on **Figure 10-1**, the former NYOW is in Onondaga County, New York, near the Finger Lakes, about 1 mile northeast of the Village of Baldwinsville and approximately 13 miles north of Syracuse, New York. Portions of the Site are currently owned by the Radisson Community, the State of New York, and private owners. For a description of current land use per AOC, please refer to subsections 10.2.1 to 10.2.4.

## 10.2 Site History/Areas of Concern

Prior to construction of the NYOW facility, the site was primarily agricultural and forested (Army Geospatial Center [AGC], 2019). In 1942, the site was acquired from private owners in various parcels to establish a facility for the manufacture of ammonium picrate during World War II. The facility was designed and built by Lummus Company and included 146 structures. Construction began on 06 April 1942 and was completed in May 1943. The site was operated by National Aniline Defense Corporation, a Division of Allied Chemical and Dye Corporation under the supervision of the Chief of Ordnance of the War Department (USACE, 1985).

Operations began on 22 January 1942 and were ceased on 15 March 1944 (USACE, 1981). The facility was designed to produce 60,000 pounds of ammonium picrate per day, seven (7) days a week. Ammonium picrate is a stable, high explosive compound used in the production of armor piercing shells. The plant included an ammonium picrate area, acid area, and magazine storage/bunker area (**Figure 10-2**) (Reconstruction Finance Corporation, undated). Historical site features are shown on **Figures 10-3** through **10-6**. The facility encompassed approximately 2,100 acres of the 6,795-acre property; the remainder was farmland. The property was declared surplus on 30 August 1945 (USACE, 1981).

On 23 January 1946, the 6,795-acre property was transferred to the custody of the Reconstruction Finance Corporation (USACE, 1991). Reconstruction Finance Corporation was a predecessor to the General Services Administration (GSA). Subsequently, 4,495 acres in the northern and western parts of the Site were classified as farmland and assigned to the Farm Credit Administration for disposal. By 1947, all tracts of land designated as farmland had been sold, including 2,600 acres which ultimately became the Three Rivers State Wildlife Management Area (WMA) and 1,895 acres were subdivided among 98 individual private owners (USACE, 2006) (**Figure 10-7**).

The remaining 2,300 acres were classified as industrial property. In 1948 and 1950, 500 acres of the industrial property were sold to Fosham Corporation, a merger of a rail company (L.B. Foster) and Hamilton Corporation of Cincinnati. A later purchase by Fosham (approximately 1,600 acres) was identified in the deed as contaminated; the deed required the purchaser to decontaminate the property and to provide proof of decontamination to the government. Fosham Corporation notified the GSA in October 1950 by letter that “all decontamination work necessary under the terms of this agreement has been performed by this company and, in particular, the drying houses and the lower portion of the ramps in each AP line have been burned.” A letter dated 14 December 1950 from the New York Regional Office of GSA noted that the premises were examined by a representative of the Ordnance Ammunition Center, U.S. Army Joliet, Illinois on 24 November 1950 and “no evidence of contamination was found” (USACE, 1981).

On 10 July 1952, the Fosham Corporation conveyed the title to the First National City Bank. On 22 October 1968, the First National City Bank conveyed the title to the 1001 East Genesee Corporation of Syracuse New York. On 09 June 1969, the 1001 East Genesee Corporation sold the 2,300-acres representing the former Ammonium Picrate Area to the New York State Urban Development Corporation (NYSUDC); this area is now known as the Radisson Community (**Figure 10-7**). There is no recreational use category; therefore, golf courses and recreational use land are shown as commercial land use.

As described and detailed within this UFP-QAPP, there are four AOCs (AOC 1 – Ammonium Picrate Area; AOC 3 – Former Landfill Area; AOC 4- Bunker Area; and AOC 5 – Former Power Plant Area). Prior to the Phase 1 RI, AOCs 1, 3, and 4, have been previously investigated. The following investigations by AOC were identified and the results summarized in the Phase 1 RI:

- AOC 1 – Dame & Moore (D&M) (1981) Site Investigation, Metcalf & Eddy, Inc. (M&E) (1990) Preliminary Impact Evaluation.
- AOC 3 – D&M (1981) Site Investigation, M&E (1990) Preliminary Impact Evaluation, and Alion (2008) Final Site Inspection.
- AOC 4 – M&E (1990) Preliminary Impact Evaluation and NYSDEC (1988-1989) Site Characterization, NYSDEC (1993) Operation and Maintenance Plan for the Three Rivers Pesticide Storage Site, NYSDEC (1994) Bunker Reclassification, and NYSDEC (1998) Long-Term Monitoring Sampling.

However, these data will be excluded from risk assessments (primarily due to the age of the data, and updated laboratory methods/standards) and therefore will not be discussed in this UFP-QAPP. The historical investigations that have been performed can be reviewed in the Phase 1 *UFP-QAPP* (USACE, 2020). The Phase 1 RI which was conducted in 2021 will be considered for the risk assessment and therefore a summary of those investigation results are included below. The Phase 1 RI project action limits (PALs) used for the Phase 1 RI data are detailed in **Exhibit 10-1** below:

**Exhibit 10-1 – Phase 1 RI Project PALs**

| Standards/Guidance Values | Media Evaluated |
|---|---|
| EPA Regional Screening Levels (RSLs) – Residential Soil, Industrial Soil, and Tapwater, dated November 2022 | Groundwater<br>Soil |
| EPA Ecological Soil Screening Levels (Eco-SSLs), Interim Final, dated February 2005 through April 2008 | Soil |
| Region III Biological Technical Assistance Group (BTAG) Freshwater Screening Values, 2006 | Tank Water |

Note, there was an additional AOC, AOC 2 - Former Acid Area, identified but this area was privately owned after DoD usage, namely Fosham Corporation, First National City Bank, and the 1001 East Genesee Corporation and the title transfer document does not obligate the Government to conduct site restoration. Due to these circumstances, the five (5) acid tanks in AOC 1 and AOC 2 were not eligible for demolition and removal under DERP-FUDS. Per Section 3-1.5.3.10 Restoration Already Initiated of Regulation No. 200-3-1 Environmental Quality - FUDS Program Policy dated 10 May 2004 (FUDS ER-200-3-1), if a Component has already initiated environmental restoration activities, then the "Component" (the acid tanks) is ineligible. Additionally, in accordance with FUDS ER 200-3-1 projects where a hazard is a result of neglect by an owner/grantee after DoD use (regardless of whether the deed or disposal document required the owner/grantee to maintain the property improvements in accordance with FUDS ER-200-3-1) are ineligible under FUDS. Subsequently residual impacts from the acid tanks are also not FUDS-eligible. Potential concerns at AOC 2 stemmed from the two (2) acid tanks and the former buildings that were removed and remediated post-DoD use. The Program Policy expressly provides that properties where restoration has already been initiated are ineligible under the FUDS Program. At AOC 2 a significant amount of work has been performed after the property was transferred out of DoD ownership. This work included the remediation of the two (2) acid tanks involving the removal of debris and corrosive water, off-site disposal of water, and the installation of limestone and drainage holes in the tanks. Subsequently the Acid Tank Area infrastructure including all the buildings, acid and water tanks, railroad tracks, scrubbers, silo, storage

areas, loading platforms, change house, coal hopper and associated foundations were demolished and disposed off-site.

Based on the information regarding the work performed at this site and several site inspections, it is apparent that restoration has been initiated at AOC 2. The USACE CENAE Office of Counsel has been consulted and they determined that AOC 2 does not meet the criteria for property eligibility under the FUDS Program.

Subsequently, residual impacts from the acid tanks located at AOC 1, the Former Ammonium Picrate Area, are also not FUDS-eligible, and this portion of AOC 1 will not be addressed.

### 10.2.1 AOC 1 – Ammonium Picrate Area

The Former Ammonium Picrate Area is located north of Willett Parkway and Town Center Road E, and west of N Entry Road (**Figure 10-3**). Note, the former locations of the change houses are located west of the APBs. The former location of Change House #35 and #36 are now in a mostly developed area off Sumac Drive and Drumlin Heights Drive, respectively (**Figure 10-3**). The former Change House #37 is now a forested area. The current land use for this AOC is housing and undeveloped land.

This area was used to manufacture ammonium picrate and included six (6) 13,500 square foot ($ft^2$) manufacturing buildings (Numbered 17 through 22), six (6) 10,676 $ft^2$ dryer houses (Numbered 26 through 31), three (3) aboveground 12-foot (ft) diameter by 12-ft-high brick liquid storage tanks (#1 through #3), and a 4,612 $ft^2$ laboratory building (Reconstruction Finance Corporation, undated). Ammonium picrate is produced by mixing picric acid and ammonia (Alion, 2008). Picric acid is formed from DNCB (substituted for phenol), sulfuric acid, and nitric acid (Olsen and Goldstein, 1924). Aerial photographic analysis (AGC, 2019) also shows an open storage area located to the northeast of the main production area, and a borrow area to the west (**Figure 10-3**). Aerial photographs also show later backfilling post- DoD use, of a former borrow pit.

The NYSUDC has developed the Former Ammonium Picrate Area (AOC 1) into the residential/light industrial community now known as the Radisson Community. Most of the Ammonium Picrate Area structures have been demolished, but some structures remain including the ramps to the Ammonia Picrate “bunkers”, the “bunkers” themselves and assorted foundations. These remaining structures are deteriorating and do not appear to be maintained.

**Phase 1 RI (2021)**

In 2021, a Phase 1 RI was initiated by USACE to investigate the nature and extent of potential DoD-related contamination in soil and groundwater. A total of 17 surface and 22 subsurface soil samples were collected throughout AOC 1 (**Figure 10-3**). Sample locations were biased towards potential source areas. Due to unexpected site conditions encountered (e.g., high angle slopes, thick vegetation) however, at most locations surrounding the APBs, only surface soil (0-1 ft [below ground surface [bgs]) samples were collected. Soil samples were analyzed for target analyte list (TAL) metals, DNCB, 2,4-DNP, and picric acid; a subset of samples were selected for total organic carbon (TOC), grain size distribution (including hydrometer analysis), and cation exchange capacity (CEC).

In addition to soil sampling, ten (10) groundwater samples were collected from 1-inch temporary wells, and most of the wells were focused at the dryer houses (**Figure 10-3**). Groundwater samples were analyzed for TAL metals (field-filtered), DNCB and 2,4-DNP, and picric acid.

Detected constituents within AOC 1 soil included picric acid and 23 metals. Maximum detected concentrations that exceeded Phase 1 RI PALs included: aluminum, antimony, arsenic, cadmium, cobalt, copper, iron, lead, manganese, mercury, picric acid, selenium, thallium, vanadium, and zinc.

Detected constituents within AOC 1 groundwater included 18 metals. Maximum detected concentrations that exceeded Phase 1 RI PALs included: antimony, arsenic, barium, cobalt, iron, manganese, and sodium.

Following completion of the Phase 1 RI field effort, the data were compiled, and a risk screening and data gap analysis was performed and documented in the *Phase 1 Risk Screening and Data Gap Analysis Report* (refer to **Appendix A**). After conducting the risk screening, the following COPCs and contaminants of potential ecological concern (COPEC) were identified in **Exhibit 10-2** below:

## Exhibit 10-2 – Phase 1 RI (2021) AOC 1 COPC/COPECs Summary

| AOC 1 | | | | |
|---|---|---|---|---|
| COPC/COPECs | Groundwater | | Soil | |
| | COPC | Rationale for Inclusion | COPC/ COPEC | Rationale for Inclusion |
| **SVOCs** | | | | |
| 2,4-DNCB | X | ND & LOQ> HA SL | X | ND & LOQ> HS, E SL |
| 2,4-DNP | X | ND & LOQ> HA SL | X | ND & LOQ> HS, E SL |
| **Explosives** | | | | |
| Picric acid | -- | -- | X | > E SL |
| **Metals** | | | | |
| Aluminum | -- | -- | X | >BTV and H SL |
| Antimony | -- | -- | X | >BTV and E SL |
| Arsenic | X | >BTV and H SL | X | >BTV and H, E SL |
| Barium | X | >BTV and H SL | X | >BTV and E SL |

H = based on human health.
HA = all LOQs > human health screening level.
HS = some LOQs > human health screening level.
LOD = limit of detection.
LOQ = limit of quantitation.
ND = non-detected result, typically reported at the LOD.
SL = Screening level.
X = Yes.

The *Phase 1 Risk Screening and Data Gap Analysis Report* (refer to **Appendix A**) noted that subsurface soils were not collected from any APB and groundwater was not collected from the vicinity of 5 of the 6 APBs. The report concluded that potential areas of release were not adequately characterized to make the determination of whether they are source areas. Therefore, additional sampling was recommended to verify Phase 1 results, adequately delineate the source areas and determine whether APBs are source areas and to characterize risks.

### 10.2.2 AOC 3 – Former Landfill Area

The Former Landfill Area is located under and to the north of the current Radisson Golf Course club house parking lot (**Figure 10-4**). This area was used for the disposal of household and office trash, paint cans, stainless-steel "spiders" (e.g., equipment used to mix the ammonium picrate), and other potential manufacturing items (D&M, 1981). Based on historical documentation there were two (2) distinct phases of dumping at the landfill 1) in 1944 during the operation of the DoD and 2) in 1949 after the DoD transferred the property and the Fosham Corporation owned the area (AGC, 2019). D&M (1981) indicated that residents used the landfill as a trash dump after the security fences were removed from the Site in 1949. Three prior studies have been completed at this AOC; the following section summarizes the results. There is no record that the Former Landfill was lined and capped. Although, D&M (1981) indicated that the landfill was covered with soil prior to removal of the security fences. A parking lot serving the golf course and club house currently covers the landfill. However, a data gap identified during the Phase 1 RI, revealed that landfill signatures were identified in the grass area just north of the landfill which was not investigated.

A former open storage area (OSA), located southwest of the former landfill on the southern side of Potter Road in an area that is currently part of the golf course fairway, has been identified (see **Figure 10-4**). The OSA is visible on two (2) aerial photographs dated February and August 1944 which suggests DoD use (AGC, 2019). Between 1944 and 1949, the OSA ceased activity and while some surface debris was still present, the area was mostly cleared, and vegetation had been reestablishing itself (AGC, 2019). No other documentation of the history or use of this storage area was found.

**Phase 1 RI (2021)**

In 2021, a Phase 1 RI was initiated by USACE to investigate the nature and extent of potential DoD-related contamination in soil and groundwater. A total of 16 surface and 18 subsurface soil samples were collected throughout AOC 3 (**Figure 10-4**). Soil samples were analyzed for TAL metals, SVOCs (including DNCB and 2,4-DNP), PAHs, and picric acid; a subset of samples were analyzed for TOC, grain size distribution (including hydrometer analysis), and CEC. PCB Aroclors were also analyzed in soil samples collected in the former landfill area. Subsurface soils were also sampled for VOCs. In addition to soil sampling, seven (7) groundwater samples were collected from 1-inch temporary wells, mostly adjacent to the northern border of the parking lot (**Figure 10-4**). Groundwater samples were analyzed for TAL metals (field-filtered), VOCs, SVOCs (including DNCB and 2,4-DNP), PAHs, and picric acid. PCB Aroclors were also analyzed in groundwater samples collected in the former landfill area.

Detected constituents within AOC 3 soil included 4 VOCs, 5 SVOCs, 18 PAHs, 1 PCB, and 23 metals. Maximum detected concentrations that exceeded Phase 1 RI PALs included: aluminum, antimony, arsenic, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, bis(2-ethylhexyl)phthalate, cadmium, carbazole, cobalt, copper, m- & p-cresols, dibenz(a,h)anthracene, indeno(1,2,3-c,d)pyrene, iron, lead, manganese, mercury, selenium, thallium, vanadium, and zinc.

Detected constituents within AOC 3 groundwater included 4 VOCs, 3 SVOCs, and 15 metals. Maximum detected concentrations that exceeded Phase 1 RI PALs included: arsenic, cobalt, manganese, 4-nitroaniline, selenium, and sodium. While PCBs were not detected in groundwater, the LOQs were above respective screening levels. Therefore, PCBs were identified a COPCs.

In addition to the soil and groundwater investigations, a geophysical survey was conducted in the former landfill area. The geophysical survey indicated that the former landfill extended further north (of the parking lot) than originally suspected.

Following completion of the Phase 1 RI field effort, the data were compiled, and a risk screening and data gap analysis was performed and documented in the *Phase 1 Risk Screening and Data Gap Analysis Report* (USACE, 2023a). After conducting the risk screening, the following COPCs and COPECs were identified in **Exhibit 10-3** below:

## Exhibit 10-3 – Phase 1 RI (2021) AOC 3 COPC/COPECs Summary

| Vanadium | X | >BTV and H SL | X | >BTV and missing E SL |

Notes:
"--" = No.
BTV = Background threshold value.
E = based on ecological receptor(s).
H = based on human health.
HA = all LOQs > human health screening level.
LOD = limit of detection.
LOQ = limit of quantitation.
ND = non-detected result, typically reported at the LOD.
SL = Screening level.
X = Yes.

The *Phase 1 Risk Screening and Data Gap Analysis Report* (refer to **Appendix A**) noted the geophysical surveys indicate that the landfill footprint extends more northwestern than sampled during the Phase 1 investigation. The extended area is topographically downgradient and currently there are no samples located beyond the most downgradient edge. Therefore, additional sampling was recommended to verify Phase 1 results, adequately delineate the source areas and determine whether the former landfill is a source area and to characterize risks.

### 10.2.3 AOC 4 – Former Bunker Area

The Former Bunker Area is located within the Three Rivers WMA (**Figure 10-5**). According to the Archives Search Report (USACE, 1999a): "…boxed ammonium picrate (AP) was taken by truck from the AP production lines and stored in the Storage Magazine Area prior to shipment." The 14 original bunkers each measured approximately 30 ft by 60 ft and were constructed with concrete walls on three sides and front wall with a barn door for access (NYSDEC, 1993). The ceilings were constructed of wooden rafters. Earth was built up around the outside walls on the three concrete sides. An apron either concrete, or hard-pack gravel allowed access to each of the bunkers. Current use of this area is recreational. It is located within the Three Rivers WMA so this area is open to the public and contains walking trails. The 14 bunkers remain intact, however two of them are used for WMA maintenance equipment and vehicle storage. These bunker areas are regularly maintained (i.e., mowed) to prevent overgrowth.

Bunkers #3 and #8 were used by NYSDEC personnel for the storage of pesticides for approximately 10 years, from the early 1970s to 1983 (M&E, 1990). A small, partitioned room (approximately 12 ft by 22 ft) within Bunker #3 was used to receive and package pesticides from citizens and/or businesses that had pesticides that were either unwanted or had been banned. Bunker #8 was used for receiving and repackaging pesticides, but was also used for pesticide storage (NYSDEC, 1993). Bunkers #3 and #8 are no longer in use. In 1992, NYSDEC emptied and cleaned Bunkers #3 and #8 and covered them with an impermeable cap. NYSDEC currently maintains responsibility for long-term management of Bunkers #3 and #8, such as lawn mowing and cap inspection. The remaining bunkers are being used by NYSDEC game management personnel for equipment and vehicle storage. Due to the initiation of environmental

restoration after DoD ownership, Bunkers #3 and #8, are not FUDS- eligible and will not be addressed. The remaining 12 bunkers (exterior) remain FUDS-eligible.

**Phase 1 RI (2021)**

In 2021, a Phase 1 RI was initiated by USACE to investigate the nature and extent of potential DoD-related contamination in soil and groundwater. A total of 16 surface and 101 subsurface discrete soil samples were collected targeting potential source areas (e.g., drainage outlets), and migration pathways (e.g., drainage swales) (**Figure 10-5**). In addition to the biased sampling, ISM was employed at each of the 12 bunkers (i.e., DUs) to collect representative samples for each DU. Three ISM samples, comprised of 30 surface soil sample increments each, were collected at each DU for a total of 36 samples. All ISM samples were collected from 0 to 1-foot bgs using a dedicated volumetric sampling device (LaMotte 1055 Soil Sampler or AMS Soil Probe). Refer to Figure 2-6 through 2-8 in Appendix A for ISM sample locations. All soil samples were analyzed for DNCB, 2,4-DNP, and picric acid. In addition to soil sampling, sixteen (16) groundwater samples were collected from 1-inch temporary wells (**Figure 10-5**). Groundwater samples were analyzed for DNCB, 2,4-DNP, and picric acid.

Results for the soil samples and groundwater samples were non-detect at the limit of quantitation (LOQ) value which were greater than PALs for DNCB, 2,4-DNP, and picric acid.

Following completion of the Phase 1 RI field effort, the data were validated, compiled, and a risk screening and data gap analysis was performed and documented in the *Phase 1 Risk Screening and Data Gap Analysis Report* (USACE, 2023a). While the validated data were non-detect, 2,4-DNCB, 2,4-DNP and picric acid in ISM surface soil had low bias attributable to low surrogate recoveries for multiple samples. Since the uniformly low bias of results reported as non-detect was identified as a data gap, confirmation sampling in soil was recommended. Please refer to the Phase 1 Risk Screening and Data Gap Analysis Report (**Appendix A**) for additional discussion of the data quality issues and usability assessment. Given the uncertainty of these results, the *Phase 1 Risk Screening and Data Gap Analysis Report* (refer to **Appendix A**) recommended additional sampling to verify Phase 1 results, adequately delineate the source areas and characterize risks.

### 10.2.4 AOC 5 – Former Power Plant Area

The Former Power Plant Area is located north of the Administration Area (**Figure 10-6**). The AOC included a large aboveground storage tank (AST), a boiler house, CSA, CABs, and an electric substation. There were also two (2) drainage ditches that ran across the area (AGC, 2019). The large AST contained “Fire Water” (Reconstruction Finance Company, undated). Additional site features are shown in **Figure 10-6** and include:

- an abandoned rail line and spur.
- three below ground CABs in line with the rail spur: a dual bin (bins A and B) located between the substation and the boiler house, and a single bin (bin C) located west of the boiler house.
- a second water AST and pipeline between the large AST and the boiler house, as well as a short water distribution pipeline located north of the Site.
- additional drainage ditches.
- a possible dump.
- former roads.

The boiler house was a two (2)-story building with a total area of 8,366 $ft^2$ (Reconstruction Finance Company, undated). No additional written historical information could be found. The former Power Plant Area was not investigated in studies by D&M (1981), M&E (1990) or Alion (2006). The current use of this AOC is undeveloped land.

No documentation was encountered regarding if the power plant was removed and disposed by the military or by some other entity after the NYOW was decommissioned. However, site walks conducted under the Phase 1 and Phase 2 RI confirm that the former power plant and associated structures are no longer present.

## Phase 1 RI (2021)

In 2021, a Phase 1 RI was initiated by USACE to investigate the nature and extent of potential DoD-related contamination in soil and groundwater. Surface and subsurface soil sampling along with groundwater sampling was conducted in potential sources areas (i.e., former boiler house, former electrical substation, former coal storage bins, former coal storage area, and potential former dump area. A total of 25 surface and 50 subsurface soil samples were collected for the Phase 1 RI (USACE, 2021) (**Figure 10-6**). Additionally, groundwater samples were collected from a total of (12) 1-inch temporary wells (**Figure 10-6**). Since 1-inch temporary wells often produce highly turbid samples, which can under/overestimate concentrations, the recommendation to install permanent 2-inch monitoring wells was made within the *Phase 1 Risk Screening and Data Gap Analysis Report* (USACE, 2023a). Additionally, the wetland located to the west of AOC 5 could represent a groundwater seep and or surface water runoff pathways. Therefore, further investigation was recommended within the *Phase 1 Risk Screening and Data Gap Analysis Report* (USACE, 2023a). Further information regarding concentration data is presented in the *Phase 1 Risk Screening and Data Gap Analysis Report* (USACE, 2023a).

A geophysical survey was conducted at the AOC 5 Possible Dump Area to meet the DQOs of assessing the area for evidence of demolition debris or disposal of other waste and delineating the horizontal and vertical extents of observed waste. The survey was conducted using a Geonics EM-31 MKII terrain conductivity meter (EM-31). The results of the survey discussed below.

The EM-31 survey indicated that the subsurface conductivity data were indicative of natural terrain and not fill material, buried metallic objects, or dissolved salts/solids that are typically associated with landfills; however, metallic responses were observed at several locations. It was confirmed in the field that the metallic responses aligned with the presence of visible, surficial metallic debris, such as discarded paint cans, drums, and tire rims, as well as the presence of a buried steel drainpipe.

It has been suggested that there is potential that the geophysical survey conducted at the AOC 5 Possible Dump Area did not entirely satisfy the DQOs of assessing the area for evidence of demolition debris or disposal of other waste and delineating the horizontal and vertical extents of observed waste. This is because it is possible that buried metallic objects beneath the surficial metallic debris may have gone undetected due to interference from the surficial metallic debris. However, the EM-31 survey covered approximately 90% of the Possible Dump area in addition to area north of the mapped footprint without any evidence of subsurface disposal activities and detected analytes and associated concentrations in the Possible Dump area are not substantially above background (refer to Tables I-65 through I-75 of **Appendix A**) or human health and ecological screening levels and are not indicative of DoD-related disposal activities (USACE, 2023a). Therefore, the DQO of assessing the area for evidence of demolition debris or disposal of other waste has been met and the absence of such debris and waste negates the need to delineate the horizontal and vertical extent of waste.

While reviewing the historical photographic analysis (USACE, 2019), a drainage ditch was identified that ran parallel to and just west of the railroad spur, east of the coal piles. The ditch appears to be unlined except for where conduit was placed underneath intersecting roadways. The ditch is no longer visible and was likely filled in during Site decommissioning or reworked and regraded during roadway improvements to Willett Parkway. However, there is the potential that DoD-related contaminants leached into the soil and groundwater beneath the ditch and/or were transported downstream (south) to low-lying wetlands. The lack of data for characterization of this potential transport pathway is a data gap.

Five primary surface soil samples were collected at two AOC 5 subareas, the CABs and CSA, and analyzed for coal and coal ash for a total of ten primary samples at AOC 5 (plus one duplicate sample). Coal was detected in moderate to very heavy concentrations in all samples submitted for analysis, excluding sample NYOW-05-SL022-A (in the CAB subarea). Coal ash was detected in trace to moderate concentrations in samples NYOW-05-SL022-A and NYOW-05-SL024-A in the CAB subarea.

PAHs were generally not detected above background in the Boiler House, Electric Substation, or Possible Dump areas (USACE, 2023b). Concentrations of PAHs in the CABs and CSA were above background and human health screening levels in the 0 to 1 ft bgs soil interval (USACE, 2023a) and were markedly decreased (generally below background and often not detected) progressing through the 1-5 bgs and 5-10 bgs depth intervals (USACE, 2023a). Also of interest was that in sample NYOW-05-SL022-A, the only

sample where coal ash was detected but coal was not, PAHs were not detected above background or human health screening levels (USACE, 2023a). Lastly, boring locations -009, -010, and -024 were the only locations among the AOCs where the PAH ratios indicated a petrogenic source (USACE, 2023a). Additional data are needed to further refine nature and extent of coal as a potential source for CERCLA contaminants.

The patterns of metals concentrations in AOC 5 are less obvious; however, the higher concentrations tend to be at the Boiler House, CABs, and CSA and maximum detected concentrations within a boring tend to be seen at depth. For example, the highest groundwater dissolved arsenic concentration among all of the AOCs was detected at the Boiler House in NYOW-05-WL019-A (140 micrograms per liter [µg/L]) with the second highest soil concentration detected in the 5 to 10 ft bgs interval from the same location (40 milligrams per kilogram [mg/kg]). The highest soil concentration of arsenic was detected in NYOW-05-PH010-C in the 5 to 10 ft bgs interval (79 mg/kg) where the third highest groundwater concentration was detected (7.9 µg/L).

Detected constituents within AOC 5 soil included 23 metals, 1 PCB, 18 PAHs, 3 SVOCs, and 4 VOCs. Maximum detected concentrations that exceeded Phase 1 RI PALs included: aluminum, antimony, arsenic, benzo(a)pyrene, benzo(b)fluoranthene, cadmium, chromium, cobalt, copper, Aroclor-1260, dibenz(a,h)anthracene, dibenzofuran, di-n-butyl phthalate, indeno(1,2,3-c,d)pyrene, iron, lead, manganese, mercury, naphthalene, selenium, thallium, vanadium, and zinc.

Detected constituents within AOC 5 groundwater included 16 PAHs, 1 VOC, 2 SVOCs, and 17 metals. Maximum detected concentrations that exceeded Phase 1 RI PALs included: aluminum, antimony, arsenic, benzo(a)anthracene, benzo(a)pyrene benzo(b)fluoranthene, cobalt, dibenz(a,h)anthracene, iron, manganese, naphthalene, and sodium.

Following completion of the Phase 1 RI field effort, the data were compiled, and a risk screening and data gap analysis was performed and documented in the *Phase 1 Risk Screening and Data Gap Analysis Report* (USACE, 2023a). After conducting the risk screening, the following COPCs and COPECs were identified per subarea in **Exhibits 10-4** through **10-7**. The *Phase 1 Risk Screening and Data Gap Analysis Report* (refer to **Appendix A**) concluded that concentrations detected in the Electric Substation and Potential Dump are not indicative of a substantial release/source area. However, metals concentrations in soil and groundwater (particularly arsenic), are greater than background and human health screening levels in the Boiler House, CABs, and CSA. The report recommended verifying Phase 1 results, adequately delineating source areas and characterizing risks.

**Exhibit 10-4 – Phase 1 RI (2021) AOC 5 Boiler House COPC/COPECs Summary**

| Vanadium | X | >BTV and H SL | X | >BTV and missing E SL |
| Zinc | -- | -- | X | >BTV and E SL |

Notes:
*Anilines were not detected but the LOQs were greater than the SLs. There was potential historical evidence that these constituents were associated with AOC 5. Anilines are components of pigments and dyes and were associated with AOC 5 solely because of the potential for paint cans to have been disposed of in the Possible Dump Area. Therefore, anilines are not considered COPCs or COPECs for the Boiler House and do not need to be included in future sampling associated with the Boiler House.
"--" = No.
BTV = Background threshold value.

Notes:
*Anilines were not detected but the LOQs were greater than the SLs. There was potential historical evidence that these constituents were associated with AOC 5. Anilines are components of pigments and dyes and were associated with AOC 5 solely because of the potential for paint cans to have been disposed of in the Possible Dump Area. Therefore, anilines are not considered COPCs or COPECs for the Coal Aggregate Bins and do not need to be included in future sampling associated with the Coal Aggregate Bins.

Detected constituents in the Electric Substation were at concentrations not substantially different from background and/or screening levels and additional sampling in the Electric Substation was not recommended during the Phase 1 RI (refer to **Appendix A**). However, one PCB (Aroclor 1260) was detected in all four surface soil samples collected near the Electric Substation. Given that one surface soil sample had a concentration above the PAL and subsurface soil samples were not analyzed for PCBs, additional surface and subsurface soil sampling for PCBs is recommended for the Electric Substation area. In the absence of PCB groundwater data from the Electric Substation, PCB groundwater samples are recommended for the Electric Substation and wells downgradient of the Electric Substation. Additional data will be collected during Phase 2 to confirm/deny Phase 1 results and identified COPCs/COPECs for the Electric Substation presented in **Exhibit 10-7** will be carried through to the Phase 2 risk assessments.

There is no evidence of subsurface disposal activities in the Possible Dump area and concentrations are not indicative of DoD-related disposal activities (refer to **Appendix A**). Therefore, additional sampling in the Possible Dump Area was not recommended in the Data Gap Evaluation. However, given the elevated PCB detection limits, additional data is needed to confirm/deny Phase 1 results and identified COPCs/COPECs for the Possible Dump Area, as presented in the table below, to indicate which analytes will be carried through to the risk assessments.

## 10.3 Physical Characteristics

The Site is in the southeastern portion of the Erie-Ontario Lowlands Physiographic Province where several episodes of glacial ice advance and recession have resulted in rolling topography dominated by the deposition of drumlin hills, flanked by flat-lying glacial lake plain deposits. Elevation at the Site ranges from approximately 400 ft near AOC 3 and AOC 4 to approximately 500 ft above mean sea level on the drumlin hill adjacent to AOC 1 (M&E, 1990).

### 10.3.1 Meteorology

Based on data for Syracuse Hancock International Airport, NY, the area receives approximately 38.5 inches of annual precipitation. The hottest month is historically July, with an average high temperature of 81.6 Degrees Fahrenheit (°F), while its coldest month is historically January with an average high temperature of 31.5 °F (National Oceanic and Atmospheric Administration [NOAA], 2017).

### 10.3.2 Surface Water Drainage

The Seneca River flows south of the Site, meandering from west to southeast of Baldwinsville, then turns north, where it joins the Oneida River to form the Oswego River northeast of the Site. From there, the Oswego River flows north-northwest and drains into Lake Ontario (refer to **Figure 10-1**). The Site lies entirely within the Oswego River drainage basin. It is expected that approximately half of the annual precipitation becomes surface water runoff (D&M, 1981). Small swampy areas are abundant at the Site due to the relatively flat-lying topography and poor drainage resulting from the former lakebed deposits. The glacial lake plains in the area are drained primarily by small streamlets which flow in a general northeasterly direction towards the Oswego River and eventually into Lake Ontario. Surface drainage is also influenced by local topography.

Surface drainage at the Former Ammonium Picrate Area (AOC 1) consists of former wastewater ditches that ran from the northeastern side of the Ammonium Picrate Area. These ditches joined northeast of the Former Acid Area and flowed northward to the Oswego River (refer to **Figure 10-2**). A second former wastewater ditch originated in the Administration Area and flowed to the north and discharged into a low area east of the present-day Willette Parkway (D&M, 1981).

At the Former Landfill Area (AOC 3) there are surficial drainage features just north of the parking lot, with one (1) draining to the west, and the other to the northeast, with intervening high ground between them (refer to **Figure 10-4**).

At the Former Bunker Area (AOC 4), inside each bunker there are two (2) interior drains that run the length of the bunker and discharge to the exterior of either side of the front of the bunker. Drainage swales run parallel along the length of West and East Igloo Roads.

At the Former Power Plant Area (AOC 5), drainage ditches to the east and southwest of the AOC were identified by AGC (2019).

### 10.3.3 Geology

The Site is located within the southeastern portion of the Erie-Ontario Lowland Physiographic Province, which is characterized by the gentle topography of a Pleistocene-age lakebed punctuated by northwest-southeast trending drumlins (M&E, 1990), reflecting the direction of ice movement. Relief in the region is not controlled by bedrock but by the Pleistocene-age glacial deposition.

#### 10.3.3.1 Surface Geology

Surface geology (overburden) at the site is of glacial origin and consists of three (3) distinct types of depositional environments. Identifying these depositional environments is important as each has distinct physical properties that affect groundwater flow. The depositional environments include 1) an offshore lacustrine environment containing silt and clay; 2) a near-shore lacustrine environment containing stratified silt, sand and gravel, and 3) a drumlin that contains till consisting of unsorted clay, silt, sand, gravel and boulders. A drumlin is an elongated oval-shaped hill that is formed beneath a glacier parallel to the direction of glacial movement (i.e., southwest to northeast at the site). Drumlins typically contain long axial sides with relatively steep slopes compared to surrounding topography and an up-gradient (i.e., northeast at the site) stoss face that is typically steeper than the down-gradient lee face (i.e., southwest at the site). Generally, AOC 3, AOC 4, and AOC 5 are underlain by lacustrine deposits and the AOC 1 contains the drumlin underlain by near-shore lacustrine deposits along its northeast and southeast flanks. The drumlin in AOC 1 is a significant geological feature as its topography has a strong local modifying effect on overburden groundwater flow.

The Phase 1 RI refined the distribution of the three (3) surface geologic units previously mapped by Pair (2014) (i.e., silt and clay [Psc], stratified silt, sand and gravel [Ps], and till/diamicton [Pd]) based on the logging of site and background soil borings advanced during the Phase 1 field investigation (USACE, 2023a). As discussed in the UFP-QAPP (USACE, 2020), surface geology was more broadly mapped by Muller and Cadwell in 1986 and by Pair in 2014. While the exact level of effort applied in developing this previous mapping is not fully understood, it is assumed to be of a smaller scale as compared with USACE's site-specific investigation. Of these two (2) available resources, the Pair (2014) mapping was selected as the basis for refining surface geology because it more accurately aligns with known landforms and more precisely defines the extent of various surface geologic units (USACE, 2020). USACE's evaluation and refinement of surface geologic distribution was informed by field observations for soil structure and gradation, photographs of the associated soil samples, and laboratory gradation test results. In instances where multiple soil types were observed in the vertical profile, the uppermost soil type identified beyond the 0 to 1 ft bgs depth interval was used for classification and mapping purposes.

A summary of the inferred distribution of site surface geology as compared to the historical interpretation (Pair, 2014) of surface geology is presented on **Figure 10-8**. The inferred distribution of the site geology was based on the 161 site soil borings and 45 background soil borings collected from Phase 1. The location of where these borings are, along with inferred surface geology by AOC, are presented on **Figures 10-9** through **10-12**. The surface geologic unit Hw (wetland deposit) can be seen on some of the figures; however, this unit was identified by Pair (2014) adjacent to but not within AOC boundaries. The figures also show that fill was encountered in ten (10) of the 161 site soil borings and two of the 45 background soil borings. Also shown on the figures, there are 19 soil borings advanced along the toe of the drumlin in AOC 1 that were sampled from the 0 to 1 ft bgs depth interval only and are therefore classified as topsoil. It is noted that fill material observed in the upper 3 to 6 ft of the AOC 1, AOC 5, and background borings appears to be indicative of localized backfilling or grading activities, as opposed to landfilling or dumping activities.

The following observations were made regarding AOC 1 surface geology:

- The previously mapped Psc and Pd units along the northeastern boundary were determined to consist of Ps soils.
- The previously mapped Ps unit along the toe of the drumlin was classified as topsoil because the Phase 1 investigation in this area was limited to hand-augured borings to a depth of 1 ft bgs. Pockets of Pd and Ps soils were also observed in this area.
- The previously mapped Pd unit along the top of the drumlin was confirmed to consist of Pd soils.

Regarding AOC 3 surface geology, the previously mapped Psc unit was confirmed to consist of Psc soils.

Regarding AOC 4 surface geology, the previously mapped Psc unit was confirmed to predominantly consist of Psc soils, except for pockets of Ps soils along the northeastern and southeastern boundaries.

Regarding AOC 5 surface geology, the previously mapped Pd and Psc units in the eastern and western portions of the AOC, respectively, were determined to consist of a mix of Psc and Ps soils, as well as fill that is indicative of localized backfilling or grading activities.

The following observations were made regarding surface geology in the background areas located southwest of AOC 1 and northwest of AOC 5:

- The previously mapped Psc unit was determined to consist of both Psc and Ps soils.
- The previously mapped Ps unit was confirmed to predominantly consist of Ps soils, except for the former borrow pit area located southwest of AOC 1. The former borrow pit area was classified as fill based on field observations of recent backfilling activities in that area.
- The previously mapped Pd unit was confirmed to predominantly consist of Pd soils, except for pockets of Ps soils, Psc soils, and fill in the northern and southern extents. The fill observed in these areas is indicative of localized backfilling or grading activities.

USACE's field observations generally confirmed the previous understanding of site geology and depositional history at the Site. The distribution of the three known surface geologic units (i.e., Psc, Ps, and

Pd) were refined by this investigation but generally aligned with previous mapping from Pair (2014). Surface geology at the Site is controlled by glacial deposition and marked by a higher relief drumlin hill spanning the southwestern edge of AOC 1, the eastern edge of the background area, and the northeast edge of AOC 5. The drumlin hill is composed of poorly sorted diamicton (till) reflective of direct glacial deposition (i.e., Pd unit) and is flanked by coarser water-worked deposits of well-sorted sand and gravel (i.e., Ps unit) present in the northeastern edge of AOC 1 and the center of the background area. As previously mapped by Pair (2014), lacustrine beach deposits composed of finer-grained, water-worked deposits of well-sorted silt and clay (i.e., Psc unit) are predominant within AOCs 3, 4, and 5 and along the western edge of the background area.

These observations indicate a data gap for surface geology along the toe of the drumlin in AOC 1. This area should be investigated further to better understand soil types beyond the 0 to 1 ft bgs depth interval.

#### 10.3.3.2 Bedrock

Bedrock geology (**Figure 10-13**) beneath the Pleistocene-age deposits consists of sedimentary rock units of the Mid to Upper Silurian-age Clinton, Lockport, and Salina Groups. It should be noted that the stratigraphic nomenclature assigned to various units in this region of New York has been modified over the last 60 years. The most current stratigraphy mapped beneath the Site and surrounding area includes the Upper Silurian Vernon Shale overlying the Mid-Silurian Sconondoa Formation of the Lockport Group. To the north of the Site, the Rochester Shale member of the Clinton Group is mapped, which is characterized as interbedded calcareous gray shales and thin limestone beds. The Rochester Shale is the oldest of the three (3) units mapped in **Figure 10-13**.

The Guelph Dolostone belongs to the Lockport Group and is characterized as an alternating light and dark gray, bituminous and irregularly bedded dolomite with stromatolite reef bioherms at the base of the member. To the northwest near Ontario, Canada, the Guelph unit ranges from 200 to 300 feet in thickness; however, the unit thins substantially to the southeast, and appears regionally as just a thin wedge of rock (Tepper et al., 1990).

The Vernon Shale belongs to the Salina Group (Schneider, 1894) and is comprised of red and gray shales with dolomitic beds (Rickard, 1969). The Vernon Shale lies conformably over the Guelph Dolostone, and the transition between the units is marked by light bluish gray wackestone to claystone, with evaporites and vertical burrows.

The Sconondoa Formation (also part of the Lockport Group) is mapped to the south of the Site, and is described as a fine-grained, medium-bedded and fractured limestone, with interbedded shale limestone and coarse- grained dolomite (Zenger, 1965). Thicknesses of the Sconondoa Formation vary but may be as great as 150 ft. Bedrock dips gently southward and no faults or folds have been detected in the overlying Vernon Shale (Chute, 1964). Based on the morphology of the Seneca River, which flows east and south of the Site, there may be northwest-southeast and northeast-southwest trending joints in the Vernon Shale. The Sconondoa has two (2) primary sets of joints, one (1) north-south and one (1) east-west (Chute, 1964). Also within the Sconondoa Formation are thrust faults that strike North 65 to 75 degrees west and dip to the south (Chute, 1964); however, there is no surface expression of these faults in the overlying Vernon Shale. The gentle southward dip of the rock units and jointing in the Vernon Shale may influence the direction of groundwater flow, and subsequently, the direction and rate of migration of potential DoD-impacts from possible source areas. The fracture trends observed in the Sconondoa Formation may be indicative of regional trends, and continue into the formations to the north.

Identification/confirmation of bedrock was not part of the Phase 1 RI (USACE, 2021/2022) nor is it part of the Phase 2 investigation. During Phase 1, a DPT rig was used to advance soil borings and temporary wells across the various AOCs. In some cases, refusal depths were recorded on soil boring logs (USACE, 2021/2022). While it is possible that DPT refusal can provide additional insight into bedrock depth and elevation, caution needs to be employed as DPT drilling methodology has depth limitations. In terms of DPT refusal, refusal can be due to limitations of percussion advancement due to a various number of subsurface conditions (i.e., boulder refusal, running sands, till) encountered.

Therefore, the following paragraphs discuss refusal depths and elevations encountered during the Phase 1 RI and are not intended to describe depth to bedrock.

In AOC 1, a distinction can be made between investigations conducted along the top of the drumlin and the bottom of the drumlin. Along the top of the drumlin, refusal depth ranged from 7 to 18.7 ft bgs (average 12.84 ft bgs), and refusal elevation ranged from 426.33 to 489.23 ft above mean sea level (AMSL) (average 450.83 ft AMSL). Along the bottom of the drumlin, refusal depth ranged from 9.1 to 16 ft bgs (average 14.51 ft bgs), and refusal elevation ranged from 412.59 to 423.47 ft AMSL (average 418.77 ft AMSL). Investigations conducted prior to the USACE Phase 1 investigation indicated refusal, presumably due to bedrock, at a maximum depth of 51 ft bgs along the bottom of the drumlin (USACE, 2020). This varies significantly from the Phase 1 investigation findings; however, many of the Phase 1 borings at the bottom of the drumlin where advanced along the northeastern boundary of the AOC, as opposed to the toe of the drumlin located approximately 500 ft to the southwest. Phase 1 investigations along the toe of the drumlin were limited to hand-augured borings to a depth of 1 ft bgs because the area could not be accessed with the drill rig due to site condition limitations. The lack of direct-push borings closer to the toe of the drumlin is a data gap.

In AOC 3, refusal depth ranged from 6 to 18.9 ft bgs (average 12.96 ft bgs), and refusal elevation ranged from 384.10 to 394 ft AMSL (average 389.4 ft AMSL). These observations correspond with investigations conducted prior to the Phase 1 investigation, which indicated bedrock at depths of approximately 15 ft bgs and elevations ranging from 385 to 389 ft AMSL (USACE, 2020).

In AOC 4, refusal depth ranged from 10.5 to 20.5 ft bgs (average 15.49 ft bgs), and refusal elevation ranged from 389.54 to 415.64 ft AMSL (average 402.94 ft AMSL). Investigations conducted prior to the Phase 1 investigation indicated that bedrock was encountered at a depth of 9 ft bgs and an elevation of approximately 400 ft AMSL at a well location about halfway between AOC 3 and AOC 4 (USACE, 2020). The Phase 1 investigation indicates that both the depth to bedrock and bedrock elevation increase moving west-northwest from AOC 3 to AOC 4.

In AOC 5, refusal depth ranged from 19 to 29 ft bgs (average 23.39 ft bgs), and refusal elevation ranged from 420.22 to 437.07 ft AMSL (average 426.14 ft AMSL). No boreholes had been completed in AOC 5 under previous investigations for comparison with these observations (USACE, 2020). The Phase 1 investigation indicates that although the depth to bedrock increases, the bedrock elevation decreases moving south from the top of the AOC 1 drumlin to AOC 5.

USACE's field observations confirmed the previous understanding that surface relief at the Site is not controlled by bedrock but by glacial deposition, as discussed in the UFP-QAPP (USACE, 2020). This is evident in variations between the surface elevation and bedrock depth observed throughout the Site. It is possible that many of the refusal depths observed during the Phase 1 investigation are attributable to till or saprolite (weathered shale) as opposed to competent bedrock. Bedrock composition below refusal could not be fully characterized during the Phase 1 investigation (USACE, 2023a).

### 10.3.4 Hydrogeology

Regional groundwater flow is toward surface water bodies (Pagano, et al., 1985), and the major river drainages in the area, toward the Seneca River to the south and the Oswego River to the north (refer to **Figures 10-1** and **10-2**). Groundwater at the AOCs generally flows northeast toward the Seneca and Oswego Rivers. However, groundwater also tends to mimic the land surface and thus influenced by local topography. Therefore, shallow groundwater locally may be controlled by nearby surface water features. Deep groundwater will be consistent with regional flow toward the rivers, ultimately draining northward to Lake Ontario.

The shallow groundwater elevations and contours observed during the Phase 1 investigation are shown on **Figures 10-14–10-18**. The groundwater contours shown on these figures were developed using water level data from the temporary site and background monitoring wells installed throughout the site.

In AOC 1, a distinction can be made between the wells installed along the top of the drumlin and those installed along the bottom of the drumlin. Along the top of the drumlin, the depth to groundwater ranged from 1.38 to 7.07 ft bgs (average 3.19 ft bgs), and the groundwater elevation ranged from 441.64 to 475.2 ft AMSL (average 452.10 ft AMSL). Along the bottom of the drumlin, the depth to groundwater ranged from 0.89 to 9.06 ft bgs (average 3.77 ft bgs), and the groundwater elevation ranged from 426.14 to 452.82 ft AMSL (average 434.2 ft AMSL). The general direction of groundwater flow in AOC 1 is northeast; however,

background wells located to the southwest of AOC 1 demonstrate flow to the southwest and potentially south of the drumlin ridge that controls the direction of shallow groundwater flow in this area.

In AOC 3, the depth to groundwater ranged from 1.92 to 10.44 ft bgs (average 6.93 ft bgs), and the groundwater elevation ranged from 393.4 to 400.87 ft AMSL (average 396.02 ft AMSL). The general direction of groundwater flow in AOC 3 is northeast. There is an unnamed creek that is located approximately 100 feet north of the edge of the parking lot (former Landfill) in AOC 3. It is currently unknown if this stream is a losing stream, gaining stream, or both on a seasonal basis (i.e., intermittent). The Phase 2 proposed investigations (e.g., sampling, stream flow measurements) provided in this UFP-QAPP (Worksheet #14.2.8 through 14.2.10 and Worksheet #17.2.3 through 17.2.6) will help determine if this stream is perennial (and therefore receiving site shallow groundwater) and help determine whether the groundwater-to-surface water pathway is complete at AOC 3. Perennial streams have not been identified within the EU/DUs of the remaining AOCs. However, the stream to be sampled as part of the background investigation, and west of AOC 3, is potentially perennial. The background stream will also be investigated (refer to Worksheet #17.5.3, 17.5.4, and 17.5.5).

In AOC 4, the depth to groundwater ranged from 0.53 to 4.75 ft bgs (average 2.63 ft bgs), and the groundwater elevation ranged from 406.3 to 423.89 ft AMSL (average 415.79 ft AMSL). The general direction of groundwater flow in AOC 4 is northeast.

In AOC 5, the depth to groundwater ranged from 0.72 to 12.03 ft bgs (average 4.77 ft bgs), and the groundwater elevation ranged from 438.96 to 451.16 ft AMSL (average 443.56 ft AMSL). The general direction of groundwater flow in AOC 5 is west-southwest.

The Phase 1 observations confirmed the previous understanding that shallow groundwater at the site mimics the land surface and is influenced by local topography, as discussed in the UFP-QAPP (USACE, 2020). The Phase 1 observations demonstrate that the direction of shallow groundwater flow in AOC 1, AOC 3, and AOC 4 is generally northeast toward the Oswego River. The exceptions are the background areas southwest of the AOC 1 drumlin where flow is to the southwest and in AOC 5 where flow is to the west-southwest; both areas flow toward wetlands located west of the site and indicate that shallow groundwater flow is controlled by nearby surface water features, as discussed in the UFP-QAPP (USACE, 2020).

Groundwater is also likely to be present within the relatively thin bedding planes and fractures of the Vernon Shale which may contain significant secondary porosity. Water yield within the bedrock is primarily a function of the interconnection of secondary porosity. This interconnection can be influenced by infilling within the bedding planes, thereby reducing yield or by dissolution of minerals from the bedding planes, allowing for higher yield. The dissolution of dolomitic layers present in the Vernon Shale would facilitate increased groundwater flow through the aquifer. Kantrowitz (1964) found that the Vernon Shale yields as much as 230 gallons per minute where dissolution of the interbedded dolomite has occurred. However, the average yield from this formation is 15 to 20 gallons per minute. The Lockport Formation is expected to be especially susceptible to dissolution by percolating groundwater because it consists primarily of fractured limestone and dolomite. LaSala (1968) has found wells in the Lockport to yield up to 100 gallons per minute. No site monitoring wells are screened in bedrock.

M&E (1990) calculated hydraulic conductivities at the Former Ammonium Picrate Area, and the Former Landfill Area. The calculated hydraulic conductivities of the deposits in the Former Landfill Area were generally higher by one (1) or two (2) orders of magnitude than the deposits in the Former Ammonium Picrate Area. The higher hydraulic conductivity in the Former Landfill Area [0.4 to 4 feet per day (ft/day)] may be attributed to the fact that the lacustrine deposits, while fine-grained (silt and clay), were not overridden by glacial ice. The Former Ammonium Picrate Area was composed of less permeable and more poorly sorted subsurface deposits, further compacted at the base of the ice sheet, and thus has lower hydraulic conductivities (0.004 to 0.024 ft/day) (M&E, 1990). The stratified silt, sand and gravel deposits flanking the drumlin would be expected to have even higher hydraulic conductivity, but there are no monitoring wells or conductivity data available for this unit. Note, the testing method for determining hydraulic conductivity during M&E (1990) is not known. However, new hydraulic conductivity values will be estimated as part of the Phase 2 investigation (refer to Worksheet #14.2.7.1).

### 10.3.5 Sources of Drinking Water

Potable water is supplied to communities in Onondaga County by the Onondaga County Water Authority, which draws water from several sources, including Otisco Lake, Lake Ontario, and/or Skaneateles Lake. For the Lysander-Baldwinsville area (including the Radisson Community and Golf Course), potable water is obtained from Otisco Lake and Lake Ontario and then treated and distributed to the community (Onondaga County Water Authority, 2019). Site impacts on these surface water sources are unlikely given that regional groundwater flow is to the north and given the distance from the Site. Otisco Lake is located about 20 miles south of the Site, far upgradient of the Site. Lake Ontario is about 20 miles northwest of the Site, far downgradient of the Site.

A water well services the NYSDEC field office at the Three Rivers Wildlife Management Area in AOC 4. Some residences in the surrounding area may have private supply wells. In 2007, NYSDOH was contacted by USACE to identify wells and water supply systems within a 4-mile radius of the Site. NYSDOH provided general information on the surrounding wells and source water assessment areas but was unable to provide specific information due to confidentiality protocols (Alion, 2008).

As presented in the RI Phase 1 Field Report – AOCs 1,3, 4 ISM, and Background (USACE, 2022), USACE conducted a potable well survey in September 2021 to identify active public and/or private domestic wells located within a 2-mile radius of the Site for the purpose of evaluating potential impacts from any off-site migration of DoD-related contaminants. The survey included a desktop component, in addition to a windshield survey.

The desktop component identified 471 parcels with a private water supply, such as a well, according to the Onondaga and Oswego Counties' 2020 Assessment Roll (331 in Onondaga County and 140 in Oswego County). The desktop component also identified 83 water well locations according to NYSDEC Water Well Completion Reports. These parcels and water well locations are shown on **Figure 10-19**.

During the windshield survey, USACE attempted to view, from public roadways, each parcel with private water supply (471) and each NYSDEC well location (83) within the 2-mile site boundary radius. A total of 118 potential wells at 115 parcels were identified (USACE, 2022).

In summary, the potable well survey identified a total of 554 potential well locations including 471 parcels with private water supply and 83 NYSDEC water wells within the 2-mile survey.

### 10.3.6 Terrestrial Habitat

General descriptions of the terrestrial habitat of each AOC are noted below. Potential ecological receptors are discussed in Section 10.5.2.

**AOC 1 – Former Ammonium Picrate Area**

The majority of the Ammonium Picrate Area terrestrial habitat is primarily northern deciduous forest, with predominately forested wetlands, in between the ammonium picrate buildings and dryer houses, with some areas of grassy fields. The Ammonium Picrate Area has maintained trails and recreational grassy areas interspersed throughout the Site.

**AOC 3 – Former Landfill Area**

The Former Landfill Area is covered by a blacktop parking lot. The areas south and east of the landfill are dominated by residential properties and west of the landfill is additional blacktop parking and commercial properties associated with the Radisson Greens Golf Course. North of the former landfill is a mature deciduous forest (roughly 200 ft wide) that continues to the northeast and borders one of the golf course fairways.

**AOC 4 – Former Bunker Area**

The bunkers are covered with grass and at most places are periodically managed to discourage the rooting of trees and shrubs on top of the bunkers. Across the road from the bunkers, a heavily vegetated drainage ditch runs parallel to the road in front of each bunker. The terrestrial habitat bordering Igloo Road and associated bunkers consists primarily of grassy fields and northern deciduous forest. The following provides a brief description of the primary terrestrial habitat location within the Bunker Area.

Grass Fields – Located predominantly along the northern portion of the Bunker Area although smaller grass field patches occur around each of the bunkers. The extent of grass maintenance around the bunkers is limited.

Woodlands – Eastern deciduous forest borders the Bunker area to the north and east; second growth forest of similar composition is located between the two bunker rows except at the northern end. The southeastern Site border is a mix of maintained grassy areas and deciduous forest.

**AOC 5 – Former Power Plant Area**

Areas within AOC 5 appear to have been filled to raise contour elevations to support infrastructure and facilitate the power plant operation. The former power plant footprint includes a grass/lawn swath which transitions into a fairly dense growth of colonizing early successional shrub and tree species. There is a forested wetland area to the west of the fill footprint that appears to have had minimal direct disturbance other than past efforts to enhance drainage with shallow open ditches.

## 10.3.7 Land Use and Demography

NYOW is currently occupied by the Three Rivers WMA and the Radisson Community with its associated industrial properties (**Figure 10-7**).

The Three Rivers WMA is situated on the northern portion of the Former NYOW property and was acquired from the US Government when the property was transferred in 1947. It was named for its proximity to the junction of the Seneca and Oneida Rivers, which form the Oswego River. The WMA is flat and poorly drained, with fields, woods, ponds, and marshes. It is used primarily for recreational use - hunting, fishing, hiking, and bird watching. Future use is expected to remain the same as current use.

The Radisson Community is a planned development community that provides approximately 3,500 homes, as well as a large Corporate Park and a wide range of recreational, educational, cultural, shopping, and community services. The area is served by underground water, sewage, gas, and telephone utilities. The Radisson Corporate Park provides building sites for industry and offices. To date, 40 firms employing 2,500 people have located in the park. These firms produce products as diverse as beer, plastic containers, printing, and electronic components. The Seneca River borders the community on the east, Three Rivers WMA borders the community on the north and west, and New York State Route 31 borders the area on the south (Radisson, 2017). The Radisson Community actively uses much of the property and some apartment buildings and residences in the Radisson Community appear to be constructed on or around the sites of former dryer houses, change houses, and other historical site features. In addition, paved walking paths and grassy areas wind between homes and wooded areas containing the old loading ramps, storage bunkers, and loading dock structures. Old concrete structures in disrepair exist in wooded areas of varying density. Current use of potentially impacted areas is limited to recreational use. Future use is expected to remain the same as current use.

## 10.3.8 Wetlands and Aquatic Resources

A wetland delineation and vernal pool survey was performed at AOCs 1, 3, and 5 in 2020. The results of these field investigations are presented in the Wetland Delineation and Vernal Pool Survey Report (USACE, 2020). Note that the following findings made in consideration of the Clean Water Act policy at that time of the survey and any impacts on revised rules/regulations should be evaluated during Phase 2. No formal wetland delineation was performed for AOC 4.

There are several forested wetland areas scattered throughout AOC 1, with the majority located in the lower elevation areas adjacent to residential properties. In total, 17.33 acres of Palustrine Forested Wetland (PFO) were identified across four areas. The largest wetland area (Wetland 1C, 10.81 acres) was identified along the northeast basal plain, with pockets of upland hills, between former Dryer Houses 29 and 31. Wetland 1B was identified along the southern portion of the basal plain, between former Dryer Houses 27 and 28. The remaining two wetlands were delineated along the second terrace (USACE, 2020).

In total, 0.26 acres of PFO/Palustrine Emergent Wetland (PEM) were identified within AOC 3, just north of the parking lot along the stream's floodplain. The only wetland areas associated with AOC 3 are associated with the unnamed stream and the northern stream bank.

Roughly 50% (the whole western side) of AOC 5 consists of a forested wetland habitat (USACE, 2020). Similar to AOC 1, AOC 5 has highly mosaic microtopography throughout and an extensive network of drainage ditches from its previous land use. Therefore, wetland boundaries had to be averaged to mappable lines. This means in some areas there are many small wetland depressions and upland mounds on both sides of the boundary. The western portion of AOC 5 was confirmed to have 3.35 acres of PFO wetlands, which likely extends westward beyond the AOC boundary (USACE, 2020).

Based on the results of the wetland delineation efforts and vernal pool assessments, approximately 20.44 wetland acres were delineated across the AOCs 1, 3, and 5. Based on the observations of the field teams, vernal pool resources do not warrant additional consideration as unique or exceptional resources. However, the pools were all found to occur within, or to have nexus to, areas that are probable Jurisdictional Wetlands as defined and regulated by USACE under the Clean Water Act.

NYSDEC regulates wetlands that are 12.4 acres (5 hectares) or larger. The NYSDEC Freshwater Wetlands Act protects wetlands smaller than this if they are considered of unusual local importance. None of the wetlands delineated at the NYOW AOCs are larger than 12.4 acres; none are identified as part of a state-mapped New York State freshwater wetland; and none contain features of unusual local importance.

According to the National Wetlands Inventory Map, managed by the United States Fish and Wildlife Service (USFWS), (USACE, 2020), there is a small PEM in the southwestern portion on the Site and two small, PFOs adjacent to western AOC 4 boundary. There are also several larger PFO and PEM areas west of AOC 4 and numerous smaller PFO wetlands south and east of AOC 4.

The National Wetlands Inventory Map also shows several freshwater forested/shrub wetland and freshwater emergent wetland areas in the western portion of the Site (primarily in the undeveloped areas of Three Rivers WMA). The freshwater forested/shrub wetland category consists of woody wetlands, forested swamp, or shrub bogs. Freshwater emergent wetlands are described as herbaceous marsh, fen, swale, and wet meadow (USFWS, 2018). There are also several state-regulated freshwater wetland areas within the site that do not necessarily directly coincide with the National Wetlands Inventory Map (the NYSDEC Environmental Resource mapper at https://www.dec.ny.gov/animals/38801.html and Wetlands Research Services, 2020). There are several small freshwater ponds located within the Radisson Community.

During a 27 June 2018 site visit, small scrub-shrub and emergent wetland patches were observed adjacent to and southwest of AOC 4 (USACE, 2020).

## 10.4 Constituent Fate and Transport

Potential release mechanisms for the DoD-related chemicals derived from the Phase 1 RI (USACE, 2020) include:

- Primary:
  - Disposal and adsorption resulting from direct releases to the ground (including spills and leaks from tanks), dumping activities, and disturbance during redevelopment and construction activities, burial of landfill wastes, including direct contact between landfill waste and groundwater in AOC 3.
- Secondary:
  - Wind erosion.
  - Infiltration/leaching to subsurface soils and groundwater
  - Runoff/erosion
- Tertiary:
  - Groundwater flow and discharge

The potential release mechanisms, along with any other updates to the CSM, associated with each AOC will be presented in the RI Report after additional site observations have been made during the Phase 2 RI field work, and after review of all of the data has been completed.

### 10.4.1 Constituent Persistence

When released to the environment, metals can be found in soil, sediment, and organic materials due to their inherit properties and interactions with various environmental factors (e.g., pH, oxic versus anoxic subsurface conditions). The process of when metals bind to soil particles, or organic matter is called adsorption. The tendency for metals to adsorb influences the mobility and bioavailability of the metals. Long-term persistence of metals in soil can therefore be a concern.

Picric acid is likely to exist in anion form in the environment; therefore, it is not expected to adsorb strongly to soils containing organic carbon and clay. Picric acid is resistant to aerobic biodegradation but can be degraded via photolysis by sunlight and hydrolysis in water (Hazardous Substances Data Bank [HSDB], 2011b). 2,4-DNP behaves similarly in the environment to picric acid (HSDB, 2011a). In contrast, DNCB has strong adsorption to clay, and adsorbs to suspended solids in water. DNCB is slow to biodegrade in water and soil and slow to volatilize from water but is susceptible to direct photolysis in sunlight (HSDB, 2013).

### 10.4.2 Constituent Migration

The soils at AOCs 1 and 3 have been extensively reworked during the development of the Radisson Community, potentially resulting in redistribution of soil horizons and any DoD-related constituents associated with them.

Due to the chemical properties of the DoD-related chemicals and time elapsed since potential releases of these DoD-related chemicals, dispersion, diffusion, and volatilization would not be considered significant contributors to constituent migration.

Most of the metals observed in the soil at the former NYOW would be bound to soil particles but could migrate via advective transport (bulk movement) or desorption (leaching) with the flow of surface water or groundwater toward adjacent water bodies. Desorption would be dependent on the solubility of the individual chemical and the properties of the soil. Arsenic is more mobile in soil at high pH (HSDB, 2009). In soil, chromium III has low solubility and low mobility (HSDB, 2016a). Lead compounds have limited mobility when released or deposited on soil (HSDB, 2016b).

Whereas there is some conflicting information about solubility of picric acid in water and mobility in soil, most references show that picric acid is highly soluble, on the order of grams per liter (PubChem, 2020; EPA, 2015). HDSB (2018) indicates that picric acid has an estimated carbon-water partition coefficient (Koc) value of 2,250 liters per kilogram (L/kg), which indicates slight mobility in soil. United States Army Center for Health Promotion and Preventive Medicine (USACHPPM, 2005) provides a much lower Koc estimate of 130 L/kg, indicating moderate to high mobility in soil. Based on this information, it will be assumed that picric acid is highly soluble and mobile in soil.

Koc values of 2,4-DNP have been reported as 13.5 L/kg and 16.6 L/kg, which indicates high mobility (HSDB, 2011), and it is highly soluble in water. The Koc of DNCB is estimated at 575 L/kg (HSDB, 2012), indicating moderate mobility. DNCB is very poorly soluble in water.

## 10.5 Potential Receptors and Exposure Pathways

The current and future land uses and ecological settings for the four (4) AOCs are provided below, while the potential human receptors and exposure pathways and ecological receptors and exposure pathways are identified in Sections 10.5.1 and 10.5.2, respectively.

**AOC 1 – Ammonium Picrate Area**

The Ammonium Picrate Area is currently within a primarily residential area of the Radisson Community with some undeveloped land with maintained paved walkways and recreational grassy areas. Paved walking paths and grassy areas wind between homes and wooded areas containing the old loading ramps, storage bunkers, and loading dock structures. Old concrete structures in disrepair exist in wooded areas of varying density. Terrestrial habitats, including maintained grassy areas and woodlands (eastern deciduous forest), are present. Forested wetlands are located within AOC 1. Current residential properties are located within AOC 1 and some apartment buildings and residences in the Radisson Community appear to be constructed on the sites of former dryer houses, change houses, and other historical site features.

**AOC 3 – Former Landfill Area:**

The Former Landfill Area is currently within the Radisson Golf Course property. As discussed in the UFP-QAPP (USACE, 2020), golf courses and recreational use land are shown as commercial land use. Based on historical documentation, the Former Landfill Area is located under and to the north of the current Radisson Golf Course club house parking lot. The geophysical evaluation indicated the former landfill extended further north of the parking lot, between the parking lot and the stream. At the landfill, a grassy strip with light poles extends along the middle and grassy landscaped areas surround the parking lot. The grassy center strip was not evaluated because it is likely reworked and above the landfill cap. The paved parking lot prevents the presence of surficial ecological habitat. As such, surface soils of potential concern are limited to the perimeter of the parking lot. Suitable subsurface soil habitat was found within the 1-5 ft interval beneath those surface soil samples collected around the perimeter of the parking lot. Ecological screenings were conducted using the analytical results of these surface and subsurface soil samples for select terrestrial ecological receptors (USACE, 2023a). Lastly, there is a small stream north of the landfill that may be receiving runoff or groundwater recharge that should be evaluated for impacts to aquatic organisms, thus representing a data gap. The former OSA is located southwest of the landfill area across Potter Road and straddles one of the golf course fairways, with wooded areas to the north and south. The portion of the former OSA that is located on what is the existing fairway was not investigated; however, the portions of the former OSA that are covered by woody vegetation were evaluated for terrestrial ecological receptors. Future use of this area is expected to remain the same as current use.

**AOC 4 – Bunker Area:**

The Bunker Area is currently located within Three Rivers WMA. NYSDEC is using several of the remaining bunkers for equipment and vehicle storage. The terrestrial habitat consists primarily of grassy fields and northern deciduous forest. Several small forested and emergent wetlands are located along the southeastern border of the Bunker Area. There are also walking trails and are available for use by the general public. The Bunker Areas are maintained regularly to limit vegetative overgrowth. Future use of this area is likely to remain wildlife management along with recreational use.

**AOC 5 – Former Power Plant Area:**

The Former Power Plant Area is currently a mostly wooded area west of a residential area. In the area of the former boiler house, a small area (~0.5 acres) of regularly maintained (i.e., mowed) grass is present. Terrestrial habitats, primarily woodlands (eastern deciduous forest), are present. Review of the Radisson Community General Project Plan (1971) and recent amendments through November 2012, indicates potential future use of AOC 5 as commercial/retail. During an inspection of AOC 5 on 02 October 2020, NYSDEC noted stakes, flagging, and survey pins that appeared to have been placed recently. NYSDEC inquired about the survey with Empire State Development (ESD) and ESD informed New York Department of Environmental Conservation that they are considering marketing and selling the area along Willett Parkway (USACE, 2020). No other potential future uses were identified during the Phase 1 investigation. The Town of Lysander Comprehensive Land Use Plan December 2014 draft shows the AOC 5 area on the map depicting Commercial and Industrial Sites. However, AOC 5 is in a district that includes Planned Unit Development, which provides flexibility in land use for a combination of single-family homes, apartments, and higher density condominium/townhouse development.

### 10.5.1 Potential Human Health Receptors and Exposure Routes

Based on Office of Solid Waste and Emergency Response (OSWER) guidance (EPA, OSWER Directive 9355.7, 2010) and DERP-FUDS guidance (DERP management guidance, 4715.20 4.b.(5)(a)3.b), receptors evaluated will be limited to current receptors and those associated with reasonably foreseeable future site uses. In addition, consistent with FUDS policy, use of groundwater for potable or other purposes will be evaluated in certain AOCs because there are no institutional controls or other restrictions on its use. These receptors will be re-visited and further refined in the BHHRA as part of the Phase 2 investigation.

Receptors may be exposed to COPCs either directly, through activities that result in contact with contaminated environmental media (e.g., digging in contaminated soil), or indirectly, because of chemical migration to locations where contact with receptors can occur (e.g., fugitive dust into an office building). An exposure pathway defines the most probable pathway in which a receptor may come into contact with

contaminated media. In order for an exposure pathway to be complete, the following four elements must be present:

(1) a source and mechanism of chemical release.

(2) a retention or transport medium.

(3) a point of contact between the human receptor and the medium.

(4) a route of exposure for the potential human receptor at the contact point.

The exposure pathway must be complete from the source of chemicals in the environment to human receptors in order for chemical intake to occur. If all exposure pathways are incomplete for human receptors, no chemical intake occurs, and no human health effects are associated with site related COPCs.

Each receptor may be evaluated for one or more exposure points and EU, and receptors exposed to soil may be evaluated for exposure to 0-1 ft soils under current conditions, 0-5 ft for excavation activities, or 0-10 ft soils under future conditions assuming regrading and redevelopment of the site. For the risk assessment, the following receptors will be evaluated based on exposure to all media within the EU. Each AOC will be defined as the EU to demonstrate that there are no actionable risks. The biased data, collected from areas of impact or anticipated impact within these AOCs, will be used conservatively to represent high-end exposure estimates. Since many receptors typically have smaller EUs than these AOCs, if the risks are deemed unacceptable, the data will be reassessed to identify if smaller areas with elevated concentrations and more reasonably sized EUs are contributing to the overall actionable risks. If this is the case, the EUs may be redefined to prevent the dilution of risks by considering the entire AOC as a single EU. Although AOC 5 contains multiple DUs, the entire AOC will initially be identified as the EU. If risks are unacceptable, the evaluation will be refined, and each subarea may be assessed separately to ensure that risks are not diluted by aggregating all subareas.

Potential receptors identified across AOCs include the following:

- On-Site Current and Future Trespasser/Visitor (including golf course users and recreational visitors).
- On-Site Current and Future Outdoor Maintenance Worker.
- On-Site Future Utility Worker.
- On-Site Future Construction Worker.
- On-Site Future Resident.
- On-Site Future Commercial Worker.
- On-Site Resident or Off-Site Nearby Resident utilizing private groundwater wells for potable water.

Based on results of screening the Phase 1 data and identification of preliminary COPCs, human receptors may be exposed to media at the AOCs through the following exposure pathways and routes of exposure:

- Direct contact with soil (incidental ingestion and dermal contact).
- Inhalation of volatiles and fugitive dust from soil.
- Incidental ingestion and dermal contact with groundwater during utility, construction, or maintenance work or during recreational activities.
- Direct contact with saturated/wet (i.e., hydric) soils (incidental ingestion and dermal contact).
- Direct contact with sediment (incidental ingestion and dermal contact).
- Direct contact with surface water ((incidental ingestion and dermal contact).
- Ingestion and dermal contact with groundwater during potable use.

Note that other pathways associated with nonpotable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the *Phase 1 Risk Screening and Data Gaps Analysis* (USACE, 2023a). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

The potential receptors, exposure media, exposure routes, and rational for selection or exclusion of exposures that have been considered relevant for each of the AOCs are listed in **Exhibit 10-9**. A preliminary exposure CSM for each of the AOCs is graphically depicted in **Figures 10-20** through **10-23**.

A description of the selected current and potential future likely receptors for exposure to COPCs in the various media at the AOCs are described here.

As noted above, future residential development at AOCs 1 and 5 are not currently expected in potentially impacted areas. If future development is indicated, future residents, future commercial/industrial workers, future construction workers, and/or future utility workers are considered at AOCs 1 and 5. Regardless, hypothetical future potable use of groundwater will be evaluated for AOCs 1 and 5 because there are no current restrictions in place that preclude this use.

### On-Site Receptors

#### *Trespasser/Visitor (AOCs 1, 3, 4, and 5)*

Trespasser/Visitors (adolescents) could encounter site surface soil (0-1 ft bgs) as part of their typical outdoor activities. During the Phase 1 investigation, evidence of trespassing or recreating (e.g., empty bottles) was found near the small stream in the northern portion of AOC 3 (Former Landfill Area). Potentially complete soil exposure pathways include incidental ingestion, dermal contact, and inhalation of windblown dust from surface soils. The Trespasser/Visitor may also come into contact with surface water and sediment associated with the unnamed stream in AOC 3 and the hydric soils, or sediments, in AOCs 1 and 5 during typical outdoor activities. A future exposure scenario for this receptor at AOCs 1 and 5 entails exposure to COPCs in mixed soil (0-10 ft) assuming regrading and redevelopment of the Site.

At AOC 3, a golf course user will also be evaluated for potential exposure to groundwater, under a hypothetical future scenario where a well is installed at the golf course and used as a source for irrigation water.

At AOC 4, a recreational visitor will also be evaluated for potential exposure to groundwater, under a hypothetical future scenario where a well is installed and used as a source for potable water for a water fountain.

#### *Outdoor Maintenance Worker (AOCs 1, 3, 4, and 5)*

An outdoor maintenance worker, representing WMA workers and groundskeepers, could encounter site surface soils as part of their typical outdoor maintenance or landscaping activities. Outdoor maintenance workers are assumed to spend the majority of their 8-hour workday outdoors with exposure to COPCs through incidental ingestion of surface soils, dermal contact with soils, and inhalation of airborne COPCs via volatilization and wind erosion. A future exposure scenario for this receptor at AOCs 1 and 5 entails exposure to COPCs in mixed soil (0-10 ft) assuming regrading and redevelopment of the Site.

At AOC 3, a maintenance worker will also be evaluated for potential exposure to groundwater, under a hypothetical future scenario where a well is installed at the golf course and used as a source for irrigation water.

#### *Utility Worker (AOCs 1, 3, and 5)*

Underground utilities are common in residential and commercial areas and often are located around roads and the areas between the roads and buildings. Underground utilities are present in AOC 1 and AOC 3 and are expected to be present in AOC 5 once development of that area occurs. A utility worker could be exposed on a short-term basis to soil from the surface down to 5 ft bgs while repairing or installing utility lines. Exposure routes could include incidental soil ingestion, dermal contact with soil, and inhalation of

dust emissions released from soil. Direct contact with COPCs in groundwater also is expected to occur for this receptor because groundwater is present at depths ranging between 2 ft and 13 ft bgs.

### *Construction Worker (AOCs 1 and 5)*

This is a short-term receptor exposed during a typical 8-hour workday. For this scenario, it is assumed that soil from the surface down to 10 ft bgs could be excavated, mixed, and used to regrade the Site such that exposure to COPCs that are present between surface and 10 ft bgs is a potential exposure possibility for the construction receptor. Direct contact with COPCs in groundwater also is expected to occur for the construction worker because groundwater is present at depths ranging between 2 ft and 13 ft bgs.

### *Resident (AOCs 1 and 5)*

AOC 1 is in a primarily residential area in the Radisson Community which is a planned development that consists of homes, a large Corporate Park, and a wide range of recreational, educational, cultural, shopping, and community services. AOC 1 is in a primarily residential area in the Radisson Community which is a planned development that consists of homes, a large Corporate Park, and a wide range of recreational, educational, cultural, shopping, and community services. Additional investigation is needed to determine if the residential receptor pathway is complete or potentially complete. Similarly, future redevelopment of AOC 5 may include residential dwellings. Therefore, a future residential receptor may have exposure to contaminants originating from mixed soil (i.e., 0 – 10 ft bgs), assuming that soil from the surface down to 10 ft bgs could be excavated, mixed, and used to regrade the Site such that exposure to COPCs that were present between surface and 10 ft bgs have now been placed at the surface.

No potable wells are currently located on the Site or near the source areas. Potable water is supplied to communities in Onondaga County by the Onondaga County Water Authority. Regardless, hypothetical future potable use of groundwater will be evaluated for AOCs 1 and 5 because there are no current restrictions in place that preclude this use.

Other pathways associated with nonpotable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the Phase 1 Risk Screening and Data Gaps Analysis (USACE, 2023). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

### *Commercial Worker (AOC 5)*

AOC 5 also may be developed in the future for commercial use. Currently, AOC 5 is mostly wooded therefore a considerable amount of construction, excavation and dirt moving will be needed to build offices buildings. As such, a future commercial worker receptor may have exposure to contaminants originating from mixed soil (i.e., 0 – 10 ft bgs) because it is assumed that soil from the surface down to 10 ft bgs could be excavated, mixed, and used to regrade the Site such that exposure to COPCs that were present between surface and 10 ft bgs have now been placed at the surface.

Other pathways associated with nonpotable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the Phase 1 Risk Screening and Data Gaps Analysis (USACE, 2023a). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

## Off-Site Receptors

### *Nearby Resident Using Groundwater as Drinking Water and Vapor Intrusion (AOCs 1, 3, 4, and 5)*

A nearby resident using a domestic well for potable water could be exposed to groundwater associated with from the Site. Exposure pathways would include ingestion of groundwater and dermal contact with groundwater (while showering or bathing), and inhalation while showering for volatile compounds detected in groundwater.

Other pathways associated with nonpotable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the *Phase 1 Risk Screening and Data Gaps Analysis* (USACE, 2023a). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

## Exhibit 10-9 – Receptor Selection and Exposure Pathways

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population[a] | Receptor Age | Exposure Route [b] | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway [c] |
|---|---|---|---|---|---|---|---|---|
| **Current and/or Future** | **Soil** | **Surface Soil (0-1 ft)** | AOC 1 | Current Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | This AOC is in primarily residential area where there are paved walking paths and grassy areas between homes and wooded areas containing the old loading ramps, storage bunkers, and loading dock structures. Activities of adolescents in these unrestricted open areas may lead to exposure to COPCs in surface soil. Similarly, outdoor workers performing grounds maintenance in these areas may lead to exposure to COPCs in surface soil. See potential future exposure to mixed subsurface soil below. |
| | | | | Current Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | AOC 3 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | This AOC is a golf course. Activities of adolescents in the open areas may lead to exposure to COPCs in surface soil. Similarly, outdoor workers performing grounds maintenance in these areas may lead to exposure to COPCs in surface soil. Current and future exposures are expected to be the same as there would be no heavy construction which would bring soil from below 1 ft bgs to the surface during regrading. |
| | | | | Current/Future Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | AOC 4 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | None [c] | This AOC is currently located within Three Rivers Wildlife Management Area (WMA). Several of the remaining bunkers are used for equipment and vehicle storage. Activities of adolescents in these unrestricted open areas may lead to exposure to COPCs in surface soil. Similarly, outdoor workers performing grounds maintenance in these areas may lead to exposure to COPCs in surface soil. The results of the Phase 1 soil sampling were nondetect. Therefore, although there are potential receptors who may come into contact with surface soil, there are no COPCs identified for the soil. Exposure routes and analysis may change depending on the results of the Phase 2 sampling effort. Note that current and future exposures are expected to be the same as there are no heavy construction activities planned for the AOC that would bring soils greater than 1 ft to the surface. |
| | | | | Current/Future Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | None [c] | |
| | | | AOC 5 | Current Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | This AOC is a mostly uninhabited wooded area west of a residential area. Activities of adolescents in these unrestricted open areas may lead to exposure to COPCs in surface soil. Similarly, outdoor workers performing grounds maintenance in these areas may lead to exposure to COPCs in surface soil. See potential future exposure to mixed subsurface soil below. |
| | | | | Current Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| **Future** | **Soil** | **Surface and Subsurface Soil (0-5 ft)** | AOC 1 | Future Utility Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | Underground utilities are common in residential and commercial areas, and often are located around roads and the areas between the roads and buildings. The residential area of AOC 1 contains underground utilities and future development would need installation of utilities. Thus, it is assumed that soil from the surface to 5 ft bgs could be excavated, mixed, and used to regrade the Site while installing or repairing utility lines. |
| | | | AOC 3 | Future Utility Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | Underground utilities are common in residential and commercial areas, and often are located around roads and the areas between the roads and buildings. As a developed commercial area, utilities are assumed to be present at AOC 3. Thus, it is assumed that soil from the surface to 5 ft bgs could be excavated, mixed, and used to regrade the Site while installing or repairing utility lines. |
| | | | AOC 4 | Future Utility Worker | Adult | None | None | AOC 4 is located in Three Rivers Wildlife Management Area, an undeveloped, natural environment. No utility lines are present in AOC 4, nor are utility lines expected to be installed in the future. |
| | | | AOC 5 | Future Utility Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | Underground utilities are common in residential and commercial areas, and often are located around roads and the areas between the roads and buildings. AOC 5 is slated for future redevelopment, either as commercial or multiple residential housing. As such, utility lines are expected to be installed in the future. Thus, it is assumed that soil from the surface to 5 ft bgs could be excavated, mixed, and used to regrade the Site while installing or repairing utility lines. |
| | | **Surface and Subsurface Soil (0-10 ft)** | AOC 1 | Future Resident | Adult | Ingestion/Dermal/Inhalation | Quantitative | This AOC is in primarily residential area in the Radisson Community which is a planned development that consists of homes, a large Corporate Park, and a wide range of recreational, educational, cultural, shopping, and community services. Although homes are not currently built on areas of |
| | | | | | Child | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | |

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population[a] | Receptor Age | Exposure Route [b] | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway [c] |
|---|---|---|---|---|---|---|---|---|
| **Future (cont'd)** | **Soil (cont'd)** | **Surface and Subsurface Soil (0-10 ft)** | | Future Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | potential impacts, homes or commercial structures may in the future be built on those potential areas of impact if results of the RI indicated those areas are not impacted. Therefore, future residential, commercial and construction worker exposure scenarios have been included. Soils at depth are assumed to be mixed with surface soil such that exposure to soils for future scenario entails contact with soils from 0-10 ft being as this interval would be used to regrade the Site. The future scenario for the trespasser/visitor and outdoor maintenance worker assumes contact with soils after regrading of the Site occurs so that exposure is to COPCs in 0-10 ft bgs interval. |
| | | | | Future Construction Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | AOC 3 | Future Resident | Adult | None | None | This AOC is a former landfill located within the golf course property. Future residential homes or commercial structures will not be constructed over the golf course or areas of the golf course. Therefore, residents, commercial workers, and construction workers will not be exposed to COPCs in subsurface soil in the future. |
| | | | | | Child | None | None | |
| | | | | Future Commercial Worker | Adult | None | None | |
| | | | | Future Construction Worker | Adult | None | None | |
| | | | AOC 4 | Future Resident | Adult | None | None | AOC 4 is in Three Rivers Wildlife Management Area; no future development is expected. Therefore, residents, commercial workers, and construction workers will not be exposure to COPCs in subsurface soil in the future. |
| | | | | | Child | None | None | |
| | | | | Future Commercial Worker | Adult | None | None | |
| | | | | Future Construction Worker | Adult | None | None | |
| | | | AOC 5 | Future Trespasser/Visitor | Adolescent | Ingestion/Dermal/Inhalation | Quantitative | This AOC will be developed in the future and based on current surrounding land use future redevelopment may include residential and/or commercial settings. Therefore, residents, commercial workers, and construction workers may be exposure to COPCs in subsurface soil in the future. Soils at depth are assumed to be mixed with surface soil such that exposure to soils for future scenario entails contact with soils from 0-10 ft being as this interval would be excavated during construction, mixed, and used to regrade the Site. The future scenario for the trespasser/visitor and outdoor maintenance worker assumes contact with soils after regrading of the Site occurs so that exposure is to COPCs in 0-10 ft bgs interval. |
| | | | | Future Outdoor Maintenance Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Resident | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | | Child | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Commercial Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | | | | Future Construction Worker | Adult | Ingestion/Dermal/Inhalation | Quantitative | |
| | **Groundwater (g)** | **On-Site Groundwater** | AOC 1 | Future Resident | Adult | Ingestion/Dermal | Quantitative | Groundwater on-Site is not currently used as a drinking water source and potable water is supplied by the Onondaga County Water Authority. Regardless, hypothetical future potable use of groundwater will be evaluated for AOCs 1 and 5 because there are no current restrictions in place that preclude this use. There are no VOCs among contaminants of potential concern at this AOC; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater are considered incomplete exposure pathways. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | | | | Future Utility Worker | Adult | Dermal | Quantitative | The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers and construction workers are likely to encounter groundwater during excavation activities. Metals were identified as COPCs in the Phase I data; therefore, inhalation exposure is not associated with groundwater and excavation activities. The groundwater ingestion pathway for the future utility and construction workers is an insignificant exposure pathway which will not be quantitatively evaluated in the risk assessment but will be addressed as part of the uncertainty evaluation. |
| | | | | Future Construction Worker | Adult | Dermal | Quantitative | |
| | | | AOC 3 | Future Golfer | Adult | Ingestion/Dermal | Quantitative | These receptors are evaluated for potential exposure to groundwater under a hypothetical future scenario where a well is installed at the golf course and used as a source for irrigation water. |
| | | | | Future Maintenance Worker | Adult | Ingestion/Dermal | Quantitative | |
| | | | | Future Utility Worker | Adult | Dermal | Quantitative | |

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population[a] | Receptor Age | Exposure Route [b] | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway [c] |
|---|---|---|---|---|---|---|---|---|
| **Future (cont'd)** | **Groundwater (g) (cont'd)** | **On-Site Groundwater (cont'd)** | AOC 3 (cont'd) | Future Construction Worker | Adult | None | None | The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers are likely to encounter groundwater during excavation activities. COPCs from the Phase I data include primarily metals, 4-nitroaniline, and benzene. Inhalation is not a significant exposure pathway associated with inorganics, and volatilization of benzene outdoors is not expected to be significant and therefore will not be evaluated. The groundwater ingestion pathway has been deemed insignificant as the amount of water incidentally ingested is going to be de minimis. No major construction is expected in this former landfill area; therefore, construction workers are not included as a potential receptor to groundwater. |
| | | | AOC 4 | Future Recreational Visitor | Adult/Child | Ingestion/Dermal | Quantitative | This receptor is evaluated for potential exposure to groundwater, under a hypothetical future scenario where a well is installed and used as a source for potable water for a water fountain. |
| | | | | Future Utility Worker | Adult | None | None | AOC 4 located in Three Rivers Wildlife Management Area; no future development is expected so exposure to groundwater while excavating is not expected for these potential receptors. |
| | | | | Future Construction Worker | Adult | None | None | |
| | | | AOC 5 | Future Resident | Adult | Ingestion/Dermal | Quantitative | Groundwater on-Site is not currently used as a drinking water source and potable water is supplied by the Onondaga County Water Authority. Regardless, hypothetical future potable use of groundwater will be evaluated for AOCs 1 and 5 because there are no current restrictions in place that preclude this use. There is no groundwater USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for 1,2,3-trichlorobenzene because this chemical does not have sufficient inhalation toxicity information. However, the maximum detected 1,2,3-trichlorobenzene concentration is below the 1,2,4-trichlorobenzene VISL used as a surrogate) for groundwater set to a target risk level of 1E-06 and a hazard quotient of 0.1. Therefore, inhalation exposure is assumed to be insignificant. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | | | | Future Utility Worker | Adult | Dermal | Quantitative | The water table is anticipated to be encountered between 2 to 13 feet bgs in the source areas; therefore, utility workers and construction workers are likely to encounter groundwater during excavation activities. COPCs from the Phase I data include primarily metals and SVOCs; therefore, inhalation of outdoor air is not a significant exposure pathway and will not be evaluated. The groundwater ingestion pathway for the future utility and construction workers is an insignificant exposure pathway which will not be quantitatively evaluated in the risk assessment but will be addressed as part of the uncertainty evaluation. |
| | | | | Future Construction Worker | Adult | Dermal | Quantitative | |
| **Current and Future** | | **Off-Site Groundwater** | Nearby AOC 1 | Current/Future Resident | Adult | Ingestion/Dermal | Quantitative | There are multiple private wells in the area as per the well survey. Will evaluate groundwater exposure as potable water exposures to current and future nearby residents. There are no VOCs among contaminants of potential concern at this AOC; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater are considered incomplete exposure pathways. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | | | Nearby AOC 3 | Current/Future Resident | Adult | Ingestion/Dermal | Quantitative | There are multiple private wells in the area as per the well survey. Will evaluate groundwater exposure as potable water exposures to current and future nearby residents. Benzene was the only VOC detected in groundwater, but the maximum detected benzene concentration is below the USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for groundwater set to a target cancer risk of 1E-06 and a hazard quotient (HQ) of 0.1; therefore, the inhalation of volatiles exposure route has been designated as potentially complete but insignificant and will not be quantitatively evaluated. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | | | Nearby AOC 4 | Current/Future Resident | Adult | Ingestion/Dermal | None (d) | There are multiple private wells in the area as per the well survey. However, Phase 1 groundwater analytical results were nondetect. Therefore, this exposure pathway is considered insignificant and will not be evaluated in the BHHRA. Groundwater sampling is not being performed as part of Phase 2 investigation. |
| | | | | | Child | Ingestion/Dermal | None (d) | |

| Scenario Timeframe | Medium | Exposure Medium | Exposure Point | Receptor Population[a] | Receptor Age | Exposure Route [b] | Type of Analysis | Rationale for Selection or Exclusion of Exposure Pathway [c] |
|---|---|---|---|---|---|---|---|---|
| **Current and Future (cont'd)** | **Groundwater (g) (cont'd)** | **Off-Site Groundwater (cont'd)** | Nearby AOC 5 | Current/Future Resident | Adult | Ingestion/Dermal | Quantitative | There are multiple private wells in the area as per the well survey. Will evaluate groundwater exposure as potable water exposures to current and future nearby residents. There is no groundwater USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for 1,2,3-trichlorobenzene because this chemical does not have sufficient inhalation toxicity information. However, the maximum detected 1,2,3-trichlorobenzene concentration is below the 1,2,4-trichlorobenzene VISL used as a surrogate) for groundwater set to a target risk level of 1E-06 and a hazard quotient of 0.1. Therefore, inhalation exposure is assumed to be insignificant. |
| | | | | | Child | Ingestion/Dermal | Quantitative | |
| | **Surface Water (Unnamed Stream)** | **Surface Water (e)** | AOC 3 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal | Quantitative | This AOC is a golf course and as such access to the stream is not restricted. Adolescents may come in contact with the stream while walking or as part of their outdoor activities. Should VOCs be detected in surface water during the Phase 2 field effort, inhalation of volatiles is assumed to be an insignificant exposure due to ambient air mixing and wind dispersal. |
| | **Sediment (Unnamed Stream)** | **Sediment (e)** | AOC 3 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal | Quantitative | |
| | **Hydric Soils (from Wetland Areas)** | **Hydric Soils (f)** | AOC 1 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal | Quantitative | This AOC is in primarily residential area where there are paved walking paths and grassy areas between homes and wooded areas. Adolescents may come in contact with the hydric soils while walking or as part of their outdoor activities. |
| | **Hydric Soils (from Wetland Areas)** | **Hydric Soils (f)** | AOC 5 | Current/Future Trespasser/Visitor | Adolescent | Ingestion/Dermal | Quantitative | This AOC is currently undeveloped and there are no restrictions preventing adolescents from traversing the area and coming into contact with COPCs in hydric soils of the wetland areas. |

Notes:
(a) Note that trespassers and visitors could be any age, but an adolescent was selected as the receptor because they are more sensitive (higher exposure frequencies than a child and higher dose than an adult). The recreational visitor in AOC 4 will be evaluated as child and adult receptors.
(b) For soil exposures, inhalation assessed as volatile or soil derived dusts (i.e., ambient air).
(c) The AOC-specific CSMs were informed by site-specific information and the COPCs identified in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). These potential receptors and exposure pathways may be revised based on risk screening results of the Phase 2 RI data.
(d) Phase 1 analytical results were nondetect which indicates exposure to environmental medium at this AOC would be insignificant. The receptors and potential exposure pathways will be revisited after completion of the Phase 2 field effort.
(e) Surface water and sediment samples are planned during the Phase 2 investigation for the unnamed stream located north of AOC 3. Should VOCs be detected in surface water, inhalation of volatiles is assumed to be an insignificant exposure due to ambient air mixing and wind dispersal.
(f) Discrete surface soil sampling of hydric soils from wetland areas are planned for the Phase 2 investigation. Standing surface water is not present at the wetlands; therefore, surface water samples will not be collected, and hydric soil samples will be evaluated under a sediment exposure scenario.
(g) Other pathways associated with nonpotable groundwater exposures, such as vapor intrusion or via inhalation of vapor in ambient air, have been determined to be incomplete because VOCs were not detected in groundwater or insignificant as concentrations of VOCs detected in groundwater were less than the USEPA Vapor Intrusion Screening Level as reported in the Phase 1 Risk Screening and Data Gaps Analysis (Bluestone, 2023). For now, these groundwater inhalation routes of exposure are not included in the preliminary CSMs; however, these exposure pathways will be revisited based on the Phase 2 field investigation results.

Acronyms:
AOC = area of concern.
bgs = below ground surface.
cont'd = continued.
COPC = contaminant of potential concern.
ft = feet.

## 10.5.2 Potential Ecological Receptors and Exposure Routes

Below is a brief summary of the currently identified potential receptors and exposure routes. All risk assessment activities will be performed during Phase 2, based on Phase 1 investigation exceedances of ecological risk-based screening levels and background levels. These receptors will be re-visited and further refined in Phase 2, if necessary, based on actual or expected changes to land use and habitat. Further details regarding habitat conditions and potential receptors are provided in **Appendix C**. Of particular focus in the SLERA is the potential exposure pathways to rare, threatened, or endangered species (RTE), their critical habitat, or other significant natural communities at or in the vicinity (e.g., Three Rivers State WMA) of the AOCs. Resources such as the NY Natural Heritage Database (NYNHD) Nature Exposure online tool and the U.S. Fish and Wildlife Service IPaC database were performed to update Phase 1 (Appendix K in USACE, 2023). For instance, the northern long-eared bat (*M. septentrionalis*) was recently upgraded to endangered status**. Exhibit 10-10** summarizes the key RTE species most critical to consider when planning appropriate avoidance and/or minimization measures that need to be implemented during the field sampling program.

**Exhibit 10-10 – Key Rare, Threatened and Endangered Species[a]**

| Common Name | Latin Name | Status (T/E/SC)[b] | Federal/ State |
|---|---|---|---|
| Bald Eagle | *Haliaeetus leucocephalus* | T | S |
| Golden Eagle | *Aquila chrysaetos* | E | S |
| Least Bittern | *Ixobrychus exilis* | T | S |
| Pied-billed Grebe | *Podilymbus podiceps* | T | S |
| Sedge Wren | *Cistothorus platensis* | T | S |
| Indiana Bat[c] | *Myotis sodalis* | E | F, S |
| Northern Long-eared Bat[c] | *Myotis septentrionalis* | E | F, S |
| Tri-colored (Eastern Pipistrelle) Bat[d] | *Perimyotis subflavus* | E (proposed) | F, S |
| Monarch Butterfly[e] | *Danaus plexippus* | T (proposed) | F |

Notes:
(a) Updated information obtained from the USFWS IPaC and NYNHD database obtained in 2024 and 2025. For state-listed species and significant natural communities, there are no current records of occurrence in the AOCs themselves.
(b) Status categories include T – threatened, E – endangered, SC – special concern and C – candidate.
(c) Nearest records of Indiana and Northern Long-eared bats are summer records along the Seneca River approximately 2.5 miles from AOC 5.
(d) On 4 September 2022, USFWS proposed listing the tricolored bat as an endangered species and is currently under review. According to communication with the Three Rivers WMA, this species was detected near AOC 4 in 2019.

The updated IPaC information also identified 22 migratory bird species that may occur in the vicinity of the Site that are protected under the Migratory Bird Species Act (MBSA). For each species, temporal variability in the likelihood of occurrence in the vicinity of NYOW is provided along with the breeding season (if applicable). The list of migratory species includes the bald and golden eagles, which are also protected by the Bald and Golden Eagle Protection Act. In addition to the above species, a relatively rare (S2) and significant nature community, a Silver Maple-Ash Swamp, is located along a tributary to the Oswego River, which is east, southeast and south of AOC 4.

An exposure pathway defines the most probable pathway in which a receptor may come into contact with contaminated media. In order for an exposure pathway to be complete and contaminant exposure to occur, the following four elements must be present:

(1) a source and mechanism of chemical release.

(2) a retention or transport medium.

(3) a point of contact between the ecological receptor and the medium.

(4) a route of exposure for the potential ecological receptor at the contact point.

Based on the Phase 1 CSM, ecological receptors may be exposed to COPECs either through activities that result in dermal/direct contact with contaminated environmental media (all receptors) or through incidental

ingestion as a result of preening activities by wildlife and/or foraging activities by both wildlife and invertebrate receptors. Each ecological receptor may be evaluated for one or more exposure points, and receptors exposed to soil may be evaluated for both exposure to surface (0-1 ft bgs) soils and subsurface (0-5 ft bgs) soils.

Ecological receptors with potential exposure to one or more AOCs include the following:

- Terrestrial plants (rooted vascular species).
- Terrestrial invertebrates (e.g., earthworms and other soil fauna).
- Terrestrial wildlife including both mammal and avian species with various trophic level characteristics (e.g., herbivores, omnivores, and carnivores).
- Aquatic life including both organisms that are principally exposed in the water column (pelagic exposures) and the sediment and sediment porewater (benthic exposures). Organisms that could be exposed to water-borne contaminants include aquatic plants, invertebrates, fish, amphibians and reptiles. Benthic invertebrates and vascular aquatic plants are the primary organisms that could be exposed to contaminants in sediment and porewater media. Note that aquatic-dependent wildlife could also be exposed to contaminants in surface water and sediment particularly if contaminants can bioaccumulate in prey tissue. Exposures to aquatic-dependent wildlife will be evaluated, and the CSM updated (Figure 10-25) if bioaccumulating analytes are detected in AOC 3 surface water or sediment.

Similar to the human health risk assessment, ecological risks will be evaluated based on exposure to media within an AOC, defined as the EU for all receptors, to demonstrate that there are no actionable risks. The biased data, collected from areas of impact or anticipated impact within these AOCs, will be used conservatively to represent high-end exposure estimates. Since many receptors typically have smaller EUs than these AOCs, if the risks are deemed unacceptable, the data will be reassessed to identify if smaller areas with elevated concentrations and more reasonably sized EUs are contributing to the overall actionable risks. If this is the case, the EUs may be redefined to prevent the dilution of risks by considering the entire AOC as a single EU. Although AOC 5 contains multiple DUs, the entire AOC will initially be identified as the EU. If risks are unacceptable, the evaluation will be refined, and each subarea may be assessed separately to ensure that risks are not diluted by aggregating all subareas. In addition, the initial screening will compare maximum detected concentrations within an AOC to screening level benchmarks and will not adjust exposures for wildlife with large foraging ranges. If risks are deemed unacceptable, risks may be refined by accounting for receptor specific EUs using area use factors (AUFs) or by redefining EUs to prevent the dilution of risks by considering the entire AOC as a single EU. For assessment endpoint wildlife receptors with AUFs larger than a given AOC, a sensitivity evaluation regarding the impact of potential exposures to multiple AOCs and/or EUs may be conducted.

The potential receptors categories, their level of ecological organization, exposure media, and for wildlife, the selected representative species for each of the AOCs are listed in **Exhibit 10-11**. Preliminary ecological CSMs that include likely exposure routes for each of the AOCs are provided in **Figures 10-24** through **10-27**.

A description of the selected ecological receptors for exposure to COPECs in the various media at the AOCs are described below by ecological habitat type.

**Terrestrial Habitat** – (Note that surficial hydric soil samples will be collected at both AOCs 1 and 5 and these will be assumed to be equivalent to upland soils from an ecological exposure perspective).

**Terrestrial Plants (AOCs 1, 3, 4, and 5)**

Terrestrial Plants are assumed to be exposed to COPECs in both surface (0-1 ft bgs) and subsurface (1-5 ft bgs) soil layers. For AOC 3, the Phase 1 CSM (**Figure 10-25**) assumed that surface soil exposures are prevented by pavement at AOC 3; however, in Phase 2, additional soil (including surface) samples will be collected laterally to address an identified data gap. If it is determined that terrestrial habitat is present in the vicinity of the pavement, these data will be evaluated in the SLERA (**Appendix C**). Dermal/direct contact is the only potentially complete soil exposure pathway for this community-level receptor.

### Terrestrial Invertebrates (AOCs 1, 3, 4, and 5)

Terrestrial Invertebrates are assumed to be exposed to COPECs in both surface (0-1 ft bgs) and subsurface (1-5 ft bgs) soil layers. For AOC 3, the Phase 1 CSM (**Figure 10-25**) assumed that surface soil exposures are prevented by pavement at AOC 3 so terrestrial invertebrate exposures to subsurface soil were identified; however, in Phase 2 additional soil (including surface) samples will be collected adjacent to the paved area to address an identified data gap. If it is determined that terrestrial habitat is present in the vicinity of the pavement, these data will be evaluated in the SLERA (**Appendix C**). Dermal/direct contact and incidental ingestion during foraging activities are the potentially complete soil exposure pathways for this community-level receptor.

### Terrestrial Wildlife (AOCs 1, 3, 4, and 5)

Terrestrial Wildlife are assumed to be exposed to COPECs in surface (0-1 ft bgs) at AOCs 1, 4 and 5 and burrowing mammals (e.g., red fox) could be exposed to COPECs in subsurface (1-5 ft bgs) at all AOCs. For AOC 3, the Phase 1 CSM (**Figure 10-25**) assumed that surface soil exposures are prevented by pavement at AOC 3; however, in Phase 2 additional soil (including surface) samples will be collected laterally to address an identified data gap. If it is determined that terrestrial habitat is present in the vicinity of the pavement, exposures to all wildlife receptors will be evaluated in the SLERA (**Appendix C**). Wildlife receptors are assumed to only be exposed to COPECs in surface soil via the incidental ingestion pathway; however, burrowing mammals could be exposed to COPECs in subsurface soils via both incidental ingestion and dermal/direct contact pathways. If COPECs that are known to bioaccumulate are detected in surface soils at any AOC, the additional ingestion of contaminated prey exposure pathway will also be evaluated for all representative wildlife species.

**Aquatic Habitat** – (Note that groundwater and/or surface runoff may have resulted in the migration of COPECs to aquatic habitat located downgradient of AOCs 1 and 5). As a result, additional samples may be collected in Phase 2 if DoD-related COPECs in groundwater are determined to discharge to this habitat. Depending on the nature of the available habitat, particularly whether standing water is present or just saturated soils are present, either or both of the following community-level receptors may be present. If so, they will be evaluated in the SLERA and the ecological CSM revised accordingly.

### Aquatic Community (AOC 3)

In AOC 3, the extent of the potential impacts downgradient from the former landfill area are uncharacterized, and aquatic life associated with the water column could be directly exposed to DoD-related constituents in surface water in the unnamed stream north of the landfill. Dermal/direct contact and incidental ingestion during foraging activities are the potentially complete aqueous exposure pathways for this community-level receptor.

### Benthic Macroinvertebrates (AOC 3)

The small stream downgradient of AOC 3 also provides benthic habitat for benthos which could be exposed to COPECs in both sediment and pore water. Dermal/direct contact and incidental ingestion during foraging activities are the potentially complete exposure pathways for this community-level receptor. The human and ecological exposure pathways identified in the subsections below were updated from those presented in the UFP-QAPP (USACE, 2020) as appropriate based on data collected during the Phase 1 investigation. A reassessment of potential human and ecological exposure pathways will be needed after completion of the data collection and analysis from the Phase 2 investigation.

## Exhibit 10-11 – Ecological Receptors

| Level of Organization | Receptor Type | Trophic Level | AOC | Exposure Media[b] | Selected Representative Taxa |
|---|---|---|---|---|---|
| Community | Terrestrial Plants | Producer | 1, 3[c], 4, 5 | Soil (0-1 ft, 1-5 ft) | All plant species that obtain nutrients primarily from soil |
| Community | Terrestrial Invertebrates | Various | 1, 3[c], 4, 5 | Soil (0-1 ft, 1-5 ft bgs) | All soil invertebrates (e.g., earthworms, insect larvae, arthropods, isopods) |
| Population | Small Mammal | Herbivorous | 1, 3[c], 4, 5 | Soil (0-1 ft bgs) | Meadow vole (*Microtus pennsylvanicus*) |
| Population | Small Mammal | Omnivorous | 1, 3[c], 4, 5 | Soil (0-1 ft bgs) | Northern short-tailed shrew (*Blarina brevicauda*) |
| Population | Medium Mammal | Carnivorous | 1, 3[c], 4, 5 | Soil (0-1 ft, 1-5 ft) | Red fox (*Vulpes vulpes*) |
| Population | Medium Mammal | Omnivorous | 1, 4, 5 | Soil (0-1 ft bgs) | Raccoon (*Procyon lotor*) |
| Population | Small Bird | Herbivorous | 1, 3[c], 4, 5 | Soil (0-1 ft bgs) | Mourning dove (*Zenaida macroura*) |
| Population | Small Bird | Omnivorous | 1, 3[c], 4, 5 | Soil (0-1 ft bgs) | American robin (*Turdus migratorius*) |
| Community | Aquatic Organisms[d] | Various | 3[d] | Water column; Pore water | Aggregate community components (e.g., fish, aquatic invertebrates, aquatic plants) |
| Community | Benthic Organisms[d] | Various | 3[d] | Sediment (0-0.5 ft bss); Pore water | Aggregate community components (e.g., insects, amphipods, microbes, aquatic plants) |

Notes:

a The Phase 1 analysis concluded that large herbivorous mammals (e.g., deer) and carnivorous birds (e.g., owls, hawks) occur in the vicinity of the individual AOCs and that exposure pathways are potentially complete; however, these pathways were determined to be insignificant due to the wide-ranging foraging behavior of these receptors.

b Surface soils (i.e., 0-1 ft bgs) include both terrestrial and "hydric" soils; the latter will be collected at both AOCs 1 and 5.

c No ecological exposure to surface soils at AOC3; however, burrowing mammals (e.g., red fox) could be exposed to subsurface soils.

d Aquatic organisms including benthic invertebrates may be exposed to contaminants in discharging groundwater downgradient of AOCs 1, 4 and 5. If so, analytical data for aquatic media will be collected and evaluated in the SLERA.

# Worksheet #11 – Project/Data Quality Objectives

## 11.1 Data Quality Objectives

This worksheet documents project DQOs using the systematic planning process outlined in *Guidance on Systematic Planning Using the Data Quality Objectives Process* (EPA, 2006), the UFP-QAPP guidance manual (IDQTF, 2005), the optimized UFP-QAPP worksheets manual (IDQTF, 2012), and the EPA QA/G4, Guidance for the Data Quality Objective Process (EPA, 2006). Project-specific DQOs were developed for this investigation using the EPA seven (7)-step process and are summarized below. Further details regarding DQOs and data use for the HHRA/SLERA/RSLERA are provided in **Appendix B** and **Appendix C**, respectively.

## 11.2 Project Quality Objectives

Project quality objectives (PQOs) define the type, quantity, and quality of data that are needed to answer specific environmental questions and support proper environmental decisions.

### 11.2.1 Who will use the data?

USACE CENAE will be making site management decisions for NYOW and will use the data to complete the RI.

### 11.2.2 What are the Project Action Limits (PALs)?

The purpose of identifying risk-based PALs in the UFP-QAPP is to ensure the analytical methods selected are sensitive enough to detect concentrations at or below the screening benchmark or absent that, the most sensitive method available. PALs on Worksheets #15 are the lower of human health screening levels and ecological benchmarks identified based on the hierarchies presented below for those media where both sets of screening criteria apply. Note, that groundwater PALs are based on human health values only and soil, sediment, and surface water PALs are based on the lower of human health and ecological values. Porewater PALs are based on surface water ecological benchmark values only.

**Human Health**

- Groundwater
  - EPA Regional Screening Level (RSL) (November 2024): Tapwater Tables for Cancer Target Risk of 1E-06 and Target Hazard Quotient of 0.1 (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables).
- Soil and Sediment:
  - EPA RSL (November 2024): for Residential Soil Tables for Cancer Target Risk of 1E-06 and Target Hazard Quotient of 0.1 (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables).
- Surface Water:
  - Screening levels were calculated using USEPA's RSL calculator for a recreational receptor's exposure to surface water using the exposure parameters for incidental ingestion and dermal contact with COPCs in surface water for a trespasser/visitor scenario listed in **Appendix B** (see Table B2.2-3 of Attachment A).

**Ecological**

Ecological screening benchmarks are derived for multiple receptor categories (see Section 10.5.2) and all expected site-specific receptor categories that need to be considered when selecting the ecological PALs. These receptor categories for exposures to the following media:

- soil: plants, invertebrates and birds and mammals.
- sediment/pore water: invertebrates (benthic).
- surface: aquatic organisms including plants, invertebrates (pelagic), fish and amphibians.

Supporting documentation for the ecological PALs is presented in **Appendix C**. Appendix C.1 presents the methodology for selecting surrogates for key constituents without ecological benchmarks and Appendix C.2 presents all of the values within the QAPP ecological PAL selection hierarchy.C.2 (Table C.2-1 [soil], Table C.2-2 [sediment] and Table C.2-3 [surface water/pore water]) presents all values in the QAPP ecological PAL selection hierarchy. The hierarchies for soil, sediment, and surface water/porewater are defined below. Table C.2-1 (soil), Table C.2-2 (sediment) and Table C.2-3 (surface water/pore water).

- Soil (if reference has more than one receptor, the lowest value was selected):
  - EPA ecological soil screening levels (eco-SSLs )(Eco-SSLs; various dates) (https://www.epa.gov/risk/ecological-soil-screening-level-eco-ssl-guidance-and-documents)
  - EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) –Soil Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).
  - EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf)
  - Los Alamos National Laboratory (LANL)/Intellus (2024). ECORISK Database (Release 4.4), (https://intellusnm/documents/documents.cfm).
- Sediment (if reference has more than one receptor, the lowest value was selected):
  - EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) –Soil Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).
  - EPA Region 3 (2006) Region III BTAG (Biological Technical Assistance Group). Freshwater Sediment Screening Benchmarks (https://www.epa.gov/sites/default/files/2015-09/documents/r3_btag_fw_sediment_benchmarks_8-06.pdf).
  - EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf)
  - LANL/Intellus (2024). ECORISK Database (Release 4.4), (https://intellusnm/documents/documents.cfm).
- Surface water/Pore water (if reference has more than one receptor, the lowest value was selected):
  - National Recommended Water Quality Criteria – Aquatic Life Criteria Table. Accessed November 11, 2022. ( https://www.epa.gov/wqc/national-recommended-water-quality-criteria-aquatic-life-criteria-table).
  - EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) –Soil Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).
  - EPA Region 3 (2006) Region III BTAG (Biological Technical Assistance Group). Freshwater Screening Benchmarks (https://www.epa.gov/sites/default/files/2015-09/documents/r3_btag_fw_benchmarks_07-06.pdf).
  - EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf)
  - LANL/Intellus (2024). ECORISK Database (Release 4.4), (https://intellusnm/documents/documents.cfm).

Note that PALs for m,p-xylene and m,p-cresol are the lower of the two isomers.

### 11.2.3 What will the data be used for?

Data collected from studies described in this UFP-QAPP and from the Phase 1 RI will be used to define the nature and extent of DoD-related contamination, identify potential/actual source areas, identify contaminant migration pathways, fate and transport, and support the HHRA and SLERA/RSLERA for the Site.

All of the Phase 1 and Phase 2 data will be combined to estimate a reasonable maximum exposure as both types of sampling methods (biased versus random) results represent high-end exposure and will be used to initially assess risks to show the absence of an actionable risk. The data will be used to estimate upper confidence limits (UCLs) as the exposure point concentrations (EPCs) for the HHRA and SLERA/RSLERA. In cases where the UCL exceeds the maximum detected concentration, the maximum concentration will be used as the EPC. Although most of the Phase 1 datasets are considered to be biased, the majority of the Phase 2 sampling program will result in unbiased data because sampling locations were selected using a spatially balanced statistical design approach. While the combination of these datasets will represent conservative exposure estimates, some of which can be considered “worse case”, the risk assessments will be conducted using a tiered approach that incorporates refinements to reduce overall uncertainties.

The HHRA will include an evaluation of the potential impact that biased data may have on the risk results, as appropriate, in the uncertainty analysis. If the estimated risks for an EU exceed acceptable levels and chemicals of concern (COCs) are identified, the sample locations and analytical results that are based on a biased sampling approach will be reviewed to determine their impact on the quantitative risk estimates. The uncertainty assessment may include recalculating potential risks for the COCs using a refined dataset that excludes biased samples and/or evaluating smaller EUs that are defined based on sample-specific risks.

As discussed in the SLERA Work Plan (**Appendix C**), the RSLERA will evaluate COPECs identified in the initial SLERA screening process using less conservative exposure assumptions and any identified screening value exceedances will also be evaluated in the uncertainty analysis, which will consider the potential impact of sample bias and data gaps on the estimates. The spatial distribution of COPEC concentrations within individual DUs, relative to the EUs of receptors with small foraging ranges, as well as the potential exposures across AOCs/DUs by wildlife receptors with broad foraging ranges, will also be considered.

A summary of the project tasks and schedule are presented in Worksheet #14/16.

### 11.2.4 What types of data are needed?

The types of data needed are described in the table in this section. Data include DoD-related concentrations in soil (both unsaturated and saturated/wet [i.e., hydric]), groundwater, surface water, porewater, and sediment. Synoptic water level data are needed in order to update groundwater flow and contaminant migration pathways, and hydraulic gradients. Stream flow measurements are needed to assist with contaminant transport physical modeling. Updated hydraulic conductivity estimates are needed to support hydrogeological CSM updates (e.g., groundwater flow velocity) and transport physical modeling. Either the radial flow steady state model or ellipsoidal flow steady state model developed by S.A. Vitale and G.A. Robbins will be used during low-flow sampling to estimate hydraulic conductivity. Additional details are provided in Section 14.2.7.1 Hydraulic Conductivity Testing. Sampling designs, locations, methods, and rationales are presented in Worksheets #17 and #18.

### 11.2.5 How “good” do the data need to be in order to support the environmental decision?

Definitive-quality data will be used as described in the table in this section. The data will be generated using rigorous sampling and analytical methods, such as approved EPA SW846 reference methods, where those methods exist. The data are not expected to be restricted in their use once data quality is established and validated. The chemical-specific analytical detection limits are presented in Worksheet #15.

### 11.2.6 How much data are needed? Where, when, and how should the data be collected/generated?

Worksheet #18, and Worksheet #20 present the number of samples to be collected for each environmental medium. It is assumed that the sampling effort, as determined based on the *Phase 1 Risk Screening and Data Gap Analysis* (USACE, 2023a), will be adequate to support the Phase 2 objectives with acceptable parameter estimation precision and decision error rates (e.g., background consistency). Two rounds of sediment, surface water and pore-water sampling will be collected at AOC 3 as well as groundwater sampling at AOC 1, AOC 3, and AOC 5. Along with two rounds of background data for these media, the data will be used to support a qualitative evaluation of potential seasonality effects. These data will be used qualitatively to determine whether seasonable variability is potentially substantial enough to impact conclusions in the RI; if so, additional data collection and a quantitative assessment will be considered. Recommendations for Phase 2 analyses were presented in Section 9 of the *Phase 1 Data Gap Analysis Report* (May 2023) (refer to **Appendix A** of this UFP-QAPP). Worksheet #20 presents the total number of QC samples to be collected. Standard operating procedures (SOPs) for field sampling and field analytical procedures described in **Appendix D** will be followed. Field forms are also included in **Appendix D**.

**Exhibit 11-1** summarizes the anticipated datasets available to evaluate human health and ecological risks at the AOCs. The tiered process of data evaluation is highlighted including the initial assessment of the combined Phase 1 and 2 datasets for consistency with background and comparison to conservative risk-based screening values. Potential refinement evaluation may follow depending on what data are not screened out initially. The exhibit also summarizes the spatial extent of overall AOCs and subunits that may be relevant to refinement level exposures and whether the datasets are considered biased which may affect interpretation of the risk calculations.

## Exhibit 11-1 – Summary of Potential Decision Units (DUs), Sampling Approaches and Available Data to Support Risk Analysis

| AOC | Decision Units | | Combine Phase 1 and Phase 2 Data in Risk Assessment? | Phase 1 Locations within DUs Considered when Selecting Phase 2 Locations | Biased vs Unbiased Sampling Approach | Summary of Media Datasets and Analytical Parameters [3] | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | Phase 1 | | | | | | | | | | | | Phase 2 [4] | | | | | | | | | | | | | | | | |

Notes:
(1) The human health risk assessment (HHRA) will initially include an evaluation of exposures and risks for the entire AOC, which will be treated as a single exposure unit. Potential risks may be further evaluated (i.e., refined) based on smaller DUs/exposure units or by using a sample-by-sample approach. The use of biased and unbiased samples in the HHRA will be addressed in the uncertainty analysis.
(2) Assumed individual wildlife receptor site foraging ranges (i.e., potential EUs) - 0.091 (vole) to 6,175 (dove) acres (see Table 5-1, Appendix C).
(3) Biased and unbiased data are light and dark shaded, respectively.
(4) Phase 2 groundwater (AOC 1, AOC 3 and AOC 5) and sediment, surface water, porewater (AOC 3) will be collected semi-annually for 1 year).
(5) Phase 2 groundwater monitoring well locations within the former landfill (AOC 3) and DU001, DU003 and DU004 (AOC 5) were selected using GRTS and are unbiased.
(6) Phase 2 sampling design also considered the presence of the following monitoring wells/soil boring locations which are located within the wetland: NYOW-01-044, NYOW-01-047,NYOW-01-050, NYOW-01-060, and NYOW-01-061.
(7) Five surface soil samples will be collected at each of the 12 remaining bunkers.
(8) No Phase 1 samples collected in DU002.
(9) Aroclor sampling at AOC 5 will be limited to soil (surface and subsurface) and groundwater at the former electrical substation as well as groundwater from the possible dump area and wells downgradient of the substation (MW-03 and MW-07) only.
AOC = Area of Concern
bgs = below ground surface
DNCB = dinitrochlorobenzene
DNP = dinitrophenol
DU = decision unit
GRTS = Generalized Random Tessellation Stratified software
GW = groundwater
ISM = incremental sampling methodology
MW = monitoring well
N/A = not applicable
PAH = polycyclic aromatic hydrocarbon
SB = subsurface
SVOC = semi-volatile organic compound
SW = surface water
TAL = target analyte list
VOC = volatile organic compound

### 11.2.7 Who will collect and generate the data?

USACE CENAE will collect the data. Eurofins Test America, Lancaster, Pennsylvania, a DoD Environmental Laboratory Accreditation Program laboratory (Certification No. 0001.01) will analyze all samples requiring standard analyses (e.g., VOCs, SVOCs, PCBs, PAHs, 2,4-DNCB, 2,4-DNP, CEC, and metals). For those analyses Eurofins Lancaster is not certified to run, JV will ship to its' sister locations as detailed below. Copies of laboratory certification are included in **Appendix E**. Note at the time of this UFP-QAPP, Eurofins Lancaster is currently (August 2025) adding 2,4-DNCB as a target compound. A change page reflecting their lab limits, along with eQAPP updates will be made as soon as possible (currently anticipating September 2025). Also of note, CEC is not in the Quality System Manual (QSM) and therefore is not part of routine accreditation nor a NYSDEC certified analysis.

- Picric Acid analyses - Eurofins Test America, Denver, a DoD Environmental Laboratory Accreditation Program laboratory (Certification No. 2907.01) and National Environmental Laboratory Accredited Program New York State Certified (11964) laboratory.
- Microscopy **–** MicroVision Laboratories, Inc. **Note microscopy is not in the QSM and therefore is not part of routine accreditation nor a NYSDEC certified analysis.** Coal samples will be analyzed and reported in accordance with *SOP MVL/05-09* provided by MicroVision Laboratories, Inc. The methods used to detect coal, will be via scanning electron microscope (SEM), energy dispersive x-ray spectroscopy (EDS), and polarized light microscope (PLM).

Data will be generated by the same sources collecting the data. Additionally, data generated from the Phase 1 RI will be utilized in the evaluations.

### 11.2.8 How will the data be reported? How will the data be archived?

The data will be reported in accordance with procedures outlined in Worksheet #36. Hard copy and electronic (such as database management system and project geographic information system) data will be stored by the EAS WSP JV for 5 years after project completion. Project reports will be archived on digital media and stored in the project file. The report and electronic data deliverable (EDD) will be uploaded to meet FUDSChem requirements.

All environmental data collected during the course of this project will be transferred to the FUDSChem database located at www.fudschem.com, following the FUDSCHem User Manual (version 6.8) 24 May 2024. Synectics Data Management Services will support this project. The following data types, will be loaded into FUDSChem:

- Geological
- Hydrogeological
- Chemical

Location data are fundamental to environmental data storage/retrieval and the relevant location information for each task that includes the collection of field data will be uploaded. These include all data collected on the project for which spatial information is appropriate (i.e., may not apply to reconnaissance activities). At project initiation, the FUDSChem workspace shall be established in FUDSChem for the project and PDT members to share work products. Synectics, who created the FUDSChem database for USACE, will be used to help setup sampling events, load data, manage the database, and conduct data validation if KGS support is unavailable in order to meet project deadlines. If Synectics is used, then the EAS WSP JV project chemist (Michael Shadle) will still oversee, manage, and direct Synectics. The FUDSChem User's Manual (https://fudschem.com; USACE, 2020b) and New England District Data Management Plan (USACE, 2016) provide guidance for the storage of all data types (geotechnical, geological, hydrogeological, chemical, GIS, etc.).

The following electronic files (FUDSChem table names identified in parentheses) will be loaded to FUDSChem when collected:

- Spatial information pertaining to sample locations (northing, easting, and elevation) (**LDI/LDI Update**) and its associated site(s) (**SLX**).
- Hydrogeological information/water levels (**GWD**) and physical parameters of groundwater samples: pH, temperature, conductivity, turbidity, ORP, dissolved oxygen) (**EMI**).
- Soil/sediment grainsize (PDF/Excel files loaded to Library).
- Monitoring well construction information such as monitoring point elevations (**WCI**), screen intervals and other aspects of well construction (sand pack, bentonite seal, etc.) (**WINT**).
- Soil lithology and logged geologic stratigraphy (**LTD**).
- Well Maintenance Information (redevelopment/well rehab stickup to flush mount) (**WMI**).
- Unexploded ordnance Discovery (**UXODISC**) data (not expected at this site).

All electronic "Data Type" files are to be loaded within two weeks following data collection. If surveyed data are required prior to data upload (GWD/WCI), then these files shall be loaded within one week after the survey data are available. Hard-copy boring, monitoring well construction forms, low-flow purge records/well development records, survey reports, grain size distribution curves (excel file, if available) shall be loaded to the FUDSChem Library within the same time frames as required above, for QA purposes.

### Exhibit 11-2 – Data Quality Objectives

| | | |
|---|---|---|
| 1 | Problem Statement | Insufficient data exists that are needed to complete the RI. The Phase 1 RI (USACE, 2023a) identified several data gaps (refer to WS#17) that need to be evaluated in order to complete the RI (USACE, 2023a). Project objectives include:<br>• Fully delineate the nature and extent of COPCs in soil, groundwater, surface water, porewater, and sediment.<br>• Update the CSM, including contaminant migration pathways, fate and transport, geologic and hydrogeologic site conditions, and exposure pathways.<br>• Define and establish background concentrations for the appropriate media (e.g., soil, groundwater, surface water, porewater, and sediment).<br>• Conduct a quantitative baseline HHRA and SLERA/RSLERA. The HHRA will estimate potential HHRA risks associated with exposure to COPCs in soil, groundwater, surface water, porewater, and sediment. The specific objective of the SLERA/RSLERA process is to determine whether the potential for ecological impacts is negligible. If this cannot be concluded for all AOCs under investigation, the SLERA/RSLERA will identify those COPECs, environmental media, exposure pathways, and representative receptor categories that can be excluded from further consideration. |
| 2 | Identify the Goals of the Study | Overall, perform additional site assessment field sampling activities (i.e., soil, groundwater, surface water, porewater, and sediment) to define/refine nature and extent of COPCs in these various media at each AOC. The Phase 1 and 2 data will be combined and used to initially assess risks to show the absence of an actionable risk. If unacceptable risks are determined, the risk assessment will be refined and/or additional investigations may be warranted. Specific sampling and goals per AOC are described below:<br><br><u>AOC 1</u>:<br>1. Determine whether potential source areas (i.e., APBs) contaminate soil and groundwater beyond an unacceptable risk. Fully delineate potential contamination as the Phase 1 RI did not collect subsurface samples in most cases surrounding the potential source areas (i.e., APBs).<br><br>2. Collect soil (saturated/wet [i.e., hydric]) samples in wetland areas in between APBs and dryer houses to determine if a contaminant migration pathway is complete to wetlands (i.e., potential groundwater seeps and/or surface water runoff pathway). |

| | | |
|---|---|---|
| 2 | Identify the Goals of the Study (cont'd) | AOC 1 (cont'd):<br>3. Characterize groundwater concentrations by installing properly constructed permanent monitoring wells.<br>4. Determine groundwater flow and contaminant migration pathways and hydraulic gradients by installing permanent monitoring wells and conducting synoptic water level surveys.<br>5. Update hydraulic conductivity values for AOC 1 by using steady-state drawdown and steady-state discharge measurements that are collected during low-flow sampling of newly installed wells. The steady-state drawdown and discharge measurements will be inputted into site specific flow models to generate an estimated hydraulic conductivity value.<br>AOC 3:<br>1. Determine whether potential source areas (i.e., former landfill and former OSA) contaminate soil, groundwater, surface water, porewater, and sediment beyond an unacceptable risk.<br>2. Determine if a groundwater to surface water and/or a surface water runoff pathway is complete in the unnamed stream to the north of the parking lot.<br>3. Characterize groundwater concentrations by installing properly constructed permanent monitoring wells.<br>4. Determine groundwater flow and contaminant migration pathways and hydraulic gradients by installing permanent monitoring wells and conducting synoptic water level surveys.<br>5. Update hydraulic conductivity values for AOC 3 by using steady-state drawdown and steady-state discharge measurements that are collected during low-flow sampling of newly installed wells. The steady-state drawdown and discharge measurements will be inputted into site specific flow models to generate an estimated hydraulic conductivity value.<br>AOC 4:<br>1. Confirm Phase 1 RI results by conducting discrete soil sampling.<br>AOC 5:<br>1. Determine whether potential source areas (i.e., boiler house, electrical substation, CABs, CSA, and/or possible dump area) contaminate soil and groundwater beyond an unacceptable risk.<br>2. Determine whether the ditch (i.e., DU002) has been impacted by contaminant migration from potential source areas by comparing these results to the results from other potential sources (i.e., boiler house, electrical substation, CSA, CABs, and potential dump area).<br>3. Evaluate soil and groundwater concentrations in potential source areas (i.e., boiler house, electrical substation, CSA, CABs, and potential dump area).<br>4. Characterize groundwater concentrations by installing properly constructed permanent monitoring wells.<br>5. Determine groundwater flow and contaminant migration pathways and hydraulic gradients by installing permanent monitoring wells and conducting synoptic water level surveys.<br>6. Determine if a contaminant migration pathway to wetlands (i.e., potential groundwater seeps and/or surface water runoff pathway) exists. Determine the presence/absence of contamination.<br>7. Update hydraulic conductivity values for AOC 5 by using steady-state drawdown and steady-state discharge measurements that are collected during low-flow sampling of newly installed wells. The steady-state drawdown and discharge measurements will be inputted into site specific flow models to generate an estimated hydraulic conductivity value. |

| | | |
|---|---|---|
| 2 | Identify the Goals of the Study (cont'd) | AOC 5 (cont'd):<br>8. Collect a subset of surface soil and subsurface soil samples within the CSA and near the CABs within AOC 5 and analyze via microscopy, similar to what was completed during the Phase 1 RI. The locations selected for microscopy samples will be biased to areas where coal particles are observed on the surface or within the soil core. (Additionally, coal particles if observed within the soil core, will be described on the boring log). The coal microscopy data (Phase 1 and Phase 2) will be used to support the CSM in terms of nature and extent (i.e., source) and fate and transport. All chemical data will be used to determine if CERCLA related contaminants pose a risk to human health and the environment. If the combined Phase 1 and Phase 2 results indicate that PAHs and metals are both above background and risk screening levels, the coal microscopy data will be used in a qualitative "lines of evidence" approach to distinguish metal and PAH contamination in coal vs. metal and PAH contamination absorbed to soils in the uncertainty section of the risk assessment.<br>Background:<br>1. Collect additional background concentration data in wetland (i.e., hydric) soil, groundwater, surface water, porewater, and sediment for use in the HHRA/SLERA/RSLERA.<br>2. Evaluate groundwater flow pathways.<br>3. Update hydraulic conductivity values for the background by using steady-state drawdown and steady-state discharge measurements that are collected during low-flow sampling of newly installed wells. The steady-state drawdown and discharge measurements will be inputted into site specific flow models to generate an estimated hydraulic conductivity value. Using site assessment data, along with background concentrations and Phase 1 RI results, prepare an HHRA for current and reasonably anticipated future land uses by AOC. The HHRA will evaluate if potential human health risks are associated with current or future land use exposures to COPCs.<br>4. Prepare a SLERA/RSLERA that evaluates the potential for adverse effects to ecological receptors associated with exposures to COPECs. |
| 3 | Identify information inputs | Soil (unsaturated and saturated/wet [i.e., hydric]), groundwater, surface water, porewater, and sediment sampling, along with synoptic gauging events and stream flow measurements as described in this UFP-QAPP and results from the Phase 1 RI. The Phase 1 and 2 data will be combined and used to initially assess risks to show the absence of an actionable risk. If unacceptable risks are determined, the risk assessment will be refined and/or additional investigations may be warranted. The following investigation techniques, field activities, and evaluation methods will be implemented by AOC:<br><br>AOC 1:<br>• Soil sampling using DPT and/or manual methods (e.g., percussion, hand auger) to collect surface (0-1 ft bgs) and subsurface (1-5, and 5-10 ft bgs) samples in the vicinity of the APBs, and within the wetlands located in between the APBs and dryer houses. Analysis will include: 2,4-DNCB, 2,4-DNP, picric acid, and total TAL metals/mercury. This is a one (1)-time event from 22 soil borings (up three (3) sample intervals per boring, resulting in 66 samples) and from 12 surface soil (0-1 ft bgs) only locations within the wetland (12 samples) for a total of up to 78 samples. Geotechnical/geochemical samples (grain size, CEC, TOC, and pH) will also be collected at five (5) borings (up to 3 samples per boring, resulting in up to 15 samples). Geotechnical/geochemical samples (grain size, CEC, TOC, and pH) will also be collected from four (4) hydric surface soil sample locations. |

| | | |
|---|---|---|
| 3 | Identify information inputs (cont'd) | AOC 1 (cont'd):<br>• Groundwater sampling from newly installed proposed monitoring well locations in potential source areas (i.e., APBs, dryer houses), and downgradient of potential sources (i.e., APBs, and dryer houses) will be conducted semi-annually for 1 year from ten (10) locations. Analysis will include 2,4-DNCB, 2,4-DNP, picric acid, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered), and hardness. The data obtained from the groundwater analyses listed above will be used to fill the gap in the evaluation of AOC 1 surface geology, hydrogeology, and human and ecological receptors as well as meet the objective of determining source areas. Section 9 of the *Final Phase 1 Data Gap Analysis Report* (May 2023) recommended installation of permanent groundwater monitoring wells and collection of representative samples for the analyses listed above in order to evaluate hydrogeologic conditions and aquifer characteristics.<br>AOC 3:<br>• Soil sampling using DPT to collect surface (0-1 ft bgs) and subsurface (1-5, and 5-10 ft bgs) samples in potential source areas (landfill area, north of parking lot, OSA) and surrounding areas. Analysis will include: VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, and total TAL metals/mercury. This is a one (1)-time event from seventeen (17) locations (up to three (3) sample intervals per boring, resulting in 51 samples). Geotechnical/geochemical analyses (grain size, CEC, TOC, and pH) will also be collected at seven (7) borings (up to 3 samples per boring, resulting in up to 21 samples).<br>• Groundwater sampling from newly installed proposed monitoring well locations in potential source areas (landfill area, north of parking lot, OSA) and surrounding areas will be taken semi-annually for 1 year from seven (7) locations. Analysis will include VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, and total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered), and hardness. Section 9 of the *Final Phase 1 Data Gap Analysis Report* (May 2023) recommended installation of permanent groundwater monitoring wells and collection of representative samples for the analyses listed above in order to evaluate hydrogeologic conditions and aquifer characteristics.<br>• Surface water sampling using direct-dip methods will be employed at eight (8) locations within the unnamed stream semi-annually for 1 year. Analysis will include VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, and total and dissolved (field-filtered) TAL metals/mercury. Sample analysis will also include DOC (field-filtered), hardness, and total suspended solids (TSS).<br>• Porewater sampling using push point sampler will be employed at eight (8) locations within the unnamed stream semi-annually for 1 year. Porewater samples will be co-located with surface water locations. Analysis will include VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, and total and dissolved (field-filtered) TAL metals/mercury.<br>• Sediment sampling using hand coring methods will be employed at eight (8) locations within the unnamed stream semi-annually for 1 year. Sediment samples will be co-located with surface water/porewater locations. Analysis will include VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, and total TAL metals/mercury. Sample analysis will also include grain size, TOC, and pH.<br>• Section 9 of the Final Phase 1 Data Gap Analysis Report (May 2023) recommended sediment, surface water and pore water sampling for the listed analyses in order to assess ecological risk.<br>AOC 4:<br>• Soil sampling using hand augering to collect surface (0-1 ft bgs) samples within Phase 1 RI DUs. Five locations at each Phase 1 RI DUs surrounding the twelve bunkers will result in a total of 60 locations. Analysis will include: 2,4-DNCB, 2,4-DNP, and picric acid. This is a one (1)-time event.<br>AOC 5:<br>• Soil sampling using DPT and/or manual methods (e.g., percussion, hand auger) to collect surface (0-1 ft bgs) and subsurface (1-5, and 5-10 ft bgs) samples in the vicinity of and downgradient of potential source areas (e.g., boiler house, CSA, etc.) and from the wetlands located to the west of AOC 5. Four DUs (eight borings per unit) will be placed along: (1) former electrical substation and boiler house, (2) along the former drainage ditch and CABs, (3) around the former CSA, and (4) at the possible dump area. Analysis will include PAHs and total TAL metals/mercury. Additionally, PCB |

| | | |
|---|---|---|
| | | analysis will be included for surface and subsurface soil samples collected within the former electrical substation only because an aroclor was detected in a Phase 1 soil sample from the area above a PAL. This is a one (1)-time event from 32 DPT soil boring locations (up to three (3) intervals per location, resulting in 96 samples) and from three (3) surface soil (0-1 ft bgs) only locations within the wetland (i.e., three (3) samples) for a total of up to 99 samples. Geotechnical/geochemical analyses (grain size, CEC, TOC, and pH) will also be collected at each DU (i.e., five (5) borings (up to 3 samples per boring, resulting in up to 15 samples. Note DU#1 will have two borings were there are geotechnical/geochemical analyses collected). Geotechnical/geochemical analyses (grain size, CEC, TOC, and pH) will also be collected at one (1) hydric soil sample location (i.e., one sample). Coal by microscopy will also be collected at all eight borings within CSA (up to three (3) intervals per location), four borings closest to the CABs (up to three (3) intervals per location), and three borings closest to the boiler house (up to three (3) intervals per location), resulting in a potential 45 samples for microscopy.<br>• Groundwater sampling from newly installed proposed monitoring well locations in the vicinity of and downgradient of potential source areas (e.g., boiler house, coal storage area, etc.) will be taken semi-annually for 1 year from eleven (11) locations. Analysis will include PAHs and total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered), and hardness. Additionally, PCB analysis will be included for groundwater samples collected at monitoring wells installed within the former electrical substation and possible dump area and wells downgradient of the substation (MW-03 and MW-07 only). Section 9 of the *Final Phase 1 Data Gap Analysis Report* (May 2023) recommended installation of permanent groundwater monitoring wells and collection of representative samples for the analyses listed above in order to evaluate hydrogeologic conditions and aquifer characteristics.<br><u>Background</u>:<br>• Soil sampling using hand augering techniques to collect surface (0-1 ft bgs) samples in hydric soils in wetlands located west of AOC 3. Analysis will include PAHs and total TAL metals/mercury, along with geotechnical/geochemical parameters (grain size, CEC, TOC, and pH). This is a one (1)-time event from eight (8) locations (a total of up to eight (8) samples). The Final Phase 1 Data Gap Analysis Report (May 2023) (Appendices F, G and H) established a process for defining background conditions for inorganic and PAH analytes and the additional background datasets will also be evaluated using this same approach to support the risk assessments. In addition, the NYSDEC (2006) statewide inorganic soil background study may also be considered to support decision-making particularly if local background concentrations (e.g., arsenic) are determined to pose unacceptable risks to human or ecological receptors.<br>• Groundwater sampling from newly installed proposed monitoring well locations in the vicinity of previously installed Phase 1 RI background temporary well locations will be taken semi-annually for 1 year from six (6) locations. Analysis will include PAHs and total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered), and hardness.<br>• Surface water sampling using direct-dip methods will be employed at eight (8) locations within the unnamed stream located west of AOC 3 semi-annually for 1 year. Analysis will include PAHs and total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered), hardness, and TSS.<br>• Porewater sampling using push point sampler will be employed at eight (8) locations within the unnamed stream located west of AOC 3 semi-annually for 1 year. Porewater samples will be co-located with surface water locations. Analysis will include PAHs and total and dissolved (field-filtered) TAL metals/mercury.<br>• Sediment sampling using hand coring methods will be employed at eight (8) locations within the unnamed stream located west of AOC 3 semi-annually for 1 year. Sediment samples will be co-located with surface water/porewater locations. Analysis will include PAHs and total TAL metals/mercury. Sample analysis will also include grain size, TOC, and pH.<br><br>The *Final Phase 1 Data Gap Analysis Report* (May 2023) (Appendices F, G and H) established a process for defining background conditions for inorganic and PAH analytes and the additional background datasets will also be evaluated using this same approach to support the risk assessments. In addition, the NYSDEC (2006) statewide inorganic soil background study may also be considered to support decision-making particularly if local |

| | | |
|---|---|---|
| | | background concentrations (e.g., arsenic) are determined to pose unacceptable risks to human or ecological receptors. Site-specific BTVs will be used as a first line of evidence to determine whether concentrations detected in site media are attributable to background levels. Comparison to the site-specific BTVs is based on the null hypothesis that the site concentrations are consistent with background concentrations. If comparison to the site-specific BTVs indicates the likelihood of false positives (Type I error or the incorrect rejection of the null hypothesis), either single- or two-sample hypothesis testing may be considered for PAH and/or inorganic analytes as an additional risk refinement. The statewide background values (NYSDEC 2006) will also be used as a supporting line of evidence in the site-to-background comparisons.<br><br>HHRA and SLERA/RSLERA evaluations will use newly collected and Phase 1 RI data as appropriate. Site data will be used to calculate potential risks to human receptors where concentrations exceed risk-based screening levels. Inputs used to calculate potential human health cancer risks and hazards will be based on default and site-specific exposure assumptions and intake equations consistent with USACE and EPA guidance. Default exposure assumptions will be sourced from EPA guidance. Toxicological inputs will be based on the EPA (2003) guidance toxicological hierarchy. For ecological receptors, site chemistry data will be used to establish exposure point concentrations for comparisons to direct contact ecotoxicological benchmarks and as inputs into dietary exposure models to evaluate wildlife ingestion pathways. |
| 3 | Identify Information Inputs (cont'd) | Dietary exposure models will be developed using literature-based exposure parameters, bioaccumulation factors, and toxicity reference values. A site reconnaissance survey will be conducted by a qualified ecologist to support the development of the ecological CSM, including the identification of representative ecological receptors for evaluation in the SLERA. |
| 4 | Define the Boundaries of the Study | <u>AOC 1</u>:<br>• Horizontal boundaries for AOC 1 extend the length of the APBs (approximately 3,000 feet northwest/southeast, and to the dryer houses (approximately 1,000 feet to the east/northeast).<br>• Vertical boundaries for AOC 3 for soil extend to 10 ft bgs. For groundwater, not to exceed 20 ft bgs.<br><u>AOC 3</u>:<br>• Horizontal boundaries for AOC 3 extend from where the unnamed stream crosses beneath Potter Road to the west of the site and extends approximately 1,200 feet to the east. Using the southern boundary of the open storage area, the boundary extends approximately 1,000 feet to the north.<br>• Vertical boundaries for AOC 3 for soil extend to 10 ft bgs. For groundwater, not to exceed 20 ft bgs.<br><u>AOC 4</u>:<br>• Horizontal boundaries for AOC 4 are the footprints of each individual bunker approximately 30 ft x 40 ft.<br>• Vertical boundaries for AOC 4 for soil extend to 1 ft bgs.<br><u>AOC 5</u>:<br>• Horizontal boundaries for AOC 5 begin at the edge of Route 631 and extend approximately 1,000 feet to the west/southwest. The north/south boundary begins across from Deep Glad Drive and extends approximately 600 feet to the south. If analytical parameters in the hydric soil samples (i.e., NYOW-05-058 through -060, Figure 17-5) collected along the current western boundary exceed both ecological screening values and hydric soil background BTVs, the PDT will consider the need to collect additional characterization samples in this wetland habitat.<br>• Vertical boundaries for AOC 5 soil extend to 10 ft bgs. For groundwater, not to exceed 20 ft bgs.<br><br>Semi-annual sampling for 1 year will be conducted to qualitatively evaluate potential temporal variability in groundwater, sediment, surface water and pore water concentrations. |

| | | |
|---|---|---|
| 5 | Develop the Analytical Approach | Soil (unsaturated and saturated [i.e.,hydric]), groundwater, surface water, porewater, and sediment concentrations will be compared to risk-based screening levels, federal (applicable) standards, and background concentrations. This comparison will be completed in the HHRA and SLERA/RSLERA using the combined Phase 1 and 2 datasets, and each AOC will initially be treated as a single EU. Cumulative Excess Lifetime Risk calculations (in accordance with state and federal guidance documents) and hazard indices will be calculated in the risk assessments (only hazard is calculated in the SLERA/RSLERA). Based on the results of the initial screening and risk calculations, the risk assessment CSMs will be used to develop refined EU assumptions for receptors and analytes that are not eliminated during the initial screening process. The risk refinement process will be included in the uncertainty analyses and will address the use of biased samples (e.g., samples collected near buildings and/or sources) in the risk assessments and the potential overestimation or underestimation of risks. This may include a sample-by-sample evaluation and/or recalculation of risks with only unbiased samples. If the risk refinement process does not adequately address the potential decision errors associated with including biased samples, the use of weighted EPCs (spatial and/or volume weighted) may be considered as an alternative approach in the uncertainty analyses. Risk assessment findings will be documented in the RI Report and will guide future decisions.<br><br>The HHRA and SLERA/RSLERA will be conducted in accordance with CERCLA requirements and consistent with US EPA and USACE risk assessment guidance and all applicable NYSDEC requirements as appropriate. |
| 6 | Specify Performance or Acceptance Criteria | All work shall have the ability to provide samples that represent current conditions to address data gaps and provide information to support the HHRA, and SLERA. Sampling design will be as specified in this QAPP; analytical data will meet USACE and EPA specifications for precision, accuracy, representativeness, completeness, and comparability. If after data collection, additional samples are needed in order to fulfill identified data gaps, further investigations will be proposed via a work plan addendum. Following the initial screening of the combined Phase 1 and 2 datasets and potential refinement of EUs, the risk assessments will evaluate the robustness of the available datasets to support decision-making. If quantitative hypothesis testing is conducted (e.g., to evaluate consistency of site data with background conditions), power analysis may be used to determine whether additional sample collection is necessary to achieve acceptable decision error rates. |
| 7 | Develop the Detailed Plan for Obtaining Data | Tasks will be conducted as described in Worksheet #14/16. Samples will be collected as described in Worksheets #17 and #18, with analytical design requirements presented in Worksheet #s 19/30, 20, 25, 26/27, and 28. |

# Worksheet #12 – Measurement Performance Criteria

The quality of the data to be collected for this project will be verified through appropriate measurement performance criteria (MPC) established for both sampling procedures and analytical methods. The criteria should relate to data quality indicators, consisting of precision, accuracy, representativeness, comparability, and completeness as well as sensitivity. MPC for NYOW methods are presented in the worksheets below: Analytical SOPs are listed in Worksheet #23 and are included in **Appendix F**. Completeness will be evaluated separately for each DU, analyte and data use to determine whether the data needs are adequate for the decisions to be made.

## Worksheet #13 – Secondary Data Uses and Limitations

Secondary data refer to historical data previously collected for the sites. The source(s) of the data, date of collection, planned uses, and limitations of the secondary data for each site are summarized in the following table.

| Secondary Data | Source | Date of Collection | How Data Will Be Used | Limitations on Data Use |
|---|---|---|---|---|
| Groundwater, soil | USACE, 2022. Final Remedial Investigation Phase 1 Field Report – AOC 1, AOC 3, AOC 4 ISM, and Background | 2021 | Historical data will be used to evaluate concentrations and trends and to place proposed Phase 2 locations | (1) Groundwater samples were collected from temporary locations which can over/underestimate concentrations. (2) Laboratory sensitivity issues were noted for the AOC 4 ISM surface soil samples. |
| Groundwater, soil | USACE, 2022. Final Remedial Investigation Phase 1 Field Report – AOC 4, and AOC 5 | 2021 | Historical data will be used to evaluate concentrations and trends and to place proposed Phase 2 locations | (1) Groundwater samples were collected from temporary locations which can over/underestimate concentrations |
| Groundwater, soil | USACE, 2023a. Phase 1 Risk Screening and Data Gaps Analysis, Former New York Ordnance Works Formerly Used Defense Site, Baldwinsville, New York. May. | 2023 | Historical data will be used to evaluate concentrations and trends (i.e., seasonal variability) and will be considered for the HHRA and SLERA/RSLERA. A statistical trend analysis will not be conducted. | (1) Groundwater samples were collected from temporary locations which can over/underestimate concentrations. (2) Laboratory sensitivity issues were noted for the AOC 4 ISM surface soil samples. |

This page intentionally left blank

# Worksheets #14 and #16 – Project Tasks and Schedule

This worksheet provides specific project tasks and responsible parties. The planned start and end dates for the project tasks are provided in the schedule. Applicable SOPs that are used to supplement the work procedures described in Worksheet #14 and #16 are provided in Worksheet #21. The proposed activities are based on the project statement of work (USACE, 2022) and project DQOs (Worksheet #11).

## 14.1 Pre-Field Work Activities

Activities required before field tasks (e.g., soil sampling) begin include: site access and work location coordination, site reconnaissance, identification of boring and well locations, and well permits.

### 14.1.1 Site Access and Location Coordination

All project work will be coordinated with the USACE CENAE PM, Ms. Amanda Martin. Notice of field activities will be provided to the NYSDEC and the NYSDOH at least two weeks prior to the start of work. Additionally, field activities will be coordinated with the property owners at least 2 weeks prior to the work being conducted at their respective AOC. Work schedules are anticipated to follow a 5-day weekly schedule, Monday through Friday. Work is anticipated to be performed during daylight and within, typically, 8:00 AM to 5:00 PM.

Photographs are required to assist with the documentation of field activities, geologic features, sites, and sampling locations. Camera permits are not required.

### 14.1.2 Private Property Access

If work is to be conducted on private property, a ROE must be obtained in order to execute field investigations before accessing private property. USACE CENAE will be responsible for obtaining ROEs for all properties. The EAS WSP JV will provide a list of property owners to be contacted prior to the field activities. The list will include the mailing address and telephone number of the property owners (if available). Field work will commence once USACE CENAE establishes an access agreement with the owner(s) of each privately owned parcel proposed for the field program. The EAS WSP JV will contact and coordinate with property owners to schedule sampling activities. During the field program, sampling crews will carry a hard copy of the signed access agreement for each parcel, as needed. Per USACE CENAE direction, a minimum of two (2) full weeks (14 business days) advanced verbal notice will be provided to the facility/property owners prior to mobilization.

Due to the intrusive nature of some field activities, it is possible that property owners may object to having a drill rig on their property or may feel that the field team is trespassing. If USACE cannot secure ROEs, the EAS WSP JV will obtain the contact information for several of the closest neighbors (if possible) and provide the information to USACE CENAE to establish ROEs to the adjacent properties. If no ROEs can be obtained, then the location would be moved to the closest area that would not need an ROE.

### 14.1.3 Site Reconnaissance and Marking of Boring and Well Locations

Site reconnaissance and marking boring/sampling locations will consist of a site visit by the EAS WSP JV to identify overhead and obvious underground utility locations and other site features that may impede or preclude drilling. Impediments to drilling include uneven or soft ground, high degree slopes, and thick vegetation. Boring/sampling locations, including buffer areas, will be marked with white or pink paint, white or pink pin flags, or wooden stakes by the FTL. Drill paths will also be flagged for future clearing events.

### 14.1.4 Well Permits

The EAS WSP JV, through its drilling subcontractor (Labella Associates), will obtain any required local and state drilling and boring permits. Upon completion of borings, boring abandonment, and well installation, the EAS WSP JV, through its drilling subcontractor (Labella Associates), will submit any required completion reports.

## 14.2 Field Activities

Field activities that will occur to support Phase 2 RI data collection include (not necessarily in chronological order):

- Mobilization/Demobilization.
- Vegetation Clearing
- Utility Clearance
- Soil sampling.
- Monitoring Well Installation & Development
- Groundwater sampling semi-annually x 1 year.
    - Synoptic water levels (manual measurements) semi-annually x 1 year.
- Surface water sampling semi-annually x 1 year.
    - Stream Velocity Measurements semi-annually x 1 year.
- Porewater sampling semi-annually x 1 year.
- Sediment sampling semi-annually x 1 year.
- Stream Piezometer Installation
    - Synoptic water levels (manual measurements) semi-annually x 1 year.
- Survey
- Temporary Well Abandonment

Field activities will be performed at various stages throughout the program and will be conducted in accordance with the SOPs identified on Worksheet #21 and indicated below as applicable. The SOPs are included as **Appendix D**. The following subsections will describe the procedure and processes that will be followed for each field activity. Worksheet #17 will provide the specific sampling design and rationale for the field activities during each specific phase of the program.

### 14.2.1 Mobilization/Demobilization

Mobilization will consist of the delivery of all equipment, materials, and supplies to the site, the complete assembly in satisfactory working order of all such equipment at the site, and the satisfactory storage at the site of all such materials and supplies. Each demobilization shall consist of prompt and timely removal of all equipment, materials, and supplies from the site following work completion. Demobilization includes the cleanup and removal of waste generated during the investigation.

#### 14.2.1.1 Field Staging Area

A field staging area will be established in the parking area located at AOC 4, next to the NYSDEC Field Office. The staging area will be large enough to accommodate portable sanitary facilities (and service access), a drive-on pad for the decontamination of drilling and sampling equipment, staging of drilling equipment and supplies, and vehicle parking. A Conex box may be leased for the long-term storage of equipment and supplies, if necessary. In addition, a secured chain-link fenced area will be constructed for the staging of investigation-derived wastes (IDW) and trash. The decontamination pad will be constructed with water-proof materials and cinder blocks (or similar), for the containment of decontamination fluids. Any fluids that collect in the bottom of the pad will be pumped into 55-gallon drums, as needed, and labeled appropriately. In addition, the secure fenced area will be used to stage drums containing impacted drill cuttings, if applicable, pending proper waste characterization and disposal.

### 14.2.2 Vegetation Clearance

Some areas may require vegetation to be cleared in order to access drilling/sampling locations. Equipment used will be commensurate of the type of clearing that will be needed. To remove brush, thin branches, cutting shears and/or loppers, or similar will be used. For overgrown grass and thick brush, a bush-hog or similar type of equipment will be used. For trees not greater than 3-inches, and/or for fallen trees, chain-saw type removal methods will be used. At drilling locations where vegetation removal is required for access, tree clearing will be kept to a minimum and trees having a breast height of 3 inches or greater shall not be cut unless approved by USACE. Furthermore, trees with shaggy or exfoliating bark will not be removed as these may provide bat habitat.

### 14.2.3 Utilities Clearance

Utility clearance will occur prior to any intrusive field activity (e.g., soil sampling). Once intrusive locations have been marked and identified (by the EAS WSP JV), New York State 811 will be contacted and a DigSafe ticket will be filed. In addition to the State DigSafe, ground-penetrating radar (GPR) will be employed as an additional safety measure prior to any subsurface soil/monitoring well location that will be drilled beyond 1 feet bgs by a drill rig. For surface soil (0-1 foot bgs) only locations (AOC 4), and because the sample collection method (i.e., hand auger) is considered a utility detection method, GPR will not be performed. The purpose of the GPR will be to identify known or unknown subsurface anomalies to avoid inherent safety risks to the field crew and property. At each intrusive drilling location, the FTL will escort the GPR subcontractor to each location. A stake or flag will be used at each location to mark the boring/sample location. The name of the boring will be marked using a sharpie and photographed by the FTL. The subcontractor will mark and measure a 10-foot by 10-foot area during the GPR survey; the four (4) corners of each area will be marked by flagging. The area will be surveyed once the location has been marked. If a particular anomaly/utility feature has been identified within the 10-foot by 10-foot area, it will be marked with flagging and spray paint. If the anomaly is located within 5-feet of the proposed boring location, then a new area will be re-surveyed in any direction to avoid the anomaly. After completion of the survey, the findings will be sketched in a field logbook by the FTL, as well as photographed. This ensures the results of the survey are documented if intrusive activity is delayed. All activities will be documented on Daily Quality Contractor Reports (DQCRs) and reviewed daily by the QCM. The DQCRs will list project name, location, date, weather, personnel and company, equipment used and serial numbers, installation IDs, footage, description of work performed, who collected samples, health and safety requirements, any changes from the work plan, and any remarks. The DQCR will be signed by the FTL daily.

### 14.2.4 Soil Boring Installation and Sampling

Following approval from Digsafe and the GPR survey, discrete soil samples will be collected at prescribed depths by AOC (refer to Worksheet #17). Soil sampling will be performed at AOC 1, AOC 3, AOC 4, and AOC 5 in order to further refine the nature and extent of COPCs and collect the data necessary to complete the RI. Background hydric soils will also be collected in order to compare background wetland concentrations to wetland concentrations located at AOC 1 and AOC 5. Background hydric soils will be compared to soil benchmarks, site-specific soil background data and/or NYSDEC background data to determine if they are a suitable dataset for background. If after the collection of the initial samples identified within this UFP-QAPP does not satisfy DQOs, then additional sample locations can be proposed in order to fulfill DQOs (refer to Worksheet #11). LaBella Associates will perform all drilling/intrusive activities with oversight provided by the JV's Field Geologist and support personnel. Hand augering tasks may be performed by the JV or drilling subcontractor.

Boreholes for soil sampling will be advanced using a combination of either hand augering, direct-push technology (DPT) track mounted rig, and/or manual percussion drilling methods. The following design rationale (i.e. if/then) will be considered:

- If a location is solely designated as a surface soil (0-1 feet bgs) only sample location, then hand augering will be the preferred sample collection method. DPT will be considered depending on terrain, and drill rate productivity.

- If a location is designated to be a surface/subsurface soil boring with sampling intervals of 0-1, 1-5, and 5-10 feet bgs, then borings will be advanced utilizing DPT.
- If a soil boring cannot be advance by DPT due to the inherent safety risks associated with drilling on steep slopes, then manual drilling methods utilizing an air-powered handheld percussion hammer or manual slide hammer will be used to advance the borehole to terminal depth.
- If a surface soil only location cannot be advanced via hand auger due to hard pack gravel/cement/pavement, then the DPT rig or manual methods (i.e., hand-held percussion/manual slide hammer) will be used.
- If a soil boring is to be co-located with a permanent monitoring well, then soil samples will be collected using dual-tube DPT. Once samples have been collected, the monitoring well will be placed within the same borehole (refer to Section 14.2.5 for additional details). Boreholes may be advanced via manual methods (i.e., hand-held percussion/manual slide hammer), also.

Typical hand auger core barrel lengths are 6-inches, therefore for surface soil collection, the first and second 6-inches of retrieval will be placed into a clean, decontaminated stainless-steel bowl. The sample will then be composited and mixed thoroughly in accordance with *SOP #9 Soil Sampling Procedure* provided in **Appendix D**. Once the sample has been mixed thoroughly, either a stainless-steel spoon or disposable plastic scoops will be used to collect the sample into the appropriate bottleware. Common collection procedures are identified below.

Due to the inherent risks associated with drilling on steep slopes at AOC 1, manual drilling methods using an air-powered hand-held percussion hammer or manual slide hammer may be used to advance a macrocore to collect soil samples, in the event an area is inaccessible to the DPT drill rig. Similar to DPT, at the end of the drill rod will be a thread on macrocore that will be used to collect the samples from 0-1, 1-5, and 5-10 feet bgs. A 3-inch diameter macrocore sampler has been requested in order to maximize soil volume collected. If a boring does not contain the required volume of sample, additional borings will be located as close as possible to the original in order to obtain the volume necessary. Manual drilling methods will not be used to install permanent monitoring wells.

If the water table is encountered at a depth shallower than 10 feet bgs, then the last soil sampling interval will be adjusted. For example, if the water table at an AOC 3 location is encountered at a depth of 8 feet bgs, then the last sample interval would be 5-8 feet bgs.

**Common Procedures Soil Sampling/Logging Procedures**

At each drilling location, soil cores will be retrieved and lifted on top of a field table with a set ruler (or equivalent). Once at the core has been cut open, the following procedure will occur:

(1) Each sampling interval will be screened immediately using a photoionization detector (PID) (10.6 electron volt lamp) if sampling for VOC analysis (AOC 3 only). Within each sampling interval, VOC samples will be collected from the area of the core exhibiting the highest PID reading or areas of staining. If no PID response or staining is observed, the VOC sample will be collected from areas showing a change in lithology such as grain size within the designated sample interval. If there is no discernable lithology change, the sample will be collected from the mid-point of the sampling interval to provide consistency between sample locations. Refer to SOP#9 for additional details.

(2) Samples that require VOC analysis will be collected using a TerraCore™ (or equivalent) and transferred within the appropriate sample bottleware first.

(3) The core will be divided into the appropriate sampling intervals, using a ruler (or similar) and a decontaminated putty knife (or similar).

(4) Once VOCs have been collected, soils at each sampling interval will be mixed using cone and quartering techniques in a decontaminated stainless-steel bowl.

(5) Once the sample has been mixed thoroughly, a stainless-steel spoon or disposable plastic scoop will be used to transfer the sample into the appropriate bottle ware.

(6) All soils will be logged following the Unified Soil Classification System (USCS). Color will be described following Munsell Charts, and moisture content (dry, moist or damp, wet, or saturated) will be included in the description. The boring log to be used is provided in Appendix D. The entire core will be photographed.

(7) All soil boring only locations will be abandoned by filling them completely with a cement/bentonite slurry or hydrated bentonite chips from the total depth to ground surface. For locations that are within pavement, the bentonite/grout will extend to an appropriate height that will allow for a cold patch seal to be placed.

(8) Samples will be placed into laboratory-prepared, pre-preserved (if required) sample bottles and packed on ice for overnight shipment to the appropriate laboratories identified on Worksheet #11 and Worksheet #19/30. The samples will be shipped to the laboratory using approved chain-of-custody procedures (Refer to Worksheet #26 and #27).

(9) Decontamination of all drill and sampling tooling will follow SOP #6 Decontamination Procedure (Appendix D). Decontamination of drilling tooling will consist of a high-pressure wash. Decontamination of the macrocore and split spoons will consist of a potable water rinse, potable water and liquinox/alconox rinse using a scrub brush, and a DI rinse. A centralized decontamination pad will be built near the drill site and all decontamination of large sampling equipment (e.g., core barrels, over-ride casing) will occur within that pad. All fluids generated will be captured within secondary containment and will be temporarily containerized. Management of IDW will follow the procedures outlined in the IDW Plan (refer to **Appendix E**).

### 14.2.5 Monitoring Well Installation and Well Development

Monitoring well installation will be performed at select locations within AOC 1, AOC 3, AOC 5, and Background (refer to Worksheet #17). LaBella Associates will perform all drilling/intrusive activities with oversight provided by the EAS WSP JV Field Geologist and support personnel. In areas where it is inaccessible to a drill rig, temporary groundwater sampling may be performed. Refer to the groundwater sampling section for further details. Monitoring well installations and development will follow *EPA Region 4 Design and Installation of Monitoring Wells SOP SESDGUID-101-R2,* provided in **Appendix D**. Decontamination of all drill and sampling tooling will follow *SOP #6 Decontamination Procedure* (**Appendix D**).

IDW will be disposed of in accordance with the Investigation-Derived Waste Plan located as **Appendix E**.

As indicated in Section 14.2.4, proposed monitoring well boreholes will be advanced using dual tube DPT (or similar). At co-located soil boring/monitoring well locations, soil samples will be collected first as described in Section 14.2.4. Depending on the height of the water table, after soil samples have been collected, the monitoring well borehole will be advanced to a depth sufficient enough to allow for a properly constructed permanent monitoring well. A properly constructed permanent monitoring well will be constructed of; a 2-inch schedule 40 PVC, 10-foot 0.010-inch screen slot pre-pack; riser; surface expression; filter pack; bentonite seal, and grout to surface. At a minimum, 6-inches of filter pack material will be placed at the bottom of the well to provide a firm base. The filter pack will then extend to a minimum of 2-feet above the top of the screen, followed by a minimum of 2-feet bentonite seal, followed by grout to surface. Filter pack will consist of #00N silica sand with approximately two feet of #00 choker sand above the filter pack. Since groundwater encountered at the site may be less than 1 ft bgs, permanent monitoring well screen placement will be flexible, determined in the field, and extend below the water table approximately 7 to 8 feet so that a proper filter pack and seal can be installed.

In an effort to alleviate the potential effects of frost heave damage to the well, it is recommended that grouting material not be placed inside the protective casing. The bottom of the protective casing would be placed on top of the grout and additional grout placed on the outside of the protective casing. The annular space between the well riser will be filled with sand. This design prevents the protective casing from being

connected to the riser. In the event of frost heaving, the protective casing may move, but not the monitoring well.

In wells with shallow water table elevation the well screen will be placed below the top of the water table to allow for sufficient placement of filter pack, bentonite seal, and grout. During sampling, wells will be allowed to adjust to atmospheric pressure before collecting depth to water measurements.

In locations that are within the woods, the surface expression will include steel casing that will extend above grade. In high foot traffic/high visibility areas, monitoring wells will be completed inside a sealed, bolted roadbox. A 2-foot x 2-foot x 4-inch thick concrete pad will be installed around each well head. No bollards will be placed.

Following installation and at least 24 hours in order to allow the monitoring well surface pad to cure, the monitoring wells will be developed using pump and surge techniques for up to two (2) hours per well to remove fine sediment from the well. Field parameters (pH, temperature, specific conductance, dissolved oxygen [DO], turbidity, color, odor, and oxidation- reduction potential [ORP]) will be recorded during well development. Monitoring well development will be considered complete when the water is clear of visible sediment and the turbidity of the well reaches an asymptotic value. The monitoring well development form is provided in **Appendix D**. If a monitoring well runs dry during well development, development will be considered complete.

Wells will be sampled to support study tasks no sooner than 24 hours following the completion of well development. The process of collecting groundwater samples is discussed in the following section.

### 14.2.6 Water Quality Equipment Calibration

Calibration of all field water quality equipment (i.e., water quality instrument, turbidity meter) will include a calibration each day of sampling. Immediately following calibration, an initial calibration verification (ICV) will occur. The ICV is meant to document how well the appropriate meter calibrated. The meter will be inserted into each appropriate calibration solution and the parameter will be recorded in read/run mode on the appropriate field form (**Appendix D**). The ICV value will be within control limits specified on field forms. In the event the ICV does not meet the specified criteria, then the meter will be re-calibrated. If the ICV continues to fail, then a new meter will be requested from the vendor. Following sampling and at the end of each day, a post-calibration check will be performed. The purpose of this check is to document instrument drift. The meter will be placed within the designated calibration fluid and the value will be recorded in read/run mode on the appropriate form (**Appendix D**). If the parameter fails the specific criteria identified on the field form, then it will be noted on the calibration form and a “J” qualifier will be applied to all effected parameters on the appropriate purge forms. Turbidity and pH will be bracketed (i.e., multiple calibrations used). For pH, calibration will beginning with pH 7 calibration solution and followed by either pH 4 and/or pH 10. The bracketed calibration will occur prior to conducting the ICV check.

For all other equipment requiring calibration please refer to Worksheet #22.

### 14.2.7 Groundwater Sampling

Following at least 24-hours post-development, groundwater sampling will be conducted by the JV field personnel. Groundwater sampling from monitoring wells will follow low-flow sampling protocol in accordance with *EPA Low-Stress (Low Flow) / Minimal Drawdown Groundwater Sampling* SOP in **Appendix D**. Based on the site CSM and identified depth-to-water measurements historically taken, a peristaltic pump will be used to collect the samples.

Teflon-lined tubing will be used to collect all groundwater and porewater samples at AOC 1, AOC 3, and AOC 5. Teflon-lined tubing is being used for VOC sample collection as well as other organic sample collection (e.g. SVOCs and PAHs). If the screen is fully saturated, then tubing intake depths will be set at the midpoint. If the screen zone is not fully saturated, tubing intake depths will be placed at the midpoint of the saturated screen interval.

Wells will be purged prior to sampling using an in-line, flow-through cell to measure water quality parameters (pH, temperature, specific conductance, ORP, DO, and turbidity) at intervals of approximately every 5 minutes. Flow rates during purging and sampling will be maintained between approximately 50 to 500

milliliters per minute, if well yield is sufficient, and will be adjusted to minimize drawdown in the well. Purging will be considered complete and sampling will commence. when the water quality parameters stabilize for three (3) consecutive readings in the following order, and in accordance with *EPA Low-Stress (Low Flow) / Minimal Drawdown Groundwater Sampling* SOP as summarized below:

- pH + 0.1 pH units.
- Temperature + 1% degree Celsius (°C).
- Conductivity + 3%.
- ORP + 10 millivolts (mV)
- DO + 10 % or all readings < 0.5 milligrams/liter (mg/L).
- Turbidity + 10 % or all readings < 10 nephelometric turbidity units (NTU).

Water quality parameters and other observations (e.g., color and odor) will be observed and recorded on field purge forms (**Appendix D**). After the parameters have stabilized, the flow-through cell will be disconnected, and sampling will commence. For dissolved metals and DOC analyses, a 0.45-micron filter will be placed in line and samples collected (refer to Worksheet #17), after the total metals analysis has been collected.

At certain locations where a drill rig cannot gain access to a proposed monitoring well location (e.g., AOC 1 APBs), due to uneven terrain/high angle slopes, or soft ground (i.e., wetlands), groundwater samples can be collected from temporary well points. The potential for this is only anticipated in 2 – 3 locations and will not be used as data points in the risk assessments. However, since the intent of these sample locations is to investigate source areas, a temporary well point will provide information on groundwater conditions in the area and a decision can be made whether to invest additional effort to provide drill rig access for installation of a permanent well. In these cases, similar to the manual soil boring collection method, groundwater samples can be collected via the vertical profiling technique using a hand-held percussion hammer or manual slide hammer to drive the drill rod(s). The first rod will consist of a mill-slotted screen with a drive point on the end of the rod. The rod will be advanced using a hand-held percussion hammer or manual slide hammer. The groundwater samples will be collected using the following procedure:

- Decontaminate each of the rods;
- Advance the rod using the hand-held percussion hammer or manual slide hammer;
- Insert LDPE tubing into the slotted portion of the rod to collect a groundwater sample via either a check valve sampling method or peristaltic pump;
- Purge the line and record one-set of field parameters (temperature, pH, conductivity, DO, ORP, and turbidity).
- Collect samples
- Remove and dispose of tubing.
- Pull rods and decontaminate and move to the next location. Repeat the process.

The appropriate length and size of drill rods will be used. Depending on the depth to groundwater, the rods will be driven to 3-foot below the encountered water table. Once at sampling depth, the rods will be extracted, and the screen will be exposed. Example, if the depth to the water table is encountered at 1 ft bgs, the screen would be driven to a depth of 4 feet, and the groundwater sample collected would represent 2-4 feet bgs. Final sample depths may be adjusted based on field conditions encountered during advancement of the rods, and if a larger screen length is used. Only one interval will be sampled. Following the collection of the temporary groundwater sample, the borehole will be abandoned using either hydrated bentonite or grout to surface.

Groundwater samples will be collected into laboratory-prepared, pre-preserved (if required) sample bottles and packed on ice for overnight shipment to Eurofins Test America Lancaster, Denver, and/or Georgia depending upon laboratory analyses (refer to Worksheet #11). Refer to Worksheet #17 for specific

analyses. The samples will be shipped to the laboratory using approved chain-of-custody procedures (Refer to Worksheet #26 and #27).

Groundwater sampling equipment calibration logs will be submitted with the Phase 2 RI Field Report. Equipment calibration logs are provided in **Appendix D**. Equipment rinsate blanks (ERBs) will not be collected because single-use disposable equipment (e.g., tubing) will be used and the equipment is not anticipated to contribute to COPCs.

### 14.2.7.1 Hydraulic Conductivity Testing

Hydraulic conductivity values will be estimated using the steady state discharge and drawdown low-flow data that will be collected during purging and sampling events as described in Section 14.2.7. Testing will follow the *Determining K while Low Flowing* SOP provided in **Appendix D**. The magnitude of drawdown must be measured. The drawdown will be determined as the difference between the depth to water during pumping and the pre-pumping static water level. In addition to the steady state depth to water, the steady state discharge rate (i.e., flowrate) will be used. The following steps will be used:

1. Determine Steady State Drawdown using the following equation:

$$S = DTW(t) – DTWo$$

Where:

S = drawdown

DTW(t) = depth to water while pumping

DTW(o) = depth to water before pumping

2. Determine Steady State Discharge using the following equation:

$$Q = V/dt$$

Where:

Q = flowrate (discharge)

V = volume of water

Dt = duration of collection

Once that data has been collected, and during the reporting stages of this program (refer to Section 14.4), the data will be inserted into either the Half Ellipsoid Model spreadsheet (Dachler (1936), Full Ellipsoid Model spreadsheet (Hvorslev (1951), or the Radial Flow Model spreadsheet (Muskat (1937). The spreadsheets are provided with the *Determining K while Low Flowing* SOP provided in **Appendix D**. The decision on which model to use won't be made until after the monitoring well is installed since the models are dependent on the lithology encountered while drilling and where the well screen is located. For example, the Half Ellipsoid Model would be selected if a the well screen is placed on top of a lower transmissive layer (e.g., silt and/or clay); the Full Ellipsoid Model would be selected if the well screen is installed in a uniform formation; and the Radial Flow Model would be selected applicable to a fully penetrating well in a confined aquifer, a well in a formation that is highly anisotropic (horizontal K >> vertical K), or a well that is screened from the water table to the bottom of a formation (low hydraulic conductivity layer). The data from all newly installed and sampled wells will be used and a range of hydraulic conductivity values will be generated per AOC and Background locations.

## 14.2.8 Surface Water, Porewater, and Sediment Sampling

A total of 16 (eight [8] locations at AOC 3, and eight [8] background locations) co-located surface water, porewater, and sediment sampling locations are proposed on **Figures 17-2** and **17-7**, respectively. At each location, surface water will be collected first, then porewater, and then sediment. All three (3) media are to

be collected at a single location before moving onto the next upstream location. Note, surface water samples will not be collected during a rain event which accumulates greater than 0.25 inches of rainfall, or at least 48-hours following a rain event. In order to separate the surface water from the pore water sample; a shallow probe will be installed into the sediment along with a sediment seal will be used to prevent short-circuiting. Samples shall be collected from downstream to upstream. Each sample location will be marked with a 4-foot long section of 0.5-inch diameter rebar (or wooden stake) driven into the stream bed about 2 feet, in order to identify the location for future sampling events. Depositional areas of the stream (i.e. bends where sediments can accumulate) will be targeted for sediment and porewater sampling. In addition to the sampling sequence described below, physical characteristics of the sampling locations (e.g., water depth, stream width, nearby vegetation, stream flow), substrate (e.g., presence of leaf litter and cobbles, general description), and presence of potential receptors (e.g., evidence of human presence or wildlife in and around the sampling location) shall be documented. Sampling will correspond to seasonal groundwater sampling events to determine the influence of groundwater to the stream (i.e., assess if the stream is a losing stream, gaining stream, or both on a seasonal basis).

Surface water sampling at new location(s) will be conducted in accordance with the procedures listed below and *SOP #12 Surface Water Sampling Procedure* provided in **Appendix D**.

The following sampling sequence was followed to minimize the potential for surface water turbidity and suspended solids:

(1) Begin at the most downgradient location.

(2) Work upstream within each stream.

(3) Collect surface water samples by inserting a capped sampling container with the opening pointing down to avoid the collection of surface films. At the time of container opening, the container must be at the mid-point of the water column, while maintaining a distance of more than 1 foot from the sediment bed and more than 1 foot below the surface water level and as close to the center of the channel as possible, where practicable.

(4) For dissolved metal analysis, either a separate unpreserved bottle can be collected or tubing can be placed within the stream (at least 12-inches below the surface) and the sample can be pumped using a peristaltic pump located onshore. If the sample is placed within the unpreserved bottle, then a piece of tubing will be placed within the unpreserved sample along with an in-line 0.45-micron filter. A peristaltic pump will be used to draw the sample through the 0.45-micron filter and into the appropriately preserved bottleware.

(5) A YSI sonde will be placed directly in the top portion of the stream, where the water samples for laboratory analyses were obtained. Turbidity samples will be obtained in the same vicinity as the YSI sonde. One (1) set of field parameters will be recorded via YSI and turbidity meter. The set of field parameters will be recorded, following 2 minutes of placement of the YSI within the water column.

Following the collection of the surface water sample, porewater sampling will be conducted in accordance with the procedures listed below and using *EPA Region 4 LSASDPROC-513-R4 Porewater Sampling SOP* (provided in **Appendix D**) as guidance. Samples will be collected from a temporary PushPoint™ sampler (M.H.E. Products 2003). At each location (**Figure 17-2** and **17-7**), the following procedures will be followed (to be done after surface water sample collection):

(1) Install pushpoint-type sampler 1 foot below the top of sediment. The sampler will be pushed into the stream bed by hand or driven with a hammer. The target total depth will be 1.0 foot below the surface of the stream bed so that the top of the screened portion is 1.0 feet below the bottom of the stream bed. However, in some cases, the sampler may need to be driven deeper to locate a zone permeable enough to sample.

(2) Place a seal at the top of the stream bed in order to minimize surface water intrusion.

(3) Record depth to surface water from the top of the sampler.

(4) Record depth to top of sediment from the top of the sampler.

(5) Retract screen.

(6) If using a peristaltic pump, purge the porewater sampler and monitor field parameters. Once field parameters have stabilized and at least one well (sampler) volume plus the volume of tubing has been purged, begin to fill up the required bottleware. Stabilization of field parameters can be used as an indicator that "short circuiting" between porewater and surface water is not occurring.

(7) If using a syringe, extract one (1) screen volume and collect the samples.

Following porewater sampling, sediment sampling will occur at each of the 16 locations (**Figures 17-2** and **17-7**). Sediment samples will be collected from 0-0.5 ft interval beginning at the top of sediment using a sediment core device (Wildco Hand Core™ or equivalent) with cellulose acetate butyrate liners. At each location, a new liner will be used to collect each sample. The outside of the corer with be decontaminated using a potable water rinse and scrub, potable water + alconox/liquinox rinse and scrub, and DI rinse.

Once the core is extruded, immediately collect samples for VOC analysis using an Encore™ or equivalent sampler and place into the appropriate bottleware. Collection of VOC analysis will be similar to the procedures identified in Section 14.2.4. Once VOC analysis has been collected, carefully remove the remaining sample with a clean, non-reactive utensil and transfer into a stainless steel container for homogenization using cone and quarter techniques for all non-VOC analysis.

### 14.2.9 Stream Flow Measurements

Stream flow measurements will occur semi-annually and will be taken at all co-located surface water/porewater/sediment locations at AOC 3 (**Figure 17-2** and **17-7**) utilizing a hand-held, electronic velocity meter to determine stream flow and velocity. The information will be used in the site assessment and HHRA/SLERA/RSLERA to assist with contaminant transport modeling. Measurements will be conducted in accordance with FDEP- Standard Operating Procedure FT1800. Field Measurement of Stage, Surface Water Velocity, and Discharge (Flow) and Computation of Streamflow, Revised January 2017, effective April 16, 2018.

A Global Water FP111 Water Flow Probe or similar will be utilized. According to the manufacturer, the water velocity probe consists of a protected propeller and water bearing for measuring water velocity, coupled to a telescoping probe handle ending with a LCD display flow computer. The Flow Probe is ideal for measuring flows in rivers and streams, and monitoring water velocity in ditches and canals. The Flow Probe handle has markers on it to measure water depth. Flow measurement range is 0.3 – 19.9 feet per second (ft/sec) and accuracy is 0.1 ft/sec. Averaging is a true digital running average and updated once per second.

The channel width at each measured location will be measured. Flow measurement locations will be selected that are relatively free of debris and in reasonably straight areas of the channel. The 0.6-depth method will be utilized (also known as the six-tenths-depth method). The following steps will be taken at each measuring location:

- Station location will be photographed and global positioning system (GPS) coordinates recorded. The location will also be marked on a map.
- A measuring tape will be used to determine channel width (perpendicular to flow direction) and the measuring tape will be anchored at each side of the channel. Measurements will be recorded to the nearest 0.1 ft.
- The measuring tape will allow the channel to be divided into 1-ft wide segments.
- The Flow Probe will be used to measure water depth at each 1 ft segment across the channel (i.e., perpendicular to flow). Measurements will be used to create a stream bed/water depth profile that will be drawn in the field notebook. Depth measurements will be recorded to the nearest 0.01 ft. If the stream is 1 ft or less in width, then one measurement equidistant will be collected.
- The Flow Probe will be used to make a velocity measurement at 0.6 of the depth below the water surface at each 1 ft segment across the channel. The six-tenths method will be used

when water depth is less than 1.5 feet. The flow measurement will be a 1- to 2-minute average and recorded as ft/sec. The average is automatically calculated by the Flow Probe.

- Flow, in cubic ft/sec and gallons per minute, will be calculated for each segment. Total flow at each location will be calculated by adding flows in each segment.

### 14.2.10 Stream Piezometer Installation and Gauging

Stream piezometers will be installed at three locations within the unnamed stream that is located north of the parking lot in AOC 3 (**Figure 17-2**). One piezometer will be installed at the most upstream location, west of the former OSA. The second piezometer will be installed approximately 600 feet downstream of the first piezometer. The last piezometer will be installed approximately 500 feet downstream of the second location and within the portion of the stream that is downgradient of the northern parking lot. A 1.25-inch or similar galvanized steel pipe (or PVC pipe) will be installed into the top of sediment. A 2-foot section of the galvanized steel pipe (or PVC) will contain open holes, or slots to allow for the inflow of water. The bottom of the pipe will be closed using a thread on or push-type cap. No glue or solvent will be used. The piezometer will be pushed or hammered into the top of the sediment. Actual field conditions will dictate the final depth of the bottom of the screen. The ideal target depth will be of sufficient depth to prevent the movement of the piezometer.

Following the installation and surveying of the piezometers, water levels will be measured from the top of the casing and from the inside and alongside the edge of the piezometer to the top of the stream. Water level measurements will occur concurrently with the AOC 3 synoptic water level events in spring and fall.

### 14.2.11 Survey

Any new temporary sampling location's (i.e., soil, surface water, porewater, sediment) horizontal position will be surveyed using a hand-held global position system (GPS). Following monitoring well installation and stream piezometers, horizontal and vertical coordinates of all new wells/piezometers will be determined by a professional land surveyor registered in the State of New York. Horizontal coordinates will be surveyed to an accuracy of 0.1 foot relative to New York State Plane coordinate system (North American Datum [NAD]83). Vertical elevations will be relative to North American Vertical Datum (NAVD) 1988 to an accuracy of 0.01 ft. Vertical elevations will be established for the top of casing and the ground surface on the well pad.

### 14.2.12 Temporary Well Abandonment

Temporary monitoring wells installed under the Phase 1 RI will be abandoned in place by backfilling with a cement bentonite mixture in accordance with New York State requirements. During backfilling, the grout mixture will be tremied into the monitoring well to ensure that the well is completely filled and bridging of grout material does not occur. Following grouting, the protective casing will be removed and the ground surface restored to current surroundings (e.g. soil, asphalt, etc.).

### 14.2.13 Investigation-Derived Waste

IDW will be generated as a result of field activities. IDW will be handled in accordance with the IDW Plan located as **Appendix E** to this UFP-QAPP.

## 14.3 Data Management, Review, and Evaluation

### 14.3.1 Data Management

Field activities will be recorded in project logbooks and on standardized field forms (**Appendix D**). Site maps will be maintained, and sample locations will be updated on the maps as necessary. Field and analytical data will be consolidated and maintained within the FUDSChem database.

### 14.3.2 Data Review

A three (3)-step data review process consisting of verification, validation, and usability assessment will be used to examine the data only so that scientifically sound data of known and documented quality are used

in making environmental decisions. The analytical data obtained during the project will be validated by a qualified chemist according to the specifications provided in Worksheets #34 through #37. Documentation of the data validation review will be provided in an appendix to the final report.

### 14.3.3 Data Evaluation

Field and analytical data collected as part of these investigations will be used to evaluate nature and extent of COPCs in soil, groundwater, surface water, porewater, and sediment. Ultimately the data, in combination with the data collected from the Phase 1 RI (USACE, 2023a) will be used to assess the risks to human health and the environment.

## 14.4 Reporting

Investigations covered under this UFP-QAPP will generate a significant amount of data and observations that will be documented in the following reporting deliverables:

- DQCRs;
- Phase 2 RI Field Report; and
- RI Report.

*DQCRs* – Will be generated daily and document field activities. These reports will be kept with the project file. It is also anticipated that periodic conference calls with the project team will be implemented before mobilization to the field, during field activities, and upon demobilization from the field, or on an as needed basis.

*Phase 2 RI Field Report* – Following completion of all field activities, a Draft and Final Phase 2 RI Field Report will be prepared to document the field effort. The Field Report will include summaries of the work performed by AOC and document any deviations from the UFP-QAPP that may have occurred. Boring logs, well completion logs, data tables, laboratory reports sampling figures, groundwater contour maps, and other field documentation (photographic logs, IDW disposal documents, etc.) will be included. Documentation required to be included in the report include all boring logs, soil sample collection logs, well construction details, well survey data, well development documentation, documentation of field parameters collected during sampling (i.e., groundwater sampling, DPT groundwater sampling, etc.), sample results and lab data validation reports, and DQCRs. The Contractor will present figures, tables, and graphs that detail the sampling results from each media source.

*RI Report* – The RI Report shall introduce the Site and summarize the Site history, characterize environmental conditions; describe the complete nature and extent (including coal); describe and portray a comprehensive groundwater flow, hydraulic conductivity, and contaminant hydrogeological conditions; and evaluate the migration pathways based on the geologic, geotechnical, hydrogeological, ecological, chemical, physical, and hydrologic data. The RI Report shall also include analysis and interpretation groundwater hydrology/modeling, enhancement of the CSM, groundwater transmissivity, document fate and transport and contaminant mass flux, calculate travel times, discuss nature and extent of the contamination, in addition to source identification. Information on the nature and extent of contamination shall be used to conduct human health and ecological risk assessments. The RI report will also address the discrepancy between AOC 1 Phase 1 recommendations to not sample for picric acid, and the rationale for including it during Phase 2 sampling (refer to Section 17.1). The RI report will address the Phase 1 RI recommendation to perform an in-depth analysis regarding the relationship between the presence of coal and presence/absence of PAHs and metals in the uncertainty section of the risk assessment if the risks from CERCLA related contaminants pose an unacceptable risk for AOC 5 where coal presence was found (refer to Worksheet #9 for additional detail). The Phase 2 RI Field Report will also be included as an appendix to the RI Report. The RI Report will be produced as a Draft, Draft-Final, and Final.

Other RI Report requirements include, but are not limited to, the following:

- Detailed preparation and discussion of an updated CSM in accordance with the July 2011 EPA CSM Best Management Practice Fact Sheet: EPA 542-F-11-011, including updates as necessary of the preliminary CSMs provided in the BHHRA and SLERA. Inclusion of one or

more three (3)-dimensional figures (s) to visually depict the vertical and horizontal aspects of groundwater contaminant migration will also be considered to enhance understanding of the overall CSM.;

- An evaluation of whether DQOs were met;
- Hydrogeologic cross section(s) showing subsurface geology and surface water bodies using AutoCad/Arc GIS;
- Potentiometric maps and evaluation of horizontal gradients;
- Evaluation of groundwater-surface water hydraulic interactions, including gaining/losing portions of the stream north of the parking lot in AOC 3 with impacts from historical activities in the area;
- Isoconcentration contaminant contour maps in both plan view and cross-sectional views;
- Summary evaluation of potential off-site sources of contaminants of potential concern as contributors to the groundwater plume;
- Analytical data tables that include all analytes listed and the test method, including appropriate data quality flags;
- Evaluation of data quality, data usability, and representativeness to conduct a baseline HHRA and SLERA/RSLERA;
- Inclusion of data validation reports;
- Integration of all habitat, species, ecological information collected in Phase 1; and
- Assessment of potential risks in the form of a baseline HHRA and SLERA/RSLERA. The risk assessments shall include the identification of potentially complete and/or complete exposure pathways and potential receptors, defining the COPC by comparing concentrations to risk-based criteria protective of human health or ecological receptors, quantifying potential risks for complete exposure pathways and receptors, and recognizing uncertainties and potential biases associated with different information sources (Lines of Evidence, LOE) used in the risk assessment.

Data from the RI sample collection for the purposes of delineation of nature and extent in soil, groundwater, surface water, porewater, and sediment shall be considered to assess risks to potential current and future human and ecological receptors for each AOC under reasonable scenarios in accordance with EPA risk assessment guidance (e.g., EPA RAGS, EPA Ecological Risk Assessment Guidance for Superfund [ERAGS]) and other pertinent DoD documents (and/or updates). The SLERA/RSLERA shall incorporate site-specific data and refinements of exposure to mitigate risk and identify whether a full baseline ecological risk assessment is warranted.

The HHRA will evaluate whether potential human health risks are associated with current or future land use exposures to COPCs are acceptable. Tasks included in the HHRA are hazard identification, exposure assessment, toxicity assessment, and risk characterization. As part of the hazard identification, the following will occur: a review and refinement of preliminary CSM; evaluation of historical (where available) and data collected during Site Assessment Field Work, statistical evaluation of data and selection of COPCs. In the exposure assessment, calculations of the exposure point concentrations of COPCs in each medium, identification of the exposure assumptions are identified, and methodology for calculation of the daily intake dose based on magnitude, frequency, and duration of exposures over a specified exposure period of time will be presented. The toxicity assessment will identify the relationship between the potential extent of exposure and toxicological effects of the exposure for each COPC-specific toxicity criteria. Finally, in the risk characterization step, the toxicity and exposure will be integrated derive quantitative estimates of human health risks for carcinogens and non-carcinogens, and presentation of the uncertainties and limitations inherent in the estimation of the potential risks, and the potential risks associated with background concentrations (where applicable).

The SLERA will evaluate the potential for adverse effects to ecological receptors associated with exposures to COPECs within the study area. As part of the SLERA, the following steps will be performed:

- Step 1 – Screening-Level Problem Formulation and Ecological Effects Evaluation: The screening-level problem formulation will evaluate, and update as necessary, the Phase I ecological CSM for the study area. The ecological CSM describes the site setting, identify known or suspected constituents and their fate, transport, and ecotoxicity, and specifies complete ecological exposure pathways and representative ecological receptors that may be exposed to known or suspected constituents in environmental media. The ecological CSM provides the basis for identifying key risk questions and defining the assessment endpoints and measurement endpoints that will be evaluated in the SLERA. The screening-level effects evaluation will identify exposure levels, or screening levels, that represent conservative thresholds for adverse ecological effects.
- Step 2 – Screening-Level Exposure Estimate and Risk Calculation: The screening-level exposure estimate and risk calculation will evaluate constituent concentrations relative to screening levels established in the preliminary effects analysis for complete exposure pathways identified in the ecological CSM. Constituents with exposure concentrations (i.e., maximum concentration in the combined Phase 1 and 2 datasets specific to a given AOC and environmental medium) exceeding screening levels for complete exposure pathways will be evaluated as COPECs that may require further ecological risk assessment.
- Step 3A – Refined Problem Formulation and Ecological Screening: The list of COPECs identified in the SLERA will be refined using less conservative and more realistic assumptions. exposure pathways and receptors potentially at risk will be identified and the ecological CSM updated. The exposure concentrations will be based on the smaller of the 95%UCL and maximum value for a given AOC and environment medium. To provide a robust understanding of the accuracy and reliability of the RSLERA hazard estimates, the RSLERA will also include a qualitative evaluation of the significant sources of uncertainty associated with all key lines of evidence (LOE), including supplemental parameters, used in the refinement phase. Appendix C specifies the key LOE for the following categories: data, toxicity, exposure and risk and the overall process is defined in the Figure 5-2 flow chart (USACE, 2023a). In addition, the uncertainty analysis will also consider potential adverse effects associated with analytes and ecological receptors without toxicity values (e.g., reptiles/amphibians) as well as the potential for adverse effects to species of special concern (e.g., bats).
- Scientific Management Decision Point (SMDP) – The results of SLERA/RSLERA process will be used to support a SMDP to inform risk management decision-making based on consensus regarding COPECs, assessment endpoints, exposure pathways and risk questions. Consistent with ERAGS, one (1) of three (3) possible SMDPs will be selected at the end of Step 3a:
    1. There is adequate information to conclude that ecological risks are negligible and therefore no need for remediation on the basis of ecological risk;
    2. The information is not adequate to make a decision at this point and the ecological risk assessment process will continue to a Tier II Baseline Ecological Risk Assessment; or
    3. The information indicates a potential for adverse ecological effects and a more thorough assessment is warranted.

## 14.5 Project Schedule

The project schedule is a dynamic process that is constantly evolving as key milestones are reached and/or delays occur. Below in are the key project milestones along with general timeframe to completion, that will be tracked through the life-cycle of the project. These key milestones must occur sequentially, meaning the project cannot move forward until the above milestone has been met. The schedule may be revised to accommodate changes that could have a positive (i.e., shorter duration) or negative (i.e., longer duration) effect on the schedule. Once a potential schedule change is recognized, potential revisions to the project schedule will be communicated to the project team so that the changes can be evaluated and, where

appropriate, efficiently accommodated within the overall schedule to minimize impacts upon the milestone dates.

- Technical Project Planning (TPP) Meeting #1 (Spring 2025)
- Final UFP-QAPP (Fall 2025)
- Field Work (Fall 2025 – Spring 2026)
- Final Phase 2 Field Report (Summer 2026)
- TPP#2 (Spring 2027)
- Final RI Report (Spring 2027)

## 14.6 Health and Safety

All site work will be performed in accordance with the Accident Prevention Plan (APP) that includes the Site Safety and Health Plan (SSHP) that includes an Accident Prevention Plan (APP). The APP/SSHP will be provided to USACE CENAE separately.

This page intentionally left blank

# Worksheet #15 – Project Action Limits and Laboratory-Specific Detection/ Quantitation Limits

This worksheet describes PALs and laboratory-specific detection/quantitation limits for this project.

Groundwater, soil, surface water, porewater, and sediment samples will be collected to support nature and extent and evaluate associated risks to human health and ecological risk receptors from former NYOW activities (USACE, 2023a). Subsection worksheets (e.g., 15-1a) have been added to show each compound/matrix specific PAL, project-quantitation goal (PQG), and laboratory-specific detection/quantitation limits. **Note, there are no subsection worksheets for grain size, CEC, TOC, pH, DOC, TSS, hardness, or microscopy**. These analyses report numeric values for the specific result with limited QC.

## 15.1 Project Action Limits

The purpose of identifying risk-based PALs in the UFP-QAPP is to ensure the analytical methods selected are sensitive enough to detect concentrations at or below the screening benchmark or absent that, the most sensitive method available. PALs on Worksheets #15 are the lower of human health screening levels and ecological benchmarks identified based on the hierarchies presented below for those media where both sets of screening criteria apply. Note, the groundwater PALs are based on human health values only, and soil, sediment, and surface water PALs are based on the lower of human health and ecological values. Porewater PALs are based on surface water ecological benchmark values only. In addition, no PALs or PQGs were developed for essential nutrients (calcium, iron, magnesium, potassium, and sodium). These analytes are necessary for metabolic processes in organisms and at naturally occurring concentrations, receptors are able to regulate uptake and metabolism of these elements. In addition, it should be noted that most of the compounds listed in the tables below are not expected to be identified as COPCs.

**Human Health**

- Groundwater
  - EPA Regional Screening Level (RSL) (November 2024): Tapwater Tables for Cancer Target Risk of 1E-06 and Target Hazard Quotient of 0.1 (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables).
- Soil and Sediment:
  - EPA RSL (November 2024): Residential Soil Tables for Cancer Target Risk of 1E-06 and Target Hazard Quotient of 0.1 (https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables).
- Surface Water:
  - Screening levels were calculated using USEPA's RSL calculator for a recreational receptor's exposure to surface water using the exposure parameters for incidental ingestion and dermal contact with COPCs in surface water for a trespasser/visitor scenario listed in **Appendix B** (see Table B2.2-3 of Attachment A).

**Ecological**

Ecological screening benchmarks are derived for multiple receptor categories (see Section 10.5.2) and all expected site-specific receptor categories that need to be considered when selecting the ecological PALs. These receptor categories apply to exposures to the following media:

- soil: plants, invertebrates and birds and mammals;
- sediment/pore water: invertebrates (benthic) and vascular rooted aquatic plants;
- surface water: aquatic organisms including plants, invertebrates (pelagic), fish and amphibians.

Supporting documentation for the ecological PALs is presented in **Appendix C**. Appendix C.1 presents the methodology for selecting surrogates for key constituents without ecological benchmarks and Appendix C.2 presents all of the values within the QAPP ecological PAL selection hierarchy. The hierarchies for soil, sediment and surface water/porewater are defined below.

- Soil (if reference has more than one receptor, the lowest value was selected):
    - EPA ecological soil screening levels (eco-SSLs )(Eco-SSLs; various dates) (https://www.epa.gov/chemical-research/interim- ecological-soil-screening-level-documents)
    - EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) –Soil Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).
    - EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf)
- LANL/Intellus (2024). ECORISK Database (Release 4.4), (https://intellusnm/documents/documents.cfm).
- Sediment (if reference has more than one receptor, the lowest value was selected):
    - EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) –Sediment Screening Values for Hazardous Waste Sites (Ecological Screening Values for Step 2) (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).
    - EPA Region 3 (2006) Region III BTAG (Biological Technical Assistance Group). Freshwater Sediment Screening Benchmarks (https://www.epa.gov/sites/default/files/2015-09/documents/r3_btag_fw_sediment_benchmarks_8-06.pdf).
    - EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf)
    - LANL/Intellus (2024). ECORISK Database (Release 4.4), (https://intellusnm/documents/documents.cfm).
- Surface water/Pore water (if reference has more than one receptor, the lowest value was selected):

    - EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) –Surface Water Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).
    - EPA Region 3 (2006) Region III BTAG (Biological Technical Assistance Group). Freshwater Screening Benchmarks (https://www.epa.gov/sites/default/files/2015-09/documents/r3_btag_fw_benchmarks_07-06.pdf).
    - EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf)
    - LANL/Intellus (2024). ECORISK Database (Release 4.4), (https://intellusnm/documents/documents.cfm).

Separate ecological benchmarks are available for soil and sediment media and these will be applied to data collected from terrestrial and aquatic habitats, respectively. Consistent with the conservative nature of the SLERA screening process, detected analyte concentrations for "hydric" soils, which are periodically inundated (e.g., vernal pools) and/or saturated to the surface, will be compared to the lower of available benchmarks for these two media (see Attachment C.2). If any of these analytes are not eliminated in the initial screening steps, additional evaluation of the nature of ecological exposures for these areas will be conducted during the Step 3A refinement (Appendix C, Section 6).

Note that PALs for m,p-xylene and m,p-cresol are the lower of the two isomers. In addition, no PALs were developed for essential nutrients (calcium, iron, magnesium, potassium, and sodium). These analytes are necessary for metabolic processes in organisms and at naturally occurring concentrations, receptors are able to regulate uptake and metabolism of these elements.

## 15.2 Laboratory Limits

Laboratory Limits (Limit of Quantitation (LOQ), Limit of Detection (LOD), and Detection Limit (DL)) are current as of when the information was requested for the UFP-QAPP. Note, Method 9081 for CEC is not DoD accredited; therefore three-tiered reporting (i.e., LOQ, LOD, and Detection Limit) is not available.

## 15.3 Project Quantitation Goals

The PQG was set to 1/3 the PAL. If the LOQ is greater than the PQG, then the PQG was set to the LOQ. If the analyte does not have a PAL, the PQG was set to 5x the LOQ.

## 15.4 Analyte Lists

Routine analytes for which there is no PAL, and which are unlikely to be site-related were considered for elimination from the analysis unless there was a PAL for that analyte in another matrix. Based on these criteria, no analytes were eliminated. Note that VOCs without PALs were retained at AOC 3 and AOC 5 because they are frequently associated with landfills and therefore will allow for a more comprehensive assessment of potential risk. The retained analytes without PALs had the PQLG set to five times the LOQ.

Analytes in the tables below high-lighted in blue were identified as COPCs in Phase 1 as listed in Worksheet 10. Most of the compounds listed in the tables below are not expected to be identified as COPCs. Consistent with the approach employed in Phase 1, the impact of the uncertainty associated with compounds not highlighted blue where LOQs are greater than PQGs will be qualitatively discussed in the risk assessments.

## 15.5 Analytes with LOQs Greater than PALs

Some analytes have analytical limits (LOQs and/or LODs) greater than PALs. This indicates that achievement of the PAL is technically infeasible by the laboratory with the selected method. Prior to the finalization of Worksheet #15, methods were changed for known COPCs when possible to meet PALs; however, many analytes do not have alternatives to achieve lower limits.

Non-detects will be reported at the LOD; therefore, if the LOD meets the PAL, there is no effect on the risk assessment process. If the LOD does not meet the appropriate PAL for the specific human health or ecological risk assessment, how non-detects are handled will depend on the characteristics of the data set. When the PAL is less than the LOQ, detections less than the LOQ (J qualified results) cannot be used to determine whether contamination is above or below the PAL, unless these results are part of a data set that contains at least one result greater or equal to the LOQ.

- If detected concentrations of an analyte exceed the PAL, the analyte will be carried through the Phase 2 risk screening using the LOD as the concentration for non-detects when calculating summary statistics and as the input in ProUCL (if applicable).
- In the cases when no detects are greater or equal to the LOQ in a data set (i.e., all detects are J- qualified), for the purposes of the Phase 2 risk screening, the concentration of the

analyte will be set equal to the LOQ because the LOQ is a more defensible concentration than the J-qualified result and this will be discussed in the Uncertainty Analysis.

- If there are no detected concentrations of an analyte, the Uncertainty Analysis will include a discussion of potential risks. The Uncertainty Analysis will first evaluate the likelihood of non-detected analytes being DoD-related chemicals based on site history and operation, and eliminate analytes that are unlikely to be DoD-related from the risk assessment. The Uncertainty Analysis will then assume the maximum LOD for a DoD-related chemical as the exposure point concentration for the EU and the results will be qualitatively discussed in the Uncertainty Analysis.

The results of the Phase 2 risk screening, among other evaluations (e.g., frequency of detection, comparisons with background), will be used to determine the need for additional investigations.

For analytes with LOQs and/or LODs greater than PALs, the impacts on data usability vary as noted below. Note that the majority of these analytes are VOCs/SVOCs that are being analyzed for in AOC 3 (Landfill Area) and AOC 5 (Former Power Plant) and are not directly related to the manufacture of ammonium picrate. This evaluation does not account for sample-specific limits that may be elevated due to matrix effects, QC issues, or other analytical issues; which, if present, would need to be considered during the risk assessment process.

### 15.5.1 Groundwater

Groundwater PALs consider human health screening levels only. See method- and medium-specific #15 tables provided at the end of Section 15 for groundwater PALs.

**Residential Tapwater PALs are less than the LOQ and/or LOD, MCL equal to or greater than the LOQ**

Although not meeting one type of risk-based screening level, these analytes would be adequately regulated based on meeting the promulgated Federal standard. See the text at the start of Section 15.5 regarding how non-detects will be treated in the risk assessments. Analytes to which this applies are:

- Antimony
- Arsenic
- Cadmium
- Mercury
- Thallium
- 1,2,4-Trichlorobenzene
- 1,1-Dichloroethene
- 1,1,2-Trichloroethane
- 1,2-Dichloroethane
- 1,2-Dichloropropane
- 1,4-Dichlorobenzene
- Benzene
- Bromodichloromethane, chloroform, dibromochloromethane, bromoform (individual LOQs of 1 µg/L versus MCL for total trihalomethanes of 80 µg/L)
- Carbon tetrachloride
- Trichloroethene
- Vinyl chloride
- Benzo(a)pyrene
- Hexachlorobenzene
- Hexachlorocyclopentadiene

**Residential Tapwater PAL is less than the LOD; cancer-based RSL is within a factor of 10 of the LOQ and/or LOD**

If concentrations in the dataset are all non-detected and/or comprised of only estimated (J) values, decisions can still be made whether the analyte is detected within the 1E-05 excess lifetime cancer risk (ELCR) range, which is within EPA's acceptable risk range. As per CERCLA guidelines, these data would be deemed usable in the risk assessments; however, quantitative risk estimates would not be reliable.

- 1,1,2,2-Tetrachloroethane
- 1,1,2-Trichloroethane
- 1,2,4-Trichlorobenzene
- 1,2-Dichloroethane
- 1,4-Dichlorobenzene
- Benzene
- Bromodichloromethane
- Carbon tetrachloride
- Chloroform
- Trichloroethene
- 1,1'-Biphenyl
- 2,4-Dinitrotoluene
- Benzo(a)anthracene
- Benzo[a]pyrene
- Dibenz(a,h)anthracene
- Atrazine
- Hexachlorobutadiene
- Hexachloroethane
- 1-Methylnaphthalene
- Naphthalene
- Nitrobenzene
- PCB-1016

**Residential Tapwater PAL is less than the LOD; cancer-based RSL is between a factor of 10 and 100 of the LOQ and/or LOD**

If concentrations in the dataset are all non-detected and/or comprised of only estimated (J flagged) values, decisions can still be made whether the analyte is detected within the 1E-04 ELCR range, which is within EPA's acceptable risk range. As per CERCLA guidelines, these data would be deemed usable in the risk assessments; however, quantitative risk estimates would not be reliable. The following additional chemicals are identified as meeting this criterion:

- 1,2-Dibromoethane
- Vinyl chloride
- 2,6-Dinitrotoluene
- 3,3'-Dichlorobenzidine
- 4-Chloroaniline
- Bis(2-chloroethyl)ether

- Hexachlorobenzene
- N-Nitrosodi-n-propylamine
- Pentachlorophenol
- PCB Aroclors 1221 through 1260
- Arsenic

**Residential Tapwater PAL falls between the LOQ and the LOD**

These chemicals may be positively identified as detected, but the quantification would be estimated. As per CERCLA guidelines, these data would be deemed usable in the risk assessments. Chemicals to which this applies are:

- 1,1-Dichloroethene
- 1,2-Dichloropropane
- 1,3-Dichlorobenzene
- 2-Hexanone
- Bromoform
- Bromomethane
- Dibromochloromethane
- Antimony
- 2,4,6-Trichlorophenol
- Benzo(b)fluoranthene
- Indeno(1,2,3-cd)pyrene

**Residential Tapwater PAL is less than or equal to the LOD**

Reliable risk-based decisions cannot be made unless the concentrations are greater than the LOQ. See text above regarding how non-detects will be treated in the risk assessments.

- Arsenic
- Cadmium
- Thallium
- Mercury
- 1,1,2,2-Tetrachloroethane
- 1,1,2-Trichloroethane
- 1,2,4-Trichlorobenzene
- 1,2-Dibromo-3-chloropropane
- 1,2-Dibromoethane
- 1,2-Dichloroethane
- 1,4-Dichlorobenzene
- Benzene
- Bromodichloromethane
- Carbon tetrachloride
- Chloroform
- cis-1,3-Dichloropropene
- trans-1,3-Dichloropropene
- Trichloroethene
- Vinyl chloride
- 1-Methylnaphthalene
- 2,4-Dinitrophenol (constituent of potential concern)
- 2,4-Dinitrotoluene
- 2,6-Dinitrotoluene
- 3,3'-Dichlorobenzidine
- 4,6-Dinitro-2-methylphenol
- 4-Chloroaniline
- Atrazine
- Benz(a)anthracene
- Benzo(a)pyrene
- Biphenyl
- Bis(2-chloroethyl) ether
- Dibenzo(a,h)anthracene
- Dibenzofuran
- Hexachlorobenzene
- Hexachlorobutadiene
- Hexachlorocyclopentadiene
- Hexachloroethane
- Naphthalene
- Nitrobenzene

- N-Nitrosodi-n-propylamine
- Pentachlorophenol
- PCB Aroclors 1016 through 1260

### 15.5.2 Soils

Soil PALs consider the lower of human health and ecological screening levels. See method- and medium-specific #15 tables provided at the end of this Section for soil PALs.

**Soil PAL (i.e., the lower of the human health and ecological screening value) falls between the LOQ and the LOD**

These chemicals may be positively identified as detected, but the quantification would be estimated. As per CERCLA guidelines, these data would be deemed usable in the risk assessments. Chemicals to which this applies are:

- Anthracene

**Soil PAL (i.e., the lower of the human health and ecological screening value) is less than the LOD**

Reliable risk-based decisions cannot be made unless the concentrations are greater than the LOQ. See text above regarding how non-detects will be treated in the risk assessments.

- Mercury
- 2,4-Dinitrophenol (constituent of potential concern)
- 2-Chloronaphthalene
- 3,3'-Dichlorobenzidine
- 4,6-Dinitro-2-methylphenol
- Anthracene
- Atrazine
- Bis(2-ethylhexyl)phthalate
- Di-n-butyl phthalate
- Hexachlorobutadiene
- Hexachlorocyclopentadiene
- Hexachloroethane
- PCB-1248

## Worksheet #15-1a – VOCs Groundwater

Matrix: Groundwater
Analytical Group: Volatile Organic Compounds (GC/MS) (SW8260C/D)
Units: µg/L

| Analyte | Human Health Risk-based Value[a] | Human Health Reference[b] | PAL | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|
| 1,1,1-Trichloroethane | 800 | 2024 Nov EPA Tapwater (THQ 0.1) | 800 | 270 | 1 | 0.6 | 0.3 |

Notes:
(a) Only human health benchmarks are presented because ecological receptors are not expected to be exposed to groundwater.
(b) References include: EPA, 2024. Regional Screening Levels (RSLs). November.
(c) 4-methylphenol is reported by the laboratory as 3 & 4-methylphenol.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Analytes shaded in blue were identified as COPCs during Phase 1 investigation.
Project Quantitation Goal shaded in purple is 5x the LOQ since there is no associated PAL.
Acronyms:
µg/L = microgram per liter
DL = detection limit
EPA = Environmental Protection Agency
GC/MS = gas chromatography/mass spec
LOD = limit of detection
LOQ = limit of quantitation
NA = Not Applicable
PAL = project action limit
THQ = target hazard quotient

## Worksheet 15-1c – SVOC Groundwater - 2,4-dinitrophenol and 2,4-dinitrochlorobenzene

Matrix: Groundwater
Analytical Group: Semivolatile Organic Compounds (GC/MS) (SW8270E)
Units: µg/L

| Analyte | Human Health Risk-based Value[a] | Human Health Reference [b] | PAL | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|
| 2,4-Dinitrophenol (2,4-DNP) | 3.9 | 2024 Nov EPA Tapwater (THQ 0.1) | 3.9 | 30 | 30 | 28 | 14 |
| 1-chloro-2,4-dinitrobenzene (2,4-DNCB) * | 0.24 | Tapwater RSL for 2,4-DNT | 3.9 | TBD | TBD | TBD | TBD |

Notes:
*Eurofins Lancaster is currently (August 2025) adding 2,4-DNCB as a target compound. A change page reflecting their lab limits, along with eQAPP updates will be made as soon as possible (currently anticipating September 2025).
(a) Only human health benchmarks are presented because ecological receptors are not expected to be exposed to groundwater.
(b) References include: EPA, 2024. Regional Screening Levels (RSLs). November.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Analytes shaded in blue were identified as COPCs during Phase 1 investigation.
Acronyms:
µg/L = microgram per liter
DL = detection limit

NA = Not Applicable

## Worksheet #15-1f – Picric Acid Groundwater

Matrix: Groundwater
Analytical Group: Nitroaromatics and Nitramines (HPLC)-SW8330D
Units: µg/L

| Analyte | Human Health Risk-based Value[a] | Human Health Reference [b] | PAL | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|
| Picric acid | 4 | 2024 Nov EPA Tapwater (THQ 0.1) | 4 | 1.3 | 0.400 | 0.120 | 0.0436 |

Notes:
(a) Only human health benchmarks are presented because ecological receptors are not expected to be exposed to groundwater.
(b) References include: EPA, 2024. Regional Screening Levels (RSLs). November.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Analytes shaded in blue were identified as COPCs during Phase 1 investigation.
Acronyms:
µg/L = microgram per liter
HPLC = high performance liquid chromatography
LOD = limit of detection
LOQ = limit of quantitation
PAL = project action limit
THQ = target hazard quotient

## Worksheet #15-1g – Metals (Total and Dissolved) Groundwater

Matrix: Groundwater
Analytical Group: Metals (ICP/MS) SW6020B
Units: µg/L

| Analyte | Human Health Risk-based Value[a] | Human Health Reference [b] | PAL | Project Quantitation Goal | LOQ | LOD | DL |

| Analyte | Human Health Risk-based Value[a] | Human Health Reference [b] | PAL | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|

Notes:
(a) Only human health benchmarks are presented because ecological receptors are not expected to be exposed to groundwater.
(b) References include: EPA, 2024. Regional Screening Levels (RSLs). November.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Analytes shaded in blue were identified as COPCs during Phase 1 investigation.
Project Quantitation Goal shaded in purple is 5x the LOQ since there is no associated PAL.
Acronyms:
µg/L = microgram per liter
DL = detection limit
EPA = Environmental Protection Agency
EN = Essential Nutrient
ICP/MS = inductively coupled plasma/mass spectrometry
LOD = limit of detection
LOQ = limit of quantitation
NA = Not Applicable
PAL = project action limit
THQ = target hazard quotient

## Worksheet #15-1h – Mercury (Total and Dissolved) Water

Matrix: Groundwater
Analytical Group: Mercury (CVAA) SW7470A
Units: µg/L

| Analyte | Human Health Risk-based Value[a] | Human Health Reference [b] | PAL | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|
| Mercury | 0.063 | 2024 Nov EPA Tapwater (THQ 0.1) | 0.063 | 0.2 | 0.200 | 0.160 | 0.0870 |

Notes:
(a) Only human health benchmarks are presented because ecological receptors are not expected to be exposed to groundwater.
(b) References include: EPA, 2024. Regional Screening Levels (RSLs). November.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Analytes shaded in blue were identified as COPCs during Phase 1 investigation.
Acronyms:
µg/L = microgram per liter
DL = detection limit
EPA = Environmental Protection Agency

(c) PALs have been selected as the lower of the human health risk-based value and ecological benchmark.

(d) Aluminum is identified as a COPC only for those soils with a pH less than 5.5. The technical basis for this procedure is that the soluble and toxic forms of aluminum are only present in soil under soil pH values of less than 5.5. Site-specific considerations could, however warrant inclusion of aluminum as a COPC.

(e) The main concern from an ecological risk perspective for iron is not direct chemical toxicity per se, but the effect of iron as a mediator in the geochemistry of other (potentially toxic) metals and the potential physical hazard of depositing flocculent. Soil pH and Eh should be included as standard soil chemical field parameters when conducting any field investigation. Although some EPA analytical methods require the collection of soil pH prior to analysis, this information is not always made available to the ultimate data users. In addition, the pH measured in the lab may no longer be representative of field conditions since the samples can be exposed to oxygen during storage prior to analysis. A determination of the geochemical conditions (i.e., pH and Eh at a minimum) of the environmental setting, as well as the presence of iron floc and the toxic metals, is critical to the determination of the relative importance of iron at a site.

LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Analytes shaded in blue were identified as COPCs during Phase 1 investigation.

LOQ = limit of quantitation
mg/Kg = milligram per kilogram
NA = Not Applicable
PAL = project action limit
THQ = target hazard quotient

## Worksheet #15-2h – Mercury Soil

Matrix: Soil
Analytical Group: Mercury (CVAA) SW7471B
Units: mg/kg

| Analyte | Human Health Risk-based Value | Human Health Reference [a] | Ecological Soil Benchmark | Ecological Reference [b] | PAL [c] | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|---|---|
| Mercury | 0.71 | RSL Resident Soil (THQ 0.1) | 0.013 | EPA Region 4 Soil | 0.013 | 0.060 | 0.060 | 0.040 | 0.020 |

Notes:
(a) References include: EPA, 2024. Regional Screening Levels (RSLs). November.
(b) References include: EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) – Soil Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf)
(c) PALs have been selected as the lowest of the human health risk-based value and ecological benchmark.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Analytes shaded in blue were identified as COPCs during Phase 1 investigation.
Acronyms:
DL = detection limit
EPA = Environmental Protection Agency
LOD = limit of detection
LOQ = limit of quantitation
mg/Kg = milligram per kilogram
PAL = project action limit
THQ = target hazard quotient

## Worksheet #15-3a – VOCs Surface Water

Matrix: Surface Water
Analytical Group: Volatile Organic Compounds (GC/MS) (SW8260C/D)

| Analyte | Human Health Risk-based Value | Human Health Reference [a] | Ecological Benchmark | Ecological Reference [b] | PAL [c] | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|---|---|

Notes:

(a) Human health risk based values were based on the EPA RSL Calculator (November 2024) to calculate risk-based screening levels for an adolescent receptor's exposure (incidental ingestion and dermal contact) to surface water based on exposure parameters in Table B2.2-3 in Appendix B of this UFP-QAPP and a target cancer risk of 1x10-6 and noncancer target hazard of 0.1.

(b) References include: EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) – Surface Water Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf); EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf); National Recommended Water Quality Criteria - Aquatic Life (EPA, 2023) (https://www.epa.gov/wqc/national-recommended-water-quality-criteria-aquatic-life-criteria-table)

(c) PALs have been selected as the lower of the human health risk-based value and ecological benchmark.

LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.

LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.

Project Quantitation Goal shaded in purple is 5x the LOQ since there is no associated PAL.

Acronyms:

µg/L = microgram per liter
2,4-DNT = 2,4-dinitrotoluene
DL = detection limit
EPA = Environmental Protection Agency
GC/MS = gas chromatography/mass spec
LOD = limit of detection
LOQ = limit of quantitation
AWQC = Ambient Water Quality Criteria
NA = Not Applicable
PAL = project action limit
RCRA = Resource Conservation and Recovery Act
RSL = Regional Screening Level
THQ – target hazard quotient
UFP-QAPP = Uniform Federal Policy – Quality Assurance Project Plan

| Analyte | Human Health Risk-based Value | Human Health Reference [a] | Ecological Benchmark | Ecological Reference [b] | PAL [c] | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|---|---|

Notes:

(a) Human health risk based values are based on References include the use of the EPA RSL Calculator (November 2024) to calculate risk-based screening levels for an adolescent receptor's exposure (incidental ingestion and dermal contact) to surface water based on exposure parameters in Table B2.2-3 in Appendix B of this UFP-QAPP and a target cancer risk of 1x10-6 and noncancer target hazard of 0.1.

(b) Reference include: EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) – Surface Water Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf).

(c) PALs have been selected as the lower of the human health risk-based value and ecological benchmark.

LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.

LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.

Acronyms:

µg/L = microgram per liter
DL = detection limit
EPA = Environmental Protection Agency
GC/MS = gas chromatography/mass spec
LOD = limit of detection
LOQ = limit of quantitation
PAL = project action limit
THQ = target hazard quotient
UFP-QAPP = Uniform Federal Policy – Quality Assurance Project Plan

## Worksheet #15-3d – PCBs Surface Water

Matrix: Surface Water
Analytical Group: Polychlorinated Biphenyls (PCBs) by Gas Chromatography (SW8082)
Units: µg/L

Notes:
(a) Human health risk based values are based on References include the use of the EPA RSL Calculator (November 2024) to calculate risk-based screening levels for an adolescent receptor's exposure (incidental ingestion and dermal contact) to surface water based on exposure parameters in Table B2.2-3 in Appendix B of this UFP-QAPP and a target cancer risk of 1x10-6 and noncancer target hazard of 0.1.
(b) References include: EPA Region 3 Biological Technical Assistance Group (BTAG) (2006) – Freshwater Screening Benchmarks (https://www.epa.gov/sites/default/files/2015-09/documents/r3_btag_fw_benchmarks_07-06.pdf).
(c) PALS have been selected as the lower of the human health risk-based value and ecological benchmark.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Project Quantitation Goal shaded in purple is 5x the LOQ since there is no associated PAL.
Acronyms:
µg/L = microgram per liter
BTAG = Biological Technical Assistance Group
DL = detection limit
EPA = Environmental Protection Agency
GC/MS = gas chromatography/mass spec
LOD = limit of detection
LOQ = limit of quantitation
PAL = project action limit
PCB = polychlorinated biphenyl
RSL = Regional Screening Level
THQ = target hazard quotient
NA = Not Applicable
UFP-QAPP = Uniform Federal Policy – Quality Assurance Project Plan

## Worksheet #15-3e – Picric Acid Surface Water

Matrix: Surface Water
Analytical Group: Nitroaromatics and Nitramines (HPLC)-SW8330D
Units: µg/L

| Analyte | Human Health Risk-based Value | Human Health Reference [a] | Ecological Benchmark | Ecological Reference [b] | PAL [c] | Project Quantitation Goal | LOQ | LOD | DL |
|---|---|---|---|---|---|---|---|---|---|
| Picric acid | 1890 | RSL | 7.1 | Derived - See Attachment C.1 | 7.1 | 2.4 | 0.40 | 0.12 | 0.0436 |

Notes:
(a) Human health risk based values are based on References include the use of the USEPA RSL Calculator (November 2024) to calculate risk-based screening levels for an adolescent receptor's exposure (incidental ingestion and dermal contact) to surface water based on exposure parameters in Table B2.2-3 in Appendix B of this UFP-QAPP and a target cancer risk of 1x10-6 and noncancer target hazard of 0.1.
(b) See Attachment C.1 in Appendix C for derivation of the picric acid PAL using the ESL for 2,4-dinitrophenol as a surrogate.
(c) PALS have been selected as the lower of the human health risk-based value and ecological benchmark.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Acronyms:
µg/L = microgram per liter
DL = detection limit
HPLC = high performance liquid chromatography
LOD = limit of detection
LOQ = limit of quantitation
PAL = project action limit
THQ = target hazard quotient
UFP-QAPP = Uniform Federal Policy – Quality Assurance Project Plan

Notes:
(a) References include: EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) – Surface Water Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf); EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf); National Recommended Water Quality Criteria - Aquatic Life (USPEA, 2023) (https://www.epa.gov/wqc/national-recommended-water-quality-criteria-aquatic-life-criteria-table).
(b) PALS have been selected as the ecological benchmark.
LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet the 1/3 PAL.
Project Quantitation Goal shaded in purple is 5x the LOQ since there is no associated PAL.
Acronyms:
µg/L = microgram per liter
DL = detection limit
EPA = Environmental Protection Agency
GC/MS = gas chromatography/mass spec
LOD = limit of detection
LOQ = limit of quantitation
AWQC = Ambient Water Quality Criteria
NA = Not Applicable
PAL = project action limit
RCRA = Resource Conservation and Recovery Act
THQ = target hazard quotient

LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet 1/3 PAL.
Project Quantitation Goal shaded in purple is 5x the LOQ since there is no associated PAL.
Acronyms:
µg/Kg = microgram per kilogram
2,4-DNT = 2,4-dinitrotoluene
DL = detection limit
EPA = Environmental Protection Agency
LOD = limit of detection
LOQ = limit of quantitation
NA = Not Applicable
PAL = project action limit
THQ = target hazard quotient

## Worksheet #15-5c – Sediment/Hydric Soils – 2,4-dinitrophenol and 2,4-dinitrochlorobenzene

(c) PALs have been selected as the lowest of the human health risk-based value and ecological benchmark.

(d) Aluminum is identified as a COPC only for those soils with a pH less than 5.5. The technical basis for this procedure is that the soluble and toxic forms of aluminum are only present in soil under soil pH values of less than 5.5. Site-specific considerations could, however warrant inclusion of aluminum as a COPC.

(e) The main concern from an ecological risk perspective for iron is not direct chemical toxicity per se, but the effect of iron as a mediator in the geochemistry of other (potentially toxic) metals and the potential physical hazard of depositing flocculent. Soil pH and Eh should be included as standard soil chemical field parameters when conducting any field investigation. Although some EPA analytical methods require the collection of soil pH prior to analysis, this information is not always made available to the ultimate data users. In addition, the pH measured in the lab may no longer be representative of field conditions since the samples can be exposed to oxygen during storage prior to analysis. A determination of the geochemical conditions (i.e., pH and Eh at a minimum) of the environmental setting, as well as the presence of iron floc and the toxic metals, is critical to the determination of the relative importance of iron at a site.

LOQs, LODs, DLs are derived by the laboratories, are current as of when the information was requested for the UFP-QAPP.
LOQ, LOD, and DL are highlighted yellow if the value does not meet 1/3 PAL.
Project Quantitation Goal shaded in purple is 5x the LOQ since there is no associated PAL.

# Worksheet #17 – Sampling Design and Rationale

Field investigation activities planned for this project are described in this worksheet. Field tasks will be conducted in accordance with this UFP-QAPP and in general accordance with the SOPs provided in **Appendix D**. Field data forms are also provided in **Appendix D**.

The number of proposed samples and the analytical parameters planned for each environmental medium by AOC are presented in Worksheet #18. All samples will be assigned a unique sample identifier (alpha-numeric code). The purpose of the numbering system is to assist in the tracking of samples and to facilitate retrieval of analytical results. The sampling numbers will be used on the sample labels, sample tracking forms, COC forms, field logs, and all other applicable documentation. Refer to Worksheet #18.

Field and laboratory quality control (QC) samples will be collected during each sampling investigation task described below in Worksheet #17. The analyses and frequency are prescribed in Worksheet #20, where applicable. Note, ERBs will not be required during soil sampling unless VOCs are being analyzed (i.e., AOC 3). ERBs are not required for solid sample analyses other than VOCs because it may not be appropriate to make a direct quantitative comparison for aqueous field blanks (such as equipment blanks reported as micrograms per milliliter) to a solid parent sample (such as a soil sample reported as mg/kg) (EPA, 2006; DoD, 2019). ERBs will not be collected during groundwater, surface water, or porewater sampling since new disposable equipment will be used. If non-dedicated equipment is used, then ERBs will be collected and analyzed for the same parameters being sampled at a particular site. Details regarding the types of information collected by each technology are described in Worksheets #14 and #16.

The results of the Phase 1 RI, along with potential data gaps were identified in the *Phase 1 Risk Screening and Data Gaps Analysis Report* (refer to **Appendix A**). In summary, additional investigations into the nature and extent, investigations into potential impacts to additional media (i.e., surface water, porewater, and sediment), and site-hydrogeological conditions (e.g., groundwater flow, hydraulic gradients) are needed to complete the RI phase.

Therefore, the project DQOs described within this UFP-QAPP include:

- Fully delineate the nature and extent of COPCs in soil, groundwater, surface water, porewater, and sediment.
- Update the CSM, including contaminant migration pathways, fate and transport, geologic and hydrogeologic site conditions, and exposure pathways.
- Define and establish background concentrations for the appropriate media (e.g., soil, groundwater, surface water, porewater, and sediment)
- Conduct a quantitative baseline HHRA and a SLERA, which will also incorporate site-specific data and refinements in RLSERA.

A spatially balanced random stratified sampling design method, Generalized Random Tessellation Stratified (GRTS), was applied to generate an updated set of sampling locations for proposed Phase 2 soil borings and select monitoring wells for portions of AOC 1 and AOC 3 and each of the DUs in AOCs 4 and 5 (Stevens and Olsen 2004). The GRTS program generates an unbiased sampling design for a given sample size and avoids inadvertent bias from field selection of alternative locations.

Proposed sampling locations using this balanced random stratified sampling design method were generated with consideration of the historical sample locations from Phase 1 (soil borings and temporary monitoring wells) and proposed Phase 2 monitoring wells locations where soil boring data will be collected within a given DU or portion of an AOC. Data from these historical locations will be analyzed together with the data from newly proposed sample locations to create a spatially balanced dataset for evaluation in the initial risk assessment screening process. Based on the sampling area and density for a given DU or portion of an AOC, each sampling design incorporated an edge buffer zone and a minimum distance between sampling locations to ensure adequate coverage and avoid potential “clumping” of locations. **Exhibit 11-1** provides details on the Phase 1 locations that were considered in the sampling designs.

Sampling designs by AOC are detailed below. Often times the specific rationale for sample collection, analyses, and data validation are consistent among AOCs and are therefore summarized here so that there is clarity and there is no debate about why and how sampling will be conducted:

- Soil sampling collection at all AOCs will include samples being collected from a combination of, or all, of the following sample intervals; 0-1, 1-5 and 5-10 ft bgs. The surface soil sample interval (0-1 ft bgs) is consistent with historical soil sampling and is a commonly encountered depth(s) for human and ecological exposures. The subsurface soil intervals (1-5 ft bgs) is also consistent with historical soil sampling, can be used to assess vertical migration of contaminants, and is a commonly encountered depth(s) for human and ecological exposures associated with digging or excavation for installation or repair of utility lines and burrowing animals. The 5-10 ft interval also is consistent with historical soil sampling, can be used to assess vertical migration of contaminants, and is useful for assessing future exposures where soil from the surface down to 10 ft bgs could be excavated, mixed, and used to regrade the Site such that exposure to COPCs that were present between surface and 10 ft bgs have now been placed at the surface.
- Wetland area samples, or hydric soils, have only been proposed to be collected from 0-1 ft bgs. As these wetland areas could represent groundwater seeps, and/or represent surface water runoff pathways, the depth of contamination is assumed to be at the shallow interval. The surface soil sample interval (0-1 ft bgs) is a commonly encountered depth(s) for human and ecological exposures that will be evaluated in the risk assessments.
- Supporting analyses for hardness, DOC (field-filtered), TSS, grain size, CEC, TOC and pH will be used to help determine appropriate background locations and/or bioavailability.
- A more sensitive PAHs analysis (i.e., 8270D-SIM) is needed because PALs cannot be met with typical SVOC analysis without the use of selective ion monitoring.

Proposed locations are shown on **Figure 17-1** through **Figure 17-7** and are subject to change based on site safety issues (i.e., presence of high angle slopes). **Exhibit 17-1** summarizes the number of borings per AOC, soil sampling intervals, estimated depth to the water table, sample collection method, and drilling method. Locations are subject to change based on terrain, utilities, along with general site access.

**Exhibit 17-1 – AOC Soil Sampling Summary**

| AOC | Number of Borings | Discrete Sample Depths (ft bgs) | Estimated Depth to Water Table (ft bgs) | Sample Collection Method | Drill Rig Type |
|---|---|---|---|---|---|
| 1 | 22 | 0-1; 1-5; 5-10 | 0.8–9.0 | 3-inch diameter macrocore | DPT/manual percussion |
| | 12 | 0-1 | | Hand auger | N/A |
| 3 | 17 | 0-1; 1-5; 5-10 | 1.5–10 | 3-inch diameter macrocore | DPT/manual percussion |
| 4 | 60 | 0-1 | 0.5–5 | Hand auger | N/A |
| 5 | 32 | 0-1; 1-5; 5-10 | 1.7–25 | 3-inch diameter macrocore | DPT/manual percussion |
| | 3 | 0-1 | | Hand auger | N/A |
| Background | 8 | 0-1 | 4–12 | Hand Auger | N/A |

## 17.1 AOC 1

The purpose of conducting further soil and groundwater sampling at AOC 1 is to address data gaps that were identified within the *Phase 1 Risk Screening and Data Gaps* Analysis (refer to **Appendix A**). These data gaps include:

1. Evaluation of Potential Source Areas and/or Areas of Higher Concentrations – Due to inaccessibility issues with high-angled slopes, difficult terrain, and thick vegetation, subsurface soil sampling along with groundwater sampling for DoD-related constituents' picric acid, 2,4-DNP, 2,4-DNCB, and to a lesser extent TAL metals/mercury, were not adequately delineated vertically. Therefore, these potential areas of release will need to be adequately characterized (i.e., sampling subsurface soil and groundwater for these DoD-related constituents) to make the determination of whether they are source areas.
2. Groundwater data not collected from permanent wells – Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Additionally, temporary wells provide only limited hydrogeologic information; therefore, they are not sufficient to evaluate hydrogeologic conditions and aquifer characteristics. Lastly, the HHRA requires the use of total, not dissolved metals concentrations. Therefore, the installation of permanent monitoring wells along with well development are needed to produce higher quality groundwater data.
3. Wetland Areas were not investigated – In order to avoid impacts to sensitive habitats, the wetlands located in between the APBs and Dryer Houses were not investigated. These wetland areas could represent groundwater seeps, and/or represent surface water runoff pathways. These areas could thus have the potential to be impacted by potential contamination emanating from the APB(s). Therefore, these wetland areas need to be characterized for potential ecological impacts to help characterize the fate and transport, as well as nature and extent, of contamination potentially emanating from the APBs.

In order to fulfill data gaps #1 and #2, biased surface and subsurface soil sampling at up to 22 soil boring locations, along with groundwater sampling at ten (10) newly installed permanent monitoring wells will be performed at AOC 1. Of the 22 locations, 18 soil borings (up to three per APB) will be installed in the vicinity of suspected contaminated areas (i.e., the APB(s). The remaining four permanent monitoring wells will be installed at the base of the drumlin near the dryer houses. The four (4) wells will be evenly spaced at dryer house locations to provide evaluation of groundwater contamination across the base of the drumlin (e.g. not placing downgradient wells in just the southern portion of AOC 1).

Upon completion of the soil borings, up to ten (10) permanent monitoring wells will be installed. Of the ten (10) locations six (6) co-located permanent monitoring wells will be installed at the base of the APBs (i.e., top of the drumlin). These well locations are considered bias as they are specifically targeting a source area. The remaining four (4) permanent monitoring wells will be installed at the base of the drumlin near the dryer houses. The four (4) wells will be evenly spaced at dryer house locations to provide evaluation of groundwater contamination across the base of the drumlin (e.g. not placing downgradient wells in just the southern portion of AOC 1). These well locations are considered bias as they are placed downgradient of a suspected source area(s). At drilling locations where vegetation removal is required for access, tree clearing will be kept to a minimum and trees having a breast height of 3 inches or greater shall not be cut unless approved by USACE. Furthermore, trees with shaggy or exfoliating bark will not be removed as these may provide bat habitat. In order to further minimize any impacts to sensitive species, tree clearing activities should be avoided during the 1-April to 31-October timeframe (e.g., bat active season), and 1-June to 31 July (in forested areas) to avoid pup-brooding season.

Following installation, the monitoring wells will be developed using pump and surge techniques. Following well development, a synoptic gauging event to include all newly installed monitoring well locations along with pre-existing well locations will occur prior to collecting groundwater samples. During low flow sampling, hydraulic conductivity estimates will be extracted from all 10 newly installed monitoring wells. This is a one time event.

In order to fulfill data gap #3, unbiased surface soil (saturated [i.e., hydric]) sampling (0-1 ft bgs) sampling using a hand auger will occur at 12 locations in the wetlands located in between the APBs and dryer houses.

The locations were statistically generated using GRTS. In the event a location is not saturated or representative of hydric soils, the location will be adjusted in the field accordingly. The use of heavy machinery for sample collection is not anticipated in wetland areas. However, in the event it is required, mitigative steps such as working during colder months, or the placement of construction mats will be utilized. Additionally, any heavy machinery will be decontaminated between AOCs to prevent the spread of contamination and invasive species.

A summary of the Phase 2 RI sampling rationale for AOC 1 is provided in **Exhibit 17-2**. With the exception of soil sampling, synoptic gauging and groundwater sampling events, will occur semi-annually for 1-year in order to evaluate seasonal variability in groundwater flow/magnitude and concentrations, respectively.

The following field activities will be conducted in support of the AOC 1 Field Investigation (refer to Worksheets #14 and #16 for additional details):

- Field Staking.
- Utility Clearance
- Soil sampling at 22 locations at three (3) depth intervals (0-1 ft bgs; 1-5 ft bgs; and 5-10 ft bgs).
- Soil sampling at 12 hydric locations at one (1) depth interval (0-1 ft bgs).
- Installation and well development of up to ten (10) permanent monitoring well locations.
- Synoptic water levels (manual) – semi-annually x 1 year
- Groundwater sampling of up to ten (10) permanent monitoring well locations – semi-annual x 1 year.
- Hydraulic conductivity testing (once).
- GPS Survey of sampling locations.
- Professional Well Survey.

**Exhibit 17-2 – AOC 1 Soil and Groundwater Sampling Rationale Summary**

| Sample Location | Discrete Sample Depth (ft bgs) | Sampling Rationale |
|---|---|---|
| **Soil** | | |
| NYOW-01-40 through -057 | 0-1; 1-5; 5-10 | Locations will be placed in the vicinity of the former APBs in order to investigate/characterize source. |
| NYOW-01-058 through -061 | 0-1; 1-5; 5-10 | Locations will be evenly spaced along a transect parallel to the former dryer houses to investigate concentrations potentially emanating from a source (i.e., former dry houses). |
| NYOW-01-062 through -073 | 0-1 | Advanced in the wetlands to evaluate potential contaminant migration pathways and ecological concerns. Soils are to be saturated/wet (i.e., hydric). |
| **Groundwater** | | |
| NYOW-01-MW01 through -MW06 | TBD | Locations will be placed within/adjacent to APBs to investigate/characterize groundwater concentrations in a potential source area. |
| NYOW-01-MW07 through 10 | TBD | Locations will be evenly spaced along a transect parallel to the former dryer houses to investigate downgradient groundwater concentrations emanating from potential source areas (i.e., APBs, former dryer houses). |

### 17.1.1 Environmental Media (Soil) Sampling

Sample locations will follow the nonmenclature that was used during the Phase 1 RI sampling (USACE, 2023a) and in accordance with FUDSChem database requirements. The last soil sample location that was conducted during the Phase 1 RI was NYOW-01-039. Therefore, the next sample location will be NYOW-01-040.

As shown on **Figure 17-1**, locations NYOW-01-040 through NYOW-01-057 will be placed in the vicinity of the former APBs in order to evaluate these potential source(s) area(s). Locations NYOW-01-058 through NYOW-01-061, will be evenly spaced along a transect parallel to the former dryer houses in order to investigate concentrations potentially emanating from a source (i.e., former dry houses).

Up to three (3) soil samples will be collected from boring locations NYOW-01-040 through NYOW-01-061, at the designated intervals described below:

- Sample Depth A – 0 to 1 ft bgs.
- Sample Depth B – 1 to 5 ft bgs.
- Sample Depth C – 5-10 ft bgs.

At locations NYOW-01-062 through NYOW-01-073, hand augering will be utilized to advance 12 borings within the wetlands (refer to **Figure 17-1**). One (1) soil (saturated/wet [i.e., hydric]) sample will be collected from the "Sample Depth A – 0 to 1 ft bgs" interval.

Samples will be collected following the procedures identified in Worksheets #14/16. During this soil sampling event, up to 78 parent samples are expected to be collected and analyzed for:

- 2,4-DNCB, 2,4-DNP, picric acid, and TAL metals with mercury.

At five (5) soil borings located at the base of the APBs (NYOW-01-041, NYOW-01-044, NYOW-01-047, NYOW-01-050, and NYOW-01-53) geotechnical/geochemical parameters (grain size, CEC, TOC, and pH) will also be collected at the three sampling intervals (i.e., 0-1, 1-5, and 5-10 ft bgs). These samples are needed in order to document the potential differences in geologic units located within the source area, as well as evaluate bioavailability potential.

At four (4) hydric soil locations (NYOW-01-63, NYOW-01-067, NYOW-01-070, and NYOW-01-073) geotechnical/geochemical parameters (grain size, CEC, TOC, and pH) will also be collected to evaluate the Psc unit.

A separate borehole(s) may be needed in order to fulfill sample volume requirements. If needed, the borehole(s) will be placed as close as possible to the original.

### 17.1.2 Environmental Media (Groundwater) Sampling

Groundwater samples will be collected semi-annually for up to 1-year at all newly installed permanent monitoring well locations (NYOW01-MW01 through NYOW-01-MW10) in order to evaluate seasonality. During each sampling event, up to ten (10) parent samples will be analyzed for 2,4-DNCB, 2,4-DNP, picric acid, total and dissolved (field-filtered) TAL metals/mercury, and geochemical parameters (DOC [field-filtered] and hardness).

### 17.1.3 Synoptic Groundwater Events

Uncertainty exists regarding groundwater flow directions and contaminant migration pathways, and hydraulic gradients. As summarized in **Exhibit 17-3**, groundwater levels will be measured in all of the ten (10) (if installed) AOC 1 newly installed monitoring wells, the three (3) newly installed proposed background wells (refer to Section 17.5), along with 20 pre-existing well locations. The synoptic water levels will be taken using a water level meter. Depth to water, total depth, along with well condition will be recorded on the appropriate form (refer to **Appendix D**). Water level frequency will be collected semi-annually prior to groundwater sampling in order to evaluate seasonal variability in AOC groundwater flow directions/magnitude. Locations are summarized below and displayed on **Figure 17-1**. Note, if a permanent

monitoring well will be installed in the vicinity of a temporary well, then that temporary monitoring well will be abandoned and will not be included in the synoptic water level event(s).

**Exhibit 17-3 – AOC 1 Synoptic Water Level Summary**

| AOC | Existing Well ID | | Proposed New Well | | Frequency |
|---|---|---|---|---|---|
| 1 | NYOW-01-001 | B-6 | NYOW-01-MW01 | NYOW-01-MW07 | Semi-Annual X 1 year |
| 1 | NYOW-01-005 | B-7 | NYOW-01-MW02 | NYOW-01-MW08 | |
| 1 | NYOW-01-006 A & B | MW-5 | NYOW-01-MW03 | NYOW-01-MW09 | |
| 1 | NYOW-01-018 | MW-6 | NYOW-01-MW04 | NYOW-01-MW10 | |
| 1 | NYOW-01-019 | MW-7 | NYOW-01-MW05 | - | |
| 1 | NYOW-01-021 | D&M-1 | NYOW-01-MW06 | - | |
| 1 | NYOW-01-022 | D&M-7 | - | - | |
| 1 | NYOW-01-023 | D&M-13 | - | - | |
| 1 | NYOW-01-024 | - | - | - | |
| 1 | B-5 | - | - | - | |
| BK | NYOW-B-031 | | NYOW-B-MW01 | NYOW-B-MW02 | |
| | | | NYOW-B-MW03 | - | |

## 17.2 AOC 3

The purpose of conducting further soil and groundwater sampling at AOC 3 is to address data gaps that were identified within the *Phase 1 Risk Screening and Data Gaps* Analysis (refer to **Appendix A**). These data gaps include:

1. Evaluation of Potential Source Areas and/or Areas of Higher Concentrations – Soil sampling was not performed below the parking lot in the footprint of the previously identified former landfill. In addition, the geophysical survey conducted during the Phase 1 RI, identified that the former landfill extended more northerly, beyond the parking lot (USACE, 2023a), than previously suspected. The area was not adequately characterized to make a determination of whether the former landfill is a source area. Therefore, this potential area(s) of release will need to be adequately characterized to make the determination of whether they are source areas.
2. Groundwater data not collected from permanent wells – Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Additionally, temporary wells provide only limited hydrogeologic information; therefore, they are not sufficient to evaluate hydrogeologic conditions and aquifer characteristics. Lastly, the HHRA requires the use of total, not dissolved metals concentrations. Therefore, the installation of permanent monitoring wells along with well development are needed to produce higher quality groundwater data.
3. Unnamed Stream located north of the site not investigated – Surface water, porewater, and sediment samples in the unnamed stream north of the parking lot were not planned for collection during Phase 1 RI. However, based on the results of the Phase 1 investigation, samples in the unnamed stream north of the parking lot are needed to assess potential ecological risk. In addition, it is not known if the stream is gaining or losing in this area. This information is needed to characterize fate and transport. Therefore, surface water, porewater, sediment sampling, in addition to hydrogeological investigations (i.e., stream flow measurements, installation of and gauging stream piezometers) are needed to fulfill this data gap.

In order to fulfill data gaps #1 and #2, co-located surface and subsurface soil sampling along with monitoring well installations will occur at seven (7) locations; one (1) biased soil boring/monitoring well (NYOW-03-019/MW01) will be installed within the former OSA; one (1) biased soil boring/monitoring well location (NYOW-03-020/MW02) will be installed upgradient/west of the former OSA;; two (2) unbiased soil boring/monitoring well locations (NYOW-03-021/MW03, NYOW-03-022/MW04), which were statistically generated using GRTS, will be in the vicinity of the former landfill DU; one (1) biased soil boring/monitoring well (NYOW-03-023/MW05) will be installed downgradient of Phase 1 RI location NYOW-03-008 to investigate extent of potential PAHs; and two (2) biased soil boring/monitoring wells (NYOW-03-024/MW06, NYOW-03-025/MW07) will be located north of the stream, primarily to document groundwater concentrations and to determine if groundwater, or a portion of, from the former landfill area is flowing beneath the stream. In addition to the seven (7) locations, ten (10) unbiased soil boring only locations (NYOW-03-026 through NYOW-03-035) will be installed within the DU surrounding the former landfill. The locations of these soil borings were statistically generated using GRTS.

Monitoring well installations will occur next to the co-located soil boring for a total of seven (7) permanent monitoring wells, and the borehole will be advanced using HSA drilling methodology. At drilling locations where vegetation removal is required for access, tree clearing will be kept to a minimum and trees having a breast height of 3 inches or greater shall not be cut unless approved by USACE. Furthermore, trees with shaggy or exfoliating bark will not be removed as these may provide bat habitat. In order to further minimize any impacts to sensitive species, tree clearing activities should be avoided during the 1-April to 31-October timeframe (e.g., bat active season), and 1-June to 31 July (in forested areas) to avoid pup-brooding season.

Following installation, the monitoring wells will be developed using pump and surge techniques. Following well development, a synoptic gauging event to include all newly installed monitoring well locations (along with newly installed stream piezometers [refer to data gap #3]) along with pre-existing wells will occur prior to collecting groundwater samples. During low flow sampling, hydraulic conductivity estimates will be extracted from all seven (7) newly installed monitoring wells. This is a one time event.

In order to fulfill data gap #3, biased surface water, porewater, and sediment co-located samples will be collected at a total of eight (8) locations along the stream in order to evaluate concentrations of suspected COPCs within these media and evaluate potential ecological risks. Locations have been placed in areas that appear to be downgradient of and/or potentially receiving groundwater from potential source areas (i.e., former OSA and former Landfill Area). In addition to collecting samples, stream flow measurements will be made at each co-located sample location. These data will be used to evaluate fate and transport. Three semi-permanent piezometers will also be installed upstream, mid-stream, and downstream. The water elevation data obtained from the stream piezometers in conjunction with the permanent monitoring wells groundwater elevation data will be used to determine the groundwater to surface water migration pathway (e.g., gaining versus losing conditions, and groundwater input). In addition to water elevation data, stream flow measurements will be collected at eight (8) sampling locations including where piezometers are placed (see Section 14.2.9). In addition to flow measurements, depth measurements will be collected at 1-foot intervals in order to develop a channel profile. Bank vegetation will also be noted. A published n-value or Manning's roughness coefficient will be used to determine stream discharge at each sampling location. Discharge at each location will be compared to determine gaining or losing stream conditions.

A summary of the Phase 2 RI sampling rationale for AOC 3 is provided in **Exhibit 17-4**.

With the exception of soil sampling, synoptic gauging and groundwater sampling events, will occur semi-annually for 1-year in order to evaluate seasonal variability in groundwater flow/magnitude and concentrations, respectively.

The following field activities will be conducted in support of the AOC 3 Field Investigation (refer to Worksheets #14 and #16 for additional details):

- Field Staking.
- Utility Clearance
- Soil sampling at seventeen (17) locations at three (3) depth intervals (0-1 ft bgs; 1-5 ft bgs; and 5-10 ft bgs).

- Installation and well development of up to seven (7) permanent monitoring well locations.
- Installation of three (3) stream piezometers.
- Surface water, porewater, and sediment sampling at eight (8) locations – semi-annual x 1 year
- Synoptic water levels (manual) – semi-annual x 1 year.
- Groundwater Sampling of up to seven (7) permanent monitoring well locations - semi-annual x 1 year.
- Hydraulic conductivity testing (once).
- GPS Survey of sampling locations.
- Professional Well Survey.

### Exhibit 17-4 – AOC 3 Soil, Groundwater, Surface Water, Porewater, Sediment Sampling Rationale Summary

| Sample Location | Discrete Sample Depth (ft bgs) | Sampling Rationale |
|---|---|---|
| **Soil** | | |
| NYOW-03-019 | 0-1; 1-5; 5-10 | Location will be placed within former OSA to investigate/characterize source |
| NYOW-03-020 | 0-1; 1-5; 5-10 | Location will be placed upgradient/west of the former OSA to represent concentrations outside of a known source area (i.e. former OSA) |
| NYOW-03-021, -022 | 0-1; 1-5; 5-10 | Locations will be placed in the vicinity of the suspected landfill area to investigate/characterize source |
| NYOW-03-023 | 0-1; 1-5; 5-10 | Location will be installed downgradient of Phase 1 RI location NYOW-03-008 to investigate extent of potential PAHs |
| NYOW-03-024; -025 | 0-1; 1-5; 5-10 | Locations will be installed north of the stream, primarily to document groundwater concentrations and to determine if groundwater, or a portion of, from the former landfill area is flowing beneath the stream. |
| NYOW-03-026 through -035 | 0-1; 1-5; 5-10 | Locations installed at unbiased locations throughout the former landfill DU |
| **Groundwater** | | |
| NYOW-03-MW01 | TBD | Location will be placed within former OSA to investigate/characterize source |
| NYOW-03-MW02 | TBD | Location will be placed upgradient/west of the former OSA to represent concentrations outside of a known source area (i.e. former OSA) |
| NYOW-03-MW03; MW04 | TBD | Locations will be placed in the vicinity of the former landfill area to investigate/characterize source |
| NYOW-03-MW05 | TBD | Location will be installed downgradient of Phase 1 RI location NYOW-03-008 to investigate extent of potential PAHs |
| NYOW-03-MW06; MW07 | TBD | Locations will be installed north of the stream, primarily to document groundwater concentrations and to determine if groundwater, or a portion of, from the former landfill area is flowing beneath the stream. |
| **Surface Water, Porewater, Sediment** | | |
| NYOW-03-SW/PW/SD01 through -03 | Varies | Evaluate concentrations in the unnamed stream potentially receiving groundwater from the former OSA. Evaluate potential ecological impacts |

| Sample Location | Discrete Sample Depth (ft bgs) | Sampling Rationale |
|---|---|---|
| NYOW-03-SW/PW/SD04 | TBD | Evaluate concentrations in portion of the stream located downstream from an area potentially receiving groundwater from the former OSA. Evaluate potential ecological impacts |
| NYOW-03-SW/PW/SD05 and -06 | TBD | Evaluate concentrations in the unnamed stream potentially receiving groundwater from the former landfill. Evaluate potential ecological impacts |
| NYOW-03-SW/PW/SD07 and -08 | TBD | Evaluate concentrations in portion of the stream located downstream from an area potentially receiving groundwater from the former landfill and OSA. Evaluate potential ecological impacts |

The following subsection describes the sampling design.

### 17.2.1 Environmental Media (Soil) Sampling

Sample locations will follow the nonmenclature that was used during the Phase 1 RI sampling (USACE, 2023a). The last soil sample location that was conducted during the Phase 1 RI was NYOW-03-018. Therefore, the next sample will be NYOW-03-019.

At locations NYOW-03-019 through NYOW-03-036 soil samples will be collected via DPT (refer to Worksheets #14/16). The proposed locations are shown on **Figure 17-2**. A total of three (3) soil samples will be collected from boring locations NYOW-03-019 through NYOW-03-025, as described below:

- Sample Depth A – 0 to 1 ft bgs.
- Sample Depth B – 1 to 5 ft bgs.
- Sample Depth C – 5-10 ft bgs.

Samples will be collected following the procedures identified in Worksheets #14/16. During this soil sampling event, a total of 51 parent samples are expected to be collected and analyzed for:

- VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury. Note, while volatilization may possibly have occurred in shallow soil, there is still the potential for VOCs to be present. Since the HHRA is cumulative there are other pathways to be concerned about if VOCs are present at shallow depth (i.e. direct contact). Additionally, shallow soil may represent exposure to terrestrial plants and invertebrates. At this time, the presence or absence of VOCs is unknown. PCB analysis is also included because of its presence in Phase I AOC 3 soil samples.

At co-located soil boring/monitoring well locations (NYOW-03-019, NYOW-03-021, NYOW-03-022, NYOW-023, and NYOW-03-025) and soil boring only locations NYOW-03-030, and NYOW-03-033, geotechnical/geochemical parameters (grain size, CEC, TOC, and pH) will also be collected at each of the three soil sample intervals 0-1, 1-5, 5-10 ft bgs.

Separate borehole(s) may be needed in order to fulfill sample volume requirements. If needed, the borehole(s) will be placed as close as possible to the original.

### 17.2.2 Environmental Media (Groundwater) Sampling

Groundwater samples will be collected semi-annually for up to 1-year at all newly installed permanent monitoring well locations (NYOW-03-MW01 through NYOW-03-MW07) to evaluate seasonality (**Figure 17-2**). During each sampling event, seven (7) parent samples, will be collected and analyzed for VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, and geochemical parameters (DOC [field-filtered] and hardness). PCB analysis is included at AOC 3 for all aqueous samples because it was detected in a Phase 1 soil sample. While PCBs are not readily soluble in water, this analysis was planned because PCBs can adhere to sediment particles in unfiltered surface

water column, porewater, and groundwater. The presence of PCBs can impact ecological receptors as well as direct contact and ingestion pathways for human health.

### 17.2.3 Environmental Media (Surface Water) Sampling

Surface water samples will be collected semi-annually for up to 1-year at all new locations (**Figure 17-2**) to evaluate seasonality. Surface water samples will be collected at the mid-point of the water column, while maintaining a distance of more than 1 foot from the sediment bed and more than 1 foot below the surface water level. If the water column is less than 2 feet, the sample will be collected from the mid-point of the water column. Sampling will not occur within 48 hours after a precipitation event totaling more the 0.25 inches (refer to Worksheet #14/16).

During each sampling event, eight (8) samples will be collected from locations NYOW-03-SW01 through NYOW-03-SW08, along with field QC samples (i.e., duplicate, MS/MSD, trip blank) and analyzed for VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, and geochemical parameters (DOC [field-filtered], and TSS). Hardness will also be analyzed but only for the parent sample. Field filtered metals analysis is needed for surface water samples because dissolved concentrations are needed for evaluation of metals that have water quality criteria that are based on the dissolved fraction.

An equipment blank will not be collected during surface water sampling since direct-dip sampling methods will be employed (refer to Worksheet #14/16).

### 17.2.4 Environmental Media (Porewater) Sampling

Porewater samples will be collected semi-annually for up to 1-year at all new locations (**Figure 17-2**) to evaluate seasonality. During each sampling event, eight (8) samples will be collected from locations NYOW-03-PW01 through NYOW-03-PW08, along with field QC samples (i.e., duplicate, MS/MSD, equipment blank, and trip blank) and analyzed for VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, and total and dissolved (field-filtered) TAL metals/mercury.

### 17.2.5 Environmental Media (Sediment) Sampling

Sediment samples will be collected semi-annually for up to 1-year at all new locations (**Figure 17-2**) to evaluate seasonality. During each sampling event, eight (8) samples will be collected from locations NYOW-03-SD01 through NYOW-03-SD08, along with field QC samples (i.e., duplicate, MS/MSD, equipment blank, and trip blank) and analyzed for VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total TAL metals/mercury, and geotechnical/geochemical parameters (grain size and TOC). Note, there is no QC for grain size or TOC. For sediment samples, the 0-0.5 depth has been proposed based primarily on information regarding burrowing and foraging behaviors of terrestrial and semi-aquatic ecological receptors.

### 17.2.6 Synoptic Groundwater Events

Uncertainty exists regarding groundwater flow directions and contaminant migration pathways, and hydraulic gradients. As summarized in **Exhibit 17-5**, groundwater levels will be measured in all of the seven (7) newly installed monitoring wells, three (3) newly installed piezometers, the two (2) new nearby proposed background wells (refer to Section 17.5), along with nine (9) pre-existing well locations. The synoptic water levels will be measured using a water level meter. Depth to water, total depth, along with well condition will be recorded on the appropriate form (refer to **Appendix D**). Water level frequency will be collected semi-annually prior to groundwater sampling in order to evaluate seasonal variability in AOC groundwater flow directions/magnitude. Locations are summarized below and displayed on **Figure 17-2**. Note, if a permanent monitoring well will be installed in the vicinity of a temporary well, then that temporary monitoring well will be abandoned and will not be included in the synoptic water level event(s).

**Exhibit 17-5 – AOC 3 Synoptic Water Level Summary Table**

| AOC | Existing Well ID | Proposed New Well | Proposed New Piezometer | Frequency |
|---|---|---|---|---|
| 3 | NYOW-03-002 | NYOW-03-MW01 | NYOW-03-SG01 | Semi-Annual X 1 year |
| 3 | NYOW-03-007 | NYOW-03-MW02 | NYOW-03-SG02 | |
| 3 | NYOW-03-009 | NYOW-03-MW03 | NYOW-03-SG03 | |
| 3 | NYOW-03-010 | NYOW-03-MW04 | - | |
| 3 | NYOW-03-013 | NYOW-03-MW05 | - | |
| 3 | NYOW-03-14 | NYOW-03-MW06 | - | |
| 3 | NYOW-03-15 | NYOW-03-MW07 | - | |
| 3 | MW-8 | - | - | |
| 3 | D&M-11 | - | - | |
| BK | - | NYOW-B-MW-05 | | |
| | | NYOW-B-MW-06 | | |

## 17.3 AOC 4

The purpose of conducting further soil sampling at AOC 4 is to address data gaps that were identified within the *Phase 1 Risk Screening and Data Gaps* Analysis (refer to **Appendix A**). These data gaps include:

1. Evaluation of Potential Source Areas and/or Areas of Higher Concentrations – The results from Phase 1 RI soil sampling were all non-detect for three analytes (2,4-DNCB, 2,4-DNP, and picric acid). However the surficial incremental sampling methodology (ISM) results from the bunkers had low bias for the SVOCs. Therefore, discrete surface soil samples are needed to verify/confirm ISM results.

In order to fulfill data gap #1, surface soil samples (0-1 ft bgs) will be collected from up to five unbiased sample locations within each of the Phase 1 RI DUs at the 12 bunkers, for a total of 60 parent sample locations. The locations were statistically generated using GRTS.

The following field activities will be conducted in support of the AOC 4 Field Investigation (refer to Worksheets #14 and #16 for additional details):

- Field Staking.
- Soil sampling at sixty (60) locations at one (1) depth interval (0-1 ft bgs)
- GPS Survey of sampling locations.

**Exhibit 17-6 – AOC 4 Soil Sampling Rationale Summary**

| Sample Location | Discrete Sample Depth (ft bgs) | Sampling Rationale |
|---|---|---|
| NYOW-04-086 through -145 | 0-1 | Locations will be placed using an unbiased (non-judgmental) approach within previously established ISM DUs to confirm Phase 1 RI ISM results. |

The following subsection describes the sampling design.

### 17.3.1 Environmental Media (Soil) Sampling

Sample identification will follow the nonmenclature that was used during the Phase 1 RI sampling (USACE, 2023a). The last soil sample location that was conducted during the Phase 1 RI was NYOW-04-085. Therefore, the next sample will be NYOW-04-086.

At locations NYOW-04-086 through NYOW-04-145 a total of sixty (60) parent soil samples will be collected from 0-1 ft bgs using a hand auger. Samples will be analyzed for 2,4-DNCB, 2,4-DNP, and picric acid. If the location is within hard compaction gravel, then macrocore sampling with DPT may be employed. The proposed locations are shown on **Figure 17-3.**

Separate borehole(s) may be needed in order to fulfill sample volume requirements. If needed, the borehole(s) will be placed as close as possible to the original.

## 17.4 AOC 5

The purpose of conducting further soil and groundwater sampling at AOC 5 is to address data gaps that were identified within the *Phase 1 Risk Screening and Data Gaps* Analysis (refer to **Appendix A**). These data gaps include:

1. Evaluation of Potential Source Areas and/or Areas of Higher Concentrations – Elevated metals concentrations in soil borings during the Phase 1 RI, is likely due to leaching from coal and/or coal ash. Elevated PAHs were not found at depth or in the sample that contained coal ash only. Therefore, additional sampling is needed to determine the source of PAHs (i.e., is PAH concentrations associated with coal particles or in the soil?).
    - These potential areas of release will need to be adequately characterized to make the determination of whether they are source areas.
    - TOC data were mostly rejected. These data are needed to evaluate suitability of background soil for comparison to site soil.
    - The background and screening-level comparisons for groundwater and discrete soil samples resulted in the identification of COPCs and COPECs within the surface and subsurface intervals in the Boiler house, CABs, and CSA. Of particular interest is the arsenic detected in groundwater at the Boiler House. Therefore, additional sampling is necessary to characterize the extent of soil and groundwater impacts and estimate representative mean sample concentrations to conduct human health and ecological risk assessments. A subset of surface soil and subsurface soil samples within the coal storage area and near the coal aggregate bins within AOC 5 need to be analyzed via microscopy, similar to what was completed during the Phase 1 RI. The locations selected for microscopy samples will be biased to areas where coal particles are observed on the surface or within the soil core. (Additionally, coal particles if observed within the soil core, will be described on the boring log). The microscopy data (Phase 1 and Phase 2) will be used to support the CSM in terms of nature and extent (i.e., source) and fate and transport, and if CERLA related contaminants pose a risk to human health and the environment. All chemical data will be used to determine if CERCLA related contaminants pose a risk to human health and the environment. If the combined Phase 1 and Phase 2 results indicate that PAHs and metals are both above background and risk screening levels, the coal microscopy data will be used in a qualitative "lines of evidence" approach to distinguish metal and PAH contamination in coal vs. metal and PAH contamination absorbed to soils in the uncertainty section of the risk assessment.

2. Groundwater data not collected from permanent wells – Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Additionally, temporary wells provide only limited hydrogeologic information; therefore, they are not sufficient to fully evaluate hydrogeologic conditions and aquifer characteristics. Lastly, human health risk assessment requires the use of total, not dissolved metals concentrations.

Therefore, the installation of permanent monitoring wells along with well development are needed to produce higher quality groundwater data.

3. Wetland Areas were not investigated – In order to avoid/reduce impact to sensitive habitats, the wetlands located east of the APBs were not sampled. These wetland areas could represent groundwater seeps, and/or represent surface water runoff pathways. Therefore, these wetland areas need to be characterized for the presence/absence of DoD related contamination in order to evaluate potential ecological impacts.

4. Evaluate PCB concentrations in soil (surface and subsurface) and groundwater in the former electrical substation, as well as groundwater only in the possible dump area and downgradient of the former electrical station (MW03 and MW07) based on the aroclor detected in a Phase 1 soil from electrical substation and elevated detection limits in the Phase 1 groundwater samples.

In order to fulfill data gaps #1 and #2, surface and subsurface soil sampling at up to 32 locations, along with groundwater sampling at ten (10) newly installed permanent monitoring wells will be performed within suspected contaminated areas at AOC 5. Four DUs (DU#1 through #4) (**Figure 17-4**), with eight (8) borings per unit (i.e., 32 locations), will be drilled utilizing DPT within the following former areas; DU#1 – former electrical substation and boiler house; DU#2 – a former drainage ditch, including the CABs; DU#3 – CSA; and DU#4 – possible dump area. All of the sample locations within the DUs are considered unbiased and were generated using GRTS. All three soil borings in and within the vicinity of the boiler house; all eight soil boring locations within the CSA, and four borings near the CABs for coal and coal ash by microscopy.

Upon completion of the soil borings, up to eleven (11) permanent monitoring wells will be installed. One (1) biased monitoring well only location (NYOW-05-MW01) will be installed in the vicinity of Phase 1 soil boring location NYOW-05-023 to evaluate groundwater concentrations downgradient of elevated PAHs detected within the borehole; one (1) biased monitoring well (NYOW-05-MW02) will be installed downgradient of Phase 1 RI soil boring location NYOW-05-019 to evaluate elevated PAHs and the highest mercury concentrations detected within that borehole; two (2) monitoring wells (NYOW-05-MW03, -MW04) will be placed within the CSA to investigate potential source releases from this area. These two wells are considered unbiased as they were placed using GRTS. Three (3) biased monitoring wells (NYOW-05-MW-05, -MW06, and -MW07) will be installed along the downgradient limits of AOC 5; one (1) monitoring well (NYOW-05-MW08) will be installed within the possible dump area. This location is considered unbiased as it was placed using GRTS. One (1) monitoring well (NYOW-05-09) will be installed within the former electrical substation. This location is considered unbiased as it was placed using GRTS. Two (2) biased monitoring wells (NYOW-05-MW10, -MW11) will be installed approximately 500 feet downgradient (west/southwest) of the site to evaluate downgradient concentrations and groundwater flow paths.

At drilling locations where vegetation removal is required for access, tree clearing will be kept to a minimum and trees having a breast height of 3 inches or greater shall not be cut unless approved by USACE. Furthermore, trees with shaggy or exfoliating bark will not be removed as these may provide bat habitat. In order to further minimize any impacts to sensitive species, tree clearing activities should be avoided during the 1-April to 31-October timeframe (e.g., bat active season), and 1-June to 31 July (in forested areas) to avoid pup-brooding season.

In order to fulfill data gap #3, discrete surface soil (saturate/wet [i.e., hydric]) sampling (0-1 ft bgs) using a hand auger will occur at three (3) drainage ditches located to the west of AOC 5; (1) one surface soil sample (NYOW-05-058) will be collected in a drainage ditch located to the north of the AOC, (2) one surface soil sample (NYOW-05-059) will be collected in a drainage ditch located to the west of the AOC; and (3) one surface soil sample (NYOW-05-060) will be collected in a drainage ditch located to the southwest of the AOC. If a soil sample is not saturated/wet (i.e., hydric) during sample collection, then location will be moved in order to obtain a saturated/wet (i.e., hydric) soil sample. These locations, in addition to groundwater sample data from NYOW-05-MW10 and NYOW-05-MW11, are selected in order to determine the presence/absence to ensure that impacts are not found beyond the AOC 5 boundary. These samples will be compared to samples from AOC 5, the PALs, and/or background concentrations, where appliable. If PAL and background exceedances are observed, the results of these samples may be used to identify potential data gaps for additional sampling efforts. The use of heavy machinery for sample collection is not

anticipated in wetlands. However, in the event it is required, mitigative steps such as working during colder months, or the placement of construction mats will be utilized. Additionally, any heavy machinery will be decontaminated between AOCs to prevent the spread of contamination and invasive species.

In order to fulfill data gap #4, surface and subsurface soils at borings located within the footprint of the electrical substation will be analyzed for PCBs. Additionally, groundwater samples for PCB analysis will also be collected from NYOW-05-MW03, NYOW-05-MW07, NYOW-05-MW08 and NYOW-05-MW09. Groundwater samples from NYOW-05-MW03 and NYOW-05-MW07 will monitor downgradient groundwater emanating from the electrical substation. Groundwater samples from NYOW-05-MW08 and NYOW-05-MW09 will be representative of a potential source.

With the exception of soil sampling, synoptic gauging and groundwater sampling events, will occur semi-annually for 1-year in order to evaluate seasonal variability in groundwater flow/magnitude and concentrations, respectively. During low flow sampling, hydraulic conductivity estimates will be extracted from all 11 newly installed monitoring wells. This is a one-time event.

The following field activities will be conducted in support of the AOC 5 Field Investigation (refer to Worksheets #14 and #16 for additional details):

- Field Staking.
- Utility Clearance
- Soil sampling at 32 locations at three (3) depth intervals (0-1 ft bgs; 1-5 ft bgs; and 5-10 ft bgs).
- Soil sampling at five (5) locations at one (1) depth interval (0-1 ft bgs)
- Installation and well development of up to ten (10) permanent monitoring well locations
- Synoptic water levels
- Groundwater Sampling of up to ten (10) permanent monitoring well locations.
- Hydraulic conductivity testing (once).
- GPS Survey of sampling locations.
- Professional Well Survey.

**Exhibit 17-7 – AOC 5 Soil and Groundwater Sampling Rationale Summary**

| Sample Location | Discrete Sample Depth (ft bgs) | Sampling Rationale |
|---|---|---|
| **Soil** | | |
| NYOW-05-026 through -033 | 0-1; 1-5; 5-10 | Locations installed to investigate potential sources (boiler house, former electrical substation) within DU#1. Please note, soil borings were statistically generated using GRTS. |
| NYOW-05-034 through -041 | 0-1; 1-5; 5-10 | Locations installed to investigate potential sources (drainage ditch, CABs) within DU#2. |
| NYOW-05-042 through -049 | 0-1; 1-5; 5-10 | Locations installed to investigate potential source (CSA) within DU#3. Please note, soil borings were statistically generated using GRTS. |
| NYOW-05-050 through -057 | 0-1; 1-5; 5-10 | Locations installed to investigate potential source (possible dump) within DU#4. Please note, soil borings were statistically generated using GRTS. |
| NYOW-05-058 through -060 | 0-1 | Locations placed to investigate drainage ditches west/south of AOC 5. Soils need to be saturated/wet (i.e., hydric). |
| **Groundwater** | | |
| NYOW-05-MW01 | TBD | Install to evaluate groundwater concentrations downgradient of elevated PAHs detected within Phase 1 borehole (NYOW-05-023). |
| NYOW-05-MW02 | TBD | Install downgradient of Phase 1 RI soil boring location NYOW-05-019 to evaluate elevated PAHs and the highest mercury concentrations detected within that borehole. |
| NYOW-05-MW03; MW04 | TBD | Install within the CSA to investigate potential source releases from this area. |
| NYOW-05-MW05; MW06; MW07 | TBD | Install downgradient of AOC 5 to evaluate groundwater concentrations leaving the site. |
| NYOW-05-MW08 | TBD | Install within the possible dump area to investigate potential source releases from this area. |
| NYOW-05-MW09 | TBD | Install within the former electrical substation area to investigate potential source releases from this area. |
| NYOW-05-MW10; MW11 | TBD | Install approximately 500 ft downgradient of AOC 5 to evaluate groundwater concentrations leaving the site. |

## 17.4.1 Environmental Media (Soil) Sampling

Sample locations will follow the nonmenclature that was used during the Phase 1 RI sampling (USACE, 2023a). The last soil sample location that was conducted during the Phase 1 RI was NYOW-05-025. Therefore, the next sample will be NYOW-05-026.

At locations NYOW-05-026 through NYOW-05-057 soil samples will either be collected using DPT drilling or manual drilling methods. The proposed locations are shown on **Figure 17-4.** A total of three (3) soil samples will be collected from boring locations NYOW-05-051 through NYOW-05-051, as described below:

- Sample Depth A – 0 to 1 ft bgs.
- Sample Depth B – 1 to 5 ft bgs.
- Sample Depth C – 5-10 ft bgs.

At locations NYOW-05-058 through NYOW-05-060 a total of three (3) parent soil (saturated/wet [i.e., hydric]) samples will be collected from 0-1 ft bgs using a hand auger within the wetlands. The proposed locations are shown on **Figure 17-5.**

Samples will be collected following the procedures identified in Worksheets #14/16. During this soil sampling event, a total of 99 parent samples are expected to be collected and analyzed for:

- PAHs, and TAL metals/mercury.

A total of 15 parent samples are also expected to be collected and analyzed for:

- PCBs – locations within the former electrical substation only.

A total of up to 45 parent samples are expected to be collected and analyzed for:

- Coal by microscopy. Coal samples will be analyzed and reported in accordance with the *SOP MVL/05-09* provided by MicroVision Laboratories. The methods used to detect coal, will be via SEM, EDS, and PLM. Samples will be collected at all three intervals (i.e., 0-1 ft bgs; 1-5 ft bgs; and 5-10 ft bgs). Boring locations for coal analysis will be as follows per DU#:
    - DU#1 – Boiler House – NYOW-05-031; -032; -033
    - DU#2 – Drainage Ditch/CABs – Four locations will be selected in the field based on the presence of coal. If no coal is found in the vicinity of the borings within DU#2, then borings closest to the locations of the CABs, the most likely source for coal within DU#2, will be selected for analysis.
    - DU#3 – CSA – All borings within the CSA will be analyzed for coal (i.e., NYOW-05-042 thru NYOW-05-049).

At locations (NYOW-05-028, NYOW-05-032, NYOW-05-036, NYOW-05-045, and NYOW-05-056) geotechnical/geochemical parameters (grain size, CEC, TOC, and pH) will also be collected at each of the three soil sample intervals 0-1, 1-5, 5-10 ft bgs. Attempts will be made to move this analysis if appropriate in DU#1, DU#2, and DU#3 to be co-located with soil borings that contain coal that is confirmed in the field visually.

Additionally, geotechnical/geochemical parameters (grain size, CEC, TOC, and pH) will be collected at the 0-1 ft bgs interval at hand auger location at NYOW-05-059.

Separate borehole(s) may be needed in order to fulfill sample volume requirements. If needed, the borehole(s) will be placed as close as possible to the original.

## 17.4.2 Environmental Media (Groundwater) Sampling

Groundwater samples will be collected semi-annually for up to 1-year at all newly installed permanent monitoring well locations (NYOW-05-MW01 through NYOW-05-MW10) to evaluate seasonality. During each sampling event, ten (10) parent samples, along with field QC samples (i.e., duplicate, MS/MSD) will be collected and analyzed for PAHs, total and dissolved (field-filtered) TAL metals/mercury, and geochemical parameters (DOC [field-filtered]. Hardness will also be collected but for parent samples only. For monitoring wells located within the former electrical substation (MW09) and possible dump area (MW08) and wells downgradient of the electric substation (MW03 and MW07), groundwater samples will also be analyzed for PCBs.

## 17.4.3 Synoptic Groundwater Events

Uncertainty exists regarding groundwater flow directions and contaminant migration pathways, and hydraulic gradients. Groundwater levels will be measured in all of the 11 (if installed) newly installed monitoring wells, one (1) newly installed proposed nearby background well, along with 14 pre-existing well locations (refer to **Exhibit 17-8**). The synoptic water levels will measured using a water level meter. Depth to water, total depth, along with well condition will be recorded on the appropriate form (refer to **Appendix D**). Water level frequency will be collected semi-annually prior to groundwater sampling in order to evaluate seasonal variability in AOC groundwater flow directions/magnitude. Locations are summarized below and

displayed on **Figure 17-4** and **Figure 17-5**. Note, if a permanent monitoring well will be installed in the vicinity of a temporary well, then that temporary monitoring well will be abandoned and will not be included in the synoptic water level event(s).

**Exhibit 17-8 – AOC 5 Synoptic Water Level Summary Table**

| AOC | Existing Well ID | | Proposed New Well | | Frequency |
|---|---|---|---|---|---|
| 5 | NYOW-05-001 | NYOW-05-012 | NYOW-05-MW01 | NYOW-05-MW07 | Semi-Annual X 1 year |
| 5 | NYOW-05-004 | NYOW-05-016 | NYOW-05-MW02 | NYOW-05-MW08 | |
| 5 | NYOW-05-005 | NYOW-05-017-01 | NYOW-05-MW03 | NYOW-05-MW09 | |
| 5 | NYOW-05-006 | NYOW-05-019 | NYOW-05-MW04 | NYOW-05-MW10 | |
| 5 | NYOW-05-008 | NYOW-05-024 | NYOW-05-MW05 | NYOW-05-MW11 | |
| 5 | NYOW-05-010 | NYOW-05-025 | NYOW-05-MW06 | - | |
| BK | NYOW-B-005 | NYOW-B-050 | NYOW-B-MW-04 | - | |

## 17.5 Background

The purpose of conducting further soil and groundwater sampling at Background locations is to address data gaps that were identified within the *Phase 1 Risk Screening and Data Gaps* Analysis (refer to **Appendix A**). These data gaps include:

1. Groundwater data not collected from permanent wells – Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Additionally, temporary wells provide only limited hydrogeologic information; therefore, they are not sufficient to fully evaluate hydrogeologic conditions and aquifer characteristics. Lastly, human health risk assessment requires the use of total, not dissolved metals concentrations.
    (a) Therefore, the installation of permanent monitoring wells along with well development, will produce higher quality groundwater data.
    (b) TOC data were mostly rejected. These data are needed to evaluate suitability of background soil for comparison to site soil.
2. Wetland Areas not Investigated – In order to compare wetland concentrations collected from the AOC 1 and AOC 5 investigation, background (hydric) soils need to be collected and analyzed.
3. Background surface water, porewater, and sediment concentrations need to be established – In order to compare concentrations in similar media collected at AOC 3, background surface water, porewater, and sediment sampling will be performed in an undeveloped area west of AOC 3.

The background analytical results will be used to estimate BTVs for each medium. The site-specific BTVs will be used as a first line of evidence to determine whether concentrations detected in site media are attributable to background levels. Comparison to the site-specific BTVs is based on the null hypothesis that the site concentrations are consistent with background concentrations. The analyte is considered potentially related to a site release if the sample size is greater than 20 and detections exceed the BTV in more than 5% of samples. For sample sizes less than or equal to 20, a single exceedance of the BTV is used to determine the potential for a site release. If comparison to the site-specific BTVs indicates the likelihood of false positives (Type I error or the incorrect rejection of the null hypothesis), either single- or two-sample hypothesis testing may be considered for PAH and/or inorganic analytes as an additional risk refinement.

In order to fulfill data gaps #1, six (6) permanent monitoring wells will be installed in the vicinity of Phase 1 RI temporary background locations; one (1) location will be installed near NYOW-B-004, one (1) location will be installed near NYOW-B-027, one (1) location will be installed near NYOW-B-010, one (1) location near NYOW-B-047, one (1) location will be installed near NYOW-B-001, and NYOW-B-003. Soil samples for laboratory analyses will not be collected. Following installation, the monitoring wells will be developed using pump and surge techniques. Following well development, a synoptic gauging event to include all newly installed monitoring well locations along with Phase 1 RI temporary well will occur prior to collecting groundwater samples. With the exception of soil sampling, synoptic gauging and groundwater sampling events, will occur semi-annually for 1-year in order to evaluate seasonal variability in groundwater flow/magnitude and concentrations, respectively. During low flow sampling, hydraulic conductivity estimates will be extracted from all six (6) newly installed monitoring wells. This is a one time event.

In order to fulfill data gap #2, discrete surface soil (saturated/wet [i.e., hydric]) sampling (0-1 ft bgs) using a hand auger will occur in the wetlands at eight (8) locations west of AOC 3. The locations were statistically generated using GRTS. In the event soil at a location is not saturated/wet (i.e., hydric) or representative of hydric soils, the location will be adjusted in the field accordingly.

In order to fulfill data gap #3, discrete surface water, porewater, and sediment co-located samples will be collected at a total of eight (8) locations along the stream and surface water body located west of AOC 3. This area was selected as it appears to be outside the influence of any previous DoD-related activity. The locations were statistically generated using GRTS.

The following field activities will be conducted in support of the Background Field Investigation (refer to Worksheets #14 and #16 for additional details):

- Field Staking.
- Utility Clearance
- Soil sampling at eight (8) locations at one (1) depth interval (0-1 ft bgs)
- Installation and well development of up to six (6) permanent monitoring well locations
- Synoptic water levels (facility-wide)
- Groundwater sampling of up to six (6) permanent monitoring well locations.
- Hydraulic conductivity testing (once).
- Surface water, porewater, and sediment sampling at eight (8) co-located locations
- GPS Survey of sampling locations.
- Professional Well Survey.

The following subsection describes the sampling design.

### 17.5.1 Background Environmental Media (Soil) Sampling

Sample identification will follow the nomenclature that was used during the Phase 1 RI sampling (USACE, 2023a). The last soil sample location that was conducted during the Phase 1 RI was NYOW-B-050. Therefore, the next sample will be NYOW-B-051.

At locations NYOW-B-051 through NYOW-B-058 a total of eight (8) parent soil (saturated/wet [i.e., hydric]) samples will be collected from 0-1 ft bgs using a hand auger within the wetlands. The proposed locations are shown on **Figure 17-6.**

Samples will be collected following the procedures identified in Worksheets #14/16. During this soil sampling event, a total of eight (8) parent samples are expected to be collected and analyzed for: PAHs, and TAL metals/mercury. At all eight (8) locations, geotechnical/geochemical parameters (grain size, CEC, TOC, and pH) will also be collected.

Separate borehole(s) may be needed in order to fulfill sample volume requirements. If needed, the borehole(s) will be placed as close as possible to the original.

### 17.5.2 Background Environmental Media (Groundwater) Sampling

Groundwater samples will be collected semi-annually for up to 1-year at all newly installed permanent monitoring well locations (NYOW-B-MW01 through NYOW-B-MW06) to evaluate seasonality. During each sampling event, six (6) parent samples, along with field QC samples (i.e., duplicate, MS/MSD) will be collected and analyzed for PAHs, total and dissolved (field-filtered) TAL metals/mercury, and geochemical parameters (DOC [field-filtered]. Hardness will also be collected for parent samples only.

### 17.5.3 Background Environmental Media (Surface Water) Sampling

Surface water samples will be collected semi-annually for up to 1-year at all new background locations (**Figure 17-7**) to evaluate seasonal variability. Surface water, samples will be collected at the mid-point of the water column, while maintaining a distance of more than 1 foot from the sediment bed and more than 1 foot below the surface water level. If the water column is less than 2 feet the sample will be collected from the mid-point of the water column. Sampling will not occur within 48 hours after a precipitation event totaling more the 0.25 inches (refer to Worksheet #14/16). During each sampling event, eight (8) samples will be collected from locations NYOW-B-SW01 through NYOW-B-SW08 and analyzed for PAHs, total and dissolved (field-filtered) TAL metals/mercury, and geochemical parameters (DOC [field-filtered], hardness, and TSS). Note, there is no QC for hardness. If after review of the round one results from AOC 3 indicates the need to sample for additional parameters (i.e., VOCs, SVOCs, PCB Aroclors, picric acid), then it will be performed.

An equipment blank will not be collected during surface water sampling since direct-dip sampling methods will be employed (refer to Worksheet #14/16).

### 17.5.4 Background Environmental Media (Porewater) Sampling

Porewater samples will be collected semi-annually for up to 1-year at all new background locations (**Figure 17-7**) to evaluate seasonal variability. During each sampling event, eight (8) samples will be collected from locations NYOW-B-PW01 through NYOW-B-PW08, along with field QC samples (i.e., duplicate, MS/MSD, equipment blank, and trip blank) and analyzed for PAHs, and total and dissolved (field-filtered) TAL metals/mercury. If after review of the round one results from AOC 3 indicates the need to sample for additional parameters (i.e., VOCs, SVOCs, PCB Aroclors, picric acid), then it will be performed.

### 17.5.5 Background Environmental Media (Sediment) Sampling

Sediment samples will be collected semi-annually for up to 1-year at all new background locations (**Figure 14-7**) to evaluate seasonal variability. During each sampling event, eight (8) parent samples will be collected from locations NYOW-B-SD01 through NYOW-B-SD08), along with field QC samples (i.e., duplicate, MS/MSD, equipment blank, and trip blank) and analyzed for PAHs, and total TAL metals/mercury, and geotechnical/geochemical parameters (grain size, and TOC). Note, there is no QC on grain size and TOC. If after review of the round one results from AOC 3 indicates the need to sample for additional parameters (i.e., VOCs, SVOCs, PCB Aroclors, picric acid), then it will be performed.

### 17.5.6 Synoptic Groundwater Events (Facility-Wide)

Uncertainty exists regarding groundwater flow directions and contaminant migration pathways, and hydraulic gradients. In order to evaluate facility-wide groundwater, a comprehensive synoptic water level event will occur that will include all new permanent monitoring well locations within AOC 1, AOC 3, AOC 5, and Background locations. The three stream piezometers within AOC 3 will also be included (refer to **Exhibit 17-9**). The synoptic water levels will be collected semi-annually prior to groundwater sampling in order to evaluate seasonal variability. The synoptic water levels will be manually collected using a water level meter. Depth to water, total depth, along with well condition will be recorded on the appropriate form (refer to **Appendix D**). Water level frequency will be collected semi-annually prior to groundwater sampling in order to evaluate seasonal variability in groundwater flow directions/magnitude. Locations are summarized below and displayed on **Figure 17-6**. Note, if a permanent monitoring well will be installed in the vicinity of a temporary well, then that temporary monitoring well will be abandoned and will not be included in the synoptic water level event(s).

## Exhibit 17-9 – Background Synoptic Water Level Summary Table

| AOC | Proposed Well ID | | Frequency |
|---|---|---|---|
| 1 | NYOW-01-MW01 | NYOW-01-MW06 | Semi-Annual X 1 year |

## Exhibit 17-10 – NYOW Phase 2 RI Field Activities Summary

| Investigation Study | Field Task | Total Number of Locations | Summary of Field Task | Frequency | Laboratory Sample Parameters | Field QA-QC*/Other Requirements | Field Parameters Collected |
|---|---|---|---|---|---|---|---|
| **Environmental Investigation Summary** | | | | | | | |
| AOC 1 | Soil Sampling with DPT or Manual Percussion Methods | 22 | Using DPT or manual percussion methods, collect soil samples from up to 22 soil boring only locations at three (3) depth intervals (0-1, 1-5, and 5-10 feet bgs) (**Figure 17-1**). | Once | -2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury<br>-Grain size, CEC, TOC, and pH | Refer to Worksheet #20 | -Soil lithologic descriptions, field sketch |
| | Soil Sampling within Wetland | 12 | Using a hand auger, collect soil (saturated/wet [i.e., hydric]) samples from up to 12 locations within the wetland in between the APBs and Dryer Houses at one (1) sample interval (0-1 ft bgs) (**Figure 17-1**). | Once | -2,4-DNCB, 2,4-DNP, picric acid, metals<br>-Grain size, CEC, TOC, and pH | Refer to Worksheet #20 | |
| | Monitoring Well Installation | 10 | Using dual-tube DPT, install up to ten (10), 2-inch monitoring wells at first occurrence of water. Install well screens at a sufficient depth to obtain a properly constructed well (filter pack 2-feet above screen, 2-foot thick bentonite seal, grout to surface). | Once | N/A | N/A | Complete monitoring well construction form |
| | Monitoring Well Development | 10 | Conduct monitoring well development through pumping and surging for up to two (2) hours per well. Well development considered complete if water is free of visible sediment, and turbidity has reached an asymptotic value (e.g., 20 NTU), or up to two (2) hours, whichever comes first. | Once (24 hours post installation); As needed going forward. | N/A | N/A | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | Synoptic Water Levels | Up to 33 | Collect manual groundwater levels from up to ten (10) newly installed AOC 1 monitoring well locations, three (3) nearby newly installed background locations, along with 19 pre-existing locations. | Semi-Annual | N/A | N/A | -Manual water level measurements |
| | Groundwater Sampling | 10 | Collect groundwater samples from newly installed monitoring wells. | Semi-annual x 1 year | -2,4-DNCB, 2,4-DNP, picric acid, total and dissolved (field-filtered) TAL metals/mercury<br>-DOC (field-filtered), and hardness | Refer to Worksheet #20 | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | GPS Survey Sampling Locations | 34 | Using a hand-held Trimble GPS, survey in the horizontal coordinates of soil sample locations. | Once | N/A | N/A | Field Sketch, notes |
| | Professional Survey Permanent Monitoring Well Locations | 10 | Conduct professional survey to include obtaining horizontal coordinates in the New York State Plane Coordinate System, latitude and longitude of each well location; NAVD88 (US feet) elevation at top of well casing, reported to 0.01 foot; NAVD88 (US feet) ground elevation at base of casing, reported to 0.1 foot. | Once | N/A | N/A | Field Sketch, notes |
| AOC 3 | Soil Sampling with DPT Methods | 17 | Using DPT, collect soil samples from 17 soil boring only locations at three (3) depth intervals (0-1, 1-5, and 5-10 feet bgs) (**Figure 17-2**). | Once | -VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury<br>-Grain size, CEC, TOC, and pH | Refer to Worksheet #20 | -Soil lithologic descriptions, field sketch |
| | Monitoring Well Installation | 7 | Using dual-tube DPT, install seven (7) 2-inch monitoring wells at first occurrence of water next to soil boring locations. Install well screens at a sufficient depth to obtain a properly constructed well (filter pack 2-feet above screen, 2-foot thick bentonite seal, grout to surface). | Once | N/A | N/A | Complete monitoring well construction form |
| | Monitoring Well Development | 7 | Conduct monitoring well development through pumping and surging for up to two (2) hours per well. Well development considered complete if water is free of visible sediment, and turbidity has reached an asymptotic value (e.g., 20 NTU), or up to two (2) hours, whichever comes first. | Once (24 hours post installation); As needed going forward. | N/A | N/A | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| AOC 3 | Groundwater Sampling | 7 | Collect groundwater samples from newly installed monitoring wells. | Semi-annual x 1 year | -VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury<br>-DOC (field-filtered), and hardness | Refer to Worksheet #20 | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | Synoptic Water Levels | Up to 21 | Collect manual groundwater levels from the seven (7) newly installed monitoring well locations, three (3) newly installed stream piezometers, two (2) newly proposed nearby background wells, and nine (9) pre-existing locations (**Figure 17-2**). | Semi-Annual | N/A | N/A | -Manual water level measurements |

| Investigation Study | Field Task | Total Number of Locations | Summary of Field Task | Frequency | Laboratory Sample Parameters | Field QA-QC*/Other Requirements | Field Parameters Collected |
|---|---|---|---|---|---|---|---|
| | Professional Survey Permanent Monitoring Well Locations | 7 | Conduct professional survey to include obtaining horizontal coordinates in the New York State Plane Coordinate System, latitude and longitude of each well location; NAVD88 (US feet) elevation at top of well casing, reported to 0.01 foot; NAVD88 (US feet) ground elevation at base of casing, reported to 0.1 foot. | Once | N/A | N/A | Field Sketch, notes |
| | Surface Water Sampling | 8 | Collect surface water samples by direct-dipping laboratory bottleware with closed cap to a depth of 12-inches below top of the stream at eight (8) locations (**Figure 17-2**). Collect one (1) set of field parameters. Collect an unpreserved sample as needed for dissolved metals analysis. Once collected, insert a piece of tubing and hook up a field filter. Extract sample from unpreserved bottle with a peristaltic pump into the appropriate preserved bottleware. | Semi-annual x 1 year | -VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury<br>-Hardness, DOC (field-filtered), and TSS | Refer to Worksheet #20 | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | Porewater Sampling | 8 | Collect porewater samples using a porewater sampler at co-located surface water/sediment locations. Install the porewater sample at least 1-1.5 foot below top of stream sediment. Purge until field parameters indicate a difference between surface water | Semi-annual x 1 year | -VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury | Refer to Worksheet #20 | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | Sediment Sampling | 8 | Collect sediment samples using a coring device at co-located surface water/pore water locations. The sample will be collected from the top of sediment to a depth of 0.5-ft (0-0.5 ft below top of sediment). | Semi-annual x 1 year | -VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total TAL metals/mercury<br>-Grain size, TOC | Refer to Worksheet #20 | Field Sketch, notes |
| | Stream Flow Measurements | 8 | Measure stream channel width and water depth. Create stream profile. Measure average flow velocity every 1-ft of channel width at the 0.6-depth interval. Document physical characteristics of the sampling locations (e.g., water depth, stream width, nearby vegetation, stream flow), substrate (e.g., presence of leaf litter and cobbles, general description), and presence of potential receptors (e.g., evidence of human presence or wildlife in and around the sampling location). | Semi-annual x 1 year | N/A | Refer to *FDEP-Standard Operating Procedure FT1800. Field Measurement of Stage, Surface Water Velocity, and Discharge (Flow) and Computation of Streamflow, Revised January 2017, effective April 16, 2018.* | Stream channel width, water depth, water velocity. |
| AOC 3 | Install stream piezometers | 3 | Install three (3) 1.25-inch galvanized steel piezometers at select locations within the unnamed stream at AOC 3 (**Figure 17-2**). | Once | N/A | N/A | Field Sketch, notes |
| | GPS Survey Sampling and stream flow measurement locations | 8 | Using a hand-held Trimble GPS, survey in the horizontal coordinates of co-located surface water, porewater, and sediment sample locations. | Once | N/A | N/A | Field Sketch, notes |
| | Professional Survey Stream Piezometers | 3 | Conduct professional survey to include obtaining horizontal coordinates in the New York State Plane Coordinate System, latitude and longitude of each well location; NAVD88 (US feet) elevation at top of well casing, reported to 0.01 foot. | Once | N/A | N/A | Field Sketch, notes |
| AOC 4 | Soil Sampling using a Hand Auger | 60 | Using a hand auger, collect soil samples from five (5) locations within each of the 12 DUs surrounding each of the 12 bunkers at one (1) depth interval (0-1 ft bgs) (**Figure 17-3**) | Once | -2,4-DNCB, 2,4-DNP, and picric acid. | Refer to Worksheet #20 | -Soil lithologic descriptions, field sketch |
| AOC 5 | Soil Sampling with DPT | 32 | Using DPT, collect soil samples from 32 soil boring only locations at three (3) depth intervals (0-1, 1-5, and 5-10 feet bgs) (**Figure 17-4**). | Once | -PAHs, TAL metals/mercury,<br>-PCBs (former electrical substation only)<br>-Grain size, CEC, TOC, and pH<br>- Coal for select samples within boiler house, CSA and CAB (up to 15 borings) | Refer to Worksheet #20 | -Soil lithologic descriptions, field sketch |
| | Soil Sampling within Wetland | 3 | Using a hand auger, collect a soil (saturated/wet [i.e., hydric]) sample (0-1 ft bgs) from three locations from within drainage ditches located within the wetland located west of the former CSA (**Figure 17-5**). | Once | -PAHs, TAL metals/mercury<br>-Grain size, CEC, TOC, and pH | Refer to Worksheet #20 | |
| | Monitoring Well Installation | 11 | Using dual-tube DPT, install eleven (11), 2-inch monitoring wells at first occurrence of water next to soil boring locations. Install well screens at a sufficient depth to obtain a properly constructed well (filter pack 2-feet | Once | N/A | N/A | Complete monitoring well construction form |

| Investigation Study | Field Task | Total Number of Locations | Summary of Field Task | Frequency | Laboratory Sample Parameters | Field QA-QC*/Other Requirements | Field Parameters Collected |
|---|---|---|---|---|---|---|---|
| | | | above screen, 2-foot thick bentonite seal, grout to surface) (**Figure 17-4** and **Figure 17-5**). | | | | |
| | Monitoring Well Development | 11 | Conduct monitoring well development through pumping and surging for up to two (2) hours per well. Well development considered complete if water is free of visible sediment, and turbidity has reached an asymptotic value (e.g., 20 NTU), or up to two (2) hours, whichever comes first. | Once (24 hours post installation); As needed going forward. | N/A | N/A | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | Synoptic Water Levels | Up to 26 | Collect manual groundwater levels from twelve (12) newly installed AOC 5 monitoring well locations, one (1) newly installed proposed background well, and 14 pre-existing wells (**Figure 17-4** and **Figure 17-5**). | Semi-Annual | N/A | N/A | -Manual water level measurements |
| | Groundwater Sampling | 11 | Collect groundwater samples from newly installed monitoring wells. | Semi-annual x 1 year | -PAHs, total and dissolved (field-filtered) TAL metals/mercury<br>-DOC (field-filtered), and hardness<br>- PCBs (former electrical substation and possible dump area and wells MW03 and MW07 downgradient of the electric substation only) | Refer to Worksheet #20 | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | GPS Survey Sampling Locations | 32 | Using a hand-held Trimble GPS, survey in the horizontal coordinates of soil sample locations. | Once | N/A | N/A | Field Sketch, notes |
| | Professional Survey Permanent Monitoring Well Locations | 11 | Conduct professional survey to include obtaining horizontal coordinates in the New York State Plane Coordinate System, latitude and longitude of each well location; NAVD88 (US feet) elevation at top of well casing, reported to 0.01 foot; NAVD88 (US feet) ground elevation at base of casing, reported to 0.1 foot. | Once | N/A | N/A | Field Sketch, notes |
| Background | Soil Sampling within Wetland | 8 | Using a hand auger, collect soil (saturated/wet [i.e., hydric]) samples from the wetland at one (1) sample interval (0-1 ft bgs) (**Figure 17-6**) to characterize the area. | Once | -PAHs, TAL metals/mercury<br>-Grain size, CEC, TOC, and pH | Refer to Worksheet #20 | Field Sketch, notes |
| | Monitoring Well Installation | 6 | Using dual-tube DPT, install six (6) 2-inch monitoring wells at first occurrence of water (**Figure 17-6**). Install well screens at a sufficient depth to obtain a properly constructed well (filter pack 2-feet above screen, 2-foot thick bentonite seal, grout to surface). | Once | N/A | N/A | Complete monitoring well construction form |
| | Monitoring Well Development | 6 | Conduct monitoring well development through pumping and surging for up to two (2) hours per well. Well development considered complete if water is free of visible sediment, and turbidity has reached an asymptotic value (e.g., 20 NTU), or up to two (2) hours, whichever comes first. | Once (24 hours post installation); As needed going forward. | N/A | N/A | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | Site Wide Synoptic Water Levels | up to 37 | Collect manual groundwater levels from the six (6) newly installed monitoring well background locations, along with newly installed proposed permanent monitoring wells within each AOC specific gauging event. | Semi-Annual | N/A | N/A | -Manual water level measurements |
| | Groundwater Sampling | 6 | Collect groundwater samples from newly installed monitoring wells. | Semi-annual x 1 year | -PAHs, total and dissolved (field-filtered) metals<br>-DOC (field-filtered), and hardness | Refer to Worksheet #20 | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | Professional Survey Permanent Monitoring Well Locations | 6 | Conduct professional survey to include obtaining horizontal coordinates in the New York State Plane Coordinate System, latitude and longitude of each well location; NAVD88 (US feet) elevation at top of well casing, reported to 0.01 foot; NAVD88 (US feet) ground elevation at base of casing, reported to 0.1 foot. | Once | N/A | N/A | Field Sketch, notes |
| Background | Surface Water Sampling | 8 | Collect surface water samples by direct-dipping laboratory bottleware with closed cap to a depth of 12-inches below top of the stream at eight (8) locations (**Figure 17-7**). Collect one (1) set of field parameters. Collect an unpreserved sample as needed for dissolved metals analysis. Once collected, insert a piece of tubing and hook up a field filter. Extract sample | Semi-annual x 1 year | -PAHs, total and dissolved (field-filtered) TAL metals/mercury<br>-Hardness, DOC (field-filtered), and TSS | Refer to Worksheet #20 | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |

| Investigation Study | Field Task | Total Number of Locations | Summary of Field Task | Frequency | Laboratory Sample Parameters | Field QA-QC*/Other Requirements | Field Parameters Collected |
|---|---|---|---|---|---|---|---|
| | | | from unpreserved bottle with a peristaltic pump into the appropriate preserved bottleware. | | | | |
| | Porewater Sampling | 8 | Collect porewater samples using a porewater sampler at co-located surface water/sediment locations (**Figure 17-7**). Install the porewater sample at least 1-1.5 foot below top of stream sediment. Purge until field parameters indicate a difference between surface water | Semi-annual x 1 year | -PAHs, PAHs, total and dissolved (field-filtered) TAL metals/mercury | Refer to Worksheet #20 | -pH, temperature, specific conductance, DO, ORP, turbidity, color, and odor |
| | Sediment Sampling | 8 | Collect sediment samples using a coring device at co-located surface water/pore water locations (**Figure 17-7**). The sample will be collected from the top of sediment to a depth of 0.5-ft (0-0.5 ft below top of sediment). | Semi-annual x 1 year | -PAHs, total TAL metals/mercury<br>-Grain size, TOC | Refer to Worksheet #20 | Field Sketch, notes |
| | GPS Survey Sampling and stream flow measurement locations | 8 | Using a hand-held Trimble GPS, survey in the horizontal coordinates of co-located surface water, porewater, and sediment sample locations. | Once | N/A | N/A | Field Sketch, notes |
| Abandonment Activities | Temporary Phase 1 RI Wells | 54 | Abandon Phase 1 RI temporary locations. Remove surface expressions and grout in place. | Once | N/A | N/A | Field Sketch, notes |
| | Soil Boring Only Locations | 154 | Between AOC 1, AOC 4, AOC 5, and Background, abandon soil boring locations that will not be a well location using hydrated bentonite or cement. | Once | N/A | N/A | Field Sketch, notes |

Notes:
APBs = ammonium picrate buildings.
bgs = below ground surface.
CAB = coal aggregate bin
CEC = cation exchange capacity.
CSA = coal storage area
DO = dissolved oxygen.
DOC = dissolved organic carbon.
DPT = direct-push technology.
GPS = global positioning system.
NAVD88 = North American Vertical Datum 1988.
NTU = nephelometric units.
OPR = oxidation-reduction potential.
PAHs = polyaromatic hydrocarbons.
PCBs = polychlorinated biphenyls.
RI = remedial investigation.
SVOCs = semi-volatile organic carbon.
TOC = total organic carbon.
TSS = total suspended solids.
VOC = volatile organic carbon

# Worksheet #18 – Sampling Locations and Methods

Samples will be collected at four (4) AOCs and three background areas. Proposed sampling locations are shown on Worksheet #11, **Figures 17-1** through **Figure 17-7**. The field sampling will include:

- AOC 1 – Up to 22 soil borings (66 soil samples), up 12 hand auger locations (12 soil samples); and ten (10) monitoring well locations (up to ten [10] groundwater samples).
- AOC 3 – Up to seventeen (17) soil borings (51 soil samples); and seven (7) monitoring well locations (seven (7) groundwater samples); eight (8) co-located surface water/porewater/sediment locations (24 total samples).
- AOC 4 – Up to 60 locations (60 parent soil samples).
- AOC 5 – Up to 32 boring locations (96 soil samples), up to three (3) hand auger locations (3 soil samples); and eleven (11) monitoring well locations (eleven [11] groundwater samples).
- Background – Up to eight (8) locations (8 soil samples); and six (6) monitoring well locations (up to six (6) groundwater samples); eight (8) co-located surface water/porewater/sediment locations (24 total samples).

Each sample container will be labeled with the project name, unique sample identification number, analysis method number, date and time collected, preservative (if any), and will be initialed by the sampler. All samples will be assigned a unique sample identifier (alpha-numeric code). The purpose of the numbering system is to assist in the tracking of samples and to facilitate retrieval of analytical results. The sampling numbers will be used on the sample labels, sample tracking forms, COC forms, field logs, and all other applicable documentation.

For the NYOW Phase 2 field work, the field sample identifiers will follow the “Recommended Naming Conventions for Locations, Field Samples, and Library File Nomenclature” – Appendix B of the most recent FUDSChem Database User’s Manual in force when the Location Definition Information (LDI) tables are uploaded and Event Planning is completed in FUDSChem. Example sample IDs based on the FUDSCHem User Manual (version 6.8) 4 May 2024. are presented below as **Exhibits 18-1, 18-2, 18-3, 18-4, 18-5, and 18-6**. Discrete sample field duplicates will be collected as blind to the laboratory. For the NYOW Phase 2 field work, the sample numbers will be in the following format: Location Type-DUP-Number-QQYY. For example, the second field duplicate collected from a borehole on 08/24/25 would be PH-DUP-002-Q325. An example of the first field duplicate sample ID during monitoring well sampling on 08/24/25 would be MW-DUP-001-Q325. Locations of duplicate and MS/MSD will be determined in the field and based on recovered sample volume during sample volume, and flow rates during groundwater/porewater sampling.

Trip blanks and ERBs not tied to specific locations will be given unique names every event. For the NYOW Phase 2 field work, the sample numbers will be in the following format: Blank Type-Number-QQYY. Where:

- ERB denotes Equipment Rinsate Blank
- QQYY denotes quarter, year
- TB denotes Trip Blank

For example, the first ERB collected on 08/24/25 would be ERB-01-Q325. The equipment rinsed and sampling team which used the equipment will be noted in the field log so that ERBs may be associated with the appropriate field samples. ERB analyses will be for all the COPCs designated for the particular AOC. Trip blank analyses will only include VOCs. A trip blank will accompany each VOC cooler generated.

## Exhibit 18-1 – AOC 1 Sample Nomenclature

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| **Soil** | | | | | |
| NYOW-01-PH040 thru 061-A | Soil | 0-1 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury. Collect one geotechnical/geochemical at NYOW-01-PH041; -044; -047; -050; and -053* | Surface Soil, AOC 1, DPT/Manual Percussion Locations 40 through 61 (1st depth interval, 0-1 ft bgs) |
| NYOW-01-PH040 thru 061-B | Soil | 1-5 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury. Collect one geotechnical/geochemical at NYOW-01-PH041; -044; -047; -050; and -053** | Subsurface Soil, AOC 1, DPT/Manual Percussion Locations 40 through 61 (2st depth interval, 1-5 ft bgs) |
| NYOW-01-PH040 thru 061-C | Soil | 5-10 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury. Collect one geotechnical/geochemical at NYOW-01-PH041; -044; -047; -050; and -053* | Subsurface Soil, AOC 1, DPT/Manual Percussion Locations 40 through 61 (3rd depth interval, 5-10 ft bgs) |
| NYOW-01-PH-DUP001-QQYY** | Soil | 0-1,1-5, 5-10 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-01-PH-DUP002-QQYY** | Soil | 0-1,1-5, 5-10 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-01-PH-DUP003-QQYY** | Soil | 0-1,1-5, 5-10 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-01-PH-DUP004-QQYY** | Soil | 0-1,1-5, 5-10 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-01-PH-DUP005-QQYY** | Soil | 0-1,1-5, 5-10 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 0XX (select depth interval with greatest sample recovery bgs). |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| NYOW-01-PH-DUP006-QQYY** | Soil | 0-1,1-5, 5-10 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-01-PH-DUP007-QQYY** | Soil | 0-1,1-5, 5-10 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 0XX (select depth interval with greatest sample recovery bgs). |

| NYOW-01-PH053-B-MS** | Soil | 1-5 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | MS Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 053 (select depth interval with greatest sample recovery bgs). |
| NYOW-01-PH053-B-MSD** | Soil | 1-5 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | MSD Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 053 (select depth interval with greatest sample recovery bgs). |
| NYOW-01-PH060-B-MS** | Soil | 1-5 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | MS Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 060 (select depth interval with greatest sample recovery bgs). |
| NYOW-01-PH060-B-MSD** | Soil | 1-5 | DPT/Manual Percussion | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | MSD Subsurface Soil Location, AOC 1, DPT/Manual Percussion Location 060 (select depth interval with greatest sample recovery bgs). |
| **Hydric Soil** | | | | | |
| NYOW-01-SL062 through 073 -A | Saturated/Wet (i.e., hydric} Soil | 0-1 | Hand Auger Only locations | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury. Collect one geotechnical/geochemical at NYOW-01-PH063; -067; -070; and -073 | Saturated/Wet (i.e., hydric) Surface Soil Only, AOC 1, Hand Auger Locations 62 thru 73 (1st depth interval, 0-1 ft bgs) |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| NYOW-01-SL-DUP001-QQYY** | Saturated/Wet (i.e., hydric} Soil | 0-1 | Hand Auger Only locations | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | Duplicate Saturated/Wet (i.e., hydric) Surface Soil Location, AOC 1, Hand Auger Location XX (1st depth interval, 0-1 ft bgs) |
| NYOW-01-SL073-A-MS** | Saturated/Wet (i.e., hydric} Soil | 0-1 | Hand Auger Only locations | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | MS Saturated/Wet (i.e., hydric) Surface Soil Location, AOC 1, Hand Auger Location 073 (1st depth interval, 0-1 ft bgs) |
| NYOW-01-SL073-A-MSD** | Saturated/Wet (i.e., hydric} Soil | 0-1 | Hand Auger Only locations | 2,4-DNCB, 2,4-DNP, picric acid, TAL metals/mercury | MSD Saturated/Wet (i.e., hydric) Surface Soil Location, AOC 1, Hand Auger Location 073 (1st depth interval, 0-1 ft bgs) |
| **Groundwater** | | | | | |
| NYOW-01-MW01-QQYY thru -MW10-QQYY | GW | TBD | Low-flow | 2,4-DNCB, 2,4-DNP, picric acid, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered), hardness | Groundwater Sample from Monitoring Wells, AOC 1, Well #01 through 10 |
| NYOW-01-MW-DUP001-QQYY** | GW | TBD | Low-flow | 2,4-DNCB, 2,4-DNP, picric acid, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered) | Duplicate Groundwater Sample from Monitoring Well, AOC 1, Well #1 |
| NYOW-01-MW02-MS-QQYY** | GW | TBD | Low-flow | 2,4-DNCB, 2,4-DNP, picric acid, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered) | MS Groundwater Sample from Monitoring Well, AOC 1, Well #2 |
| NYOW-01-MW02-MSD-QQYY** | GW | TBD | Low-flow | 2,4-DNCB, 2,4-DNP, picric acid, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered) | MSD Groundwater Sample from Monitoring Well, AOC 1, Well #2 |

Notes:
*Select 8 random locations for geotechnical/geochemical analysis. Geotechnical/geochemical analyses include: grain size, CEC, TOC, and pH. Field QC will not be collected for geochemical analysis.
**Locations of duplicate and MS/MSD shown as an example. Actual locations will be determined in the field and based on sample volume.
Acronyms:
CEC = cation exchange capacity.
DOC = dissolved organic carbon
DPT = direct-push technology
DUP = duplicate. Collection frequency 10% total number of parent samples.
GW = groundwater
MS = matrix spike. Collection frequency 5% total number of parent samples.
MSD = matrix spike duplicate. Collection frequency 5% total number of parent samples.
PH = Direct-push technology
QQYY = quarters/year. Example. Q225 would indicate the sample was collected during Quarter 2 in the year 2025.
NYOW = New York Ordnance Works
SL = surface location (surface soil via hand auger only)
TBD=screen depth to be determined.
TOC = total organic carbon

## Exhibit 18-2 – AOC 3 Example Nomenclature

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| **Soil** | | | | | |
| NYOW-03-PH019 thru 035-A | Soil | 0-1 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury. Collect one geotechnical/geochemical at NYOW-03-PH019; -021; -022; -023; -025; -030, and -033 *. | Surface Soil, AOC 3, DPT Locations 019 thru 036 (1st depth interval, 0-1 ft bgs) |
| NYOW-03-PH019 thru 035-B | Soil | 1-5 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury. Collect one geotechnical/geochemical at NYOW-03-PH019; -021; -022; -023; -025; -030, and -033 *. | Subsurface Soil, AOC 3, DPT Locations 019 thru 036 (2st depth interval, 1-5 ft bgs) |
| NYOW-03-PH019 thru 035-C | Soil | 5-10 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury. Collect one geotechnical/geochemical at NYOW-03-PH019; -021; -022; -023; -025; -030, and -033 *. | Subsurface Soil, AOC 3, DPT Locations 019 thru 036 (3rd depth interval, 5-10 ft bgs) |
| NYOW-03-PH-DUP001-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 3, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-03-PH-DUP002-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 3, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-03-PH-DUP003-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 3, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-03-PH-DUP004-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 3, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-03-PH-DUP005-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | Duplicate Subsurface Soil Location, AOC 3, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-03-PH025-B-MS** | Soil | 1-5 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | MS Subsurface Soil Location, AOC 3, DPT Location 025 (select depth interval with greatest sample recovery bgs). |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| NYOW-03-PH025-B-MSD** | Soil | 1-5 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | MSD Subsurface Soil Location, AOC 3, DPT Location 025 (select depth interval with greatest sample recovery bgs). |
| NYOW-03-PH032-C-MS** | Soil | 5-10 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | MS Subsurface Soil Location, AOC 3, DPT Location 032 (3rd depth interval, 5-10 ft bgs) |
| NYOW-03-PH032-C-MSD** | Soil | 5-10 | DPT | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, TAL metals/mercury | MSD Subsurface Soil Location, AOC 3, DPT Location 032 (select depth interval with greatest sample recovery bgs). |
| **Surface Water** | | | | | |
| NYOW-03-SW001 through 008-QQYY | SW | 1 | Direct-dip | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, hardness, DOC (field-filtered), and TSS. | Surface Water Sample, AOC 3, Locations 001 through 008 |
| NYOW-03-SW-DUP001-QQYY** | SW | 1 | Direct-dip | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, hardness, DOC (field-filtered) and TSS. | Duplicate Surface Water Sample, AOC 3, Location 006 |
| NYOW-03-SW001-MS-QQYY** | SW | 1 | Direct-dip | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, hardness, DOC (field-filtered), and TSS. | MS Surface Water Sample. AOC 3, Location 001 |
| NYOW-03-SW001-MSD-QQYY** | SW | 1 | Direct-dip | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, hardness, DOC (field-filtered), and TSS. | MSD Surface Water Sample, AOC 3, Location 001 |
| **Porewater** | | | | | |
| NYOW-03-PW001 through 008-QQYY | PW | 1-1.5 feet below top of sediment | Syringe/peristaltic | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury. | Porewater Sample, AOC 3, Locations 001 through 008 |
| NYOW-03-PW-DUP001-QQYY** | PW | 1-1.5 feet below | Syringe/peristaltic | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and | Duplicate Porewater Sample, AOC 3, Location 006 |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| | | top of sediment | | dissolved (field-filtered) TAL metals/mercury. | |
| NYOW-03-PW001-MS-QQYY** | PW | 1-1.5 feet below top of sediment | Syringe/peristaltic | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury. | MS Porewater Sample. AOC 3, Location 001 |
| NYOW-03-PW001-MSD-QQYY** | PW | 1-1.5 feet below top of sediment | Syringe/peristaltic | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury. | MSD Porewater Sample, AOC 3, Location 001 |
| **Sediment** | | | | | |
| NYOW-03-SD001 through 008-QQYY | SD | 0-0.5 | Sediment Core | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total TAL metals/mercury, grain size, TOC. | Sediment Sample, AOC 3, Locations 001 through 008 |
| NYOW-03-SD-DUP001-QQYY** | SD | 0-0.5 | Sediment Core | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total TAL metals/mercury. | Duplicate Sediment Sample, AOC 3, Location 006 |
| NYOW-03-SD001-MS-QQYY** | SD | 0-0.5 | Sediment Core | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total TAL metals/mercury. | MS Sediment Sample. AOC 3, Location 001 |
| NYOW-03-SD001-MSD-QQYY** | SD | 0-0.5 | Sediment Core | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total TAL metals/mercury. | MSD Sediment Sample, AOC 3, Location 001 |
| **Groundwater** | | | | | |
| NYOW-03-MW01 thru -MW07-QQYY | GW | TBD | Low-flow | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered), hardness | Groundwater Sample from Monitoring Wells, AOC 3, Well #01 through 07 |
| NYOW-03-MW-DUP001-QQYY** | GW | TBD | Low-flow | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered) | Duplicate Groundwater Sample from Monitoring Well, AOC 3, Well #1 |
| NYOW-03-MW02-MS-QQYY** | GW | TBD | Low-flow | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and | MS Groundwater Sample from Monitoring Well, AOC 3, Well #2 |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| | | | | dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered) | |
| NYOW-03-MW02-MSD-QQYY** | GW | TBD | Low-flow | VOCs, SVOCs, PAHs, PCB Aroclors, picric acid, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered) | MSD Groundwater Sample from Monitoring Well, AOC 3, Well #2 |

Notes:
*Select 8 random locations for geotechnical/geochemical analysis. Geotechnical/geochemical analyses include: grain size, CEC, TOC, and pH. Field QC will not be collected for geochemical analysis.
**Locations of duplicate and MS/MSD shown as an example. Actual locations will be determined in the field and based on sample volume.
Acronyms:
CEC = cation exchange capacity.
DOC = dissolved organic carbon
DPT = direct-push technology
DUP = duplicate. Collection frequency 10% total number of parent samples..
GW = groundwater
MS = matrix spike. Collection frequency 5% total number of parent samples.
MSD = matrix spike duplicate. Collection frequency 5% total number of parent samples.
NYOW = New York Ordnance Works
PH = Direct-push technology
PW = porewater
QQYY = quarters/year. Example. Q225 would indicate the sample was collected during Quarter 2 in the year 2025.
SD = sediment
SW = surface water
TBD=screen depth to be determined.
TOC = total organic carbon
TSS = total suspended solids

## Exhibit 18-3 – AOC 4 Sample Nomenclature

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| NYOW-04-SL086 thru 145-A | Soil | 0-1 | Hand auger | 2,4-DNCB, 2,4-DNP, picric acid | Surface Soil, AOC 4, Hand auger Locations 086 thru 144 (1st depth interval, 0-1 ft bgs) |
| NYOW-04-SL-DUP001-QQYY** | Soil | 0-1 | Hand auger | 2,4-DNCB, 2,4-DNP, picric acid | Duplicate Surface Soil Location, AOC 4, Hand Auger Location 095 (1st depth interval, 0-1 ft bgs) |
| NYOW-04-SL-DUP002-QQYY** | Soil | 0-1 | Hand auger | 2,4-DNCB, 2,4-DNP, picric acid | Duplicate Surface Soil Location, AOC 4, Hand Auger Location 0XX (1st depth interval, 0-1 ft bgs) |
| NYOW-04-SL-DUP003-QQYY** | Soil | 0-1 | Hand auger | 2,4-DNCB, 2,4-DNP, picric acid | Duplicate Surface Soil Location, AOC 4, Hand Auger Location 0XX (1st depth interval, 0-1 ft bgs) |
| NYOW-04-SL-DUP004-QQYY** | Soil | 0-1 | Hand auger | 2,4-DNCB, 2,4-DNP, picric acid | Duplicate Surface Soil Location, AOC 4, Hand Auger Location 0XX (1st depth interval, 0-1 ft bgs) |

Acronyms:
DUP = duplicate. Collection frequency 10% total number of parent samples..
MS = matrix spike. Collection frequency 5% total number of parent samples.
MSD = matrix spike duplicate. Collection frequency 5% total number of parent samples.
NYOW = New York Ordnance Works
QQYY = quarters/year. Example. Q225 would indicate the sample was collected during Quarter 2 in the year 2025.

## Exhibit 18-4 – AOC 5 Sample Nomenclature

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| **Soil – DU#1 – Electrical Substation Portion** | | | | | |
| NYOW-05-PH026 thru 030-A | Soil | 0-1 | DPT | PAHs, TAL metals/mercury, PCB Aroclors. Collect one geotechnical/geochemical at NYOW-05-PH028. | Surface Soil, AOC 5, DPT Locations 026 through 030 (1st depth interval, 0-1 ft bgs) |
| NYOW-05-PH026 thru 030-B | Soil | 1-5 | DPT | PAHs, TAL metals/mercury, PCB Aroclors. Collect one geotechnical/geochemical at NYOW-05-PH028. | Subsurface Soil, AOC 5, DPT Locations 026 through 030 (2nd depth interval, 1-5 ft bgs) |
| NYOW-05-PH026 thru 030-C | Soil | 5-10 | DPT | PAHs, TAL metals/mercury, PCB Aroclors. Collect one geotechnical/geochemical at NYOW-05-PH028. | Subsurface Soil, AOC 5, DPT Locations 026 through 030 (3rd depth interval, 5-10 ft bgs) |
| NYOW-05-PH-DUP001-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | PAHs, TAL metals/mercury, PCB Aroclors. | Duplicate Subsurface Soil Location, AOC 5, DU#1, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| **Soil – DU#1 – Boiler House** | | | | | |
| NYOW-05-PH031 thru 033-A | Soil | 0-1 | DPT | PAHs, TAL metals/mercury. Collect one geotechnical/geochemical sample at NYOW-05-PH032*. Select three soil boring locations for coal/coal ash by microscopy. | Surface Soil, AOC 5, DPT Locations 031 through 033 (1st depth interval, 0-1 ft bgs) |
| NYOW-05-PH031 thru 033-B | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. Collect one geotechnical/geochemical sample at NYOW-05-PH032*. Select three soil boring locations for coal/coal ash by microscopy. | Subsurface Soil, AOC 5, DPT Locations 031 through 033 (2nd depth interval, 1-5 ft bgs) |
| NYOW-05-PH031 thru 033-C | Soil | 5-10 | DPT | PAHs, TAL metals/mercury. Collect one geotechnical/geochemical sample at NYOW-05-PH032*. Select three soil boring locations for coal/coal ash by microscopy. | Subsurface Soil, AOC 5, DPT Locations 031 through 033 (3rd depth interval, 5-10 ft bgs) |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| NYOW-05-PH-DUP002-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | PAHs, TAL metals/mercury. | Duplicate Subsurface Soil Location, AOC 5, DU#1, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH032-B-MS** | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. | MS Subsurface Soil Location, AOC 5, DU#1 DPT Location 032 (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH032-B-MSD** | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. | MSD Subsurface Soil Location, AOC 5, DU#1 DPT Location 032 (select depth interval with greatest sample recovery bgs). |
| **Soil – DU#2** | | | | | |
| NYOW-05-PH034 thru 041-A | Soil | 0-1 | DPT | PAHs, TAL metals/mercury. Collect one geotechnical/geochemical sample at NYOW-05-PH036*. Select four soil boring locations for coal/coal ash by microscopy. | Surface Soil, AOC 5, DPT Locations 034 through 042 (1st depth interval, 0-1 ft bgs) |
| NYOW-05-PH034 thru 041-B | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. Collect one geotechnical/geochemical sample at NYOW-05-PH036*. Select four soil boring locations for coal/coal ash by microscopy. | Subsurface Soil, AOC 5, DPT Locations 034 through 042 (2nd depth interval, 1-5 ft bgs) |
| NYOW-05-PH034 thru 041-C | Soil | 5-10 | DPT | PAHs, TAL metals/mercury. Collect one geotechnical/geochemical sample at NYOW-05-PH036*. Select four soil boring locations for coal/coal ash by microscopy. | Subsurface Soil, AOC 5, DPT Locations 034 through 042 (3rd depth interval, 5-10 ft bgs) |
| NYOW-05-PH-DUP003-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | PAHs, TAL metals/mercury. | Duplicate Subsurface Soil Location, AOC 5, DU#2, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH-DUP004-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | PAHs, TAL metals/mercury. | Duplicate Subsurface Soil Location, AOC 5, DU#2, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH037-B-MS** | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. | MS Subsurface Soil Location, AOC 5, DU#2 DPT Location 037 (select depth interval with greatest sample recovery bgs). |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| NYOW-05-PH037-B-MSD** | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. | MSD Subsurface Soil Location, AOC 5, DU#2 DPT Location 037 (select depth interval with greatest sample recovery bgs). |
| **Soil – DU#3** | | | | | |
| NYOW-05-PH042 thru 049-A | Soil | 0-1 | DPT | PAHs, TAL metals/mercury. Collect one geotechnical/geochemical sample at NYOW-05-PH045*. All eight soil boring locations for coal/coal ash by microscopy. | Surface Soil, AOC 5, DPT Locations 043 through 055 (1st depth interval, 0-1 ft bgs) |
| NYOW-05-PH042 thru 049-B | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. Coal by microscopy. Collect one geotechnical/geochemical sample at NYOW-05-PH045*. All eight soil boring locations for coal/coal ash by microscopy. | Subsurface Soil, AOC 5, DPT Locations 043 through 055 (2nd depth interval, 1-5 ft bgs) |
| NYOW-05-PH042 thru 049-C | Soil | 5-10 | DPT | PAHs, TAL metals/mercury. Coal by microscopy. Collect one geotechnical/geochemical sample at NYOW-05-PH045*. All eight soil boring locations for coal/coal ash by microscopy. | Subsurface Soil, AOC 5, DPT Locations 043 through 055 (3rd depth interval, 5-10 ft bgs) |
| NYOW-05-PH-DUP006-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | PAHs, TAL metals/mercury. | Duplicate Subsurface Soil Location, AOC 5, DU#3, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH-DUP007-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | PAHs, TAL metals/mercury. | Duplicate Subsurface Soil Location, AOC 5, DU#3, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH044-B-MS** | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. | MS Subsurface Soil Location, AOC 5, DU#3 DPT Location 044 (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH044-B-MSD** | Soil | 1-5 | DPT | PAHs, TAL metals/mercury. | MSD Subsurface Soil Location, AOC 5, DU#3 DPT Location 044 (select depth interval with greatest sample recovery bgs). |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| **Soil – DU#4** | | | | | |
| NYOW-05-PH050 thru 057-A | Soil | 0-1 | DPT | PAHs, TAL metals/mercury, Collect one geotechnical/geochemical sample at NYOW-05-PH056*. | Surface Soil, AOC 5, DPT Locations 056 through 064 (1st depth interval, 0-1 ft bgs) |
| NYOW-05-PH050 thru 057-B | Soil | 1-5 | DPT | PAHs, TAL metals/mercury , Collect one geotechnical/geochemical sample at NYOW-05-PH056*. | Subsurface Soil, AOC 5, DPT Locations 056 through 064 (2nd depth interval, 1-5 ft bgs) |
| NYOW-05-PH050 thru 057-C | Soil | 5-10 | DPT | PAHs, TAL metals/mercury,. Collect one geotechnical/geochemical sample at NYOW-05-PH056*. | Subsurface Soil, AOC 5, DPT Locations 056 through 064 (3rd depth interval, 5-10 ft bgs) |
| NYOW-05-PH-DUP008-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | PAHs, TAL metals/mercury. | Duplicate Subsurface Soil Location, AOC 5, DU#4, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH-DUP009-QQYY** | Soil | 0-1,1-5, 5-10 | DPT | PAHs, TAL metals/mercury. | Duplicate Subsurface Soil Location, AOC 5, DU#4, DPT Location 0XX (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH058-B-MS** | Soil | 5-10 | DPT | PAHs, TAL metals/mercury. | MS Subsurface Soil Location, AOC 5, DU#2 DPT Location 058 (select depth interval with greatest sample recovery bgs). |
| NYOW-05-PH058-B-MSD** | Soil | 5-10 | DPT | PAHs, TAL metals/mercury. | MSD Subsurface Soil Location, AOC 5, DU#2 DPT Location 058 (select depth interval with greatest sample recovery bgs). |
| **Hydric Soil** | | | | | |
| NYOW-05-SL058 through 060 -A | Saturated/Wet (i.e., hydric) Soil | 0-1 | Hand Auger Only locations | PAHs, TAL metals/mercury Collect one geotechnical/geochemical sample at NYOW-05-PH059*. | Saturated/Wet (i.e., hydric) Surface Soil Only, AOC 5, Hand Auger Locations 065 thru 067 (1st depth interval, 0-1 ft bgs) |
| **Groundwater** | | | | | |
| NYOW-05-MW01, NYOW-05-MW02, NYOW-05-MW04, NYOW-05-MW05, NYOW-05-MW06-QQYY** | GW | TBD | Low-flow | PAHs, TAL metals/mercury (total and dissolved [field-filtered]), DOC (field-filtered), hardness. | AOC 5 wells not likely impacted by PCBs detected in electric substation soils. Groundwater Sample from Monitoring Wells, AOC 5, Well #01, -02, -04 through. |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| NYOW-05-MW08, and NYOW-05-MW09-QQYY** | GW | TBD | Low-flow | PAHs, TAL metals/mercury (total and dissolved [field-filtered]), DOC (field-filtered), hardness, PCB Aroclors. | Electric substation and possible dump. Groundwater Sample from Monitoring Wells, AOC 5, Well #08 and -09 |
| NYOW-05-MW03 and NYOW-05-MW07-QQYY** | GW | TBD | Low flow | PAHs, TAL metals/mercury (total and dissolved [field-filtered]), DOC (field-filtered), hardness, PCB Aroclors. | Groundwater Sample from Monitoring Wells downgradient of electric substation in AOC 5, Well #03 and -07. |
| NYOW-05-MW10 and NYOW-05-MW11-QQYY** | GW | TBD | Low-flow | PAHs, TAL metals/mercury (total and dissolved [field-filtered]), DOC (field-filtered), hardness. | Wells downgradient of AOC 5 - Groundwater Sample from Monitoring Wells, AOC 5, Well #10, and 11. |
| NYOW-05-MW-DUP001-QQYY** | GW | TBD | Low-flow | PAHs, TAL metals/mercury (total and dissolved [field-filtered]), DOC (field-filtered). | Duplicate Groundwater Sample from Monitoring Well, AOC 5, Well #1 |
| NYOW-05-MW02-MS-QQYY** | GW | TBD | Low-flow | PAHs, TAL metals/mercury (total and dissolved [field-filtered]), DOC (field-filtered). | MS Groundwater Sample from Monitoring Well, AOC 5, Well #2 |
| NYOW-05-MW02-MSD-QQYY** | GW | TBD | Low-flow | PAHs, TAL metals/mercury (total and dissolved [field-filtered]), DOC (field-filtered). | MSD Groundwater Sample from Monitoring Well, AOC 5, Well #2 |

Notes:
*Select 8 random locations for geotechnical/geochemical analysis. Geotechnical/geochemical analyses include: grain size, CEC, TOC, and pH. Field QC will not be collected for geochemical analysis.
**Locations of duplicate and MS/MSD shown as an example. Actual locations will be determined in the field and based on sample volume.
Acronyms:
CEC = cation exchange capacity.
DOC = dissolved organic carbon
DPT = direct-push technology
DU = decision unit
DUP = duplicate. Collection frequency 10% total number of parent samples..
GW = groundwater
MS = matrix spike. Collection frequency 5% total number of parent samples.
MSD = matrix spike duplicate. Collection frequency 5% total number of parent samples.
NYOW = New York Ordnance Works
PH = Direct-push technology
QQYY = quarters/year. Example. Q225 would indicate the sample was collected during Quarter 2 in the year 2025.
SL = surface location (surface soil via hand auger only)
TBD=screen depth to be determined.
TOC = total organic carbon

## Exhibit 18-5 – Background Sample Nomenclature

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| **Soil** | | | | | |
| NYOW-BK-SL001 thru 008-A | Saturated/Wet (i.e., hydric) Soil | 0-1 | Hand Auger | PAHs, TAL metals/mercury. Collect one geotechnical/geochemical at each location)*. | Saturated/Wet (i.e., hydric) Surface Soil, Background, Hand Auger Locations 001 thru 008 (1st depth interval, 0-1 ft bgs) |
| NYOW-BK-SL-DUP001-QQYY** | Saturated/Wet (i.e., hydric) Soil | 0-1 | Hand Auger | PAHs, TAL metals/mercury. | Duplicate Saturated/Wet (i.e., hydric) Surface Soil Location, Background, Hand Auger Location 001 (1st depth interval, 0-1 ft bgs) |
| NYOW-BK-SL005-A-MS-QQYY** | Saturated/Wet (i.e., hydric) Soil | 0-1 | Hand Auger | PAHs, TAL metals/mercury. | MS Saturated/Wet (i.e., hydric) Surface Soil Location, Background, Hand Auger Location 005 (1st depth interval, 0-1 ft bgs) |
| NYOW-BK-SL005-A-MSD-QQYY** | Saturated/Wet (i.e., hydric) Soil | 0-1 | Hand Auger | PAHs, TAL metals/mercury. | MSD Saturated/Wet (i.e., hydric) Surface Soil Location, Background, Hand Auger Location 005 (1st depth interval, 0-1 ft bgs) |
| **Surface Water** | | | | | |
| NYOW-BK-SW001 through 008-QQYY* | SW | 1 | Direct-dip | PAHs, total and dissolved (field-filtered) TAL metals/mercury, hardness, DOC (field-filtered), and TSS. | Surface Water Sample, Background, Locations 001 through 008 |
| NYOW-BK-SW-DUP001-QQYY** | SW | 1 | Direct-dip | PAHs, total and dissolved (field-filtered) TAL metals/mercury, hardness, DOC (field-filtered), and TSS. | Duplicate Surface Water Sample, Background, Location 001 |
| NYOW-BK-SW002-MS-QQYY** | SW | 1 | Direct-dip | PAHs, total and dissolved (field-filtered) TAL metals/mercury, hardness, DOC (field-filtered), and TSS. | MS Surface Water Sample. Background, Location 002 |
| NYOW-BK-SW002-MSD-QQYY** | SW | 1 | Direct-dip | PAHs, total and dissolved (field-filtered) TAL metals/mercury, hardness, DOC (field-filtered), and TSS. | MSD Surface Water Sample, Background, Location 002 |
| **Porewater** | | | | | |
| NYOW-BK-PW001 through 008-QQYY** | PW | 1-1.5 feet below top of sediment | Syringe/peristaltic | PAHs, total and dissolved (field-filtered) TAL metals/mercury | Porewater Sample, Background, Locations 001 through 008 |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| NYOW-BK-PW-DUP001-QQYY** | PW | 1-1.5 feet below top of sediment | Syringe/peristaltic | PAHs, total and dissolved (field-filtered) TAL metals/mercury | Duplicate Porewater Sample, Background, Location 001 |
| NYOW-BK-PW002-MS-QQYY** | PW | 1-1.5 feet below top of sediment | Syringe/peristaltic | PAHs, total and dissolved (field-filtered) TAL metals/mercury | MS Porewater Sample. Background, Location 002 |
| NYOW-03-PW002-MSD-QQYY** | PW | 1-1.5 feet below top of sediment | Syringe/peristaltic | PAHs, total and dissolved (field-filtered) TAL metals/mercury | MSD Porewater Sample, Background, Location 002 |
| **Sediment** | | | | | |
| NYOW-BK-SD001 through 008-QQYY** | SD | 0-0.5 | Sediment Core | PAHs, total TAL metals/mercury, grain size, TOC. | Sediment Sample, Background, Locations 001 through 008 |
| NYOW-BK-SD-DUP001-QQYY** | SD | 0-0.5 | Sediment Core | PAHs, total TAL metals/mercury, grain size, TOC. | Duplicate Sediment Sample, Background, Location 001 |
| NYOW-BK-SD002-MS-QQYY** | SD | 0-0.5 | Sediment Core | PAHs, total TAL metals/mercury, grain size, TOC. | MS Sediment Sample, Background, Location 002 |
| NYOW-BK-SD002-MSD-QQYY** | SD | 0-0.5 | Sediment Core | PAHs, total TAL metals/mercury, grain size, TOC. | MSD Sediment Sample, Background, Location 002 |
| **Groundwater** | | | | | |
| NYOW-BK-MW01 thru -MW06-QQYY | GW | TBD | Low-flow | PAHs, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered), hardness | Groundwater Sample from Monitoring Wells, Background, Well #01 through 06 |
| NYOW-BK-MW-DUP001-QQYY** | GW | TBD | Low-flow | PAHs, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered) | Duplicate Groundwater Sample from Monitoring Well, Background, Well #01 |
| NYOW-BK-MW02-MS-QQYY** | GW | TBD | Low-flow | PAHs, total and dissolved (field-filtered) TAL | MS Groundwater Sample from Monitoring Well, Background, Well #02 |

| Sample ID | Matrix | Depth (ft bgs) | Collection Method | Analyte/Analytical Group | Comments |
|---|---|---|---|---|---|
| | | | | metals/mercury, DOC (field-filtered) | |
| NYOW-BK-MW02-MSD-QQYY** | GW | TBD | Low-flow | PAHs, total and dissolved (field-filtered) TAL metals/mercury, DOC (field-filtered) | MSD Groundwater Sample from Monitoring Well, Background, Well #02 |

Notes:
*Select 8 random locations for geotechnical/geochemical analysis. Geotechnical/geochemical analyses include: grain size, CEC, TOC, and pH. Field QC will not be collected for geochemical analysis.
**Locations of duplicate and MS/MSD shown as an example. Actual locations will be determined in the field and based on sample volume.
Acronyms:
CEC = cation exchange capacity.
DOC = dissolved organic carbon
DPT = direct-push technology
DUP = duplicate. Collection frequency 10% total number of parent samples..
GW = groundwater
MS = matrix spike. Collection frequency 5% total number of parent samples.
MSD = matrix spike duplicate. Collection frequency 5% total number of parent samples.
NYOW = New York Ordnance Works
PH = Direct-push technology
PW = porewater
QQYY = quarters/year. Example. Q225 would indicate the sample was collected during Quarter 2 in the year 2025.
SD = sediment
SW = surface water
TBD=screen depth to be determined.
TOC = total organic carbon
TSS = total suspended solids

## Exhibit 18-6 – IDW Sample Nomenclature

| IDW – Example Sample IDs | Nomenclature | Analyte/Analytical Group |
|---|---|---|
| IDW, Solid 1st Sample | NYOW-IDWS001 | TCLP VOCs, TCLP SVOCs, TCLP Pesticides, TCLP Herbicides, TCLP Metals, RCI, PCBs |
| IDW, Aqueous, 3rd Sample | NYOW-IDWA003 | TCLP VOCs, TCLP SVOCs, TCLP Pesticides, TCLP Herbicides, TCLP Metals, RCI, PCBs |

Acronyms:
NYOW = New York Ordnance Works
IDW = investigation-derived waste
RCI = reactivity, corrosivity, ignitability
SVOCs = semi-volatile organic compounds
TCLP = toxic characteristic leaching procedure

# Worksheets #19 and #30 – Sample Containers, Preservation, and Holding Times

The analytical methods for each sample matrix, sample volume, containers, preservation, holding times, and analytical laboratories are identified below. Samples will be shipped to respective laboratories for analysis. Applicable analytical SOPs are provided in **Appendix F**. All sample coolers will be shipped to Eurofins Lancaster Laboratories Environmental Testing, LLC (ELLE). All sample analyses will be conducted by ELLE with the exception of picric acid which will be performed by Eurofins Denver. For these analyses, the JV will collect in separate bottleware, and ship under separate chain of custody to the appropriate laboratory in order to reduce the risk of missing hold times. Preliminary POCs that are currently available are provided below, however due to staffing/scheduling, POCs can change due to project demands. Therefore, prior to going in the field, the initial bottleware order along with shipping information will be coordinated through ELLE. Along with the appropriate bottleware, ELLE will provide pre-printed courier labels with the appropriate individual laboratory destinations and POCs. Data will be generated by the same sources collecting the data. All communication regarding samples will be through ELLE. Additionally, data generated from the Phase 1 RI will be utilized in the evaluations.

**Laboratory:** **Eurofins Lancaster Laboratories Environment Testing, LLC (ELLE)**

2425 New Holland Pike
Lancaster, PA 17601
**POC:** Barbara Weyandt (670) 658-7330
**Accréditations/Certifications:** DoD A2A 1.01 (exp 11/30/2026)

**Eurofins Denver**
4955 Yarrow St, Suite 100
Arvada, CO 80002
POC Joy Chang (303) 467-7396
**Accreditations/Certifications:** DoD L2907 (exp. 10/31/2026) / NY No. 11964 (exp. 04/01/2026)

**MicroVision Laboratories, Inc.**
Samples for coal analysis only
187 Billerica Road
Chelmsford, MA 01824
POC John Knowles (978) 315-5768
**Accreditations/Certifications:** ISO/IEC 17025:2017 (exp 9/30/2025)

**Sample Delivery Method:** Federal Express (or equivalent)

| Analyte/Analyte Group | Matrix | Method/SOP | Sample Volume | Container(s) | Preservation | Preparation Holding Time | Analytical Holding Time | Data Package Turnaround |
|---|---|---|---|---|---|---|---|---|

# Worksheet #20 – Field QC Summary

The following information is a summary of the field QC samples to be collected during sampling activities. Field QC samples are summarized in the tables at the end of this section.

## Field Duplicate Samples

Field duplicates are two (2) (or more) field samples taken at the same time in the same location. They are intended to represent the same population and are taken through all steps of the analytical procedure in an identical manner. These samples are used to assess precision of the entire data collection activity, including sampling, analysis, and site heterogeneity. The standard collection frequency for duplicate samples is one (1) for every ten (10) field samples.

## Matrix Spike/Matrix Spike Duplicates

A MS/MSD is an aliquot of sample spiked with known concentrations of specific analytes. The spiking occurs before sample preparation and analysis at the laboratory. Additional volumes of a selected sample will be collected in the field to provide sufficient sample volume for the MS/MSD analysis. One (1) MS and one (1) MSD sample will be analyzed at a rate of approximately every 20 samples collected. MS/MSD samples will apply to soil and aqueous samples only.

## Equipment Rinsate Blanks

ERBs monitor the on-site sampling environment, sampling equipment decontamination, sample transport and storage conditions for water, soil, or sediment samples. ERBs are collected when non-dedicated equipment is used to collect environmental samples. ERBs for VOCs will be collected at a frequency of 5-percent of the total number of parent samples collected.

# Worksheet #21 – Field SOPs

Field SOPs associated with the project include, but are not limited to, sample collection, field equipment cleaning and decontamination, field equipment testing, inspection and maintenance, and sample handling and custody. The SOPs and summary information are listed in the following table. The SOPs provided are used to guide investigation techniques described in Worksheet #14 and #16. The headers of some of the SOPs state "WSP" however they are considered the JV's for their intended purpose. The actual field SOPs (and field forms) are provided in **Appendix D**.

| Reference Number | Title/Revision (Rev), Date | Originating Organization | Equipment Type | Modified for Project Work? |
|---|---|---|---|---|
| SOP 1 | Note Taking and Field Book Entries Procedure, 8/28/2020 | WSP | Field logbook, field forms, black or blue ballpoint pent | No |
| SOP 3 | Sample Packaging and Shipment Procedure | WSP | Coolers, COCs, custody seals, mailing address labels, shipping form, tape, bubble wrap, large plastic garbage bag | No |
| SOP 5 | Investigation-Derived Waste Management, 8/28/2020 | WSP | Permanent ink marking pen, paint, stick/pen, sampling equipment, drum labels, waste manifest | No |
| SOP 6 | Decontamination Procedure, 8/28/2020 | WSP | Phosphate free laboratory grade soap, analyte-free water, brushes, buckets, solvents, reagent grade acid, aluminum foil | No |
| SOP 7 | Water Quality Monitoring Equipment, 8/3/2020 | WSP | Water quality meter, flow-through cell, display/logger, calibration | No |
| SOP 9 | Soil Sampling, 9/8/2020 | WSP | DPT tools and equipment, hand auger, hand lens, sample containers, sample labels, Munsell color chart, calculator, decontamination supplies, stainless-steel trowels/bowls/spoons | No. |
| SOP 10 | Sediment Sampling Procedure, 8/28/2020 | WSP | Sample containers, waders, sampling equipment, sample labels | No |
| SOP 11 | Groundwater Sampling/Water level measurements, 9/8/2020 | WSP | Water level indicator, water quality meter, dissolved oxygen meter, pumps, tubing, turbidity meter, field filtering for dissolved metals, sample containers, sample labels, field data sheets | No |
| SOP 12 | Surface Water Sampling, 9/8/2020 | WSP | Water quality meter, waders, sample containers, sample labels surface water sampler, decontamination supplies | No |

| Reference Number | Title/Revision (Rev), Date | Originating Organization | Equipment Type | Modified for Project Work? |
|---|---|---|---|---|
| SESDGUID-101-R2 | Design and Installation of Monitoring Wells | EPA | Drill Rig(s) tools and equipment, filter pack sand, bentonite/fine sand, construction materials, PVC, tremie apparatus, water level indicator, well sounder, bailer, surge block, pumps, water quality meter, turbidity meter, calculator | No |
| LSASDPROC-513-R4 | Porewater Sampling | EPA | Water level indicator, water quality meter, pumps, tubing, turbidity meter, field filtering for dissolved metals (if required), sample containers, sample labels, field data sheets, porewater sampler | No |
| FT1800 | Field Measurement of Stage, Surface Water Velocity, and Discharge (Flow) and Computation of Streamflow, 01/2017 | FDEP | Water flow velocity meter, measuring tape (50 or 100 ft long in 0.01 ft increments), staff gauge in 0.01 ft increments (built-in to water flow velocity meter) | No |
| ASTM-D-2488-visual-USCS | Standard Practice for Description and Identification of Soils (Visual-Manual Procedure) | ASTM | N/A | No |
| SOP Low-Stress (Low-Flow) | Standard Operating Procedure for Low-Stress (Low-Flow) / Minimal Drawdown ground-water sample collection | EPA | Water level indicator, water quality meter, pumps, tubing, turbidity meter, field filtering for dissolved metals (if required), sample containers, sample labels, field data sheets | No |
| Use of GPS | For GPS use please use appropriate manual that is provided with rental unit | N/A | GPS, field logbook | No |

## Worksheet #22 – Field Equipment Calibration, Maintenance, Testing, and Inspection

Field equipment and instruments to be used during the field investigation and requiring calibration, maintenance, testing are listed below. Field SOPs are included in **Appendix D**.

| Field Equipment | Calibration Activity | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|---|
| PID | Each day calibrate fresh air (0 ppm); and to 100 ppm Isobutylene gas. | Perform maintenance per manufacturer's instructions. | Measures VOCs as an air concentration. | Per manufacturer's | Daily before use, an ICV following calibration, and at the end of the day (CCV) | Each day calibrate fresh air (0 ppm); and to 100 ppm Isobutylene gas. ±5% | Perform maintenance per manufacturer's instructions. | Measures VOCs as an air concentration. | Per manufacturer's recommendation |
| Water Level Indicator | Rental agency to calibrate quarterly to determine the accuracy of the measurement. | Perform maintenance per manufacturer's instructions. | Measures depth to water and total well depth | Per manufacturer's instructions. | Daily before use. | ±0.01 foot | Do not use if meter fails calibration criteria. | FTL | SOP 11 |
| Peristaltic Pump | None. | Perform maintenance per manufacturer's instructions. | Not applicable. | Per manufacturer's instructions. | Daily before use. Periodic checks throughout day of use. | Up to 25' | Not applicable. | FTL | SOP 11 |
| GPS | A QC check for the GPS unit will involve collecting the coordinates over a known structure (e.g., manhole, catch basin) will occur each day of GPS use. | Perform maintenance per manufacturer's instructions. | Collects horizontal coordinates of soil boring/surface water/porewater/sediment locations | Per manufacturer's instructions | Each day the GPS is in use | ±3 to 6 feet | Post-correct the data if coordinates accuracy exceeds 6 feet | FTL | Per manufacturer's recommendation |

| Field Equipment | Calibration Activity | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|---|
| Water Quality Meter | Calibrate daily prior to collecting water quality data; Perform an ICV immediately following calibration in read/run mode and record. At the end of each day, a post calibration in read/run mode will be performed and recorded | Perform maintenance per manufacturer's instructions. | Measures aqueous dissolved oxygen, oxidation-reduction potential, conductance, pH, turbidity, and temperature. | Per manufacturer's instructions. | Daily before use, immediately following calibration, and post-sampling | Check operations manual for acceptable range of calibrated probes and appropriate field forms. | If ICV fails initially, then re-calibrate. If ICV continues to fail, then do not use if meter fails calibration criteria. If Post-Calibration fails, "J" qualify appropriate parameters that failed on purge forms | FTL | SOP 7 |
| Global Water Flow Probe FP111 | Factory calibrated. Additional calibration recommended when turbo-prop propeller is replaced | Check for and remove any debris from the propeller and propeller housing. Assure that propeller spins freely. | Water velocity in open channels. | Per manufacturer's instructions. | Prior to each measurement. | 0.01 ft/sec accuracy. 0.3 – 19.9 ft/sec range. | Do not use if flow rate is outside of range. | FTL | None |

# Worksheet #23 – Analytical SOPs

The following laboratory SOP references were provided by Eurofins Lancaster (ELLE). The laboratory SOPs and procedures are provided in **Appendix F** and have not been modified for this project.

| Lab SOP Number | Title, Revision Date, and / or Number | Definitive or Screening Data | Matrix and Analytical Group | Instrument | Organization Performing Analysis | Modified for Project Work? (Y/N) |
|---|---|---|---|---|---|---|
| WI9238 | Analysis of Polychlorinated Biphenyls (PCBs) by 8082A in Aqueous Samples using GC-ECD, Version 9, 01/27/2023 | Definitive | PCBs | GC | ELLE | N |
| WI7965 | Mercury in Aqueous, Solid and Tissue Samples by EPA 7471A, 7471B, 7470A, and 245.1 rev 3 by Cold Vapor AA, Version 21, 4/30/2023 | Definitive | Solid, liquid, tissues Metals | ICP | ELLE | N |

# Worksheet #24 – Analytical Instrument Calibration

Analytical instruments will be calibrated in accordance with the procedures in the analytical laboratory SOPs (**Appendix F**). Following is a summary of the calibration procedures. All analytical instrument calibration procedures follow QSM criteria.

## Worksheet #24-1 – GC/MS VOC Instrument Calibration Table

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| GC/MS Volatiles 8260C/D | GC/MS Tuning | Tune with BFB before an ICAL and every 12 hours | Per ion abundance criteria in SW-846 method | Retune, injection port maintenance, clean the source and/or change the column | ELLE analyst | WI8236 |
| | Initial Calibration with minimum 5 points; Solid and 5 mL waters 1 ppb through 300 ppb; 25 mL waters 0.2 ppb through 25 ppb; 5 mL UST waters 0.5 ppb through 200 ppb | After continuing calibration fails. | %RSD of ≤15% is required for all analytes using an average relative response factor. 10% of the analytes may fail this criteria. For any analytes with a %RSD >15%, a first-degree linear regression can be used providing that the correlation coefficient (CC) is ≥ 0.99 and a minimum of five (5) levels are used. A quadratic curve fit may be used providing that the coefficient of determination is ≥ 0.99 and a minimum of six (6) levels are used. If >10% of the analytes fail, the calibration is not valid and must be repeated. Minimum response factor criteria must be met for select compounds. | Perform more aggressive instrument maintenance and recalibrate | | |
| | Retention Time Window Establishment | Once per ICAL and at the beginning of the analytical sequence | Position is set using the midpoint standard of the ICAL curve when ICAL is performed. On days with | N/A | | |

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| | | | no ICAL use the initial CCV | | | |
| | Evaluation of Relative Retention Times (RRT) | With each sample | RRT of each reported analyte within ±0.06 RRT units | Correct problem, then recalibrate | | |
| | MDL Standard | After each calibration | All compounds must be detected | Repeat tuning and ICAL procedure prior to analyzing samples. Repeat maintenance if needed. | | |
| | LOD standard | Quarterly | All compounds must be detected | Re-prep and re-analyze LOD | | |
| | CCV standard | Every 12 hours and at the end of analytical run | All target analytes ≤20% Drift; Ending CCV - All reported analytes and surrogates within ± 50%. | Re-analyze CCV in duplicate immediately. If both pass, samples can be reported. If either fails or if immediate reanalysis of CCV in duplicate cannot be performed all samples since acceptable CCV must be re-analyzed. If the CCV fails high any associated samples that are ND can be reported. | | |

Acronyms:
ICAL = Initial Calibration
ICV = Initial Calibration Verification
CCV = Calibration Check Verification
RF = Response Factor
RSD = Relative Standard Deviation
RRF = Relative Response Factor
LOD = Limit of Detection
MDL = Method Detection Limit

## Worksheet #24-2 – GC/MS SVOC Instrument Calibration Table

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| GC/MS Semivolatiles 8270E | GC/MS Tuning and Performance Check | Tune with DFTPP before an ICAL or CCV | Per ion abundance criteria in SW-846 method; DDT breakdown ≤20%; tailing factors: benzidine ≤2; pentachlorophenol ≤2 | Retune, injection port maintenance, clean the source and/or change the column | ELLE analyst | WI9617 |
| | Initial calibration with a minimum 5 points: Solid, tissue and water 1000 mL= 0.5 ppm through 120 ppm; Water 250 mL= 0.125 ppm through 30 ppm | After continuing calibration fails. or after major maintenance. | Avg RRF is used if % RSD ≤15%, if >15% a linear fit can be used if $r^2$≥0.99. A linear curve fit is a suitable alternative when only five (5) calibration standards have been analyzed. When calculating the calibration curves using the linear regression model, a minimum quantitation check on the viability of the lowest calibration point should be performed by re-fitting the response from the low concentration calibration standard back into the curve. The recalculated concentration of the low calibration point should be within ±30% of the standard's true concentration. | Perform more aggressive instrument maintenance and recalibrate | | |
| | Retention Time Window Establishment | Once per ICAL and at the beginning of the analytical sequence | Position is set using the midpoint standard of the ICAL curve when ICAL is performed. On days with no ICAL use the initial CCV | NA | | |

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| | Evaluation of Relative Retention Times (RRT) | With each sample | RRT of each reported analyte within ±0.06 RRT units | Correct problem, then recalibrate | | |
| | ICV standard (required only for 2,4-dinitrochlorobenzene) | After each initial calibration | Target compounds ≤20% drift | Re-analyze the ICV and samples associated with the non-compliant ICV. If ICV fails again do system maintenance, recalibrate, and re-analyze samples. | | |
| | CCV standard | Every 12 hours | Target compounds ≤20% drift. Ending CCV - All reported analytes and surrogates within ± 50%. | Re-analyze CCV in duplicate immediately. If both pass, samples can be report. If either fails or if immediate reanalysis of CCV in duplicate cannot be performed all samples since acceptable CCV must be re-analyzed. If the CCV fails high any associated samples that are ND can be reported. | | |
| | Tune-ending check standard (CCVC) | End of analytical run | Run within 12 hour tune time; ±50% drift | Re-analyze the CCVC if within the 12 hour tune period. If not or if the re-analyzed CCVC fails do system maintenance, retune, recalibrate, and re-analyze samples. | | |
| | LOD Verification | Quarterly | Spike at LOD, goes through all preparative methods. Meets qualitative detection criteria | Re-prep and re-analyze the LOD standard. If needed, LODs are raised by performing a new initial LOD verification | | SOP11892 |
| | MDL Verification | Quarterly | Per 40 CFR 136 Appendix B Rev 2.0. Goes through all preparative methods. Meets qualitative detection criteria. May be combined with the LOD verifications. | Re-prep and re-analyze the MDL standard. If needed, a new initial MDL study is performed with a higher concentration. | | |

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| | LOQ Verification | Quarterly | Goes through all preparative methods. Meets quantitative detection criteria. May be combined with the LOD and MDL verifications. | Re-prep and re-analyze the RL standard. If needed, LOQs are raised by performing a new initial LOQ verification | | |

Acronyms:
SPCC = System Performance Check Compound
CCC = Calibration Check Compounds
ICAL = Initial Calibration
ICV = Initial Calibration Verification
CCV = Calibration Check Verification
RF = Response Factor
RRF = Relative Response Factor
RSD = Relative Standard Deviation
SECC = Shift Ending Calibration Check
DFTPP = Decafluorotriphenylphosphine
LOD = Limit of Detection
CF = Calibration Factor

## Worksheet #24-3 – Explosives HPLC Instrument Calibration Table

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| HPLC Nitroaromatics and Nitroamines 8330B | Initial calibration with a minimum 6 points. Ranges from a standard at or near the reporting limit through 80x the first level | After continuing calibration fails | % RSD ≤15%, if >15% then alternate fit linear $r^2$ ≥0.99 or quadratic r2 ≥0.99. Must use 6 points for quadratic curve. | Perform more aggressive instrument maintenance and recalibrate | Eurofins-Denver Analyst | DV-LC-0002 |
| | MDL Standard | After each initial calibration | All compounds must be detected | Repeat ICAL procedure prior to analyzing samples. Repeat maintenance if needed. | | |
| | LOD Standard | Quarterly | All compounds must be detected | Re-prep and re-analyze LOD | | |
| | CCV Standard | Prior to sample analysis, after every 10 field samples, and at the end of the sequence. | Target compounds +/- 20% of the nominal concentration and within established retention time windows | All samples since acceptable CCV must be re-analyzed. If the CCV fails high, any associated samples that are ND can be reported. | | |
| | Confirmation of positive results | All positive results | Calibration and QC criteria are the same for the confirmation analysis as for primary analysis. For results > LOQ, RPD for results between the primary and confirmation is ≤ 40%. | Report both columns in data package | | |
| | LOD Verification | Quarterly | Spike at LOD, goes through all | Re-prep and re-analyze the LOD | | SOP11892 |

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| | | | preparative methods. Meets qualitative detection criteria | standard. If needed, LODs are raised by performing a new initial LOD verification | | |
| | MDL Verification | Quarterly | Per 40 CFR 136 Appendix B Rev 2.0. Goes through all preparative methods. Meets qualitative detection criteria. May be combined with the LOD verifications. | Re-prep and re-analyze the MDL standard. If needed, a new initial MDL study is performed with a higher concentration. | | |
| | LOQ Verification | Quarterly | Goes through all preparative methods. Meets quantitative detection criteria. May be combined with the LOD and MDL verifications. | Re-prep and re-analyze the LOQ standard. If needed, LOQs are raised by performing a new initial LOQ verification | | |

Acronyms:
ICAL = Initial Calibration
ICV = Initial Calibration Verification
ICB = Initial Calibration Blank
CCV = Continuing Calibration Verification
CCB = Continuing Calibration Blank

## Worksheet #24-5 – Metals-ICP-MS Instrument Calibration Table

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| ICP/MS: 6020B | Tuning | Daily | No AMUA difference of >0.1 AMU.<br>Peak Width < 0.9 AMU at 10% height.<br>%RSD < 5 for masses used for tuning. | Perform mass calibration for AMU. Adjust mass calibration for PW. | ELLE Analyst | WI11933 |
| | Initial Calibration consists of Blank and 1 point: 0 and 10,000 ppb for Al, Ca, Fe, Mg, K, Na; 0 and 1,000 ppb for As, Ba, Cr, Co, Cu, Mn, Ni, Ti, V, Zn; 0 and 100 ppb for Sb, Be, Cd, Pb. Mo, Se, Ag, Sr, Tl, Sn | Each new run | Passing ICB | Recalibrate, perform instrument maintenance if calibration cannot conform to criteria, recalibrate | | |
| | ICB | Immediately after the ICV | No analytes > LOD | Re-analyze | | |
| | LOD Verification | Quarterly | Spike at LOD, goes through all preparative methods. Meets qualitative detection criteria | Re-prep and re-analyze the LOD standard. If needed, LODs are raised by performing a new initial LOD verification | | |
| | MDL Verification | Quarterly | Per 40 CFR 136 Appendix B Rev 2.0. Goes through all preparative methods. Meets qualitative detection criteria. May be combined with the LOD verifications. | Re-prep and re-analyze the MDL standard. If needed, a new initial MDL study is performed with a higher concentration. | | |
| | LOQ Verification | Quarterly | Goes through all preparative methods. Meets quantitative detection criteria. May be combined with the LOD and MDL verifications. | Re-prep and re-analyze the RL standard. If needed, LOQs are raised by performing a new initial LOQ verification | | |
| | CCV | Immediately after the ICSAB and every 10 samples | ±10% of true value | Re-analyze | | |

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| | CCB | Immediately after the CCV and every 10 samples | No analytes > LOD | Re-analyze | | |
| | Interference Check Sample-A | At the beginning of each run immediately following the LLC | Absolute value of concentration for all non-spiked project analytes <1/2 LOQ | Recalibrate | | |
| | Interference Check Sample-AB | At the beginning of each run immediately following the LLC | ± 20% of the true value for each analyte | Recalibrate | | |
| | Low Level Check (LLC) | Beginning of each sequence and before the interference check samples | ± 20% True Value | Re-analyze the sample | | |
| | Linear Dynamic Range (LDR) Check | Quarterly | ±10% of true value | Samples > 90% of the linear range must be re-analyzed as a dilution | | |

Acronyms:
ICSAB = Interference Check Standard AB
ICV = Initial Calibration Verification
ICB = Initial Calibration Blank
CCV = Continuing Calibration Verification
CCB = Continuing calibration Blank
CRA = Contract-required detection limit

## Worksheet #24-6 – Mercury CVAA Instrument Calibration Table

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| CVAA: 7471A/7470A (water and soil) | Initial Calibration consists of a Blank and 5 points ranging from 0.2 ppb to 5 ppb | Each new run | Correlation coefficient (r) >0.995 | Recalibrate, perform instrument maintenance if calibration cannot conform to criteria, recalibrate | ELLE Analyst | WI7965 |
| | ICV | After each calibration | ±10% of true value | Re-analyze | | |
| | ICB | Immediately after the ICV | No analytes > LOD | Re-analyze | | |
| | LOD Verification | Quarterly | Spike at LOD, goes through all preparative methods. Meets qualitative detection criteria | Re-prep and re-analyze the LOD standard. If needed, LODs are raised by performing a new initial LOD verification | | |
| | MDL Verification | Quarterly | Per 40 CFR 136 Appendix B Rev 2.0. Goes through all preparative methods. Meets qualitative detection criteria. May be combined with the LOD verifications. | Re-prep and re-analyze the MDL standard. If needed, a new initial MDL study is performed with a higher concentration. | | |
| | LOQ Verification | Quarterly | Goes through all preparative methods. Meets quantitative detection criteria. May be combined with the LOD and MDL verifications. | Re-prep and re-analyze the RL standard. If needed, LOQs are raised by performing a new initial LOQ verification | | |
| | CCV | Immediately after the CRA and every 10 samples | ±10% of true value | Re-analyze | | |
| | CCB | Immediately after the CCV and at a frequency of every 10 samples | No analytes > LOD | Re-analyze | | |
| | Low level Check (CRA) | Immediately after the ICB | ± 20% True Value | Re-analyze | | |

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|

Acronyms:
ICSAB = Interference Check Standard AB
ICV = Initial Calibration Verification
ICB = Initial Calibration Blank
CCV = Continuing Calibration Verification
CCB = Continuing calibration Blank
CRA = Contract-required detection limit

## Worksheet #24-7 – TOC/DOC Instrument Calibration Table

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| TOC Analyzer: TOC, DOC, & TIC in Water | Initial calibration with a minimum 6 points ranging from 1.0 ppm to 100 ppm | Monthly or after continuing calibration fails | $r^2$ ≥0.995. Relative Error for CAL1 and midpoint must be less than 15% | Perform more aggressive instrument maintenance and recalibrate | ELLE Analyst | WI11637 (5310C); WI10038 (9060A) |
| | ICB Standard | After each initial calibration | No analytes detected > MDL | Perform more aggressive instrument maintenance and recalibrate | | |
| | ICV Standard | After each initial calibration | Method Acceptance Criteria | Re-analyze the ICV. If ICV fails again do system maintenance and recalibrate. | | |
| | Total Inorganic Check Standard | Daily | Within +/- 20% of the nominal concentration | All affected samples are re-analyzed | | |
| | CCV Standard | If instrument is idle > 4 hours, after every 10 field samples, and at the end of the sequence | Method Acceptance Criteria | All affected samples are re-analyzed | | |
| | CCB Standard | If instrument is idle > 4 hours, after every 10 field samples, and at the end of the sequence | No analytes detected > MDL | All affected samples are re-analyzed | | |
| TOC in Soil, 9060A | Initial calibration with a minimum 4 points ranging from 0.3 mg C to 6 mg C | Monthly or after continuing calibration fails | $r^2$ ≥0.995. %Relative Error for low and midpoint cal standards must meet lab criteria | Perform more aggressive instrument maintenance and recalibrate | ELLE Analyst | WI11627 |
| | ICB Standard | After each initial calibration | No analytes detected > ½ LOQ | Perform more aggressive instrument maintenance and recalibrate | | |
| | ICV Standard | After each initial calibration | Laboratory Acceptance Criteria | Re-analyze the ICV. If ICV fails again do system maintenance and recalibrate. | | |
| | CCV Standard | After every 10 analyses, and at | Manufacturer acceptance limits | All affected samples are re-analyzed | | |

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| | | the end of the sequence | | | | |
| | CCB Standard | After every 10 analyses, and at the end of the sequence | No analytes detected > ½ LOQ | All affected samples are re-analyzed | | |

Acronyms:
TC = Total Carbon
TOC = Total Organic Carbon
TIC = Total Inorganic Carbon
DC = Dissolved Carbon
DOC = Dissolved Organic Carbon
DIC = Dissolved Inorganic Carbon
DO = Dissolved Oxygen

## Worksheet #24-8 – Hardness Instrument Calibration Table

| Parameter | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| Hardness, SM2340C | CCV Standard | Every 10 samples | ±10% Difference | Re-analyze affected samples | ELLE Analyst | WI11475 |
| | CCB Standard | Every 10 samples | <MDL | Re-analyze affected samples >ND | ELLE Analyst | |

## Worksheet #24-9 – pH Instrument Calibration Table

| Parameter | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| pH using pH meter liquid | 3 point: 4, 7, 10 buffers | Every 24 hours | Percent slope by be within 92% and 102% | Perform instrument maintenance if calibration cannot conform to criteria, recalibrate | ELLE Analyst | WI11518, WI11519 |
| | CCV Standard | After every 10 samples and end of batch | ±10% D | Re-analyze affected samples | ELLE Analyst | |

## Worksheet #24-10 – CEC Instrument Calibration Table

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| ICP: 6010D/ CEC: 9081 | Initial Calibration consists of Blank and 1 point: 0 and 10,000 ppb for Na | Each new run | Passing ICB | Recalibrate, perform instrument maintenance if calibration cannot conform to criteria, recalibrate | ELLE Analyst | WI11933 |
| | ICB | Immediately after the ICV | No analytes > LOD | Re-analyze | | |

| Instrument | Calibration Procedure/Range | Frequency of Calibration | Acceptance Criteria | Corrective Action (CA) | Person Responsible for CA | SOP Reference |
|---|---|---|---|---|---|---|
| | LOD Verification | Quarterly | Spike at LOD, goes through all preparative methods. Meets qualitative detection criteria | Re-prep and re-analyze the LOD standard. If needed, LODs are raised by performing a new initial LOD verification | | |
| | MDL Verification | Quarterly | Per 40 CFR 136 Appendix B Rev 2.0. Goes through all preparative methods. Meets qualitative detection criteria. May be combined with the LOD verifications. | Re-prep and re-analyze the MDL standard. If needed, a new initial MDL study is performed with a higher concentration. | | |
| | LOQ Verification | Quarterly | Goes through all preparative methods. Meets quantitative detection criteria. May be combined with the LOD and MDL verifications. | Re-prep and re-analyze the RL standard. If needed, LOQs are raised by performing a new initial LOQ verification | | |
| | CCV | Immediately after the ICSAB and every 10 samples | ±10% of true value | Re-analyze | | |
| | CCB | Immediately after the CCV and every 10 samples | No analytes > LOD | Re-analyze | | |
| | Interference Check Sample-A | At the beginning of each run immediately following the LLC | Absolute value of concentration for all non-spiked project analytes <1/2 LOQ | Recalibrate | | |
| | Interference Check Sample-AB | At the beginning of each run immediately following the LLC | ± 20% of the true value for each analyte | Recalibrate | | |
| | Low Level Check (LLC) | Beginning of each sequence and before the interference check samples | ± 20% True Value | Re-analyze the sample | | |
| | Linear Dynamic Range (LDR) Check | Quarterly | ±10% of true value | Samples > 90% of the linear range must be re-analyzed as a dilution | | |

# Worksheet #25 – Analytical Instrument and Equipment Maintenance, Testing, and Inspection

Laboratory analytical equipment will undergo maintenance and testing procedure in accordance with the laboratory SOPs (**Appendix F**). Instrument maintenance is not required for isotopic signature analyses. All analytical instrument calibration procedures follow QSM criteria. Following is a summary of the procedures.

## Worksheet #25-1 – VOC Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| Agilent 6890 GC/5973 MSD (or equivalent) | As needed, replacement of components | CCV | Visual inspection of components | As needed | Initial calibration or continuing calibration verification passes method criteria | Perform additional maintenance prior to instrument calibration or CCV | Analysts or group leaders | WI7619 & WI9598 |
| Analytical Balance | Annual Calibration/ Verification | Daily Check with Class 1 weights | Visual inspection | Annual Calibration/ Daily Check | The reading must be ±0.1% or ±0.5mg, whichever is greater. Weight must be 1000X heavier than sensitivity of balance. | 1) verify cleanliness of weights 2) remove balance from service and place a call to service firm 3) management must evaluate data generated since last acceptable reading to determine any potential impacts to data quality | Outside vendor for calibration/ Analyst for daily checks | SOP11880 |

## Worksheet #25-2 – SVOC Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| 8270 Agilent 6890 or 7890 GC/5973, 5975, or 5977 MSD (or equivalent) | As needed, replacement of components (Injection port; column, ion source; other) | Continuing calibration verification (CCV) and DFTPP per 12 hour tune period | Visual inspection of components | Daily routine maintenance (injection port); as needed for other components | Initial calibration or continuing calibration verification passes method criteria | Perform maintenance again; re-calibration if necessary | Analysts or group leaders | WI9598 |

## Worksheet #25-3 – Explosives Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| HPLC, HP1100 with 2HPLC UV detectors | Replacing frits and check valves | Calibration Check<br>All analytes within +/- 15% of the nominal concentration and within established retention time windows | Visual Inspection | As needed | Initial calibration after maintenance is within specifications | Perform maintenance again | HPLC analyst | WI10008 |

## Worksheet #25-4 – PCBs Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| Gas Chromatograph, HP5890, HP 6890, and HP7890 with ECD Detector | Injection port maintenance; ECD maintenance | Calibration Check All analytes within +/- 20% of the nominal concentration and within established retention time windows | Visual Inspection | As needed | Initial calibration after maintenance is within specifications | Perform maintenance again | GC analyst | WI10007 |

## Worksheet #25-5 – Metals-ICP-MS Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| Agilent 7900/7700X | As needed replacement of components | Calibration checks | Visual inspection of components | As needed maintenance/ calibration checks every 10 injections | 90-110% for the calibration checks | Recalibration | ELLE Analyst | WI21590, WI11933 |

## Worksheet #25-6 – Mercury Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| Leeman Labs Hydra II Mercury Analyzer | As needed replacement of components | Calibration checks | Visual inspection of components | As needed maintenance/ calibration checks every 10 injections | 90-110% for the calibration checks | Recalibration | ELLE Analyst | WI7965 |

## Worksheet #25-7 – TOC/DOC Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| TOC Analyzer | As needed replacement of components | Calibration checks | Visual inspection of components | As needed maintenance/calibration checks every 10 injections | Per Method Criteria | Recalibration | ELLE Analyst | WI11637 (5310C waters); WI10038 (9060A waters); WI11627 (soil) |
| Analytical balance | Assure the balance is in a vibration-free area, is level, and the interior housing is clean. | Verification with ASTM certified weights | Visual inspection and weight verification | Each day of use | The reading must be ±0.1% or ±0.5mg, whichever is greater. | 1) verify cleanliness of weights 2) remove balance from service and place a call to service firm 3) management must evaluate data generated since last acceptable reading to determine any potential impacts to data quality | ELLE analyst | SOP11880 |

## Worksheet #25-8 – Hardness Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsible Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| Man-Tech Autotitrator | As needed replacement of components | Continuing calibration verification (CCV) | Visual inspection of components | As needed | Initial calibration or continuing calibration verification passes method criteria | Perform maintenance again; re-calibration if necessary | Analysts or group leaders | WI11475 |

## Worksheet #25-9 – pH Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsibl e Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| pH/ISE Meter | As needed replacement of components | Calibration checks | Visual inspection of components | As needed maintenance/c alibration checks every 10 injections | 90-110% for calibration checks | Recalibration | ELLE Analyst | WI11518 |

## Worksheet #25-10 – Metals-ICP/CEC Analytical Instrument Maintenance

| Instrument/ Equipment | Maintenance Activity | Testing Activity | Inspection Activity | Frequency | Acceptance Criteria | Corrective Action | Responsibl e Person | SOP Reference |
|---|---|---|---|---|---|---|---|---|
| Thermo Scientific iCAP 6000, 6500, 7000 | As needed replacement of components | Calibration checks | Visual inspection of components | As needed maintenance/ calibration checks every 10 injections | 90-110% for the calibration checks | Recalibration | ELLE Analyst | WI7562/WI 11931 |

# Worksheets #26 and #27 – Sampling Handling, Custody, and Disposal

Proper sample collection, labeling, custody, and shipping procedures will be followed from the time of sample collection to final sample disposal. SOPs related to sampling are in **Appendix D**. Analytical laboratory staff will prepare and analyze the samples in accordance with the laboratory SOPs provided in **Appendix F**.

**Sampling Organization:** **EAS-WSP JV**

**Laboratories:** ELLE
Eurofins Test America, Denver, CO

**Method of Sample Delivery:** Federal Express (or equivalent) Overnight

**Number of Days from Reporting Until Sample Disposal:** 60 days

| Activity | Organization/Title/Position of Person Responsible for Activity | SOP Reference (Appendix D) |
|---|---|---|
| Sample Collection | Field Team Members: WSP/KGS | SOP#9, #10, #11, #12, LSASDPROC-513-R5 |
| Sample Labeling | Field Team Members: WSP/KGS | SOP #3 |
| Chain-of-Custody Form Completion | Field Team Members: WSP/KGS | SOP #3 |
| Packaging | Field Team Members: WSP/KGS | SOP #3 |
| Shipping Coordination | Field Team Members: WSP/KGS; JV Chemist: Michael Shadle – EAS WSP JV PM – Russ McCormick JV QC Manager – George Lukert | SOP #3 |
| Sample Receipt, Inspection, and Log In | Laboratory Sample Custody Staff | Laboratory Procedures |
| Sample Custody and Storage | Laboratory Sample Custody Staff | Laboratory Procedures |
| Sample Disposal of 60 days once data has been received and validated | Laboratory Sample Custody Staff | Minimum of 60 days following analysis. |
| Extract/Digestate Disposal | Laboratory Sample Custody Staff | Minimum of 60 days, if any extract remains |

# Worksheet #28 – Analytical Quality Control and Corrective Action

The purpose of laboratory QC activities is to produce data of known quality that satisfy the project-specific DQOs. The QC requirements apply to laboratory analysis of samples that will produce definitive data. The purpose of laboratory QC activities is to produce data of known quality that satisfy the project-specific DQOs. The following worksheets contain information for each analytical method/SOP, matrix, and analytical group.

This page intentionally left blank

## Worksheet #28-1

Matrix: Aqueous/Solids
Analytical Group: VOCs
Concentration Level: Low
Analytical Method/SOP Reference: 8260C/D; WI8236/WI8194
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Surrogate Spike | Per sample (including MS/MSD, LCS, and Blanks) | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for surrogates not in QSM 6.0 and above. | If obvious matrix interference report data with a comment. Otherwise, re-analyze. | ELLE Analyst | Accuracy | Results within acceptance limits |
| Method blanks | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater | Re-analyze to confirm detections. If detects confirm re-analyze samples that are not ND or not >10x the blank value or regulatory limit | ELLE Analyst | Accuracy/Laboratory Contamination | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater |
| MS/MSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM 6.0 and above; RPD ≤30% | Flag outliers | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| LCS/LCSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM 6.0 and above.; RPD ≤30% | Analytes in the LCS that fail high and are ND in the samples can be reported. For all others re-analyze LCS and samples. If it still fails, perform instrument maintenance, restart the tune period and re-analyze all QC and samples. | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| Internal standards | Per sample (including MS/MSD, LCS, and blanks) | -50% to + 100% of internal standard area of 12 hour STD. RT change | Check the instrument for possible problems and then re-analyze samples. If reinject confirms, report with a comment. | ELLE Analyst | Precision | Results within acceptance limits |

## Worksheet #28-2

Matrix: Aqueous/Solids
Analytical Group: SVOC
Concentration Level: Low
Analytical Method/SOP Reference: 8270E WI9617
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Surrogate Spike | Per sample (including MS/MSD, LCS/LCSD, and Blanks) | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for surrogates not in QSM.6.0 | If obvious matrix interference report data with a comment. Otherwise, re-extract and re-analyze. | ELLE Analyst | Accuracy | Results within acceptance limits |
| Method blanks | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater | Re-analyze to confirm detections. If detects confirm re-extract samples that are not ND or not >10x the blank value | ELLE Analyst | Accuracy/Laboratory Contamination | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater |
| MS/MSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM.6.0; RPD ≤30% | Flag outliers | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| LCS/LCSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM.6.0; RPD ≤30% | Analytes in the LCS that fail high and are ND in the samples can be reported. All others are re-extracted. | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| Internal standards | Per sample (including MS/MSD, LCS/LCSD, and blanks) | -50% to +100% of internal standard area of 12 hour STD. RT within ±10 sec. of referenced standard | Flag data | ELLE Analyst | Precision | Results within acceptance limits |
| MDL | 2 spiked samples per instrument per quarter (or per batch, whichever is less frequent | Analyte(s) meet qualitative identification criteria | Raise MDL spike concentration and re-calculate | ELLE Analyst | Sensitivity | Results within acceptance limits |
| LOD | 1 spiked sample per quarter prepared and analyzed at the concentration of the LOD (or per batch, whichever is less frequent) | Analyte(s) meet qualitative identification criteria | Raise LOD spike concentration, raise LOD reported | ELLE Analyst | Sensitivity | Results within acceptance limits |

## Worksheet #28-3

Matrix: Aqueous/Solids
Analytical Group: SVOC-2,4-DNCB & 2,4-DNP
Concentration Level: Low
Analytical Method/SOP Reference: 8270E WI9617
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Surrogate Spike | Per sample (including MS/MSD, LCS/LCSD, and Blanks) | See Worksheet 12-3 for limits. | If obvious matrix interference report data with a comment. Otherwise, re-extract and re-analyze. | Analyst | Accuracy | Results within acceptance limits |
| Method blanks | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater | Re-analyze to confirm detections. If detects confirm re-extract samples that are not ND or not >10x the blank value | Analyst | Accuracy/Laboratory Contamination | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater |
| MS/MSD | 1 per prep batch of up to 20 samples | See Worksheet 12-3 for limits RPD ≤30% | Flag outliers | Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| LCS/LCSD | 1 per prep batch of up to 20 samples | See Worksheet 12-3 for limits. RPD ≤30% | Analytes in the LCS that fail high and are ND in the samples can be reported. All others are re-extracted. | Analyst | Accuracy/Bias/Precision | Results within acceptance limits |

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Internal standards | Per sample (including MS/MSD, LCS/LCSD, and blanks) | -50% to +100% of internal standard area of 12 hour STD. RT within ±10 sec. of referenced standard | Flag data | Analyst | Precision | Results within acceptance limits |
| MDL | 2 spiked samples per instrument per quarter (or per batch, whichever is less frequent | Analyte(s) meet qualitative identification criteria | Raise MDL spike concentration and re-calculate | Analyst | Sensitivity | Results within acceptance limits |
| LOD | 1 spiked sample per quarter prepared and analyzed at the concentration of the LOD (or per batch, whichever is less frequent) | Analyte(s) meet qualitative identification criteria | Raise LOD spike concentration, raise LOD reported | Analyst | Sensitivity | Results within acceptance limits |

## Worksheet #28-4

Matrix: Aqueous/Solids
Analytical Group: Alkylated PAHs
Concentration Level: Low - SIM
Analytical Method/SOP Reference: SW-846 8270E SIM/ WI9995
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Surrogate Spike | Per sample (including MS/MSD, LCS, and Blanks) | QSM 6.0 or above limits for those listed, otherwise use laboratory statistical limits | If obvious matrix interference report data with a comment. Otherwise, re-extract and re-analyze. | ELLE Analyst | Accuracy | Results within acceptance limits |
| Method blanks | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater | Re-analyze to confirm detections. If detects confirm re-extract samples that are not ND or not >10x the blank value | ELLE Analyst | Accuracy/Laboratory Contamination | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater |
| MS/MSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 or above. Laboratory statistical limits for compounds not in QSM 6.0; RPD ≤30% | Flag outliers | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| LCS/LCSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM 6.0; RPD ≤30% | Analytes in the LCS that fail high and are ND in the samples can be reported. All others are re-extracted. | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Internal standards | Per sample (including MS/MSD, LCS, and blanks) | -50% to +100% of internal standard area of 12 hour STD.<br>RT change ≤30 sec. of associated reference standard | Re-analyze, document if confirmed. | ELLE Analyst | Precision | Results within acceptance limits |
| MDL Standard | 2 spiked samples per instrument per quarter (or per batch, whichever is less frequent) | Analyte(s) meet qualitative identification criteria | Raise MDL spike concentration and re-calculate | ELLE Analyst | Sensitivity | Results within acceptance limits |
| LOD | 1 spiked sample per quarter prepared and analyzed at the concentration of the LOD (or per batch, whichever is less frequent) | Analyte(s) meet qualitative identification criteria | Raise LOD spike concentration, raise LOD reported | ELLE Analyst | Sensitivity | Results within acceptance limits |

## Worksheet #28-5

Matrix: Aqueous/Solids
Analytical Group: Picric Acid
Concentration Level: low
Analytical Method/SOP Reference: SW-846 8330B/DV-LC-0002
Analytical Organization: Eurofins - Denver

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Surrogate Spike | Per sample (including MS/MSD, LCS, and Blanks) | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM | If obvious matrix interference report data with a comment. Otherwise, re-extract and re-analyze. | Eurofins-Denver Analyst | Accuracy | Results within acceptance limits |
| Method blanks | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater | Re-analyze to confirm detections. If detects confirm re-extract samples that are not ND or not >10x the blank value | Eurofins-Denver Analyst | Accuracy/Laboratory Contamination | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater |
| MS/MSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM; RPD ≤20% | Flag outliers | Eurofins-Denver Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| LCS/LCSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM; RPD ≤20% | Analytes in the LCS that fail high and are ND in the samples can be reported. All others are re-extracted. | Eurofins-Denver Analyst | Accuracy/Bias/Precision | Results within acceptance limits |

## Worksheet #28-6

Matrix: Aqueous/Solids
Analytical Group: PCBs
Concentration Level: Low
Analytical Method/SOP Reference: 8082A/WI10004/WI9238
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Surrogate Spike | Per sample (including MS/MSD, LCS, and Blanks) | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for surrogates not in QSM | If obvious matrix interference report data with a comment. Otherwise, re-extract and re-analyze. | ELLE Analyst | Accuracy | Results within acceptance limits |
| Method blanks | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater | Re-analyze to confirm detections. If detects confirm re-extract samples that are not ND or not >10x the blank value | ELLE Analyst | Accuracy/Laboratory Contamination | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample or 1/10 the regulatory limit, whichever is greater |
| MS/MSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM; RPD ≤30% | Flag outliers | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| LCS/LCSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0 and above. Laboratory statistical limits for compounds not in QSM; RPD ≤30% | Analytes in the LCS that fail high and are ND in the samples can be reported. All others are re-extracted. | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |

## Worksheet #28-7

Matrix: Aqueous/Solids
Analytical Group: Metals
Concentration Level: Low
Analytical Method/SOP Reference: SW-846 6020B/WI11933
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Method Blank | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample | Re-analyze blank to confirm detections. If detects confirm, redigest samples that are not ND or not >10x the blank value. | ELLE Analyst | Accuracy/Laboratory Contamination | Results within acceptance limits |
| MS/MSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0; ±25% for elements not in QSM; RPD ≤20% | Analyze post digestion spike and serial dilution | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| LCS/LCSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0; ±20% for elements not in QSM; RPD ≤20% | Analytes in the LCS that fail high and are ND in the samples can be reported. All others are re-digested and re-analyzed. | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| Duplicate | 1 per prep batch of up to 20 samples | RPD must be ≤20% | Flag data | ELLE Analyst | Precision | Results within acceptance limits |
| Serial Dilutions | Must be prepared with each background sample, evaluated only when analyte concentrations are >50x the LOQ | The percent difference must be ≤10% | Flag data | ELLE Analyst | Precision | Results within acceptance limits |

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Post Digestion Spike | Prepare with each background sample | ± 20% True Value | No specific action needed unless required by the project. PDS is reported in data package | ELLE Analyst | Accuracy/Bias | Results within acceptance criteria |
| Internal Standard | Every sample and QC | Must be 30%-120% of the calibration blank | Re-analyze at a dilution | ELLE Analyst | Precision | Results within acceptance criteria |

## Worksheet #28-8

Matrix: Aqueous/Solids
Analytical Group: Metals- Hg
Concentration Level: Low
Analytical Method/SOP Reference: SW-846 7470A /WI7965
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Method Blank | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample | Re-analyze blank to confirm detections. If detects confirm, redigest samples that are not ND or not >10x the blank value. | ELLE Analyst | Accuracy/Laboratory Contamination | Results within acceptance limits |
| MS/MSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0; RPD ≤20% | Flag outliers | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| LCS/LCSD | 1 per prep batch of up to 20 samples | Recovery limits per QSM 6.0; RPD ≤20% | Analytes in the LCS that fail high and are ND in the samples can be reported. All others are re-digested and re-analyzed. | ELLE Analyst | Accuracy/Bias/Precision | Results within acceptance limits |
| Duplicate | 1 per prep batch of up to 20 samples | RPD must be ≤20% | Flag data | ELLE Analyst | Precision | Results within acceptance limits |

## Worksheet #28-9

Matrix: Aqueous/Solids
Analytical Group: Total Organic Carbon (TOC)/Dissolved Organic Carbon (DOC)
Concentration Level: Low
Analytical Method/SOP Reference: SM 5310C-2014 WI11637 9060A; WI11627
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Method blanks | 1 per prep batch of up to 20 samples | No analytes detected > MDL or >1/10 the amount measured in any sample | Re-analyze blank to confirm detections. If detects confirm, re-prep samples that are not ND or not >10x the blank value. | ELLE Analyst | Accuracy/Laboratory Contamination | Results within acceptance limits |
| MS | 1 per 10 samples | Laboratory Statistical Limits | Flag outliers | ELLE Analyst | Accuracy/Bias | Results within acceptance limits |
| LCS | 1 per prep batch of up to 20 samples | Method windows or Laboratory Statistical Limits if tighter | Correct problem, reprepare and re-analyze the LCS and all sample associated | ELLE Analyst | Accuracy/Bias | Results within acceptance limits |
| Duplicate | 1 per 10 samples | Laboratory statistical RPD | Flag data | ELLE Analyst | Precision | Results within acceptance limits |

## Worksheet #28-8

Matrix: Solids
Analytical Group: Cation Exchange Capacity (CEC)
Concentration Level: Low
Analytical Method/SOP Reference: SW-846 6010D/WI11931 and SW-846 9081/WI7562
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Method Blank | 1 per prep batch of up to 20 samples | No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample | Re-analyze blank to confirm detections. If detects confirm, redigest samples that are not ND or not >10x the blank value. | ELLE Analyst | Accuracy/Laboratory Contamination | Results within acceptance limits |
| Duplicate | 1 per prep batch of up to 20 samples | RPD must be ≤20% | Flag data | ELLE Analyst | Precision | Results within acceptance limits |

## Worksheet #28-9

Matrix: Aqueous/Solids
Analytical Group: Total Organic Carbon (TOC)/Dissolved Organic Carbon (DOC)
Concentration Level: Low
Analytical Method/SOP Reference: SM 5310C-2014 WI11637 9060A; WI11627
Analytical Organization: ELLE

| QC Sample | Frequency/Number | Method/SOP QC Acceptance Limits | Corrective Action | Person(s) Responsible for Corrective Action | Data Quality Indicator (DQI) | Measurement Performance Criteria |
|---|---|---|---|---|---|---|
| Method blanks | 1 per prep batch of up to 20 samples | No analytes detected > MDL or >1/10 the amount measured in any sample | Re-analyze blank to confirm detections. If detects confirm, re-prep samples that are not ND or not >10x the blank value. | ELLE Analyst | Accuracy/Laboratory Contamination | Results within acceptance limits |
| MS | 1 per 10 samples | Laboratory Statistical Limits | Flag outliers | ELLE Analyst | Accuracy/Bias | Results within acceptance limits |
| LCS | 1 per prep batch of up to 20 samples | Method windows or Laboratory Statistical Limits if tighter | Correct problem, reprepare and re-analyze the LCS and all sample associated | ELLE Analyst | Accuracy/Bias | Results within acceptance limits |
| Duplicate | 1 per 10 samples | Laboratory statistical RPD | Flag data | ELLE Analyst | Precision | Results within acceptance limits |

# Worksheet #29 – Project Documents and Records

All project files will be held by the JV until the USACE PM requests transfer of items. However, all important project files and deliverables will be uploaded to the FUDSCHem database.

| Record | Generation | Verification | Storage Location/Archival |
|---|---|---|---|
| **Sample Collection and Field Records** | | | |
| Field Logbook or Data Collection Sheets (field forms) | Field Sampler or FTL or Designee | RI TM | Project File (electronically on Contractor Server and within FUDSChem) |
| Field SOPs | FTL or Designee | RI TM | Project File /Included as Attachments to QAPP |
| Chain-of-Custody Forms | Sample Manager or Designee | FTL or Designee | Project File/included in laboratory SDGs |
| Air Bills | Sample Manager or Designee | FTL or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Sample Tracking Forms | Sample Manager or Designee | FTL or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Daily Quality Control (QC) Reports | FTL or Designee | RI TM or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Deviations from Scope of Work - Field Change Notification Forms (Refer to Appendix C of the Project-Specific Quality Management Plan) | FTL or Designee | RI TM or Designee | Project File (electronically on Contractor Server and within FUDSChem). Appendix C of the Project-Specific Quality Management Plan |
| Corrective Action Reports | FTL | FTL or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Correspondence | FTL | FTL or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Soil Boring Logs /Groundwater Elevation Logs | FTL or Designee | Field Geologist or Designee | Project File (electronically on Contractor Server and within FUDSChem library) and Final Report. |
| Water Quality Data Logs (field parameters) | FTL or Designee | Field Geologist or Designee | Project File /Field parameters (EMI and GWD) will be loaded into FUDSChem. |
| Equipment Calibration and Maintenance Logs | FTL or Designee | Field Scientist or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Photographs | FTL or Designee | Field Scientist or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Field Equipment Inspection and Maintenance records | FTL or Designee | Field Geologist or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Monitoring Well Construction Diagrams | FTL or Designee | Field Geologist or Designee | Project File /to be included in FUDSCHem library and Final Report. |

| Record | Generation | Verification | Storage Location/Archival |
|---|---|---|---|
| Waste Manifests | FTL or Designee | Field Scientist or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| **Project Assessments** | | | |
| Audit Plans and Reports | Auditor | QA Manager or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Field Audit Checklists | Auditor | QA Manager or Designee | Project File (electronically on Contractor Server and within FUDSChem) |
| Corrective Action Report | QA Manager | FTL | Project File (electronically on Contractor Server and within FUDSChem) |
| Self-Assessment Checklist | FTL or Designee | QA Specialist | Project File (electronically on Contractor Server and within FUDSChem) |
| Data Verification Checklists | FTL or Designee | ASC | Project File/to be included in Data Validation Reports. |
| Data Validation Report | Data validator | Chemist | Project File/to be included in FUDSCHem library and Final Report. |
| Data Usability Assessment Report | Chemist and project team | Chemist | Project File/to be included in FUDSCHem library and Final Report. |
| **Laboratory Records** | | | |
| Bid Sheets, Scopes of Work | RI TM or Designee | Technical Reviewer and Procurement Specialist | Procurement File |
| Subcontract Laboratory Certifications | Laboratory QA Officer | Chemist or QA Specialist | Procurement File/included as Attachment to QAPP |
| Laboratory SOPs | Laboratory QA Officer | Chemist or QA Specialist | Procurement File/included as Attachment to QAPP |

**Laboratory Data Deliverables to be loaded to FUDSChem library**

# Worksheets #31, #32, and #33 – Assessments and Corrective Action

Periodic assessments may be performed during the course of the project so that the planned project activities are implemented in accordance with this UFP-QAPP. The routine data quality verification steps described in Worksheet #34 will be used to assess the effectiveness of the project data reporting system. If additional assessments become necessary; this worksheet will be amended as needed.

| Assessment Type | Responsible Party and Organization | Frequency | Assessment Deliverable | Timeframe of Response | Person(s) Responsible for Response and Implementing Corrective Actions | Person(s) Responsible for Monitoring Corrective Action Implementation |
|---|---|---|---|---|---|---|
| Field Procedure Assessment | Russ McCormick, Field Team /EAS WSP JV | Weekly | Internal e-mail | 1 business day | Field Team Lead | Russ McCormick/EAS WSP JV |
| Field Documentation Reviews | Russ McCormick/EAS WSP JV | Weekly | Internal e-mail | 3 business days | Field Team Lead | Russ McCormick/EAS WSP JV |
| Sample Condition Report/ Log-in receipt | Michael Shadle/EAS WSP JV | After sample receipt at laboratory. | External e-mail if laboratory issue. Internal e-mail if JV issue. | 24-48 hours after notification | Laboratory log-in personnel if sample ID error, or JV if sample collection issue. | Michael Shadle/EAS WSP JV |
| Analytical Discrepancy | Michael Shadle/EAS WSP JV | After data receipt from laboratory and during data validation. | External e-mail | 7 business days | Barbara Weyandt/Eurofins | Michael Shadle/EAS WSP JV |
| Data Validation Reports | Michael Shadle/EAS WSP JV | Prepared for each Sample Delivery Group. | FUDSChem Data Validation reports | 21 days after receipt of certified EDD and completed data package. | Michael Shadle/EAS WSP JV | Russ McCormick/EAS WSP JV |

# Worksheet #34 – Data Verification and Validation Inputs

The following three-step data review will be performed: Step I (verification) will confirm that all sampling and analytical requirements have been met. Step II (validation) will assess whether the sampling and analytical processes comply with the contract-specific and the UFP-QAPP specific requirements. Step III (usability assessment) will determine whether the resulting data are suitable as a basis for the decision being made. Worksheets #34, #35, and #36 describe the processes to be followed for the three steps, respectively.

This worksheet establishes the procedures that will be followed to verify project data, including, but not limited to, sampling documents and analytical data package.

| Item | Description | Verification (completeness) | Validation (conformance to specifications) |
|---|---|---|---|
| **Planning Documents/Records** | | | |
| 1 | Approved QAPP | X | |
| 2 | Contract | X | |
| 3 | Field SOPs | X | |
| 4 | Laboratory SOPs | X | |
| **Field Records, as needed** | | | |
| 5 | Field logbooks/Daily Reports | X | |
| 6 | Equipment calibration records | X | |
| 7 | Chain-of-Custody Forms | X | |
| 8 | Sampling diagrams/surveys | X | |
| 9 | Drilling logs | X | |
| 10 | Relevant Correspondence | X | |
| 11 | Change orders/deviations | X | |
| 12 | Field audit reports, if audited | X | |
| 13 | Field corrective action reports | X | |
| 14 | Photographs | X | |
| 15 | Sampling forms | X | |
| 16 | Well development forms | X | |
| 17 | Water level forms | X | |
| **Analytical Data Packages[a]** | | | |
| 18 | Cover sheet (laboratory identifying information) | X | X |
| 19 | Case narrative | X | X |
| 20 | Internal laboratory chain-of-custody | X | |
| 21 | Sample receipt records | X | X |
| 22 | Sample chronology (i.e., dates and times of receipt, preparation, & analysis) | X | |
| 23 | Communication records | X | X |
| 24 | LOD/LOQ establishment and verification | X | |
| 25 | Standards Traceability | X | |
| 26 | Instrument calibration records | X | |
| 27 | Definition of laboratory qualifiers | X | X |
| 28 | Results reporting forms | X | X |
| 29 | QC sample results | X | X |
| 30 | Corrective action reports | X | X |
| 31 | Raw data | X | X |
| 32 | Electronic data deliverable | X | X |
| 33 | Air Bills | X | X |

(a) The items to be reviewed during the validation process are determined by the validation stage as specified in Worksheet #36.

# Worksheet #35 – Data Verification Procedures

| Records Reviewed | Requirement Documents | Description | Responsible Person, Organization |
|---|---|---|---|
| Field Logbook/Daily Reports | Field SOPs (Appendix D), Daily Reports, Field Corrective Action Reports | Verify that records are present and complete for each day of field activities, and daily reports are submitted. Verify that all planned samples including field QC samples were collected and that sample collection locations are documented. Verify that meteorological data were provided for each day of field activities. Verify that changes/exceptions are documented and were reported in accordance with requirements. Verify that field instruments were calibrated appropriately, and field monitoring was performed as required, and results are documented. | Daily – FTL/PM<br>At conclusion of field activities - Project QC Staff |
| COC Forms | Field SOPs (Appendix D), QAPP, and field logbook | Verify the completeness of COC records. Examine entries for consistency with the field logbook. Check that appropriate methods and sample preservation have been recorded. Verify that the required volume of sample has been collected and that sufficient sample volume is available for QC samples (e.g., MS/MSD). Verify that all required signatures and dates are present. Check for transcription errors. | Daily – FTL/PM/Project Chemist - Project QC Staff |
| Laboratory Deliverable | QAPP, eQAPP | Verify that the laboratory deliverable contains all records specified in the QAPP. Check sample receipt records to ensure sample condition upon receipt was noted, and any missing/broken sample containers were noted and reported according to plan. Compare the data package with the COCs to verify that results were provided for all collected samples. Review the narrative to ensure all QC exceptions are described. Check for evidence that any required notifications were provided to project personnel as specified in the QAPP. Verify that necessary signatures and dates are present. Determine potential impacts from noted/approved deviations in regard to Project Quality Objectives (PQOs).<br><br>With the exception of IDW samples, Grain Size, and Methods for which the laboratories are not DoD certified (CEC, 2,4-DNP), analytical data will be verified through FUDSChem, a web-based data review program. IDW samples will not be validated but the data package will be verified for completeness and that limits for expected disposal requirements are met. | Before release - Laboratory QAM<br>Upon receipt – KGS Validator |
| Audit Reports, Corrective Action Reports | QAPP | Verify that all planned audits were conducted. Examine audit reports. For any deficiencies noted, verify that corrective action was implemented according to plan. | Project QC Staff |

This page  intentionally left blank

# Worksheet #36 – Data Validation Procedures

The objective of data validation is to assess the performance associated with the analysis to determine the quality of the data. This will be accomplished by evaluating whether the collected data comply with the predefined requirements of the project, including method, procedural, or contractual requirements and by comparing the collected data with criteria established based on the project DQOs.

All types of data, including screening and definitive data, are relevant to the usability assessment. The following sections focus on the data review requirements for definite data only.

The KGS Project Chemist will be the data validator responsible for reviewing the routine analytical data.

**Validation Code and Label Identifier Table:**

| Validation Code | Validation Label | Description/Reference |

| NV | Not Validated | EPA 540-R-08-005 |

## Data Validation Qualifiers

The following data qualifiers will be applied during DV by WSP. Potential impacts on project DQOs will be discussed in the data usability report.

- U: The analyte was not detected and was reported as less than the LOD (practical quantitation limit [PQL] for non-DoD QSM analyses). The LOD (or PQL) has been adjusted for any dilution or concentration of the sample.
- J: The associated numerical value is an estimated quantity.
- J+: The associated numerical value is an estimated quantity that may be biased high.
- J-: The associated numerical value is an estimated quantity that may be biased low. UJ: The undetected result is estimated due to QC sample considerations.
- X: The sample results (including non-detects) were affected by serious deficiencies in the ability to analyze the sample and to meet published method and project quality control criteria. The presence or absence of the analyte cannot be substantiated by the data provided. Acceptance or rejection of the data should be decided by the project team (which should include a project chemist), but exclusion of the data is recommended.

| Analytical Group/Method | Metals – Aqueous and Solid – SW-846 6020A | Mercury – Aqueous and Solid – SW-846 7470A/7471B |
|---|---|---|
| Data deliverable requirements: | SEDD 2a, version 5.2 with three-tier reporting, Level 4 data package (pdf) and uploaded by the laboratory without errors to FUDSChem within 3 weeks of sample date. | SEDD 2a, version 5.2 with three-tier reporting, Level 4 data package (pdf) and uploaded by the laboratory without errors to FUDSChem within 3 weeks of sample date. |

# Worksheet #37 – Data Usability Assessment

Identify personnel (organization and position/title) responsible for participating in the data usability assessment:

- Project Manager
- Risk Assessor
- Project Chemist
- Data Manager
- Task Leader
- Geologist/Hydrogeologist
- Data Validator
- Data Coordinator
- FTL
- Project Engineer
- Project QA Specialist
- Data Specialist

| | |
|---|---|
| Step 1 | Review the project's objectives and sampling design.<br>Review the key outputs defined during systematic planning (i.e., PQOs or DQOs and method performance criteria [MPCs]) to make sure they are still applicable. Review the sampling design for consistency with stated objectives. This provides the context for interpreting the data in subsequent steps. |
| Step 2 | Review the data verification and DV outputs.<br>Review available QA reports. Perform basic calculations and summarize the data (using graphs, maps, tables, etc.). Look for patterns, trends, and anomalies (i.e., unexpected results). Review deviations from planned activities (e.g., number and locations of samples, holding time exceedances, damaged samples, non-compliant proficiency testing [PT] sample results, and SOP deviations) and determine their impacts on the data usability. Evaluate implications of unacceptable QC sample results. |
| Step 3 | Verify the assumptions of the selected statistical method.<br>If statistics will be used for the project, verify whether underlying assumptions for selected statistical methods (if documented in the QAPP) are valid. Common assumptions include the distributional form of the data, independence of the data, dispersion characteristics, homogeneity, etc. Depending on the robustness of the statistical method, minor deviations from assumptions usually are not critical to statistical analysis and data interpretation. If serious deviations from assumptions are discovered, then another statistical method may need to be selected. |
| Step 4 | Implement the statistical method.<br>Implement the specified statistical procedures for analyzing the data and review underlying assumptions. Consider the consequences for selecting the incorrect alternative; for estimation projects (e.g., establishing a boundary for surface soil impacts), consider the tolerance for uncertainty in measurements. |
| Step 5 | Document data usability and draw conclusions.<br>Determine if the data can be used as intended, considering implications of deviations and corrective actions. Discuss DQIs (see Usability Assessment details below). Assess the performance of the sampling design and Identify limitations on data use. Update the CSM and document conclusions. |

**The usability assessment will be documented as follows:**

The Data Usability tool in FUDSChem will be used to prepare the Data Usability Assessment Report. The Data Usability Assessment will be performed by the project team and a recommendation will be made to the project delivery team. The Project Manager will be responsible for information in the Data Usability Assessment and will also be responsible for assigning task work to the individual task members who will be supporting the Data Usability Assessment. Note that the Data Usability Assessment will be conducted on validated or reviewed data. After the Data Usability Assessment has been performed, data deemed appropriate for use will then be used in the subsequent project evaluation. The results of the Data Usability Assessment will be presented in the project measurement report such as the Risk Assessment, RI or other report. Tables will be prepared of the samples and analytical parameters, field and trip blank results, field duplicates comparison, and completeness of the data set. The following items will be assessed, and conclusions drawn based on their results.

**Describe the evaluative procedures used to assess overall measurement error associated with the project:**

*Precision* – Results of laboratory duplicates will be assessed during DV and data will be qualified according to the DV procedures cited on **Worksheet #36**. Field duplicates will be assessed by matrix using the RPD for each pair of results reported above the LOQ for organic and inorganic analyses respectively. Absolute difference will be used for low results as described in **Worksheet #28**. A discussion summarizing the results of laboratory and field precision and any limitations on the use of the data will be described in the Data Usability Report.

*Field duplicates* – Field duplicates will be evaluated against the MPCs outlined in **Worksheet #12**. The PM will review the extent of exceedance of the field duplicate criteria. For groundwater, the sample results will be flagged according to the DV protocol.

*Accuracy/Bias Contamination* – Laboratory blank results will be assessed as part of DV. During the DV process the validator will qualify the data following the procedures listed on **Worksheet #36**. A discussion summarizing the results of laboratory accuracy and bias based on contamination will be presented and limitations on the use of the data will be described.

*Accuracy/Bias* – The results for all matrix spike and surrogate standard spike analyses will be evaluated based on the requirements listed in **Worksheets #12 and #28**. A discussion will follow, summarizing accuracy and bias. Any conclusions about the accuracy and bias of the analyses will be drawn and any limitations on the use of the data will be described.

*Sensitivity* – Data results will be compared to criteria provided on **Worksheet #15**. A discussion summarizing any conclusions about sensitivity of the analyses will be presented and any limitations on the use of the data will be described.

*Representativeness* – Representativeness is achieved through adherence to sampling and analytical procedures described in this QAPP and compliance with stipulated sample holding times. After evaluation of relative compliance with specified procedures and holding times, conclusions about data representativeness will be drawn and any limitations on the use of data will be described. DV narratives will also be reviewed and any conclusions about the representativeness of the data set will be discussed in the Data Usability Report. Although discrete sampling is being conducted, it does not preclude evaluating the representativeness parameter.

*Comparability* – Study results will be used in conjunction with existing data to make qualitative and quantitative assessments of the data to be used to produce the Site reports.

*Reconciliation* – The DQIs presented in **Worksheet #12** will be examined to determine if the MPCs were met. This examination will include a combined overall assessment of the results of each analysis pertinent to an objective. Each analysis will first be evaluated separately in terms of major impacts observed from DV, DQIs and measurement performance criteria assessments. Based on the results of these assessments, the quality of the data will be determined. As a result of the quality determined, the usability of the data for each analysis will be established. After the combined usability of the data from all analyses for an objective is determined, it will be concluded if the DQIs were met and whether project goals were achieved. As part of the reconciliation of each objective, conclusions will be drawn and any limitations on the usability of any of the data will be described.

*Completeness* – A completeness check will be done on all data generated. The number of planned samples and samples with non-rejected results will be used to calculate the completeness of the obtained data set for each DU/EU, analyte and data use. The field completeness will be calculated by the ratio of the number of samples received in acceptable condition by the laboratories to the number of samples planned to be collected as specified in this document. The equation for field completeness is:

$$\% \text{ Field Completeness} = \frac{\text{Number of Samples Received by Laboratories}}{\text{Total Number of Samples Planned to be Collected}} \times 100$$

The analytical completeness will be calculated by the ratio of total valid analytical data results (including estimated values) to the total number of analytical results requested on samples submitted for analysis. Valid analytical data results are defined as those that were not rejected during DV, due to a significant quality assurance/quality control problem. The equation for analytical completeness is:

$$\% \text{ Analytical Completeness} = \frac{\text{Total Valid Analytical Data}}{\text{Analytical Data Obtained}} \times 100$$

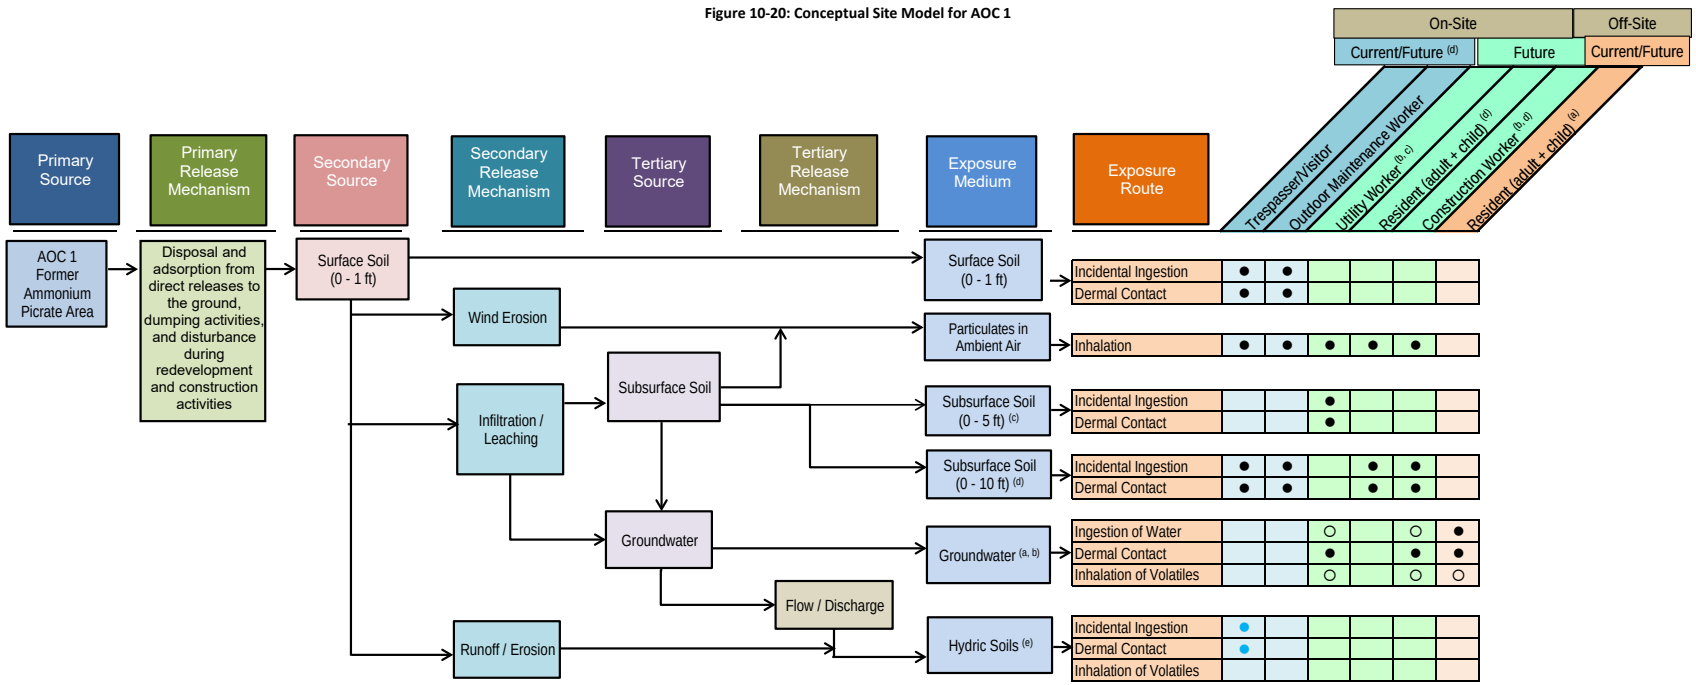
**Figure 10-19**

**Potable Well Survey**

**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works**
**Baldwinsville, New York**
**December 2022**

D:\GIS\NYOW\TripReport_P1_AOC134ISMBkgd\Fig 2 - Potable Well Survey.mxd 10/27/2021 10:33 Bluestone Environmental Group, Inc.

**Figure 10-20: Conceptual Site Model for AOC 1**



Indicates a potentially complete migration pathway

| | |
|---|---|
| ● | Potentially complete exposure pathway |
| ○ | Potentially complete but insignificant exposure pathway |
| | Exposure not applicable |
| ● | Potentially complete exposure pathway depending on results of Phase 2 sampling event. |

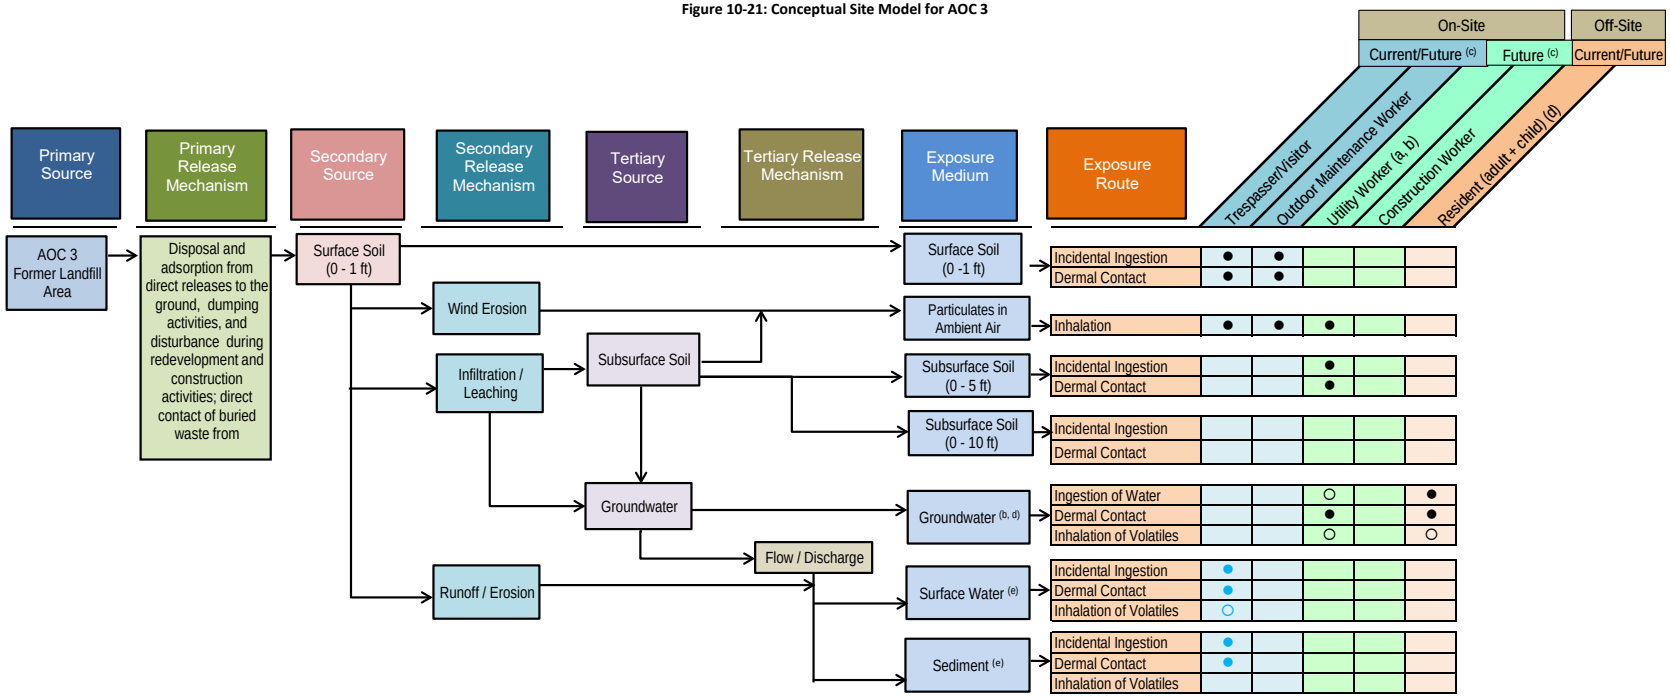
Notes:

(a) Groundwater on-Site is not currently used as a drinking water source and potable water is supplied by the Onondaga County Water Authority; therefore, a groundwater potable use scenario for the on-Site future residents will not be included. However, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for an off-Site nearby resident. There are no VOCs among contaminants of potential concern at this AOC; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater are considered incomplete exposure pathways.
(b) The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers and construction workers are likely to encounter groundwater during an excavation on-Site. The groundwater ingestion pathway has been deemed insignificant as the amount of water incidentally ingested is going to be de minimis. The inhalation of volatiles exposure route is deemed complete but insignificant due to ambient air mixing and wind dispersal and will not be quantitatively evaluated.
(c) Utility workers are assumed to install or repair utility lines such that incidental ingestion, dermal contact, and inhalation exposure to COPCs that are present between surface and 5 ft bgs may potentially occur. The soil is assumed to be placed back in the hole once work has been completed.
(d) Construction worker is assumed to be exposed to soil within the 0-10 ft bgs interval. It is assumed that subsurface soils are brought to the surface as a result of construction work during redevelopment of the Site, which would mean that future receptors would also be exposed to COPCs in the 0-10 ft range as it is assumed that subsurface soils are brought to the surface, mixed amd used to regrade the Site during redevelopment activities.
(e) Discrete surface soil sampling of hydric soils from wetland areas are planned for the Phase 2 investigation. Standing surface water is not present at the wetlands; therefore, surface water samples will not be collected and hydric soil samples will be evaluated under a sediment exposure scenario.

Acronyms:

AOC = area of concern
bgs = below ground surface
COPC = contaminant of potential concern
ft = feet
VOC = volatile organic compound

**Figure 10-21: Conceptual Site Model for AOC 3**



Indicates a potentially complete migration pathway

| | |
|---|---|
| ● | Potentially complete exposure pathway |
| ○ | Potentially complete but insignificant exposure pathway |
| | Exposure not applicable |
| ● | Potentially complete exposure pathway depending on results of Phase 2 sampling event. |
| ○ | Potentially complete but insignificant exposure pathway depending on results of Phase 2 sampling event. |

Notes:

(a) Utility workers are assumed to install or repair utility lines such that incidental ingestion, dermal contact, and inhalation exposure to COPCs that are present between surface and 5 ft bgs may potentially occur. The soil is assumed to be placed back in the hole once work has been completed.

(b) The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers are likely to encounter groundwater during an excavation on-Site. The groundwater ingestion pathway has been deemed insignificant as the amount of water incidentally ingested is going to be de minimis. The inhalation of volatiles exposure route is deemed complete but insignificant due to ambient air mixing and wind dispersal and will not be quantitatively evaluated.

(c) No major construction work is expected in this area as AOC 3 is a former landfill. As such, there will be no subsurface soils brought to the surface as a result of construction work during redevelopment of the Site, which would mean that future receptors would also be exposed to COPCs originating between 0-10 ft bgs.

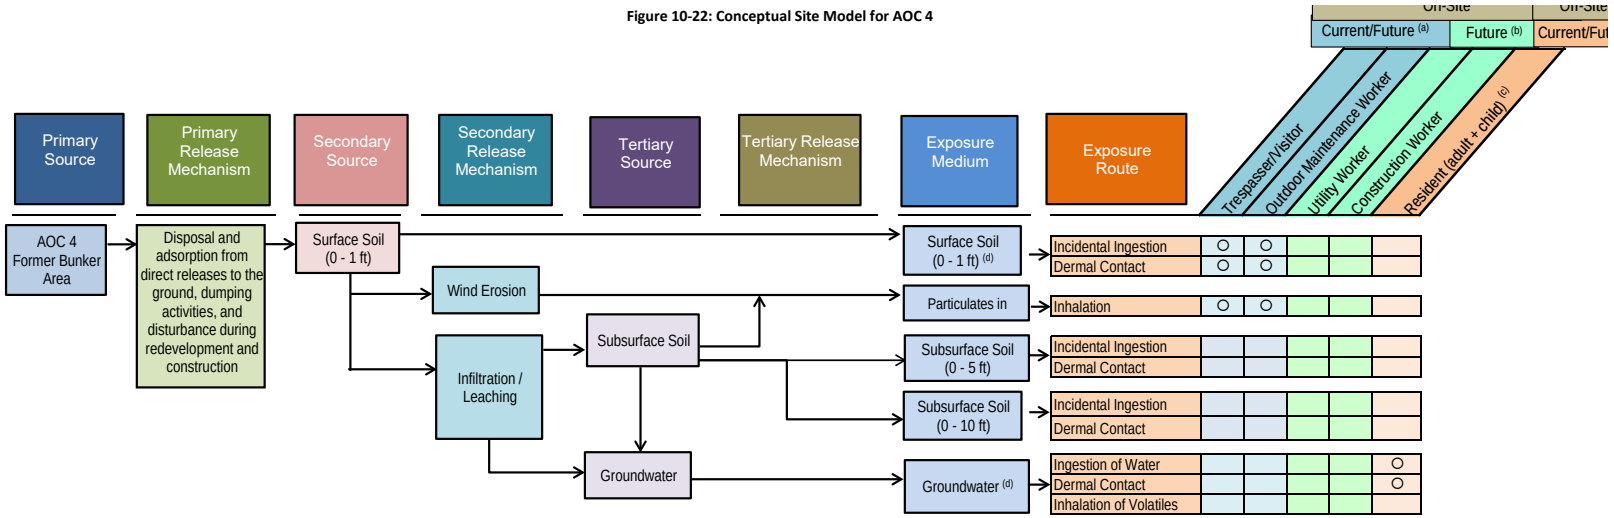
(d) Groundwater on-site is not currently used as a drinking water source and potable water is supplied by the Onondaga County Water Authority. However, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for the hypothetical residents. Benzene was the only VOC detected in groundwater but the maximum detected benzene concentration is below the USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for groundwater set to a target cancer risk of 1E-06 and a hazard quotient (HQ) of 0.1; therefore, the inhalation of volatiles exposure route has been designated as potentially complete but insignificant and will not be quantitatively evaluated.

(e) Surface water and sediment samples are planned during the Phase 2 investigation for the unnamed stream located north of AOC 3. Should VOCs be detected in surface water, inhalation of volatiles is assumed to be an insignificant exposure due to ambient air mixing and wind dispersal.

Acronyms:

AOC = area of concern
bgs = below ground surface
COPC = contaminant of potential concern
ft = feet
VOC = volatile organic compound

**Figure 10-22: Conceptual Site Model for AOC 4**



Indicates a potentially complete migration pathway

| | |
|---|---|
| ● | Potentially complete exposure pathway |
| ○ | Potentially complete but insignificant exposure pathway |
| | Exposure not applicable |

Notes:

(a) AOC 4 is located within the Three Rivers State Wildlife Management Area. Current and future use of this area is wildlife management with remaining bunkers used for maintenance equipment and vehicle storage. The only potential current and future receptors are trespasser/visitor and outdoor maintenance worker to COPCs remaining in surface soil.

(b) There are no plans for future development thus, no future utility or construction work likely to occur in this AOC that is a wildlife management area..

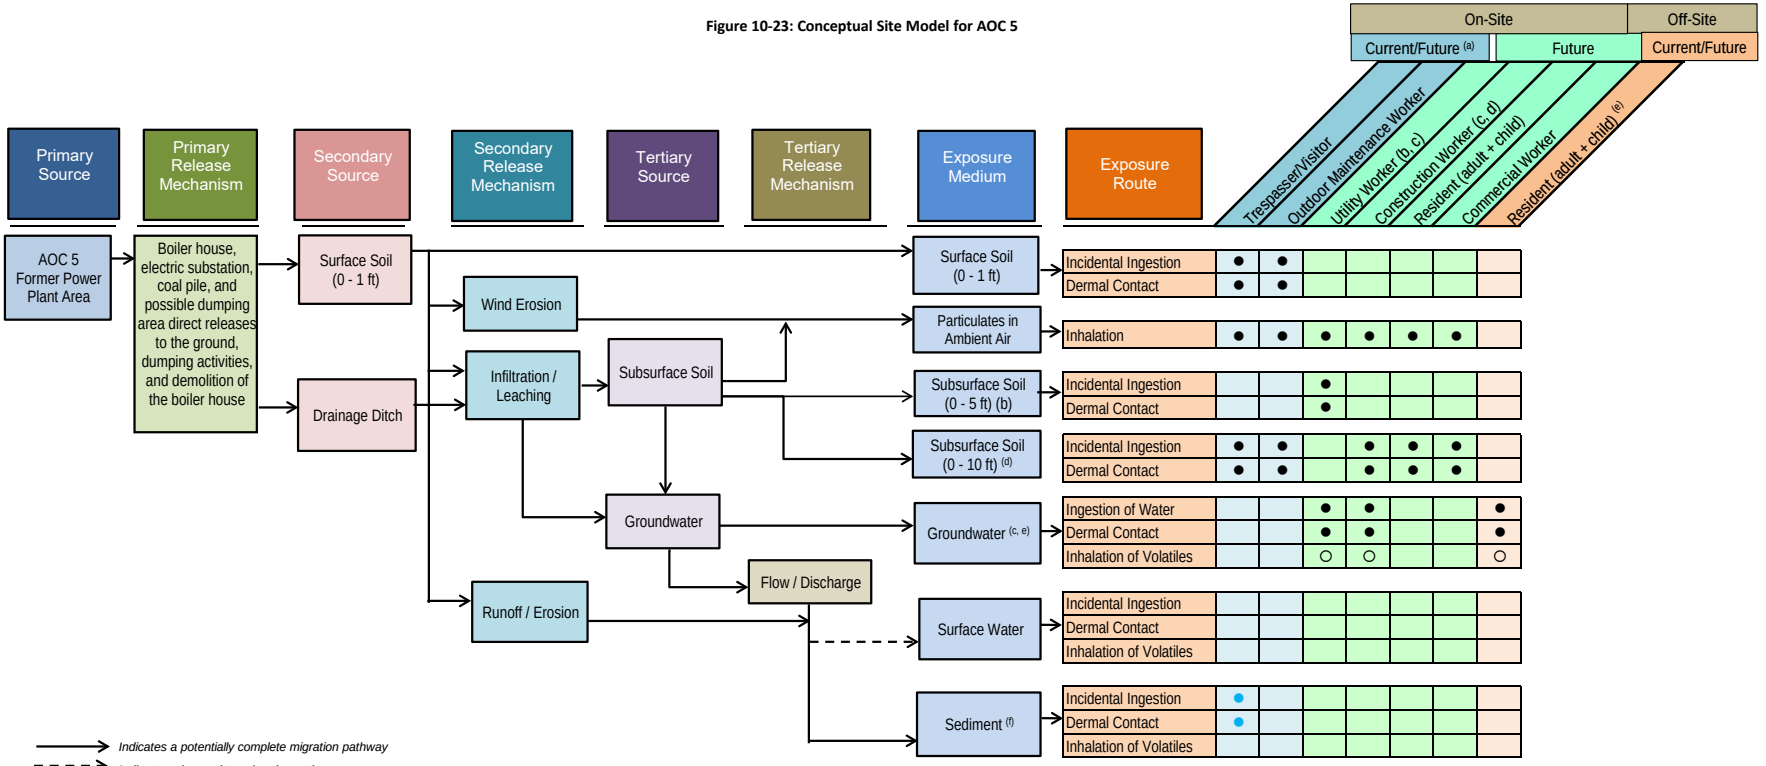
(c) Groundwater on-site is not currently used as a drinking water source as potable water is supplied by the Onondaga County Water Authority; however, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for the hypothetical residents. There are no VOCs among contaminants of concern; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater used as drinking water by current or future nearby residents are not considered applicable pathways.

(d) Soil and groundwater samples collected in Phase 1 were nondetect for 2,4-DNCB, 2,4-DNP, and picric acid; therefore, although exposure to surface soil and groundwater may occur, exposures are deemed insignificant. Surface soil sampling during Phase 2 may result in a revised CSM depending on the analytical results.

Acronyms:

2,4-DNP = 2,4-dinitrophenol
2,4-DNCB = 2,4-dinitrochlorobenzene
AOC = area of concern
bgs = below ground surface
COPC = contaminant of potential concern
ft = feet
VOC = volatile organic compound

**Figure 10-23: Conceptual Site Model for AOC 5**



Notes:

(a) Current soil exposures assume no intrusive activities and exposures are associated with COPCs in the surface soil. For future soil exposures, it is assumed that subsurface soils are brought to the surface as a result of construction work during redevelopment of the Site, which would mean that future receptors would be exposed to COPCs in the 0-10 ft range as it is assumed that subsurface soils are brought to the surface and mixed during redevelopment regrading activities.

(b) Utility worker is assumed to be exposed to soil within the 0-5 ft bgs interval while installing or repairing utility lines. The soil is assumed to be placed back in the hole once work has been completed.

(c) The water table is anticipated to be encountered between 2 to 13 ft bgs in the source areas; therefore, utility workers and construction workers are likely to encounter groundwater during an excavation on-Site. The inhalation of volatiles exposure route is deemed complete but insignificant due to ambient air mixing and wind dispersal.

(d) Construction worker is assumed to be exposure to soil within the 0-10 ft bgs interval. Soils at depth are assumed to be mixed with surface soil such that exposure to soils for a future scenario entails contact with soils from 0-10 ft being as this interval would be used to regrade the Site.

(e) Groundwater on-site is not currently used as a drinking water source; however, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource is considered potentially complete pathways for the hypothetical residents. There is no groundwater USEPA Vapor Intrusion Screening Level (VISL, USEPA, 2022) for 1,2,3-trichlorobenzene because this chemical does not have sufficient inhalation toxicity information. However, the maximum detected 1,2,3-trichlorobenzene concentration is below the 1,2,4-trichlorobenzene VISL(used as a surrogate) for groundwater set to a target risk level of 1E-06 and a hazard quotient of 0.1. Therefore, inhalation exposure is assumed to be insignificant.

(f) Discrete surface soil sampling of hydric soils from wetland areas are planned for the Phase 2 investigation. Standing surface water is not present at the wetlands; therefore, surface water samples will not be collected and hydric soil samples will be evaluated under a sediment exposure scenario.

Acronyms:

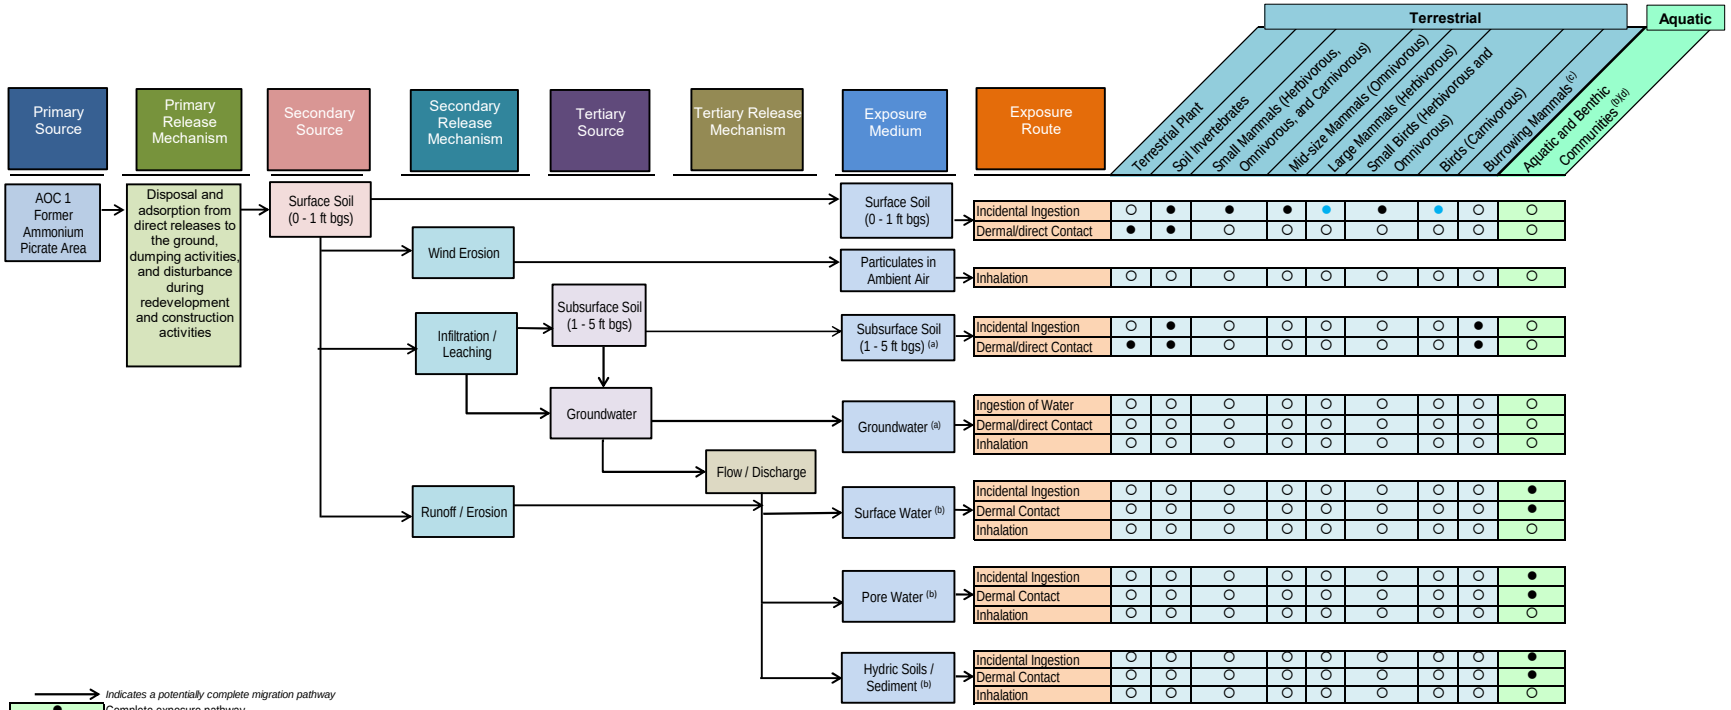
AOC = area of concern

bgs = below ground surface

COPC = contaminant of potential concern

ft = feet

**Figure 10-24 Preliminary Ecological Conceptual Site Model: AOC 1 – Former Ammonium Picrate Area**



Notes:

(a) Chemical concentrations in discrete subsurface soil samples were compared to appropriate ecological screening levels as part of the Phase 1 risk screening (Subsection 5.7) process and will be used to determine the need for additional sampling and subsequent risk evaluation.

(b) Surface water, pore water, and sediment may be sampled as part of a phased assessment of groundwater contamination and will only be considered if DOD-related COPECs identified in groundwater are potentially discharging to nearby wetland areas.

(c) Burrowing mammals are included in the "small mammal" receptor category when considering surface soil exposure.

## TABLE OF CONTENTS

## VOLUME 1:

1.0 INTRODUCTION ..... 1-1
1.1 OBJECTIVES ..... 1-1
1.2 APPROACH ..... 1-1
1.3 REPORT ORGANIZATION ..... 1-2
2.0 AVAILABLE DATA ..... 2-1
3.0 DATA USABILITY ..... 3-1
3.1 DATA VALIDATION ..... 3-1
3.2 DATA USABILITY ASSESSMENT SUMMARY ..... 3-1
3.2.1 AOC 1 DUA Findings ..... 3-1
3.2.2 AOC 3 DUA Findings ..... 3-3
3.2.3 AOC 4 Discrete DUA Findings ..... 3-4
3.2.4 AOC 4 ISM DUA Findings ..... 3-5
3.2.5 AOC 5 DUA Findings ..... 3-6
3.2.6 Background DUA Findings ..... 3-8
3.3 INITIAL CONCLUSIONS – DATA USABILITY ..... 3-10
3.4 SAMPLE-LEVEL LESSONS LEARNED ..... 3-10
4.0 DATA REDUCTION ..... 4-1
5.0 RISK SCREENINGS ..... 5-1
5.1 ANALYTES WITHOUT SCREENING VALUES OR FOR WHICH THE LOQ IS GREATER THAN THE PAL ..... 5-1
5.1.1 Analytes Without Screening Values ..... 5-1
5.1.1.1 Selection of Surrogates for DoD-related and Potentially DoD-related Analytes ..... 5-2
5.1.1.2 Analytes that are Unlikely to be DoD-related ..... 5-3
5.1.2 Analytes for Which the LOQ is Greater than the PAL ..... 5-3
5.1.2.1 DoD-related and Potentially DoD-related Analytes ..... 5-4
5.1.2.2 Analytes that are Unlikely to be DoD-related ..... 5-4
5.1.3 Initial Conclusions – Analytes without Screening Values or for Which the LOQ is Greater than the PAL ..... 5-4
5.2 NON-DETECT ANALYTES FOR WHICH THE LOQ IS LESS THAN A SCREENING LEVEL ..... 5-5
5.3 ANALYTES NOT RELATED TO DOD ACTIVITIES ..... 5-5
5.3.1 Literature Review Results ..... 5-6
5.3.2 AOC-Specific Constituent Characterization ..... 5-6
5.3.3 Initial Conclusions – Analytes Not Related to DoD Activities ..... 5-7
5.4 BACKGROUND COMPARISONS ..... 5-7

5.4.1 Background Threshold Value Development ..... 5-7
5.4.1.1 Site Versus Background Surface Geologic Unit Comparison ..... 5-8
5.4.1.1.1 Grain Size Distribution ..... 5-9
5.4.1.1.2 Total Organic Carbon ..... 5-10
5.4.1.1.3 Cation Exchange Capacity ..... 5-10
5.4.1.1.4 Geochemical Ratios ..... 5-11
5.4.1.1.5 LMW and HMW PAHs ..... 5-12
5.4.1.1.6 Pyrogenic and Petrogenic PAHs ..... 5-13
5.4.1.1.7 Summary and Recommendations ..... 5-14
5.4.1.2 Intra-Background Soil Concentration Comparisons ..... 5-14
5.4.1.2.1 Intra-Background Soil Depth Interval Conclusions ..... 5-15
5.4.1.2.2 Intra-Background Surface Geologic Unit Conclusions ..... 5-17
5.4.1.3 Background Threshold Value Calculation ..... 5-20
5.4.2 Comparisons of Site Concentrations to BTVs ..... 5-21
5.4.3 Initial Conclusions – Background Comparisons ..... 5-22
5.5 NATURE, FREQUENCY OF DETECTION, MAGNITUDE, AND SPATIAL DISTRIBUTION ..... 5-23
5.5.1 Initial Conclusions – Nature, Frequency of Detection, Magnitude, and Spatial Distribution ..... 5-24
5.6 HUMAN HEALTH RISK SCREENING ..... 5-25
5.7 ECOLOGICAL RISK SCREENING ..... 5-27
6.0 RISK SCREENING RESULTS AND DISCUSSION ..... 6-1
6.1 INTRODUCTION ..... 6-1
6.2 RESULTS ..... 6-1
6.2.1 Human Health ..... 6-1
6.2.1.1 AOC 1 Human Health Risk Screening ..... 6-1
6.2.1.2 AOC 3 Human Health Risk Screening ..... 6-1
6.2.1.3 AOC 5 Boiler House Human Health Risk Screening ..... 6-2
6.2.1.4 AOC 5 Coal Aggregate Bins Area Human Health Risk Screening ..... 6-2
6.2.1.5 AOC 5 Coal Storage Area Human Health Risk Screening ..... 6-3
6.2.1.6 AOC 5 Electric Substation Human Health Risk Screening ..... 6-3
6.2.1.7 AOC 5 Possible Dump Area Human Health Risk Screening ..... 6-3
6.2.1.8 Human Health Risk Screening Discussion ..... 6-4
6.2.2 Ecological ..... 6-5
6.2.2.1 AOC 1 Ecological Risk Screening ..... 6-5
6.2.2.2 AOC 3 Ecological Risk Screening ..... 6-6
6.2.2.3 AOC 5 Boiler House Ecological Risk Screening ..... 6-6
6.2.2.4 AOC 5 Coal Aggregate Bins Area Ecological Risk Screening ..... 6-7
6.2.2.5 AOC 5 Coal Storage Area Ecological Risk Screening ..... 6-8

6.2.2.6 AOC 5 Electric Substation Ecological Risk Screening ....6-8
6.2.2.7 AOC 5 Possible Dump Area Ecological Risk Screening....6-9
6.2.2.8 Ecological Risk Screening Discussion....6-10
6.2.3 Initial Conclusions – Risk Screening Results and Discussion ....6-11
6.3 UNCERTAINTY ANALYSIS ....6-21
6.3.1 Data ....6-21
6.3.1.1 Media ....6-21
6.3.1.2 Analytes with Screening Levels Not Achieved at the LOQ ....6-21
6.3.1.3 Data Reduction ....6-23
6.3.1.4 Sample Size....6-23
6.3.2 COPC Selection ....6-24
6.3.3 Exposure ....6-24
6.3.4 Toxicity ....6-24
6.4 DISCUSSION ....6-26
6.4.1 Groundwater ....6-26
6.4.2 Soil ....6-27
6.4.2.1 Human Health ....6-28
6.4.2.2 Ecological ....6-29
7.0 CONCEPTUAL SITE MODEL UPDATES....7-1
7.1 SURFACE GEOLOGY ....7-1
7.2 BEDROCK ....7-2
7.3 HYDROGEOLOGY ....7-3
7.4 SOURCES OF DRINKING WATER....7-4
7.5 WETLANDS AND AQUATIC RESOURCES ....7-5
7.6 AOC 3 GEOPHYSICAL SURVEY – SUSPECTED LANDFILL AREA....7-5
7.7 AOC 5 GEOPHYSICAL SURVEY – POSSIBLE DUMP AREA....7-6
7.8 AOC 5 – OTHER POTENTIAL SOURCES ....7-7
7.8.1 Historical Drainage Ditch ....7-7
7.8.2 Source of PAHs and Metals ....7-7
7.9 POTENTIAL RECEPTORS AND EXPOSURE PATHWAYS....7-8
7.9.1 Potential Human and Ecological Exposure Pathways ....7-9
7.9.1.1 Potential Human Health Receptors and Exposure Routes ....7-10
7.9.1.2 Potential Ecological Receptors and Exposure Routes ....7-11
7.10 INITIAL CONCLUSIONS – CONCEPTUAL SITE MODEL UPDATES ....7-12
8.0 DATA GAPS ANALYSIS....8-1
8.1 PHASE 1 RISK SCREENING AND DATA GAPS ANALYSIS OBJECTIVES ....8-1
8.1.1 Assess Data Usability....8-1

8.1.2 Determine Presence or Absence of DoD-related CERCLA Constituents Above Risk-based Screening Levels and Background Concentrations ..... 8-2
8.1.3 Identify Potential Source Areas and/or Areas of Higher Concentrations ..... 8-2
8.1.4 Focus Additional Fieldwork ..... 8-3
8.2 POTENTIAL DATA GAPS ..... 8-3
8.2.1 AOC 1 ..... 8-4
8.2.2 AOC 3 ..... 8-5
8.2.3 AOC 4 ..... 8-5
8.2.4 AOC 5 ..... 8-6
8.2.5 Background ..... 8-7
8.2.6 Sampling and Analytical ..... 8-7
8.2.7 Surrogate Chemicals and Chemicals Without Screening Levels ..... 8-9
9.0 RECOMMENDATIONS FOR PHASE 2 ..... 9-1
9.1 AOC 1 ..... 9-1
9.2 AOC 3 ..... 9-2
9.3 AOC 4 ..... 9-3
9.4 AOC 5 ..... 9-3
9.5 BACKGROUND AREA ..... 9-4
9.6 SAMPLING AND ANALYTICAL ..... 9-5
9.7 SURROGATE CHEMICALS AND CHEMICALS WITHOUT SCREENING LEVELS ..... 9-6
9.8 CONSTITUENTS OF POTENTIAL CONCERN FOR EVALUATION DURING PHASE 2 9-6
9.9 SUMMARY OF SUGGESTED PHASE 2 FIELD SAMPLING ..... 9-16
10.0 REFERENCES ..... 10-1

## VOLUME 2:

## LIST OF APPENDICES

**Appendix A** Phase 1 Risk Screening Approach Technical Memorandum

**Appendix B** Data Usability Assessment

**Appendix C** Data Reduction Support Tables

Appendix C.1 LOQ Censoring
Appendix C.2 PAH summation support

**Appendix D** Reduced Datasets

Appendix D.1 Reduced Dataset – Groundwater
Appendix D.2 Reduced Dataset – Soil

**Appendix E** Comparison of Non-detect Analyte LOQs with Screening Levels

Appendix E.1 Sample by Sample Comparison Tables
Appendix E.2 Non-detect Analytes – Frequency Exceeding Screening Levels

**Appendix F** Site Versus Background Surface Geologic Unit Comparison

Appendix F.1 Data Summary Tables (Augmented RAGS 2)
Appendix F.2 Grain Size
Appendix F.3 Total Organic Carbon
Appendix F.4 Cation Exchange Capacity
Appendix F.5 Geochemical Analysis
Appendix F.6 Low Molecular Weight and High Molecular Weight PAHs
Appendix F.7 Pyrogenic and Petrogenic PAH Evaluation

**Appendix G** Intra-Background Soil Concentration Comparison

Appendix G.1 Depth Interval Comparisons
Appendix G.2 Geologic Unit Comparisons

**Appendix H** Background Threshold Value Calculation Backup

**Appendix I** Comparison of Site Concentrations to Background Threshold Values

**Appendix J** Human Health Screening Level Comparisons

Appendix J.1 Human Health Sample by Sample Screening – Groundwater
Appendix J.2 Human Health Sample by Sample Screening – Soil
Appendix J.3 Human Health Screening Summary – Groundwater
Appendix J.4 Human Health Screening Summary – Soil

**Appendix K** Resource Receptor Inventory

**Appendix L** Ecological Screening Level Comparisons

Appendix L.1 Plant Sample by Sample Screening – Soil
Appendix L.2 Soil Invertebrate Sample by Sample Screening – Soil
Appendix L.3 Bird Sample by Sample Screening – Soil
Appendix L.4 Mammal Sample by Sample Screening – Soil
Appendix L.5 Ecological Screening Summary – Plants
Appendix L.6 Ecological Screening Summary – Soil Invertebrates
Appendix L.7 Ecological Screening Summary – Birds
Appendix L.8 Ecological Screening Summary – Mammals

# ACRONYMS AND ABBREVIATIONS

| | |
|---|---|
| 2,4-DNCB | 2,4-Dinitrochlorobenzene |
| 2,4-DNP | 2,4-Dinitrophenol |
| ADR | Automated Data Review |
| Al | Aluminum |
| AMSL | Above Mean Sea Level |
| an/(an+ph) | anthracene/(anthrancene+phenanthrene) |
| ANCOVA | Analysis of Covariance |
| AOC | Area of Concern |
| ASTM | American Society for Testing and Materials |
| B/N | Base Neutral |
| BaA/(BaA+chry) | benzo(a)anthracene/(benzo(a)anthracene+chrysene) |
| BH | Benjamini-Hochberg |
| Bluestone | Bluestone Environmental Group, Inc. |
| BNASIM | Base/Neutral/Acid Extractable Compounds by Selective Ion Monitoring |
| BTV | Background Threshold Value |
| CCV | Continuing Calibration Verification |
| CEC | Cation Exchange Capacity |

# 1.0 INTRODUCTION

Bluestone Environmental Group, Inc. (Bluestone) was tasked by the United States Army Corps of Engineers (USACE), New England District (CENAE) under Contract Number W912WJ-19-D-0001, Task Order W912WJ19F0056 to complete Remedial Investigation (RI), Feasibility Study (FS), Proposed Plan (PP) and Decision Document (DD) activities at the Former New York Ordnance Works (NYOW), Formerly Used Defense Site (FUDS) in Baldwinsville, New York (Property No. C02NY0290).

This report presents the Data Usability Assessment, Phase 1 Risk Screenings, and Data Gaps Analysis for Areas of Concern (AOCs) 1, 3, 4, and 5 and is based on the data collected during the RI Phase 1 field investigations. RI Phase 1 field investigations were completed in 2021 and were detailed in the *Final RI Phase 1 Field Report – AOC 4 and AOC 5* (USACE, 2021) and the *Final RI Phase 1 Field Report – AOCs 1, 3, 4 ISM, and Background* (USACE, 2022). The available data are discussed in more detail in **Section 2** of this report. Recommendations also are presented herein for additional RI field activities (i.e., Phase 2). An RI Report will be prepared upon the completion of all field activities.

The report objectives, approach, and organization are presented below.

## 1.1 OBJECTIVES

The objectives of this report are as follows.

- Assess the usability of the analytical data collected as part of the Phase 1 field investigations.
- Assess if any Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) constituents related to historical Department of Defense (DoD) activities are present, and if these constituents are present above risk-based screening levels and background concentrations.
- Identify potential source areas and/or areas of higher concentrations.
- Focus additional fieldwork to collect data for an RI and to meet risk assessment-related Data Quality Objectives (DQOs) if potential impacts from DoD-related constituents are indicated.

Whether these objectives were met is discussed in **Subsection 8.1**.

## 1.2 APPROACH

The Phase 1 Risk Screening approach was developed in conjunction with the New York Ordnance Works (NYOW) Site USACE project delivery team (PDT) and Environmental and Munitions Center of Expertise (EMCX). The *New York Ordnance Works Phase 1 Risk Screening Approach Technical Memorandum, Final* (Bluestone, 2022) is included as **Appendix A** of this document.

Prior to implementing the RI Phase 1 Risk Screening approach, the usability of the data was determined in accordance with the project's Uniform Federal Policy-Quality Assurance Project Plan (UFP-QAPP) Worksheet #37, *Data Usability Assessment* (DUA; USACE, 2020). The DUA is included as **Appendix B** of this document and is summarized in **Subsection 3.2**.

## 1.3 REPORT ORGANIZATION

The remainder of this report is organized as follows:

- Section 2 – Available Data
- Section 3 – Data Usability Summary
- Section 4 – Data Reduction
- Section 5 – Risk Screenings
- Section 6 – Risk Screening Results and Discussion
- Section 7 – Conceptual Site Model Update
- Section 8 – Data Gaps Analysis
- Section 9 – Recommendations for Phase 2
- Section 10 – References

# 2.0 AVAILABLE DATA

Historical chemistry data are available for the Site from reports ranging from 1981 through 2008. During writing of the *Uniform Federal Policy for Quality Assurance Project Plan* (UFP-QAPP) (USACE, 2020), it was determined that those data are of limited use due to issues associated with their age (e.g., comparability with recently collected data). Therefore, only data collected during the Phase 1 field efforts are included in this Phase 1 Risk Screening and Data Gaps Analysis. The Phase 1 field collection efforts were completed in 2021 as follows.

1) January 2021 – AOC 5;
2) February 2021 – AOC 4, discrete sampling;
3) March/April 2021 – AOCs 1 and 3;
4) May 2021 – Background and investigation-derived waste (IDW); and
5) June 2021 – AOC 4, incremental sampling methodology (ISM) sampling.

The locations of the AOCs and background sample areas with respect to the entire NYOW Site are provided on **Figure 2-1**. **Figures 2-2 through 2-10** show all Phase 1 sample locations. All work was completed in accordance with applicable Federal, State, and local regulations, as well as industry standards and best management practices. In general, samples were collected and analyzed in accordance with the *Final Uniform UFP-QAPP* (USACE, 2020), with any deviations noted in the *RI Phase 1 Field Report – AOC 4 and AOC 5* (USACE, 2021) or *RI Phase 1 Field Report – AOCs 1,3, 4 ISM, and Background* (USACE, 2022), as applicable.

Field documents, field data, and laboratory data were loaded into and managed within the Formerly Used Defense Sites Chemical (FUDSChem) database.

Separate screenings (described in **Section 5**) were conducted for each of the following four AOCs:

- Ammonium Picrate Area (AOC 1);
- Former Landfill Area (AOC 3);
- Bunker Area (AOC 4); and
- Former Power Plant Area (AOC 5).

For AOC 4, the surface soil data from the discrete and ISM samples were screened separately.

AOC 5 was divided into five subareas based on historical use and potential source areas as follows:

- Boiler House;
- Coal Aggregate Bins;
- Coal Storage Area;
- Electric Substation; and
- Possible Dump.

With the exception of ISM samples collected from surface soil (0 to 1 feet below ground surface [ft bgs]) in the bunker aprons of AOC 4, all samples collected were discrete soil samples collected from 0 to 10 ft bgs (i.e., 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs). ISM data were not collected from the same sampling units as the discrete samples and were screened independently of data collected using conventional discrete

samples. Refer to **Section 5** for more details on the screening approach. If, in the future, based on the Phase 1 Risk Screening and data gaps analysis, ISM samples were to be collected from a sampling unit (SU) overlapping existing discrete samples used in the Phase 1 risk screening, only the ISM results would be evaluated in the risk assessment (USACE, 2020).

**Table 2-1** summarizes the number of samples per medium (and depth interval for soils) available for use in this Phase 1 Risk Screening and Data Gaps Analysis for each AOC and the background area. **Tables 2-2** through **2-6** present the analyses conducted per sample, for each AOC and background. Soil and groundwater analytical results presented in this Phase 1 Risk Screening and Data Gaps Analysis are based on validated data that were subjected to data reduction steps outlined in **Section 4**. Validated analytical results without the data reduction steps applied are presented as appendices to the field investigation reports (USACE, 2021 and 2022) and are not presented herein.

Five primary surface soil samples were collected at two AOC 5 subareas, the Coal Aggregate Bins and Coal Storage Area, and analyzed for coal and coal ash by a combination of microscopy techniques for a total of ten primary samples at AOC 5 (plus one duplicate sample). Coal was detected in moderate to very heavy concentrations in all samples submitted for analysis, excluding sample NYOW-05-SL022-A (in the Coal Aggregate Bins subarea). Coal ash was detected in trace to moderate concentrations in samples NYOW-05-SL022-A and NYOW-05-SL024-A in the Coal Aggregate Bins subarea. Coal ash results are further evaluated in **Section 8.1.3**, to aid in the interpretation of polycyclic aromatic hydrocarbon (PAH) concentrations detected within AOC 5.

To facilitate determining appropriate background datasets for the Site, geologic units for each sample were determined. Soil geologic groupings presented within correspond with the final boring logs submitted to CENAE on 10 February 2022. The Site has three distinct surface geologic units (lacustrine silt and clay [Psc]; sorted sand and gravel [Ps]; and diamicton (till) [Pd]). The surface soil interval (i.e., 0 to 1 ft bgs) is categorized as topsoil. Geologic units assigned to the soil borings are presented in **Table 2-7**. **Table 2-8** presents a summary of the geologic unit distribution. The AOC 4 groupings are included for informational purposes only. The DoD-specific compounds of concern in AOC 4 are explosives and explosives do not represent a background condition; therefore, AOC 4 will not be compared to background. The significance of the geology will be discussed in the RI.

Two background sample borings (NYOW-B-047 and NYOW-B-048) were determined to be fill due to the presence of non-native materials, such as brick and concrete fragments, in the shallow interval above the native soil. Fill in borings appears to be indicative of localized backfilling or grading activities, as opposed to landfilling or dumping activities. Samples from borings in fill were excluded from the dataset used to calculate background threshold values (BTVs) as they may contain concentrations not representative of native soil.

# 3.0 DATA USABILITY

## 3.1 DATA VALIDATION

Analytical data were uploaded to FUDSChem by Eurofins/TestAmerica and then validated by Bluestone. Data validation was performed in accordance with the *U.S. Department of Defense (DoD) General Data Validation Guidelines* (16 September 2019), the *DoD Data Validation Guidelines Module 1* (11 May 2020), the United States Environmental Protection Agency's (EPA) *National Functional Guidelines for Organic Superfund Methods Data Review* (January, 2017), the EPA's *National Functional Guidelines for Inorganic Superfund Methods Data Review* (January, 2017), the *Uniform Federal Policy Quality Assurance Project Plan* (UFP-QAPP) (USACE, 2020), and the specifics of the methods employed. Data validation reports were generated for all laboratory analytical data upon completion of the review. Data validation reports are included in **Appendix B**.

Bluestone's data validation was performed to conform with Stage 2B guidelines as defined by EPA in *Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use*, EPA 540-R-08-005 for combined automated and manual data verification and validation. Automated data review was performed using the Automated Data Review (ADR) module in FUDSChem for all quality control summary results as provided by the Laboratory in the Staged Electronic Data Deliverable (SEDD) files submitted with the data packages. No calibration information is included in this file format; therefore, all calibrations (initial and continuing) were evaluated manually. Sample results for grain size distribution and cation exchange capacity (CEC) underwent Stage 1 manual validation.

## 3.2 DATA USABILITY ASSESSMENT SUMMARY

The purpose of the DUA report is to determine if the DQOs outlined in the UFP-QAPP (USACE, 2020) were met. The laboratory sample delivery groups (SDGs) that are included in the data usability assessment for each investigation are listed in **Appendix B**. In accordance with Worksheet #37 (DUA) of the UFP-QAPP, the DUA included the following elements:

- Data Collection Objective and Sampling Design – determine whether the collected data are of the right type and quantity to support decision-making for the project.
- Data Quality Indicator (DQI) Evaluation – evaluate data quality indicators (precision, accuracy/bias, representativeness, comparability, completeness, and sensitivity).
- Statistical Method Evaluation – verify whether the underlying assumptions for the selected statistical method are valid; consider the consequences for selecting the incorrect alternative and/or the tolerance for uncertainty in measurements.
- Conclusions – describe how data quality issues will be addressed and how limitations of the use of the data will be handled.

### 3.2.1 AOC 1 DUA Findings

Based on this assessment of DQIs for AOC 1, the data obtained during the site investigation are of sufficient quantity and quality to support the Phase 1 investigation and human health and ecological risk screenings (**Appendix B Section 2.1.3**). Furthermore, the quantity and quality of data are sufficient to update the conceptual site model (CSM) and support the identification of data gaps. The rejected surface soil result for

2,4-dinitrophenol (DNP) in AOC 1 does not affect the overall usability of the dataset. A description of the findings that may affect future RI activities at AOC 1 is presented below. All findings associated with accuracy are presented in **Appendix B**; however, the findings presented below are limited to those affecting greater than 20% of results to focus the evaluation of data gaps. The findings presented below offer only a general assessment of precision; all findings associated with precision are presented in **Appendix B**.

Surface and Subsurface Soil Findings

1. Samples were not collected at two locations (NYOW-01-003 and NYOW-01-004) because Bluestone did not have right-of-entry (ROE) for either property. These borings could not be relocated and may represent an existing data gap.
2. Soil sample heterogeneity was documented through the analysis of field duplicate (FD) and matrix spike/matrix spike duplicate (MS/MSD) sample pairs, affecting primarily metals and TOC in surface soil and subsurface soil. Soil heterogeneity is defined as a parent/FD relative percent difference (RPD) greater than 50%, MS/MSD RPD for metals greater than 20%, or MS/MSD RPD for TOC greater than 20%. The specific FD and RPD outliers identified during data validation are presented in **Appendix B Section 2.2.1.3**. Uncertainty related to soil sample heterogeneity should be considered and options to improve soil characterization and support the calculation of representative mean sample concentrations for metals should be identified.
3. 2,4-Dinitrochlorobenzene (DNCB) in surface soil had low bias attributable to low surrogate recoveries at a frequency greater than 20% of samples (8 in 30 samples, or 27%). 2,4-DNCB in subsurface soil also had low bias attributable to low surrogate recoveries at a frequency greater than 20% of samples (6 in 22 samples, or 27%). There was no obvious indication that chromatographic interference was responsible for the low recoveries based on a review of the sample chromatograms and the data are considered usable; however, suppressed recoveries may be attributable to sample matrix. The extraction efficiency of EPA Method 3546 is comparable or better than other available methods; therefore, the selected extraction method may be retained for future sampling events.
4. All of the 2,4-DNP surface and subsurface soil sample results were non-detect, with the limits of quantitation (LOQs) and limits of detection (LODs) greater than the ecological Project Action Limits (PALs). One surface soil sample had a positive detection for picric acid; the remaining surface and subsurface soil results were non-detect, with the LOQs and LODs greater than the PAL. The PALs for 2,4-DNP and picric acid are not attainable with contemporary analytical methodology; exceedances of these PALs were anticipated prior to sampling as documented in the UFP-QAPP (USACE, 2020). See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

Groundwater Findings

1. The planned groundwater sample from NYOW-01-003 could not be collected because Bluestone did not have ROE for the property. The unsampled location may represent a data gap.
2. At AOC 1, all of the 2,4-DNP groundwater sample results were non-detect, with the LOQ and LOD greater than the PAL. The PAL for 2,4-DNP is not attainable with contemporary analytical methodology; exceedances of the PAL were anticipated prior to sampling as documented in the UFP-QAPP (USACE, 2020). The PALs for all metal analytes in groundwater were met by the

LOQs, with the exception of antimony, arsenic, cadmium, mercury, nickel, selenium, silver, thallium, and vanadium. Of those analytes, the PALs were met by the LODs for nickel, silver, and vanadium. Cadmium and selenium were analyzed by Method 6010C; changing to Method 6020A may be warranted for future sampling events to improve analytical sensitivity. See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

### 3.2.2 AOC 3 DUA Findings

Based on this assessment of DQIs for AOC 3, the data obtained during the site investigation are of sufficient quantity and quality to support the Phase 1 investigation and human health and ecological risk screenings (**Appendix B Section 2.1.4**). Furthermore, the quantity and quality of data are sufficient to update the CSM and support the identification of data gaps. A description of the findings that may affect future RI activities at AOC 3 is presented below. The findings presented below offer only a general assessment of precision; all findings associated with precision are presented in **Appendix B**.

Surface and Subsurface Soil Findings

1. Soil sample heterogeneity was documented through the analysis of FD and MS/MSD sample pairs, affecting primarily PAHs in surface soil and PAHs and metals in subsurface soil. Soil heterogeneity is defined as a parent/FD RPD greater than 50%, MS/MSD RPD for metals greater than 20%, or MS/MSD RPD for PAHs greater than 40%. The specific FD and RPD outliers identified during data validation are presented in **Appendix B Section 2.2.1.4**. Heterogeneity can result in over- or underestimating contaminant concentrations and lead to decision errors. Uncertainty related to soil sample heterogeneity should be considered and options to improve soil characterization and support the calculation of representative mean sample concentrations for PAHs and metals should be identified.

2. Due to their clay matrix, eight of the 32 (25%) soil samples collected from AOC 3 could not be thoroughly homogenized by the laboratory before sub-sampling and extraction for polychlorinated biphenyls (PCBs), semi-volatile organic compound (SVOC), and PAH analyses were performed. Heterogeneity can result in over- or underestimating contaminant concentrations and lead to decision errors. Uncertainty related to soil sample heterogeneity should be considered and options to improve soil characterization and support the calculation of representative mean sample concentrations for PCBs, SVOCs, and PAHs should be identified.

3. All of the 2,4-DNP and picric acid surface and subsurface soil sample results were non-detect, with the LOQs and LODs greater than the ecological PALs. The PALs for 2,4-DNP and picric acid are not attainable with contemporary analytical methodology; exceedances of these PALs were anticipated prior to sampling as documented in the UFP-QAPP (USACE, 2020). See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

Groundwater Findings

1. The PALs for all PAH analytes in groundwater were met by the LOQs, with the exception of benzo(a)anthracene, benzo(a)pyrene, and dibenz(a,h)anthracene. PAHs in groundwater were

analyzed by the more sensitive analytical method (i.e., Base/Neutral/Acid Extractable Compounds by Selected Ion Monitoring [BNASIM]). The PALs for all metal analytes in groundwater that were not met by LOQs were either attained by the LOD or were analyzed by the more sensitive analytical technique (i.e., Inductively Coupled Plasma-Mass Spectrometry [ICP-MS]), with the exception of cadmium and selenium. Cadmium and selenium may be analyzed by Method 6020A during Phase 2 Sampling events. The groundwater PALs for PCBs were not met. Future sampling of PCBs could employ concentrated extracts during sample preparation; however, PCBs were not identified as risk-drivers in soil and are not soluble in water. PCBs may represent a current data gap in the AOC 3 groundwater investigation area. See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

2. All groundwater 2,4-DNP sample results were non-detect, with the LOQs and LODs greater than the human health PAL. The PAL for 2,4-DNP is not attainable with contemporary analytical methodology; exceedance of this PAL was anticipated prior to sampling as documented in the UFP-QAPP (USACE, 2020).

### 3.2.3 AOC 4 Discrete DUA Findings

Based on this assessment of DQIs for AOC 4, the data obtained during the site investigation are of sufficient quantity and quality to support the Phase 1 investigation and human health and ecological risk screenings (**Appendix B Section 2.1.2**). Furthermore, the quantity and quality of data are sufficient to update the CSM and support the identification of data gaps. The rejected groundwater result for picric acid in AOC 4 is downgradient and bounded by results that are considered usable. A description of the findings that may affect future RI activities at AOC 4 is presented below. All findings associated with accuracy are presented in **Appendix B**; however, the findings presented below are limited to those affecting greater than 20% of results to focus the evaluation of data gaps. The findings presented below offer only a general assessment of precision; all findings associated with precision are presented in **Appendix B**.

Surface and Subsurface Soil Findings

1. All of the 2,4-DNP and picric acid surface and subsurface soil sample results were non-detect, with the LOQs and LODs greater than ecological PALs. The PALs for 2,4-DNP and picric acid are not attainable with contemporary analytical methodology; exceedances of these PALs were anticipated prior to sampling as documented in the UFP-QAPP (USACE, 2020). See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

Groundwater Findings

1. Temporary monitoring wells were not developed, and discrete groundwater samples were collected using a peristaltic pump as grab samples in accordance with the UFP-QAPP. Upon initial discharge of groundwater from the sampling tubing, the field water quality parameters were measured, and samples were collected without development, purging, or field parameter stabilization. Sample turbidity ranged from 10.8 NTU (NYOW-04-004) to the upper instrument limit (> 1,000 NTU). The presence of particles in the sample may result in an overestimation of groundwater concentrations for all analytical parameters; however, all of the groundwater sample results were non-detect for the AOC-4 target analytes. The effect of particulate in groundwater samples on the

reported concentration cannot be assessed during data validation. It is noted that 9 of 16 groundwater samples (approximately 56%) clogged the solid phase extraction (SPE) cartridge (i.e., flow rate <4 mL/min) during extraction for the explosives analysis and one sample (NYOW-04-WL005-A) required vacuum filtration through glass fiber filter paper prior to analysis due to turbidity. While the extraction volumes were sufficient to avoid re-preparation of the samples at dilutions, the reduced extraction volumes may impact representativeness. It is possible that the extraction efficiency was compromised for those samples with high particulate load and reduced flow rates due to the small volume of solvent employed and the short contact time. Installation of permanent wells may address elevated turbidity, potential low bias of samples with low extraction efficiency, and potential representativeness concerns for samples with low extraction volume.

2. The following analytes in groundwater had low bias qualifiers primarily attributable to low surrogate recoveries at a frequency greater than 20% of samples: 2,4-DNCB at 45% and picric acid at 30%. The picric acid result for one groundwater sample (NYOW-04-WL080-A) was rejected based on surrogate recovery of less than 10% but all other results are considered usable. Installation of permanent monitoring wells may be necessary to obtain representative groundwater samples from AOC 4.

3. In AOC 4, all 2,4-DNP sample results in groundwater were non-detect, with the LOQs and LODs greater than the human health PAL. The PAL for 2,4-DNP is not attainable with contemporary analytical methodology; exceedance of this PAL was anticipated prior to sampling as documented in the UFP-QAPP (USACE, 2020). See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

### 3.2.4 AOC 4 ISM DUA Findings

Based on this assessment of DQIs for AOC 4 ISM, the data obtained during the site investigation are not of sufficient quantity and quality to support the Phase 1 investigation and human health and ecological risk screenings at all of the decision units (DUs) (**Appendix B Sections 2.1.4 and 2.2.8.5**). A description of the findings that may affect future RI activities at AOC 4 is presented below. All findings associated with accuracy are presented in **Appendix B**; however, the findings presented below are limited to those affecting greater than 20% of results to focus the evaluation of data gaps. The findings presented below offer only a general assessment of precision; all findings associated with precision are presented in **Appendix B**.

ISM Surface Soil Findings

1. The ISM samples for SVOC analysis of 2,4-DNP and 2,4-DNCB underwent the complete ISM processing and subsampling procedures, rather than having aliquots removed for SVOC analysis and moisture content prior to drying, as was specified in the UFP-QAPP. The decision to process ISM samples for the SVOC analysis was based on information provided in the ISM Update guidance (Interstate Technology and Regulatory Council [ITRC], 2020) regarding the loss potential of various SVOCs during air drying and the consideration that air exposure at the laboratory was not likely to produce analyte loss for surface soils that have been exposed to ambient air for many years. In addition, there is no laboratory control spike solid reference material (LCSSRM) available that contains the SVOC analytes 2,4-DNCB and 2,4-DNP, and the explosives LCSSRM does not contain picric acid. As a result, the impact that air drying and sample milling to generate a flour-

like matrix may have on the recovery of all analytes cannot be quantified. If ISM samples are collected in the future, air drying and milling of ISM samples analyzed for 2,4-DNCB and 2,4-DNP may be avoided and LCSSRMs for target analytes should be identified by the analytical laboratory.

2. Generally low surrogate recoveries were associated with the ISM samples for SVOC analysis. The laboratory added an equivalent mass of Ottawa Sand to the samples before reanalysis to increase solvent contact with the flour-like soil matrix generated by milling; however, this approach did not typically improve surrogate recoveries.

3. 2,4-DNCB in ISM surface soil had low bias attributable to low surrogate recoveries at a frequency greater than 20% of samples (33 of 34 samples, or 97%). 2,4-DNP had low bias attributable to low surrogate recoveries at a frequency greater than 20% of samples (27 of 29 samples, or 93%). Picric acid had low bias attributable to low surrogate and MS recoveries at a frequency greater than 20% of samples (9 of 36 samples, or 25%). The uniformly low bias of ISM results reported as non-detect may represent a data gap at AOC 4.

4. For Decision Unit 1, all three replicates had results rejected for low bias of 2,4-DNP based on low MS/MSD recoveries. For Decision Unit 5, one replicate had results rejected for 2,4-DNCB and 2,4-DNP due to holding time exceedances. At Decision Unit 9, all three replicates had results rejected for low bias of 2,4-DNP due to an MSD that did not recover. For Decision Unit 10, one replicate had the result for 2,4-DNCB rejected based on a low surrogate recovery. All other Decision Units had usable results for all three replicates. Three valid ISM replicates are considered necessary to provide information regarding the reproducibility and heterogeneity of the data; therefore, the lack of three valid replicates may represent a data gap at the AOC 4 ISM Decision Units.

5. All of the 2,4-DNP and picric acid ISM soil sample results were non-detect, with the LOQs and LODs greater than the invertebrate and mammal ecological PALs. The PALs for 2,4-DNP and picric acid are not attainable with contemporary analytical methodology; exceedances of these PALs were anticipated prior to sampling as documented in the UFP-QAPP (USACE, 2020). See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

### 3.2.5 AOC 5 DUA Findings

Based on this assessment of DQIs for AOC 5, the data obtained during the site investigation are of sufficient quantity and quality to support the Phase 1 investigation and human health and ecological risk screenings (**Appendix B Section 2.1.1**). Furthermore, the quantity and quality of data are sufficient to update the Conceptual Site Model (CSM) and support the identification of data gaps. The rejected results in AOC 5 are for compounds not likely to be DoD-related nor risk drivers; however, analytical completeness for base/neutral (B/N) extractable SVOCs was less than 90% for many compounds in groundwater. The data needs will continue to be assessed by the project team as findings are evaluated and the CSM evolves. A description of the findings that may affect future RI activities at AOC 5 is presented below. All findings associated with accuracy are presented in **Appendix B**; however, the findings presented below are limited to those affecting greater than 20% of results to focus the evaluation of data gaps. The findings presented below offer only a general assessment of precision; all findings associated with precision are presented in **Appendix B**.

Surface and Subsurface Soil Findings

1. Due to an equipment failure at the laboratory, TOC results at AOC 5 were usable, but uniformly biased low. While microbial degradation is significantly reduced by storing samples at 4°C, some loss of organic material can occur, and the loss is exacerbated by prolonged storage. The bioavailability of many constituents is dependent upon the TOC content. In general, higher TOC leads to lower bioavailability and subsequently, a lower potential for toxicity. Given that the Site TOC results were compared to background TOC results, the low-biased TOC results may represent a data gap.

2. Soil sample heterogeneity was documented through the analysis of FD and MS/MSD sample pairs. Imprecision affecting primarily PAHs and metals in surface soil and metals in subsurface soil was identified. Soil heterogeneity is defined as a parent/FD RPD greater than 50%, MS/MSD RPD for metals greater than 20%, or MS/MSD RPD for PAHs greater than 40%. The specific FD and RPD outliers identified during data validation are presented in **Appendix B Section 2.2.1.1**. Surface soil heterogeneity of PAHs is likely attributable to their anthropogenic (pyrogenic) disposition and the depositional mechanism of PAH transport to the shallow soil interval. Uncertainty related to soil sample heterogeneity should be considered and options to improve soil characterization and support the calculation of representative mean sample concentrations for PAHs and metals should be identified.

3. The following analytes in surface soil had usable results with low bias primarily attributable to low surrogate or MS/MSD recoveries at a frequency greater than or equal to 20% of samples (5 in 25 samples, or 20%): benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, fluoranthene, dibenz(a,h)anthracene, indeno(1,2,3-cd)pyrene, and pyrene. Analytes in subsurface soil had usable results low bias attributable to low surrogate or MS/MSD recoveries affecting more than 20% of samples (10 in 50 samples, or 20%) included benzo(a)pyrene, benzo(g,h,i)perylene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene. These low recoveries may be associated with the significantly greater difficulty in homogenizing clay soil and extracting PAHs from high clay content soil due to the strong adsorption of PAHs to clay surfaces. The extraction efficiency of EPA Method 3546 (microwave-assisted extraction [MAE]) is comparable or better than available alternatives (e.g., Soxhlet and ultrasonic extraction); therefore, the selected extraction method may be retained for future sampling events. For the Phase 1 sampling event, samples were field homogenized by thorough mixing in a Ziplock bag. Future discrete soil samples may be homogenized sequentially, first in quarter-sample segments and then in combined half-sample and full sample segments (EPA, 1995). Quartering samples for manual homogenization is described by EPA (1995), followed by remixing of opposite quarters (combined half-sample) and full sample mixing. Uncertainty related to soil sample heterogeneity should be considered and options to improve the representativeness of soil samples should be identified.

4. To reduce the impact to sensitive habitat areas, mapped wetland areas were avoided by relocating two soil borings. Wetland avoidance may have resulted in a data gap for collection of spatially representative soil samples at AOC 5 that may be addressed in the Phase 2 Investigation, if necessary.

Groundwater Findings

1. Temporary monitoring wells were not developed, and discrete groundwater samples were collected using a peristaltic pump as grab samples in accordance with the UFP-QAPP. Upon initial discharge of groundwater from the sampling tubing, the field water quality parameters were measured, and samples were collected without development, purging, or field parameter stabilization. Sample turbidity ranged from 30.2 Nephelometric Turbidity Units (NTU; NYOW-05-008) to the upper instrument limit (> 1,000 NTU). The presence of particles in the sample may result in an overestimation of groundwater concentrations for all analytical parameters. The effect of particulate in groundwater samples on the reported concentration cannot be assessed during data validation. Installation of permanent monitoring wells may be necessary to obtain representative groundwater samples from AOC 5.

2. All three groundwater samples collected from the Possible Dump (NYOW-05-WL001-A, NYOW-05-WL004-A, and NYOW-05-WL005-A) did not attain PALs for PCBs. Future sampling of PCBs could employ concentrated extracts during sample preparation; however, PCBs were not identified as risk-drivers in soil and are not soluble in water. See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

3. All 12 groundwater samples from AOC 5 had low B/N surrogate recoveries. Results for B/N compounds associated with well locations NYOW-05-WL-024-A (west of the Dual Coal Aggregate Bins A&B) and NYOW-05-WL-010-A (within the southern portion of the Coal Storage Area) were rejected based on surrogate recoveries less than 10%. Installation of permanent wells may lessen matrix effects in Phase 2 Sampling; PCBs and B/Ns may represent a current data gap in the AOC 5 groundwater investigation area.

4. The PALs for PAHs in groundwater (benzo(a)anthracene, benzo(a)pyrene, and dibenz(a,h)anthracene) that were not met by LOQs were analyzed by the more sensitive analytical technique (i.e., BNASIM). With the exception of cadmium and selenium, the PALs for aqueous metals that were not met by the LOQ were either attained by the LOD or were analyzed by the more sensitive analytical technique (i.e., ICP-MS). Cadmium and selenium may be analyzed by EPA Method 6020A during Phase 2 Sampling events to achieve lower LOQs. See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

### 3.2.6 Background DUA Findings

Based on this assessment of DQIs for background, the data obtained during the site investigation are of sufficient quantity and quality to support the Phase 1 investigation and human health and ecological risk screenings (**Appendix B Section 2.1.6**). Furthermore, the quantity and quality of data are sufficient to update the CSM and support the identification of data gaps. A description of the findings that may affect future RI activities is presented below. All findings associated with accuracy are presented in **Appendix B**; however, the findings presented below are limited to those affecting greater than 20% of results to focus the evaluation of data gaps. The findings presented below offer only a general assessment of precision; all findings associated with precision are presented in **Appendix B**.

Surface and Subsurface Soil Findings

1. The objective of the subsurface soil sampling to obtain 15 samples for each soil type was not achieved; however, the sample size is sufficient (i.e., n ≥ 8) to compare site soil to background using summary statistics (e.g., ranges, means, medians, standard deviations), exploratory graphical displays (e.g., side-by-side box plots) and to calculate BTVs (Bluestone, 2022). In the case of AOC 5, where the investigation is an initial Site Investigation (SI), any comparisons with background is for informational purposes and not used to eliminate methods and/or analytes from further investigation (Bluestone, 2022). Due to wetland avoidance, the Psc unit could not be sampled south of the edge of the wetland, resulting in a potential data gap.

2. Soil sample heterogeneity was documented through the analysis of FD and MS/MSD sample pairs, affecting PAHs and metals in surface soil and subsurface soil. Soil heterogeneity is defined as a parent/FD RPD greater than 50%, MS/MSD RPD for metals greater than 20%, or MS/MSD RPD for PAHs greater than 40%. The specific FD and RPD outliers identified during data validation are presented in **Appendix B Section 2.2.1.6**. Uncertainty related to soil sample heterogeneity should be considered and options to improve soil characterization and support the calculation of representative mean sample concentrations for PAHs and metals should be identified.

3. The following analytes in surface soil had usable results with low bias primarily attributable to low surrogate or MS/MSD recoveries at a frequency greater than 20% of samples (9 in 45 samples): benzo(g,h,i)perylene (22%), benzo(k)fluoranthene (22%), chrysene (24%), fluoranthene (27%), and pyrene (27%). These low recoveries may be associated with the significantly greater difficulty in homogenizing clay soil and extracting PAHs from high clay content soil because of the strong adsorption of PAHs to clay surfaces. Future discrete soil samples may be homogenized sequentially, first in quarter-sample segments and then in combined half-sample and full sample segments. It is noted that ISM processing may address homogenization issues.

4. The following analytes in surface soil had low bias attributable to low laboratory control spike/laboratory control spike duplicate (LCS/LCSD) recoveries at a frequency greater than 20% of samples (9 in 45 samples): indeno(1,2,3-cd)pyrene (27%). The following analytes in subsurface soil had low bias attributable to low LCS/LCSD recoveries at a frequency greater than or equal to 20% of samples (18 in 90 samples): indeno(1,2,3-cd)pyrene (26%). LCS/LCSD anomalies are reflective of laboratory accuracy.

5. Due to a laboratory equipment failure, 74 samples were analyzed outside the holding time period for TOC (i.e., 28 days) but within the holding time rejection threshold (56 days) and are therefore usable. While microbial degradation is significantly reduced by storing samples at 4°C, some loss of organic material can occur, and the loss is exacerbated by prolonged storage. Given that the Site TOC results were compared to background TOC results, the low-biased TOC results may represent a data gap.

Groundwater Findings

1. The PALs for all PAH analytes in groundwater were met by the LOQs or LODs, with the exception of benzo(a)anthracene, benzo(a)pyrene, and dibenz(a,h)anthracene. PAHs in groundwater were analyzed by the more sensitive analytical method (i.e., BNASIM). The PALs for all metals analytes in groundwater that were not met by LOQs were either attained by the LOD or were analyzed by

the more sensitive analytical technique (i.e., ICP-MS), with the exception of cadmium and selenium. Cadmium and selenium can be analyzed by Method 6020A during Phase 2 Sampling events. See **Subsection 5.1.2** for a discussion of how data with LOQs greater than the PALs were treated in the Phase 1 Risk Screening.

## 3.3 INITIAL CONCLUSIONS – DATA USABILITY

Based on the assessment of DQIs, the data obtained during the site investigation for all datasets except for AOC 4 ISM samples are of sufficient quantity and quality to support the Phase 1 investigation and human health and ecological risk screenings. Overarching data usability issues to be considered during the development of potential data gaps and recommendations are noted below.

The validated data are usable for the Phase 1 Risk Screening with the exception of the rejected data. The overall usability of the AOC 1 and AOC 4 discrete datasets are not affected by the rejected results. Three valid ISM replicates are considered necessary to provide information regarding the reproducibility and heterogeneity of the data; three DUs did not meet this criteria for at least one of the three analytes. The rejected results in AOC 5 are for compounds not likely to be DoD-related nor likely to be risk drivers; however, because of these rejections, analytical completeness for base/neutral (B/N) extractable SVOCs was less than 90% for many compounds in groundwater. None of the AOC 3 results were rejected.

All groundwater samples were collected from temporary wells that were not developed or purged and samples tended to be turbid. The field team often experienced issues with slow and at times insufficient recharge while collecting samples.

All 2,4-DNP results and all but one picric acid result were non-detects, but the soil PALs for 2,4-DNP and picric acid and the groundwater PAL for 2,4-DNP are not attainable with contemporary analytical methodology and almost all were non-detects.

Cadmium and selenium were analyzed by Method 6010C; changing to Method 6020A may be warranted for future sampling events to improve analytical sensitivity. The groundwater PALs for PCBs were not met and any future sampling of PCBs could employ concentrated extracts during sample preparation.

## 3.4 SAMPLE-LEVEL LESSONS LEARNED

This subsection discusses observations made by the field team during the RI Phase 1 field investigations that resulted in several sample-level lessons learned. These lessons learned are presented for consideration during future sampling design and have no impact on the data usability assessment presented elsewhere in this section (**Section 3**), **Subsection 8.1.1**, or **Appendix B**.

The following are noted for AOC 1 discrete sampling:

- Groundwater recharge in the temporary monitoring well installed at the NYOW-01-021 location was minimal with respect to available sample volume. Future sampling design should consider the potential for encountering similar groundwater conditions at this location.
- Fill material was encountered in the shallow interval above native soil at the NYOW-01-006A and NYOW-01-006B sample locations. Future sampling design should consider the presence of fill material at these locations.

The following is noted for AOC 3 discrete sampling:

- Refusal was encountered at 10.5 ft bgs at sample location NYOW-03-011 where a temporary monitoring well was planned but not installed because groundwater was not observed in this interval. Future sampling design should consider the potential for encountering similar subsurface and groundwater conditions at this location.

The following is noted for AOC 4 discrete sampling:

- Groundwater recharge in the temporary monitoring wells installed at the NYOW-04-037, NYOW-04-038, and NYOW-04-082 locations was minimal with respect to available sample volume. Future sampling design should consider the potential for encountering similar groundwater conditions at these locations.

The following is noted for AOC 4 ISM sampling:

- Gravel encountered in the bunker driveway aprons prevented ISM sample collection using hand tools and required relocation of several ISM increments within their respective incremental sample units. Future sampling design should consider the presence of gravel in the bunker driveway aprons when determining ISM increment locations.

The following are noted for AOC 5 discrete sampling:

- Refusal was encountered at 25.5 ft bgs at sample location NYOW-05-015 where a temporary monitoring well was planned but not installed because no groundwater was observed in this interval. Shallow refusal was encountered at 5 ft bgs at sample location NYOW-05-017 where a temporary monitoring well was planned but not installed. Shallow refusal was encountered at sample location NYOW-05-018 due to concrete at 6 ft bgs. Future sampling design should consider the potential for encountering similar subsurface conditions at these locations.
- Fill material was encountered in the shallow interval above native soil at the following sample locations: NYOW-05-006, NYOW-05-017, NYOW-05-017-1, NYOW-05-018, NYOW-05-021, NYOW-05-022, NYOW-05-023, NYOW-05-024, and NYOW-05-025. Future sampling design should consider the presence of fill material in these locations.

The following is noted for background discrete sampling:

- Fill material was encountered in the shallow interval above native soil at the NYOW-B-047 and NYOW-B-048 sample locations. Future sampling design should consider the presence of fill material in these locations.

*This page intentionally left blank.*

# 4.0 DATA REDUCTION

FDs and associated discrete primary samples were reduced to obtain only one result per location/depth/analyte combination using the following approach.

- When two non-detections were reported, the non-detection with the lowest LOD (to reduce data censoring), along with its associated qualifier and bias (i.e., "+" or "-") was selected. If the LODs were equal and the qualifiers and biases were not in agreement, the qualifier and bias associated with the least uncertainty was selected. For example, if the LOD primary and duplicate results were 10 U and 10 UJ-, respectively, the "U" qualifier was assigned.
- When a detection and a non-detection were reported, the detection (to reduce data censoring) along with its associated qualifier and bias was selected.
- When two detections were reported, the mean of the two values was selected. If the qualifiers and biases were in agreement, both were assigned to the reduced concentration. If the qualifiers were in agreement, but the biases were not, only the qualifiers were assigned. If the qualifiers were not in agreement, neither a qualifier nor a bias were indicated.

Detections less than the LOQ (J qualified results) cannot be used to determine whether contamination is above or below the PAL, unless these results are part of a dataset that contains at least one result greater or equal to the LOQ. The LOQ is a more defensible concentration than the J qualified result. Therefore, in the cases where all detections within a dataset were less than the LOQ (i.e., all detects are J qualified), for the purposes of the Phase 1 risk screening, the concentration of the analyte was set equal to the LOQ. These LOQ-censored detects were still considered a detect and assigned a J+ flag. The datasets used to determine if an analyte had all detections less than the LOQ were based on AOC (and subarea, if applicable), matrix, and depth interval (for soil). The data for which the J values were raised to the LOQs are presented in **Appendix C.1**. The effects of raising J qualified detections to the LOQ is discussed in the Uncertainty Analysis (**Subsection 6.3**).

PAH sums (high molecular weight [HMW], and low molecular weight [LMW]) were calculated as follows (see **Appendix C.2**):

- Low molecular weight PAHs are those with ≤ 3 benzene rings and high molecular weight PAHs are those with ≥ 4 benzene rings (EPA, 2007 – Eco Guidance for Developing Ecological Soil Screening Levels (Eco-SSLs), Attachment 4-1; https://www.epa.gov/sites/default/files/2015-09/documents/ecossl_attachment_4-1.pdf )

| LMW PAHs | HMW PAHs |
|---|---|
| 1-Methylnaphthalene | Benzo(a)anthracene |
| 2-Methylnaphthalene | Benzo(a)pyrene |
| Acenaphthene | Benzo(b)fluoranthene |
| Acenaphthylene | Benzo(g,h,i)perylene |
| Anthracene | Benzo(k)fluoranthene |
| Fluoranthene | Chrysene |
| Fluorene | Dibenz(a,h)anthracene |
| Naphthalene | Indeno(1,2,3-c,d)pyrene |
| Phenanthrene | Pyrene |

- Within a sample, if all of the analytes within a PAH category were detected, the total was sum of the results for the category.
- Within a sample, if any of the analytes within a PAH category were non-detect, the total was the Kaplan-Meier (KM) sum for the PAH category. This approach is after Helsel (2009) Summing Nondetects: Incorporating Low-level Contaminants in Risk Assessment, *Integrated Environmental Assessment and Management*. 6(3):361-366. The use of the LMW PAH and HMW PAH categories are based on ecological risk assessment; therefore, there are no relative toxicity weighting factors to consider.

In AOC 3, locations were resampled because of laboratory QC issues with the Method 8260 analysis (volatile organic compounds [VOCs]). Samples NYOW-03-PH005-B_R, NYOW-03-PH006-B_R, NYOW-03-PH007-B_R, and NYOW-03-PH0016-B_R were inadvertently submitted for analysis for Methods 8260 and 8270 (SVOCs); therefore, resulting in two sets of SVOC results for virtually the same location. Both datasets are valid and both were included in the AOC 3 Phase 1 risk screening dataset.

The reduced datasets are presented in **Appendix D**.

# 5.0 RISK SCREENINGS

Several steps in the human health and ecological risk screenings are essentially the same. Where specific details of the similar steps differ, the more conservative of the two was selected to streamline and provide uniformity in the Phase 1 risk screenings. The common steps are presented in **Subsections 5.1 through 5.4.** The remainder of the human health and ecological risk screenings were performed in parallel, with approaches specific to each presented in **Subsections, 5.5 and 5.6**, respectively.

## 5.1 ANALYTES WITHOUT SCREENING VALUES OR FOR WHICH THE LOQ IS GREATER THAN THE PAL

There are almost always analytes without screening values or for which the LOQ is greater than the PAL. Worksheet #15 of the *Uniform Federal Policy Quality Assurance Project Plan, Former New York Ordnance Works, Baldwinsville, New York, Final* (USACE, 2020) indicates the analytes for which it was known that PALs do not exist or for which PALs would not be achieved at the LOQ. During the UFP-QAPP development, ecological PALs were either available or derived for all of the known constituents of potential concern (COPCs) (i.e., picric acid, 2,4-DNCB, and 2,4-DNP) in AOCs 1 and 4. The analyte lists for AOCs 3 and 5 were longer than for AOCs 1 and 4 based on their historical uses. The selection of surrogates for PALs for additional AOCs 3 and 5 analytes was not performed during the UFP-QAPP development phase. Research to determine DoD-related COPCs other than the ammonium picrate-related analytes (i.e., picric acid, 2,4-DNCB, and 2,4-DNP) was not within the UFP-QAPP task scope. That research is within the Phase 1 Risk Screening task scope and is described in **Subsection 5.1.1.1**.

The approaches for evaluating analytes without screening values and for which the LOQ is greater than the PAL are discussed in **Subsections 5.1.1 and 5.1.2**, respectively.

### 5.1.1 Analytes Without Screening Values

Screening values are medium-specific (i.e., soil or groundwater) and are needed for each of the AOC-specific receptors for the Phase 1 Risk Screening. During UFP-QAPP development, analytes for which there are no PALs, and which were not related to the manufacture of ammonium picrate were considered for elimination from the analysis unless there was a PAL for that analyte in another matrix. Based on these criteria, no analytes were eliminated. During UFP-QAPP development, VOCs without PALs were retained at AOC 3 and AOC 5 because they are frequently associated with landfills and therefore would allow for a more comprehensive assessment of potential risk.

The Phase 1 Risk Screening approach for evaluating analytes without screening values is dependent upon whether it was DoD-related/potentially DoD-related or unlikely to be DoD-related as described in **Subsections 5.1.1.1 and 5.1.1.2**, respectively. Whether an analyte advances to the screening-level comparison based on the initial screening steps is presented for human health and ecological receptors in **Subsections 5.6 and 5.7**, respectively.

#### *5.1.1.1 Selection of Surrogates for DoD-related and Potentially DoD-related Analytes*

Analytes without a screening value that are either DoD-related or potentially DoD-related (**Table 5-1**) were discussed with the PDT risk assessors (during regularly scheduled biweekly calls on 14 September, 28 September, and 26 October 2022) to determine if a surrogate screening value may be used for risk screening; and if so, what value should be used. Human health surrogate screening values are limited to regional screening levels (RSLs) as appropriate for the medium. Ecological surrogate screening value references are limited to those used in QAPP Worksheet #15 for PAL selection. For analytes without site-specific derived values, the hierarchy of benchmarks for use in the Phase 1 Ecological Risk Screening is as follows:

- EPA Eco-SSLs (Eco-SSLs; various dates) (https://www.epa.gov/chemical-research/interim-ecological-soil-screening-level-documents);
- EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) –Soil Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf);
- EPA Region 5 (2003) Resource Conservation and Recovery Act (RCRA) Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf); and
- Los Alamos National Laboratory (LANL) ECORISK Database Ecological Screening Levels (2017) (https://rais.ornl.gov/documents/ECO_BENCH_LANL.pdf).

Surrogates are selected based on similarities to the COPC in structure and functional groups. The following general rules were used to inform the selection of surrogate screening values.

1) For isomers, the isomer with the highest similarity coefficient in EPA's Toxicity Estimation Software Tool (TEST) or with a published toxicological comparison (e.g., Provisional Peer-Reviewed Toxicity Values [PPRTV]) was selected.
2) For Aroclors with risk assigned based on the percent (%) of congeners with more than four chlorines, the Aroclor with the closest percent chlorination was selected.
3) For PAHs, an analog with a similar number and orientation of benzene rings and bay or bay-like region was selected.
4) For heterocyclic compounds, a structurally similar surrogate that shares similar electronegativity and reactivity was selected and verified with TEST.

Justification for each of the surrogates that were chosen for human health and ecological risk screening are provided in **Tables 5-2 through 5-7**.

For analytes for which a surrogate was selected, the screening value for the surrogate was used as-is without any modifications (e.g., safety factors) with the exception of picric acid and 2,4-DNCB; specific consideration of surrogates for the DoD-related COPCs picric acid and 2,4-DNCB are provided below.

Picric acid is an aromatic compound with three electron-withdrawing (nitro) substituents at the para and at both ortho positions relative to the hydroxyl group; as a result, the phenolic proton is quite acidic (pKa < 1). As a starting point, the minimum requirements for finding an acceptable surrogate for picric acid included finding another phenolic compound with similar substituents in terms of steric hindrance, location on the aromatic ring and electron-withdrawing capacity (USACE, 2020). As a result of these considerations,

2,4-DNP was selected as the best surrogate for picric acid. A safety factor of ten was applied to the 2,4-DNP benchmarks for ecological screening to account for potential differences between picric acid and 2,4-DNP toxicity.

2,4-DNCB is an aromatic compound with two nitro substituents at the para- and ortho- positions relative to the chloride group. Since another polynitrobenzene with a similar substituent pattern on the aromatic ring with toxicity information was not available, a dinitro-substituted benzene with the nitro groups oriented in the meta position relative to each other, 2,4-dinitrotoluene (DNT), was identified (USACE, 2020). A safety factor of ten was applied to the surrogate benchmark for ecological screening to account for the difference between 2,4-DNCB and 2,4-DNT.

The list of analytes for which screening levels were available after the assignment of surrogates is provided in **Tables 5-8 through 5-12.** Screening values were not derived by Bluestone from primary literature. Derivation of screening values is beyond the current scope of the Phase 1 Risk Screening but may be considered in Phase 2. Uncertainties regarding the use of surrogates are discussed in **Subsection 6.3**.

Surrogates were available for all likely and potentially DoD-related analytes for human health and mammalian ecological receptors. Analytes for which surrogates could not be developed (**Tables 5-13 through 5-15**) cannot be quantitatively evaluated. Analytes for which surrogates could not be developed are discussed in the uncertainty analysis (**Subsection 6.3**) with respect to any historical use, analytical, or toxicological reasons as to why the analyte may be considered a COPC and subsequently presented in the data gaps analysis (**Section 8**) for potential investigation during Phase 2. Whether an analyte advances to the screening-level comparison based on the initial screening steps is presented for human health and ecological receptors in **Subsections 5.6 and 5.7**, respectively.

#### *5.1.1.2 Analytes that are Unlikely to be DoD-related*

As noted in **Subsection 5.2.3**, with the exception of PAHs and metals, analytes that are unlikely to be DoD-related (**Tables 5-16 through 5-21)** were not evaluated further.

### 5.1.2 Analytes for Which the LOQ is Greater than the PAL

To meet measurement quality objectives (MQOs) for sensitivity, the LOQs for detections and LODs for non-detections must be less than the PALs. When MQOs for sensitivity are not met, the results are typically unusable for reliably determining whether concentrations are above or below the PALs.

As noted in **Subsection 5.1**, the analytes for which it was known that PALs would not be achieved at the LOQ were presented in the UFP-QAPP. Prior to the finalization of the UFP-QAPP, methods were changed for known constituents of potential concern, when possible, to meet PALs; however, many analytes did not have alternatives to achieve lower limits. Any additional analytes that did not achieve the PAL at the LOQ based on analytical issues associated with the Phase 1 sample collection effort (conducted in 2021) were identified in the DUA (**Appendix B**). If the data gaps analysis (**Section 8**) identifies COPCs for analysis during Phase 2 sampling for which the LOQ did not meet PALs during the Phase 1 analyses, analytical method, laboratory, and laboratory location options will be explored in an attempt to lower the LOQs below PALs.

The approach for evaluating an analyte that did not achieve the individual receptor PALs (hereafter referred to as screening values/levels when not discussed in context of the UFP-QAPP) at the LOQ is dependent

upon whether it is DoD-related/potentially DoD-related or unlikely to be DoD-related as described in **Subsections 5.1.2.1 and 5.1.2.2**, respectively. Analytes that were never detected in a medium on an AOC/subarea-specific basis and the frequency with which they exceed the screening level are presented in **Appendix E.** Whether an analyte advances to the screening-level comparison based on the initial screening steps is presented for human health and ecological receptors in **Subsections 5.6 and 5.7**, respectively.

#### *5.1.2.1 DoD-related and Potentially DoD-related Analytes*

Analytes with screening levels not achieved at the LOQ that were not detected within a medium on an AOC/subarea-basis in the Phase 1 samples collected in 2021 and are potentially site-related (see **Subsection 5.3**) are typically unusable for reliably determining whether concentrations are above or below the screening levels and will not proceed through the remaining screening steps. These analytes are presented in **Tables 5-22 through 5-27** and discussed in the uncertainty analysis with respect to any historical use, analytical, or toxicological reasons as to why the analyte may be a COPC and subsequently presented in the data gaps analysis for potential investigation during Phase 2.

#### *5.1.2.2 Analytes that are Unlikely to be DoD-related*

As noted in **Subsection 5.3.2**, with the exception of PAHs and metals, analytes that are unlikely to be DoD-related are noted as such (**Tables 5-16 through 5-21**) and not evaluated further.

### 5.1.3 Initial Conclusions – Analytes without Screening Values or for Which the LOQ is Greater than the PAL

An attempt was made to identify surrogates for analytes without screening values that were likely or potentially DoD-related. Surrogates were available for all likely and potentially DoD-related analytes for human health and mammalian ecological receptors. Analytes for which surrogates could not be developed for plants, soil invertebrates, or birds cannot be quantitatively evaluated and are presented in **Tables 5-13 through 5-15**. The likely or potentially DoD-related analytes without screening values should be considered during the development of potential data gaps and recommendations.

If a likely or potentially DoD-related analyte did not achieve the individual receptor screening levels at the LOQ and were not detected within a medium on an AOC/subarea-basis, the results are typically unusable for reliably determining whether concentrations are above or below the screening level. These analytes are presented in **Tables 5-22 through 5-27** and are discussed in the uncertainty analysis with respect to any historical use, analytical, or toxicological reasons as to why the analyte may be a COPC. The likely or potentially DoD-related analytes that did not achieve the individual receptor screening levels at the LOQ and were not detected within a medium on an AOC/subarea-basis should be considered during the development of potential data gaps and recommendations.

Analytes that are unlikely to be DoD-related (**Tables 5-16 through 5-21**) and are without screening values or for which the LOQ is greater than the PAL should be considered during the development of potential data gaps and recommendations.

## 5.2 NON-DETECT ANALYTES FOR WHICH THE LOQ IS LESS THAN A SCREENING LEVEL

To meet MQOs for sensitivity, the LOQs for detections and LODs for non-detections must be less than the screening levels. When MQOs for sensitivity are met, the results are reliable for determining whether concentrations are above or below the screening levels. Analytes with screening levels achieved at the LOQ that were not detected within a medium on an AOC-basis in the Phase 1 samples collected in 2021 are usable for reliably determining whether concentrations are above or below the screening levels (see **Appendix E** and **Tables 5-22 through 5-27**). With the exception of PAHs and metals, these analytes do not proceed through the remaining screening steps**.** PAHs and metals do proceed to background comparisons (**Subsection 5.4**). Whether an analyte advances to the screening-level comparison based on the initial screening steps is presented for human health and ecological receptors in **Subsections 5.6 and 5.7**, respectively. Analytes that were not detected within a medium on an AOC-basis for which the LOQ is less than all screening levels should be considered for elimination from analysis in future sampling events.

## 5.3 ANALYTES NOT RELATED TO DOD ACTIVITIES

Prior to conducting the human health and ecological risk screenings, the data were reviewed to determine if detected analytes or non-detected analytes with LOQs greater than the screening level for each human health and ecological receptor are present as a result of historical DoD-related activities. To streamline the process, analytes with LOQs less than the screening level were to be eliminated from this step (see Subsection 5.2 of **Appendix A**). The non-detected analytes for which the LOQ is less than the screening level for each of the AOC-specific receptors (o-xylene in AOC 3 and m-/p- and o-xylene in AOC 5) were few in number. Therefore, the complete list of analytes were included in this Phase 1 screening step.

Site chemistry results from the Phase 1 sampling activities were tabulated and evaluated on an AOC-specific basis because each of the four AOCs had different uses. AOCs 1 and 4 likely have similar constituents, and the analytical methods were limited as to what was expected based on the manufacture or storage of picric acid. AOCs 3 and 5 are different in that AOC 3 was a landfill and AOC 5 was a power plant that had not been investigated previously; therefore, sufficient information regarding the site-specific constituents of concern was not available to cull the analysis lists during UFP-QAPP development.

Research for identifying analytes as DoD-related, potentially DoD-related, and unlikely to be DoD-related was limited to the following DoD-produced site-specific documents provided by the PDT.

- Metcalf & Eddy, Inc. 1990. *Contamination Evaluation at the Former New York Ordnance Works, Lysander, New York, Final Report*. January.
- USACE. 1992. *Site Survey Summary Sheet (Revised) for DERP-FUDS Site No. C02NY029000, New York Ordnance Works, Lysander, New York.* 2 February.
- USACE. 1999. *Archives Search Report Findings for the Former New York Ordnance Works, Lysander Township, New York.* September.
- USACE. 2004. ASR Supplement. New York Ordnance Works, FUDS Property Num*ber: C02NY0290.* 26 November.
- USACE. 2019. *New York Ordnance Works – Baldwinsville, New York Historical Photographic Analysis, Draft.* November.

### 5.3.1 Literature Review Results

AOC-specific DoD-related constituents/items identified in the above listed literature are noted below:

- AOC 1
  - Raw materials
    - 2,4-DNCB
    - Caustic soda (sodium hydroxide)
    - Sulfuric acid
    - Nitric acid
    - Aqueous ammonia
  - Manufacturing Intermediates
    - 2,4-DNP
    - Picric Acid
  - Final Product
    - Ammonium picrate
- AOC 3
  - Solid waste
    - Canvas filters
    - NYOW trash
    - Fly ash from boiler house
    - Wood
    - Stainless steel mixing "spiders" with incidental picric acid contamination
    - Drums and cans of paint
- AOC 4 – Bunker Area
  - Ammonium picrate
- AOC 5 – Power Plant Area (presumptive evidence based on site use)
  - Coal
  - Fly ash
  - PCBs
  - NYOW trash

Information regarding constituents and/or environmental degradation products of the above listed items were also researched (see **Table 5-28**).

### 5.3.2 AOC-Specific Constituent Characterization

The following criteria were used to categorize constituents.

- DoD-related – the analyte was noted in the reviewed literature as being used at the Site;
- Potentially DoD-related – the analyte was not confirmed in the reviewed literature as site-related, but is detected in at least 5% of the AOC-specific samples collected during Phase 1; and
- Unlikely to be DoD-related – the analyte was not confirmed in the reviewed literature as site-related and is detected in less than 5% of the AOC-specific samples collected during Phase 1. An exception to this rule is that PAHs and metals categorized as unlikely to be site-related are carried through the remaining screening steps as appropriate and discussed in the uncertainty section.

The 5% indicated in the 2nd and 3rd bullets above is derived from EPA (1989) example statistic for eliminating infrequently detected analytes from risk assessment.

DoD-related categorization is presented by AOC in **Table 5-29**. All AOC 1 analytes were either "DoD-related" or "potentially DoD-related". Although some analytes from AOC 3 and AOC 5 were categorized as "unlikely to be DoD-related", given the site history, AOC-specific uses, and lack of additional information to categorize constituents regarding DoD-relatedness, no detected constituents were eliminated from proceeding to the next step of Phase 1 risk screening from either AOC 3 or AOC 5. For AOC 4, only constituents known to be used in the manufacture of ammonium picrate were analyzed (i.e., 2,4-DNCB, 2,4-DNP, and picric acid); therefore, no constituents were eliminated from further evaluation from AOC 4. In summary, every analyte from each AOC was subjected to the evaluations in **Subsection 5.1**.

DoD-relatedness may be re-evaluated after Phase 2 sampling results are available.

### 5.3.3 Initial Conclusions – Analytes Not Related to DoD Activities

Based on the criteria applied to determine DoD-relatedness, every analyte from each AOC initially was considered likely or potentially DoD-related. At this time, only metals and PAHs considered to be within background would be considered analytes not related to DoD activities (see **Subsection 5.4**). DoD-relatedness for non-PAHs and non-metals may be re-evaluated after Phase 2 sampling results are available.

## 5.4 BACKGROUND COMPARISONS

Background surface and subsurface soil samples were collected for each of the three distinct surface geologic units to assess the contribution of natural and anthropogenic sources to total PAH and metal concentrations. PAHs and metals that are detected in site soils are frequently unrelated to a historical release associated with operation of the Site. Given the potential that these analytes, and especially metals, will leach into groundwater, background samples were also collected from temporary background monitoring wells within the background reference area (**Section 2**). The following sections describe the procedures that were used to determine the representativeness of the background dataset and to compare media concentrations in the background samples to their counterparts on the Site.

### 5.4.1 Background Threshold Value Development

BTVs were developed for AOCs 1, 3, and 5 at the NYOW Site for use in the phased site assessment process. In order to determine that the background dataset is both robust and appropriate to the Site, the following objectives must be achieved:

1) Determine whether background location geophysical/geochemical characteristics are representative of site location characteristics.
2) Determine if data from differing soil sampling intervals (0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs) within the assigned surface geologic units (Pd, Psc, and Ps) for the background locations can be combined.
3) Determine if surface geologic units within the background locations can be combined.
4) Determine if there are data gaps in the background soil dataset(s) that would prohibit the development of appropriate background threshold values for AOCs 1, 3, and 5 at the NYOW Site.

If data gaps exist after these four evaluation steps, a sampling program would need to be developed and executed. Resulting data would be combined with existing data as appropriate and the exercise in Background Dataset Objectives 1-4 would be repeated.

Prior to developing soil BTVs for use in determining whether PAH and metal concentrations at AOCs 1, 3, and 5 are within background concentrations, the background dataset must be compiled. To date, AOC 4 soil and groundwater samples have been analyzed only for site-specific COPCs, i.e., picric acid, 2,4-DNCB, and 2,4-DNP. Therefore, BTVs for AOC 4 are not required.

The dataset for calculating groundwater BTVs is less complicated than the soil dataset in that data from all wells located outside the area of influence of the Site may be combined regardless of geologic units. Therefore, **Subsections 5.4.1.1 and 5.4.1.2** below are not applicable to groundwater. All nine of the wells will be used to calculate groundwater BTVs as described in **Subsection 5.4.1.3**.

#### *5.4.1.1 Site Versus Background Surface Geologic Unit Comparison*

The site versus background surface geologic unit comparison will satisfy Background Dataset Objective 1, i.e., determine whether background location geophysical/geochemical characteristics are representative of site location characteristics.

Geologic variability in soil material plays an important role in the elemental composition of the soil. Therefore, it is necessary to determine that soil samples of similar characteristics and origin are being compared during background studies. Parameters that are indicative of soil geochemical composition include lithology (represented by grain size), TOC, CEC, and indicator analytes such as iron, aluminum, and PAHs. See **Appendix F.1** for data summary tables**.** Note that the KM method was used to calculate the mean and standard deviation for datasets that contain non-detects (see **Section 4**).

The comparability of soil on site (all AOCs combined) for each of the three discrete soil intervals within a surface geologic unit (0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs) with the soil background reference area was confirmed by evaluating these parameters as described in detail below. Best professional judgment was used to determine if site and background locations are similar based on the magnitude of differences and utility of each of the parameters. For most parameters, graphical displays (e.g., side-by-side box plots, ternary charts) were used to visually compare data.

Standard side-by-side box plots were presented only for analytes that have at least five samples within the dataset and that meet the following criteria:

- n = 5 – at least 3 detects;
- n = 6 to 10 – at least 4 detects;
- n = 11 to 20 – at least 5 detects; and
- n > 20 – greater than 20% detects.

If an analyte did not have at least five samples within the dataset, scatter plots were used to qualitatively compare datasets.

Probability plots were not used for visual assessment of the data because point-by-point comparisons of the grouped datasets was not necessary.

#### 5.4.1.1.1 Grain Size Distribution

Grain size is the physical measurement of the size of particles in soil. Many experimental studies have documented that for most contaminants, soil fractions composed of smaller particle sizes have higher loadings than fractions composed of larger particles (ITRC, 2020). Therefore, the representativeness of background is heavily dependent on the grain size characteristics of the reference area and the AOCs.

Grain size was evaluated by comparing the percentage of sand, silt, and clay from the background soil dataset to the AOC soil dataset with box plots for each depth interval (**Appendix F.2**). When the sample size was less than five or contained fewer than three detects, a scatter plot was developed for comparison purposes. Ternary diagrams were also generated to illustrate the relative percentages of silt, clay, and sand for background and site data for each depth (**Appendix F.2**). The results of the comparison were documented by designating the box plots and ternary diagrams as depicting a "highly similar" (+), "moderately similar" (0), or "dissimilar" (-) relationship between site and background (**Table 5-30**). The data used to perform the comparisons is presented in **Appendix D**.

Grain Size Distribution Results - Psc

The side-by-side Psc box plots for clay at depths of 0-1 ft bgs, 1-5 ft bgs, and 5-10 ft bgs were assigned scores of "+", "0", and "-", respectively. The side-by-side Psc box plots for silt at increasing depth intervals were assigned scores of "-", "+", and "+", respectively. The side-by-side Psc box plots for sand at increasing depth intervals were assigned scores of "-", "+", and "+", respectively. Box plots could not be developed for the background dataset 5-10 ft bgs interval due to small sample size; consequently, the data was evaluated using scatter plots. The ternary diagrams for Psc were scored as "0", indicating moderately similar characteristics for each depth interval. Refer to **Appendix F.2** for box plots and/or scatter plots and ternary diagrams and **Table 5-30** for the associated scores.

Grain Size Distribution Results - Ps

The side-by-side Ps box plots for clay at depths of 0-1 ft bgs, 1-5 ft bgs, and 5-10 ft bgs were assigned scores of "+", "+", and "+", respectively. The side-by-side Ps box plots for silt at increasing depth intervals were assigned scores of "+", "+", and "+", respectively. The side-by-side Ps box plots for sand at increasing depth intervals were assigned scores of "0", "+", and "+", respectively. Box plots could not be developed for the background dataset due to small sample size; consequently, the data was evaluated using scatter plots. The ternary diagrams for Ps were scored as "+", indicating highly similar characteristics for each depth interval. Refer to **Appendix F.2** for box plots and/or scatter plots and ternary diagrams and **Table 5-30** for the associated scores.

Grain Size Distribution Results - Pd

The side-by-side Pd box plots for clay at depths of 0-1 ft bgs, 1-5 ft bgs, and 5-10 ft bgs were assigned scores of "-", "+", and "+", respectively. The side-by-side Pd box plots for silt at increasing depth intervals were assigned scores of "+", "0", and "+", respectively. The side-by-side Pd box plots for sand at increasing depth intervals were assigned scores of "-", "0", and "0", respectively. Box plots could not be developed for the background dataset due to small sample size; consequently, the data was evaluated using scatter plots. The ternary diagrams for Ps were scored as "0" for surface soil and "+" for both subsurface soil intervals, indicating moderately and highly similar characteristics. Refer to **Appendix F.2** for box plots and/or scatter plots and ternary diagrams and **Table 5-30** for the associated scores.

Grain Size Distribution Results - Summary

Overall, site and background surface soil grain size classes tended to be less similar than subsurface soil. This result is expected due to the potential historical backfilling of low-lying land. In addition, the Ps and Pd surface geologic units scored higher than Psc, indicating greater similarity between site and background soil samples. All of the surface geologic units had net positive scores for grain size which are interpreted to indicate the background data are representative of site conditions.

#### 5.4.1.1.2 Total Organic Carbon

TOC is the carbon present in the soil organic matter fraction of the soil sample. Due to organic matter's ability to form complexes with metal ions, interact with clay minerals and bind particles together, and sorb and desorb organic compounds, the amount of organic matter in background and the corresponding site soil is essential to evaluate (EPA, 2002). As a result of these characteristics, the abundance of TOC can substantially affect how chemicals behave in the soil and, ultimately, their chemical concentrations. Therefore, TOC was measured in background and site soil samples to confirm the representativeness of the background dataset.

The TOC of the background sample locations was compared to the TOC of the AOCs (all combined) using box plots (**Appendix F.3**). The results of the comparison were documented by designating the box plots as depicting a "highly similar" (+), "moderately similar" (0), or "dissimilar" (-) relationship between site and background (**Table 5-30**). The data used to perform the comparisons is presented in **Appendix D**.

Total Organic Carbon Results

Box plots were developed for the background TOC datasets for all three geologic units and depth intervals. Box plots could not be developed for the site Psc dataset 5-10 ft bgs interval and all site Ps and Pd depth intervals due to small sample sizes; consequently, the data were evaluated by comparing background box plots to scatter plots. The side-by-side Psc comparisons for TOC at depths of 0-1 ft bgs and 1-5 ft bgs, were assigned scores of "+", "-", and "-", respectively. The side-by-side Ps comparisons for TOC with increasing depth were assigned scores of "+", "+", and "+", respectively. The side-by-side Pd comparisons for TOC with increasing depth were assigned scores of "-", "+", and "+", respectively. s Refer to **Appendix F.3** for box plots and/or scatter plots and **Table 5-30** for the associated scores.

With the exception of Psc, the surface geologic units had net positive scores for TOC which are interpreted to indicate the background data are representative of site conditions. TOC within Psc soil was higher in subsurface background soil relative to site subsurface soil. Psc site TOC concentrations within the 0-1 ft bgs interval were determined to be highly similar to background concentrations for Psc. The assessment of background may be limited by sample size (e.g., n = 2 for 5-10 ft bgs).

#### 5.4.1.1.3 Cation Exchange Capacity

Most metal analytes exist as cations in soil solutions; therefore, the adsorption of metals to soil particle surfaces depends on the magnitude of negative charge present on the surface. The total number of positively charged ions that a soil can hold is referred to as the soil's cation exchange capacity, measured as millequivalents per 100 grams of soil (meq/100g). A high CEC is indicative of a high negative charge and a greater capacity to attract and retain cations (Mengel, 2022). CEC is an inherent characteristic of the soil

that will vary according to the amount of clay and organic matter that are present because each have net negative charges (Mengel, 2022).

CEC was measured in this investigation in order to confirm the representativeness of background sample locations relative to the AOCs. Since CEC is difficult to significantly alter, comparison of the site and background CEC values by depth and soil type was used to determine if the AOCs and the reference area have the same or similar intrinsic composition. The CEC of the background sample locations was compared to the CEC of the AOCs (all combined) using box plots (**Appendix F.3**). The results of the comparison were documented by designating the box plots as depicting a "highly similar" (+), "moderately similar" (0), or "dissimilar" (-) relationship between site and background (**Table 5-30**). The data used to perform the comparisons is presented in **Appendix D**.

Cation Exchange Capacity Results

The side-by-side Psc box plots for CEC at depths of 0-1 ft bgs, 1-5 ft bgs, and 5-10 ft bgs were assigned scores of "0", "-", and "-", respectively. The side-by-side Ps box plots for CEC with increasing depth were assigned scores of "+", "+", and "+", respectively. The side-by-side Pd box plots for CEC with increasing depth were assigned scores of "+", "+", and "+", respectively. Box plots could not be developed for the Psc site dataset 5-10 ft bgs interval and all Ps and Pd site depth intervals due to small sample sizes; consequently, the data was evaluated using scatter plots. Refer to **Appendix F.3** for box plots and/or scatter plots and **Table 5-30** for the associated scores.

With the exception of Psc, the surface geologic units had net positive scores for CEC which are interpreted to indicate the background data are representative of site conditions. CEC within Psc soil was higher in subsurface background soil relative to site subsurface soil. CEC within the 0-1 ft bgs interval was determined to be moderately similar to background for Psc. The assessment of background may be limited by sample size (e.g., n = 2 for 5-10 ft bgs).

#### 5.4.1.1.4 Geochemical Ratios

Aluminum and iron are dominant (i.e., abundant), naturally occurring metals in soils. High aluminum (Al) and iron (Fe) concentrations are associated with a high percentage of clay minerals and fine-grained soils; therefore, the similarity of the physical matrices of the site and background soil can be assessed by evaluating their relationship (EPA, 2019). Aluminum and iron are also chosen because their concentrations are not usually influenced by anthropogenic sources and they covary with grain size (ITRC, 2022).

The geochemical ratio of Al/Fe was used as an indicator to determine if the background area matrix is similar to the combined AOC matrices. The relationship between Al/Fe in background soils was initially compared to the Al/Fe ratios of site soils through regression analysis consistent with EPA's methodology used as prelude to further chemical/reference metal evaluations (**Appendix F.5**). To determine if Al/Fe ratios were similar, Analysis of Covariance (ANCOVA) was used to compare regression lines for background soil and site soil ratios (EPA, 2019). Two null hypotheses were subsequently tested: 1) are the slopes of the background and site Al/Fe ratio regression lines equal (i.e., parallel to each other) and 2) are the means of the Fe concentrations the same when excluding the effects of covariates (McDonald, 2014). A significance level of 0.05 was used as cutoff. The results of the comparison were designated as "highly similar" (+), "moderately similar" (0), or "dissimilar" (-) relationship between site and background (**Table 5-30**). The data used to perform the comparisons is presented in **Table F.5-1**.

Geochemical Ratios Conclusions

The Psc Al/Fe regression lines for depths of 0-1 ft bgs, 1-5 ft bgs, and 5-10 ft bgs were assigned scores of "+", "-", and "+", respectively, on the basis of the ANCOVA p-values for regression line slope and mean concentrations. The Al/Fe regression lines for Ps with increasing depth were assigned scores of "-", "-", and "-", respectively. The Al/Fe regression lines for Pd with increasing depth were assigned scores of "+", "+", and "+", respectively. Refer to **Appendix F.5** for box plots, regression analyses, and ANCOVA and **Table 5-30** for the associated scores.

With the exception of Ps, the surface geologic units had net positive scores for Al/Fe which are interpreted to indicate the background data are representative of site conditions. In the 0-1 ft bgs interval, the slopes of the regression lines were similar; however, the site data had several samples with lower Al/Fe ratios (e.g., 0.2 at NYOW-05-SL007-A and 0.17 at NYOW-05-SL005-A) that result in a p-value for the means test that is less than 0.05. It is noted that each of the Psc locations with lower aluminum concentrations relative to iron were located in AOC 5.

In the 1-5 ft bgs interval, the slopes of the regression lines were dissimilar; therefore, the means test was not performed. The site data had a single sample with an elevated Al/Fe ratio (i.e., 0.7 NYOW-05-PH012-B) that increased the regression line slope of the combined AOCs. Similarly, AOC 5 samples NYOW-05-PH003-C, NYOW-05-PH004-C, and NYOW-05-PH012-C had Al/Fe ratios that were inconsistent with the background dataset and resulted in a means test p-value less than 0.05. It is noted that the grain size distribution evaluation for Ps resulted in 11 "+" scores (highly similar) and 1 "0" score (moderately similar) out of 12 total box plot and ternary diagram comparisons.

#### 5.4.1.1.5 LMW and HMW PAHs

PAHs represent a class of organic compound comprised of carbon and hydrogen atoms grouped into at least two aromatic ring structures. They are categorized as pyrogenic or petrogenic based on their origin and can be divided into LMW compounds composed of fewer than four rings and HMW compounds of four or more rings (Amodu, et al., 2013). Pyrogenic sources of PAHs (i.e., anthropogenic or fill) are dominated by HMW PAHs and petrogenic sources are generally dominated by LMW PAHs associated with gasoline, kerosine, or diesel/fuel oil #2 (Patel, et al., 2020). PAHs tend to adsorb onto soil and sediment, making them persistent in the environment and useful in distinguishing background soil from site soils. Soil properties such as organic matter content, soil depth, particle size, and CEC, control their sorption (Amodu, et al., 2013).

To determine if soil samples collected within the AOCs and assigned to a surface geologic unit are of similar composition to background of the same geologic unit and depth (i.e., similar soil properties), hypothesis testing was completed (**Appendix F.6**). For normally distributed datasets with equal variance determined by Levene's Test for Equality of Variances, the Tukey's Honestly Significant Difference (HSD) test was performed. For datasets without a normal distribution, the nonparametric Dunn's test with Bonferroni Adjustment was performed. Background and site surface geologic units with similar characteristics were assigned based on p-values > 0.05. The results of the comparison were documented by designating comparison results as "highly similar" (+), "moderately similar" (0), or "dissimilar" (-) relationship between site and background (**Table 5-30**). The data used to perform the comparisons is presented in **Appendix D**.

LMW and HMW PAHs Conclusions

Low and high molecular weight comparisons could not be made for the Pd surface geologic unit because PAH concentration data was not available. Scatter plots were developed when the sample size was insufficient to generate box plots. The LMW and HMW PAH concentrations within Psc and Ps surface soil were determined to be higher than background soil concentrations, indicating that there may be additional sources of PAHs in the 0-1 ft bgs interval on-site. Psc and Ps each had net positive scores for the combined depth interval (see **Table 5-30**) for both the LMW and HMW comparisons, which indicate the background data are representative of site conditions.

#### 5.4.1.1.6 Pyrogenic and Petrogenic PAHs

PAHs can be generated through the incomplete combustion of fossil fuels and organic material (pyrogenic, anthropogenic origin) or can be derived directly from petroleum products such as oil (petrogenic source origin) and their degradation products. Pyrogenic PAHs have different chemical composition and distribution pattern than petrogenic PAHs (Tobiszewski, 2012). To determine if PAHs present in background soil have the same, anthropogenic origin as PAHs detected within site AOCs, diagnostic ratios identified through literature were calculated and compared.

Four diagnostic PAH ratios were computed for each background and site soil sample: 1) anthracene/(anthrancene+phenanthrene) [an/(an+ph)], 2) benzo(a)anthracene/(benzo(a)anthracene+chrysene) [BaA/(BaA+chry)], 3) fluoranthene/(fluoranthene+pyrene) [fla/(fla+py)], and 4) LMW/HWM (see **Appendix F.7**). The four diagnostic ratios were selected based on the following ratio value ranges presented in PAH diagnostic ratios for the identification of pollution emission sources (Tobiszewski, 2012):

- an/(an+ph) > 0.1 = pyrogenic
- BaA/(BaA+chry) < 0.2 = petrogenic; > 0.2 = coal, petroleum combustion and vehicular emissions (pyrogenic)
- fla/(fla+py) < 0.4 = petrogenic; > 0.5 = grass, wood, pyrogenic diesel combustion
- LMW/HMW < 1 = pyrogenic; > 1 = petrogenic

Where three of the four ratios resulted in the same source designation, that designation was selected; otherwise, the source was considered inconclusive (**Table 5-30**).

Pyrogenic and Petrogenic PAHs Conclusions

A total of 181 site and background samples were evaluated and assigned a petrogenic or pyrogenic origin based on the ratios described above (**see Appendix F.7**). Of the total number of samples, only three were designated as petrogenic in origin (NYOW-05-SL009-A, NYOW-05-SL010-A, and NYOW-05-SL024-A). Fifty-five samples were designated as inconclusive because the majority of ratios (three out of four) were not in agreement. Of them, one was from AOC 3 (NYOW-03-PH002-B), 26 were from AOC 5 (all depths), and 28 were from background samples (all depths). The majority of samples (n = 123) were determined to have a pyrogenic source, including 24 samples from AOC 3, 39 samples from AOC 5, and 60 samples from the background reference area. It is noted that AOC 5 contained a coal pile and three concrete coal aggregate bins that would be consistent with a finding of petrogenic PAHs. Sample locations NYOW-05-SL009-A and NYOW-05-SL010-A reside within the coal storage area (**Figure 2-9**). Sample NYOW-05-SL024-A is between the coal storage area and the dual coal aggregate bin A&B (**Figure 2-9**). Given that approximately

70% of the site and background samples were determined to have pyrogenic sources, and only three samples from known historical petroleum areas were found to have a petrogenic origin, a "+" score was assigned to each depth interval to document site and background similarity (i.e., site and background depths and geologic units were comparable and dominated by pyrogenic PAHs, see **Table 5-30**).

#### 5.4.1.1.7 Summary and Recommendations

Based on the results of the site versus background surface geologic unit comparisons, no background soil samples are recommended for removal from the dataset. The Psc surface geologic unit had the weakest overall total scores of +1, +2, and +3 for the 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals, respectively (**Table 5-30**). However, given that the scores were net positive, indicative of similar characteristics to site soil, and that no single background soil sample was responsible for the "dissimilar" scores among the parameters tested, it is recommended that the dataset remain in full. The comparisons for the Ps and Pd surface geologic units resulted in higher total positive scores. For Ps, the net positive scores were +3.5, +8, and +8 for the 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals, respectively (**Table 5-30**). For Pd, the net positive scores were +1.5, +7, and +7.5, respectively (**Table 5-30**).

It is noted that for each surface geologic unit, the strength of the similarity improved with depth, indicating that the surface soil interval was subject to a greater range of values for several parameters, including HMW and LMW PAHs and % sand. The large-scale heterogeneity associated with surface soil may be attributable to anthropogenic transport mechanisms (e.g., differences in atmospheric deposition) and mobilization of larger grain size materials such as sand via air dispersion and erosion. Given that the site versus background comparisons resulted in positive similarity scores, and that the strength of the relationship between site and background improved with depth as expected, the results were considered to support extended intra-background soil concentration comparisons.

### *5.4.1.2 Intra-Background Soil Concentration Comparisons*

The intra-background comparison will satisfy Background Dataset Objectives 2 and 3 presented in **Subsection 5.4.1** and reiterated below.

- Objective 2 – Determine if data from differing soil sampling intervals (0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs) within the assigned surface geologic units (Pd, Psc, and Ps) for the background locations can be combined.
- Objective 3 – Determine if surface geologic units within the background locations can be combined.

Chemical deposition from anthropogenic sources is more likely to remain bound to organic matter at the surface, resulting in a potential accumulation of metals and PAHs in the 0 to 1 ft bgs soil interval. Although it was anticipated that the 0 to 1 ft bgs soil interval could have differing PAH and metal concentrations from the subsurface intervals, the statistical comparisons among all three intervals will be undertaken in order to compile the most robust dataset for the calculation of BTVs.

Initial comparisons were based on the chemistry (i.e., PAHs and metals) from 0 to 1 ft bgs, 1 to 5 ft bgs, and the 5 to 10 ft bgs intervals within a surface geologic unit to determine if the depth intervals could be combined. The second set of comparisons was between surface geologic units using the datasets resulting from the initial exercise.

Multiple comparison tests for centrality were used initially to determine whether or not data can be grouped; multiple comparison tests are more effective in controlling false positives than multiple pairwise tests alone. False positive and false negative error rates are inversely related; controlling false positives (i.e., rejecting the null hypothesis incorrectly) is more desirable in this context so that the most robust datasets are compiled.

- Data distributions were determined using Q-Q plots and goodness of fit tests performed in ProUCL and interpreted in accordance with guidance provided in the ProUCL Technical Guide (EPA, 2015a). For normally distributed datasets with equal variance, the Tukey's HSD multiple comparison test was performed. The Tukey's HSD can be used with both equal and unequal group sample sizes and is more powerful than most other parametric multiple comparisons and its correction from family-wise error (FWER) to pairwise error rates is relatively small (Helsel et.al 2020). For datasets that are normally distributed with unequal variance or without a normal distribution, the nonparametric Dunn's (rank-sum) test with Bonferroni Adjustment multiple comparison test was performed. Both the Tukey's HSD test and Dunn's test with Bonferroni Adjustment are able to control for the FWER, which is the probability of making any Type 1 errors. The *p-value* for the FWER for both tests was set at $p \leq 0.05$.

If the null hypothesis was rejected during the pairwise comparisons as part of either the Tukey's HSD or the Bonferroni-adjusted Dunn's test, the Benjamini-Hochberg (BH) method was used to reduce the overall false discovery rate (FDR; i.e., the expected proportion of incorrect rejections of the null hypothesis) for the pairwise tests. The BH approach was implemented as described below. For k groups there are c = k(k-1)/2 possible pairwise (combinations) comparisons.

- Set the FDR rate to the desired p-value (i.e., 0.05).
- Order the observed p-values from hypothesis tests from high to low.
- Compare each p-value with the product (i/c)FDR, where i = c, c-1, c-2,…1.

A pairwise difference is significant if the observed p-value < (i/c)FDR. Data groupings that were statistically significantly different were not combined.

Supporting exploratory graphics, statistical outputs, and results are presented in **Appendix G** as follows:

- **Appendix G.1** Depth Interval Comparisons and
- **Appendix G.2** Geologic Unit Comparisons.

#### 5.4.1.2.1 Intra-Background Soil Depth Interval Conclusions

Based on the results of the statistical approach described above, all three soil depth intervals (i.e., 0-1 ft bgs, 1-5 ft bgs, and 5-10 ft bgs) can be combined into one 0-10 ft bgs dataset for the Psc, Ps, and Pd surface geologic units and the analytes listed below (Group 1). The associated box plots, scatter plots, and multiple comparison test p-values are provided in **Appendix G.1**.

- Antimony
- Arsenic
- Barium
- Chromium

- Cobalt
- Copper
- Iron
- Nickel
- Selenium
- Silver
- Sodium
- Thallium
- Dibenzo(a,h)anthracene
- Fluorene

Subsurface soil intervals (i.e., 1-5 ft bgs and 5-10 ft bgs) can be combined for each of the three surface geologic units for the analytes presented below (Group 2). For each Group 2 analyte, the difference in sample concentrations in surface soil was determined to be statistically significant and the 0-1 ft bgs interval soil data was not combined with subsurface data.

- Mercury
- Benzo(a)anthracene
- Benzo(a)pyrene
- Benzo(b)fluoranthene
- Benzo(g,h,i)perylene
- Benzo(k)fluoranthene
- Chrysene
- Fluoranthene
- Indeno(1,2,3-cd)pyrene
- Pyrene

Cadmium was the only analyte for which no depth interval combinations were determined to be appropriate for any of the surface geologic units (**Appendix G.1**). Beryllium and calcium comparisons resulted in the combination of the 0-1 ft bgs and 1-5 ft bgs intervals for each surface geologic unit; however, chemical concentrations in the 5-10 ft bgs intervals were significantly different (**Appendix G.1**). Therefore, the 5-10 ft bgs interval soil depths were not combined with other depth intervals. A discussion of the results of the statistical comparisons for the remaining metals and PAHs is presented in the following section.

Metals

- Aluminum – All three depth intervals can be combined for the Psc surface geologic unit. Only the subsurface soil intervals (1-5 ft bgs and 5-10 ft bgs) can be combined for Ps soils. No depth intervals can be combined for Pd soils (**Appendix G.1**).
- Lead – For the Psc and Ps surface geologic units, surface soil (0-1 ft bgs) was determined to be significantly different than subsurface soil at depths greater than 1 ft bgs. The 1-5 ft bgs and 5-10 ft bgs intervals can be combined. No depth intervals can be combined for Pd soils (**Appendix G.1**).
- Magnesium – No depth intervals can be combined for Psc or Ps soils (**Appendix G.1**). Within the Pd surface geologic unit, the 0-1 ft bgs and 1-5 ft bgs intervals can be combined. Deeper soil (i.e.,

5-10 ft bgs) was found to be significantly different and cannot be combined with soil from other depths (**Appendix G.1**).

- Manganese – All three depth intervals can be combined for the Psc and Ps surface geologic units. The subsurface soil interval (5-10 ft bgs) can be combined with the 0-1 ft bgs and 1-5 ft bgs interval soils within the Pd soil type (**Appendix G.1**).
- Potassium – All three depth intervals can be combined for the Psc and Pd surface geologic units. The subsurface soil interval (5-10 ft bgs) cannot be combined with the 0-1 ft bgs and 1-5 ft bgs interval soils within the Ps soil type (**Appendix G.1**).
- Vanadium – All three depth intervals can be combined for the Psc surface geologic unit. Only the subsurface soil intervals (1-5 ft bgs and 5-10 ft bgs) can be combined for Ps soils. No depth intervals can be combined for Pd soils (**Appendix G.1**).
- Zinc – All three depth intervals can be combined for the Psc and Ps surface geologic units. The subsurface soil interval (5-10 ft bgs) cannot be combined with the 0-1 ft bgs and 1-5 ft bgs interval soils within the Pd soil type (**Appendix G.1**).

PAHs

- 1-Methylnaphthalene, 2-methylnapthalene, and acenaphthylene – All three depth intervals can be combined for the Psc surface geologic unit. Only the subsurface soil intervals (1-5 ft bgs and 5-10 ft bgs) can be combined for Ps and Pd soils (**Appendix G.1**).
- Acenaphthene and anthracene – All three depth intervals can be combined for the Psc and Pd surface geologic units. Only the subsurface soil intervals (1-5 ft bgs and 5-10 ft bgs) can be combined for Ps soils (**Appendix G.1**).
- Naphthalene – All three depth intervals can be combined for the Psc and Ps surface geologic units. Only the subsurface soil intervals (1-5 ft bgs and 5-10 ft bgs) can be combined for Pd soils (**Appendix G.1**).
- Phenanthrene – All three depth intervals can be combined for the Ps surface geologic unit. Only the subsurface soil intervals (1-5 ft bgs and 5-10 ft bgs) can be combined for Psc and Pd soils (**Appendix G.1**).

**Table 5-31** summarizes the results of the initial comparison of depth intervals within surface geologic units as well as the comparison across surface geologic units (as described in **Subsection 5.4.1.2.2**) and highlights the depth interval and surface geologic unit combinations that were implemented.

#### 5.4.1.2.2 Intra-Background Surface Geologic Unit Conclusions

To determine if further consolidation of the background data could be achieved, statistical tests were performed across surface geologic units. Where it was concluded that all depth intervals could be combined within each surface geologic unit, the secondary comparison was performed between surface geologic units using the soil data from 0-10 ft bgs for each unit (e.g., antimony). For every other combination of data that resulted from the initial depth interval comparison, the secondary comparison was performed between surface geologic units with shared vertical grouping. For example, lead soil data from 1-10 ft bgs was combined for the Psc and Ps surface geologic units. Therefore, the inter-unit comparisons were performed between the 0-1 ft bgs interval for all three 0-1 ft bgs surface geologic units and the 1-10 ft bgs intervals of the Psc and Ps units as illustrated below.

| Lead (Comparisons Performed) | | | |
|---|---|---|---|
| Psc | **0-1 ft bgs** | **1-5 ft bgs** | **5-10 ft bgs** |
| Ps | **0-1 ft bgs** | **1-5 ft bgs** | **5-10 ft bgs** |
| Pd | **0-1 ft bgs** | 1-5 ft bgs | 5-10 ft bgs |

Notes: Patterned = 0-1 ft bgs depth interval inter-surface geologic unit comparison; Green Patterned = 1-5 ft bgs+5-10 ft bgs depth interval inter-surface geologic unit comparison

Based on the statistical tests performed, it was determined that the 0-10 ft bgs soil intervals for Psc, Ps, and Pd could be combined and a single BTV calculated for the Group 1 analytes listed below (**Table 5-31**).

- Barium
- Chromium
- Selenium
- Sodium
- Dibenz(a,h)anthracene
- Fluorene

For the following list of Group 1 analytes, only the Ps and Pd surface geologic units could be combined for the 0-10 ft bgs intervals (**Table 5-31**).

- Arsenic
- Cobalt
- Copper
- Iron
- Nickel
- Silver

For antimony, only Psc and Ps data could be further consolidated.

For thallium, the results of the multiple comparison tests indicate that Psc and Pd can be combined and Ps and Pd can be further combined; however, the p-value for Psc and Ps was slightly less than 0.05 at 0.042 following the Benjamini Hochberg adjustment. Therefore, separate BTVs will be calculated of the combined Psc + Pd, and Ps + Pd. Soil sample results for thallium from the Pd surface geologic unit will be compared to the lower BTV in order to maintain conservatism.

All Group 2 surface geologic units could be combined for surface soil. Subsurface soil intervals (i.e., 1-5 ft bgs and 5-10 ft bgs) were combined for each of the three surface geologic units for the Group 2 analytes below (**Table 5-31**). The associated box plots, scatter plots, and p-values are provided in **Appendix G.2**.

- Benzo(a)anthracene
- Benzo(a)pyrene
- Benzo(b)fluoranthene
- Benzo(g,h,i)perylene
- Benzo(k)fluoranthene
- Chrysene
- Fluoranthene

- Indeno(1,2,3-cd)pyrene
- Pyrene

Only Ps and Pd could be further combined for subsurface soil mercury data.

Cadmium was the only analyte for which no depth interval combinations were determined to be appropriate for any of the surface geologic units; therefore, each depth interval was compared separately across the surface geologic units. The results of the multiple comparison tests indicate that the individual depth interval data can be combined for Psc, Ps, and Pd soil (**Table 5-31**).

All three surface geologic units could be combined for beryllium (0-5 ft bgs) and calcium (0-5 ft bgs). All surface geologic unit data for the beryllium (5-10 ft bgs) was also able to be consolidated. For calcium (5-10 ft bgs) the results of the multiple comparison tests indicate that Psc and Pd, and Ps and Pd can be further combined; however, the p-value for Psc and Ps was slightly less than 0.05 at 0.044 following the Benjamini Hochberg adjustment. Therefore, separate BTVs will be calculated of the combined Psc + Pd, and Ps + Pd. Soil sample results for calcium from the Pd surface geologic unit will be compared to the lower BTV in order to maintain conservatism (**Table 5-31**).

A discussion of the results of the statistical comparisons for the remaining metals and PAHs is presented in the following section (**Table 5-31**).

Metals

- Aluminum – Ps and Pd surface geologic unit data collected from the surface soil interval (0-1 ft bgs) can be combined (**Appendix G.2**).
- Lead – Ps and Pd surface geologic unit data collected from the surface soil interval (0-1 ft bgs) can be combined (**Appendix G.2**).
- Magnesium – Psc and Ps surface geologic unit data collected from the 1-5 ft bgs soil interval can be combined. For the 5-10 ft bgs interval, all surface geologic units can be combined (**Appendix G.2**).
- Manganese – No combination of soil data between soil geologic units was determined to be appropriate (**Appendix G.2**).
- Potassium – Psc and Pd surface geologic unit data from 0-10 ft bgs can be combined (**Appendix G.2**).
- Vanadium – Ps and Pd surface geologic unit data from 0-1 ft bgs can be combined (**Appendix G.2**).
- Zinc – No combination of soil data between soil geologic units was determined to be appropriate (**Appendix G.2**).

PAHs

- 1-Methylnaphthalene – Ps and Pd surface geologic unit data can be combined for 1-methylnaphthalene at 0-1 bgs and at 1-10 ft bgs (**Appendix G.2**).
- 2-Methylnaphthalene – Ps and Pd surface geologic unit data can be combined at 0-1 bgs and at 1-10 ft bgs (**Appendix G.2**).
- Acenaphthylene – Ps and Ps surface geologic unit data can be combined for acenaphthylene at the 1-10 ft bgs soil intervals (**Appendix G.2**).

- Acenaphthene – No combination of soil data between soil geologic units was determined to be appropriate for acenaphthene (**Appendix G.2**).
- Anthracene – Psc and Pd surface geologic data can be combined for anthracene for 0-10 ft bgs soil (**Appendix G.2**).
- Naphthalene – Psc and Ps surface geologic data can be combined for 0-10 ft bgs soil (**Appendix G.2**).
- Phenanthrene – Psc and Pd surface geologic data can be combined for the 0-1 ft bgs soil interval and for the 1-10 ft bgs soil interval (**Appendix G.2**).

**Table 5-31** summarizes the results of the surface geologic units that were combined with depth intervals.

#### *5.4.1.3 Background Threshold Value Calculation*

Background soil datasets determined in **Subsection 5.4.1** and data from the nine background wells were used to calculate soil and groundwater BTVs, respectively. As noted in **Subsection 5.4.1**, all of the background groundwater wells were located outside the area of influence of the site and data from the nine wells were used to calculate groundwater BTVs.

For the purposes of the Phase 1 Risk Screening, soil BTVs were calculated for each dataset determined in **Subsection 5.4.1**. If the project proceeds to Phase 2, background soil may need to be collected via ISM techniques for comparability with anticipated additional site data.

For the BTV calculations, non-detects were included in the ProUCL input at the LOD and potential outliers were not removed. BTVs were calculated in ProUCL assuming a 95% confidence limit to develop 95% Upper Tolerance Limits (UTLs) or Upper Prediction Limits (UPLs), depending upon sample size. UPLs are more effective for reducing false positives in small (< 25 samples) datasets. BTVs were selected as follows.

- When all of the detections for an analyte are less than the LOQ (i.e., J-qualified due to trace concentrations), the BTV was judgmentally set as less than the Site sample-specific LOQ.
- When the dataset contained less than 3 detects that were also above the LOQ, the BTV was a non-parametric BTV.
- When the dataset contains at least 3 detects above the LOQ and has < 50 samples, parametric KM BTVs were selected preferentially over non-parametric BTVs.
- When the dataset contains at least 3 detects above the LOQ and has ≥ 50 samples, the data distribution was used to determine if the parametric or non-parametric KM BTV was selected.

If an analyte within a background dataset does not have any detections, a BTV was calculated as the 95$^{th}$ percentile of the LODs that are less than the PAL identified in the QAPP (USACE, 2020).

Groundwater and soil BTVs are presented in **Table 5-32 and 5-33**, respectively. Backup for the calculations is presented in **Appendix H**. BTVs that were developed using a non-detected dataset were only for groundwater analytes as follows: 1-methylnaphthalene, 2-methylnaphthalene, anthracene, fluoranthene, fluorene, naphthalene, pyrene, beryllium, silver, and zinc. In addition, groundwater BTVs were not developed for antimony, cadmium, mercury, selenium, and thallium because they were never detected in background dissolved groundwater and the LODs are greater than the respective screening level. BTVs developed using a non-detected dataset are discussed in the uncertainty analysis (**Subsection 6.3**).

### 5.4.2 Comparisons of Site Concentrations to BTVs

Comparisons between site and background were made for AOCs 1, 3, and AOC 5 subareas separately. To date, AOC 4 soil and groundwater samples have been analyzed only for site-specific contaminants of concern (COCs); therefore, a background comparison is not appropriate. Site soil datasets were compiled based on the depth intervals for the AOC-specific exposure scenarios.

Depending upon how the soil depth intervals were combined for BTV calculation and site exposure units (EUs), there are variations on how comparisons to BTVs were made. If BTVs were not available for an EU depth interval, the approach was to either:

- compare the concentrations in the EU depth interval to BTVs that span the EU depth interval (e.g., a 0 to 1 ft bgs EU might be compared with a BTV that was developed by combining data from 0 to 10 ft bgs), or
- compare the concentrations in the EU depth interval to the most conservative BTV developed for depth intervals within the EU depth interval range (e.g., a 0 to 5 ft bgs EU might be compared to the lower of the BTVs developed for 0 to 1 ft and 1 to 5 ft bgs).

As noted in **Section 2**, BTVs were not developed for fill material. Based on the site history, it is assumed that on-site fill is related to DoD activities. Therefore, in order to not be considered a potential source, site fill should not contain concentrations of metals and PAHs exceeding native soil background concentrations. As such, site sample concentrations located in fill were compared with the BTV developed for the geologic unit identified for the surrounding site locations. If the fill is surrounded by site locations from more than one geologic unit, the most conservative BTV (i.e., lowest) for the applicable units was used in the comparison. See **Table 5-34** for geologic unit assignments for site fill locations.

As noted in the field report covering AOC 1 activities (USACE, 2021), existing concrete building foundations and steep slopes prohibited drill rig access and the sampling plan was changed from collecting samples at three depths to collection shallow (0 to 1 ft bgs) samples biased to downgradient areas. Therefore, data were not available from the 1 to 5 ft bgs and 5 to 10 ft bgs depths to assign a geologic unit for the location. In order to compare the site concentrations with BTVs, site sample concentrations from locations where only the 0 to 1 ft bgs interval was sampled were compared with the BTV developed for the geologic unit identified based on the inferred geology. See **Table 5-35** for geologic unit assignments for AOC 1 locations with samples collected only from 0 to 1 ft bgs.

A conclusion of a potential site-related release was made for soil if the maximum concentration for site datasets with ≤ 20 samples was greater than the BTV or if more than 5% of the results for site datasets > 20 samples was greater than the BTV. When the BTV was set at less than the LOQ and the site concentration was not less than any sample-specific LOQ for the exposure interval, a conclusion of a potential site-related release for an analyte was made.

Only one round of groundwater data are available from temporary wells located mainly to determine groundwater flow direction. At this time there are no identifiable plumes. As such, the conclusion of a potential site-related release was made if the maximum detected groundwater concentration for AOC 1, AOC 3, or the AOC 5 subarea exceeded the BTV.

Comparisons with BTVs are presented by AOC for groundwater and for EUs per geologic unit for surface soil exposure at 0 to 1 ft bgs, and subsurface soil exposures at 0 to 5 ft bgs and 0 to 10 ft bgs. For AOC 4,

statistics for the surface soil discrete data and for each of the twelve ISM DUs were to be calculated and presented separately, for a total of at least 13 AOC 4 surface soil datasets. However, all of the analytes in AOC 4 ISM surface soil samples were non-detect. Comparisons of site concentrations to BTVs are presented in **Appendix I**. A summary of the background comparison results is presented in **Table 5-36**.

For AOCs 1 and 3, PAHs and metals with concentrations considered to be within background were not evaluated further. In the case of AOC 5 where the investigation is an initial SI, comparisons with background are for informational purposes and not used to eliminate analytes from further investigation because insufficient site data are available to perform a robust statistical comparison. Further sampling may be proposed for AOC 5 for analytes detected above screening levels or with uncertainties surrounding the relationship between the screening level and LOQ.

Whether an analyte advances to the screening-level comparison based on the initial screening steps is presented for human health and ecological receptors in **Subsections 5.6 and 5.7**, respectively.

Given how BTVs are defined (i.e., the null hypothesis is that the site concentrations are consistent with background concentrations), false positives (Type I error or the incorrect rejection of the null hypothesis) overestimate contamination and false negatives (Type II error or failure to reject the null hypothesis) underestimate contamination. BTVs typically control false positives only. From a statistical perspective, results greater than BTVs demonstrate likely site-related releases but results less than BTVs are inconclusive. PDT concurrence will be achieved prior to eliminating contaminants less than BTVs from further Phase 1 evaluation. Stakeholder concurrence will be sought prior to Phase 2 sampling activities. Hypothesis testing for centrality can simultaneously control Type I and Type II errors for background comparisons and may be undertaken during Phase 2.

### 5.4.3 Initial Conclusions – Background Comparisons

Background comparisons were not made for the analytes in AOC 4 and in the case of AOC 5 where the investigation is an initial SI, comparisons with background are for informational purposes and should not be used to eliminate analytes from further investigation because insufficient site data are available to perform a robust statistical comparison.

As noted in **Subsection 5.4.2**, from a statistical perspective, results greater than BTVs demonstrate likely site-related releases but results less than BTVs are inconclusive. The following is a summary of analytes in AOCs 1 and 3 with maximum detected concentrations below BTVs that were eliminated from the comparison with screening levels. These analytes could be considered for elimination from analysis in future sampling events.

| | AOC 1 | | | |
|---|---|---|---|---|
| | Soil | | | |
| Analyte | 0 to 1 ft bgs | 0 to 5 ft bgs | 0 to 10 ft bgs | Groundwater |
| Aluminum | | | | X |
| Antimony | | | | X |
| Barium | | | X | |
| Beryllium | | | | X |
| Cadmium | | | | X |
| Cobalt | | | | X |

| Analyte | AOC 1 | | | |
|---|---|---|---|---|
| | Soil | | | Groundwater |
| | 0 to 1 ft bgs | 0 to 5 ft bgs | 0 to 10 ft bgs | |
| Mercury | | | | X |
| Selenium | | | | X |
| Silver | | | | X |
| Thallium | X | X | X | X |
| Vanadium | X | | | |

| Analyte | AOC 3 | | |
|---|---|---|---|
| | Soil | | Groundwater |
| | 0 to 1 ft bgs | 0 to 5 ft bgs | |
| PAHs | | Naphthalene only | All 18 PAH analytes |
| Aluminum | | | X |
| Antimony | | | X |
| Arsenic | X | | |
| Barium | X | X | X |
| Beryllium | | | X |
| Cadmium | | X | X |
| Chromium | X | X | X |
| Copper | | | X |
| Iron | | | X |
| Mercury | X | | X |
| Selenium | | | X |
| Silver | | | X |
| Thallium | | | X |

Note: AOC 3 0 to 10 ft bgs – no analytes had maximum detected concentrations less than the BTV.

## 5.5 NATURE, FREQUENCY OF DETECTION, MAGNITUDE, AND SPATIAL DISTRIBUTION

For chemicals with a frequency of detection (FOD) ≤ 5% across media and depth intervals (see **Table 5-29**), the nature, frequency, magnitude, and spatial clustering of exceedances was evaluated to determine if there was a decision point surrounding the data (e.g., does it elucidate a data gap where additional sampling may be needed). Chemicals with no detected results (e.g., FOD = 0%) were not further evaluated within the context of this subsection. Chemicals detected in 5% or less of samples across media and depth intervals are listed below per exposure area; **bolded** chemicals had an exceedance of their respective human health and/or ecological screening levels and will be discussed further within this subsection.

- AOC 1
  - **Picric acid** (1/62 detected)
- AOC 3
  - Cumene (1/25 detected)
  - m,p-Xylene (1/25 detected)

- **4-Nitroaniline** (1/43 detected)
- Bis(2-ethylhexyl)phthalate (2/43 detected)
- Caprolactam (1/43 detected)
- **Cresols, m- & p-** (1/43 detected)
- **Dibenzofuran** (2/43 detected)

- AOC 5

- **Benzaldehyde** (1/74 detected)
- Caprolactam (1/75 detected)
- **Dibenzofuran** (3/75 detected)
- **di-n-Butyl phthalate** (1/75 detected)
- Phenol (1/77 detected)
- Silver (1/87 detected)

For AOC 1, picric acid had a single detection at surface soil location NYOW-01-026, which was located near the perimeter of the northernmost former ammonium picrate building (**Figure 2-2**). The detected concentration exceeded ecological screening levels (soil invertebrate and mammal); however, analytical limits (i.e., the LOD) exceeded the screening levels in all soil samples.

For AOC 3, only 4-nitroaniline, m- & p-cresols, and dibenzofuran exceeded a human health and/or ecological screening level. The single occurrence of 4-nitroaniline was in groundwater (NYOW-03-015; **Figure 2-3**) in the northwest quadrant of the former landfill area, just south of the June 1949 dumping extent. The concentration exceeded the human health screening level; however, analytical limits (i.e., the LOD) exceeded the screening level in all groundwater samples. For m- & p-cresols and dibenzofuran, the exceedances were limited to soil invertebrates in surface soil (0 to 1 ft bgs) at sample locations NYOW-03-011 (dibenzofuran only) and NYOW-03-012 (**Figure 2-3**). These two locations are in the southeast quadrant of the former landfill area, outside the extents of the August 1944 and June 1949 dumping, between the parking lot and Potter Road. Both chemicals were only detected below the LOQ, therefore, the detected concentrations of each chemical were censored at the LOQ.

For AOC 5, only benzaldehyde, dibenzofuran, and di-n-butyl phthalate exceeded an ecological screening level. Dibenzofuran was detected in sample NYOW-05-024 at 1 to 5 ft bgs, which is located just to the west of the dual A and B Coal Aggregate Bins, between the Coal Storage Area and the bins (**Figure 2-9**). Two additional exceedances of the soil invertebrate screening level for dibenzofuran occurred in surface soil at NYOW-05-003 and -005 within the Possible Dump Area (**Figure 2-9**). The other exceedances in the Possible Dump Area in surface soil: benzaldehyde (NYOW-05-001, soil invertebrates) and di-n-butyl phthalate (NYOW-05-005, birds and soil invertebrates). The detections of benzaldehyde and dibenzofuran were censored at the LOQ and exceeded the soil invertebrate ecological screening level.

### 5.5.1 Initial Conclusions – Nature, Frequency of Detection, Magnitude, and Spatial Distribution

For constituents detected in 5% or less of samples across media and depth intervals, initial conclusions are presented by AOC.

AOC 1

The picric acid (detected in 1 of 62 samples) concentration was censored at the LOQ and exceeded the soil invertebrate and mammal screening levels. This trace-level result was the only detect among a combined 269 groundwater and soil samples (0 to 1, 1 to 5, and 5 to 10 ft bgs) between AOC 1 – Ammonium Picrate Area and AOC 4 – Bunker Area (where the ammonium picrate was stored). These sampling results support the hypothesis that picric acid remaining on site would have been degraded since the cessation of ammonium picrate manufacturing almost 80 years ago. There does not appear to be a data gap for picric acid that would elicit further sampling.

AOC 3

4-Nitroaniline was detected in 1 of 43 samples that was censored at the LOQ. The detect was in groundwater but not soil. However, the sample was collected along what would be an most upgradient estimated edge of the historical 1949 dumping with no groundwater samples collected within the historical dumping area. Although the one detection does not necessarily indicate a release, the lack of concentration data within the historical footprint of the dumping is a potential data gap.

Dibenzofuran (detected in 2 of 43 samples) and m- & p-cresols (detected in 1 of 43 samples) concentrations were censored at the LOQ and exceeded only the soil invertebrate screening level. All of these detects were in surface soil in the southeast quadrant of the former landfill area, outside the extents of the historical dumping, between the parking lot and Potter Road. Given the reworking of the soil in that area and the proximity to the road, attribution of surface soil concentrations in that area to DoD activities is suspect. Therefore, a substantial data gap for these analytes does not seem to exist.

AOC 4

Not applicable. There were no detections in groundwater or discrete or ISM soil samples collected from AOC 4.

AOC 5

Benzaldehyde (detected in 1 of 74 samples) and dibenzofuran (detected in 3 of 75 samples) concentrations were censored at the LOQ and exceeded only the soil invertebrate screening level. Di-n-butyl phthalate (detected in 1 of 75 samples) was the only phthalate detected in AOC 5. Therefore, a substantial data gap for these analytes does not seem to exist given there is no discernible pattern of hits or source area identified.

## 5.6 HUMAN HEALTH RISK SCREENING

With the exception of essential nutrients (calcium, magnesium, potassium, and sodium), for analytes remaining after the steps presented in **Subsections 5.1 through 5.4**, a risk-based human health screening was performed. A summary of the results of the completed steps and whether the analyte advances to the screening-level comparison is presented for groundwater and soil in **Table 5-37 and Table 5-38**, respectively.

The human health screening was limited to groundwater and soils (both surface and subsurface) and was conducted in accordance with CERCLA guidance, and the procedures documented in the Phase 1 Risk Screening Approach (**Appendix A**). Published guidance from USACE and New York State Department of Environmental Conservation (NYSDEC) were also considered. Sources include but are not limited to:

- USACE *Risk Assessment Handbook, Volume I: Human Health Evaluation* (EM 200-1-4) (USACE, 1999)
- Risk Assessment Guidance for Superfund (RAGS):
  - *Volume I: Human Health Evaluation Manual (Part A) (Interim Final)* (EPA, 1989);
  - *Volume I: Human Health Evaluation Manual: Supplemental Guidance – "Update of Standard Default Exposure Factors"* (EPA, 2014a);
  - *Volume I: Human Health Evaluation Manual (Part D, Standardized Planning, Reporting and Review of Superfund Risk Assessments)* (EPA, 2001);
  - *Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) (Final)* (EPA, 2004);
  - *Volume I: Human Health Evaluation Manual (Part F, Supplemental Guidance for Inhalation Risk Assessment) (Final)* (EPA, 2009);
- EPA *Child Exposure Factors Handbook* (EPA, 2008)
- EPA *Exposure Factors Handbook: 2011 Edition* (EPA, 2011) and relevant chapter updates
- EPA *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (EPA, 2005)
- EPA RSL Table (EPA, 2022, or latest version)
- EPA *Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors* (EPA, 2014)
- USACE *Environmental Quality, Standard Scopes of Work for Environmental Risk Assessments* (EP 200-1-15) (USACE, 2016)
- Input from NYSDEC

The human health screening was completed stepwise to focus the COPC list to those chemicals that may pose a potential risk to human receptors. A brief description of the process is noted below.

- Compare the site screening concentrations to the most recent versions of the Residential Soil and Tap Water RSLs (EPA, 2022). For discrete samples, the screening concentration was the maximum detected concentration regardless of the size of the dataset. For ISM samples, 2x the maximum detected concentration was used as a conservative screening concentration in lieu of the recommended 95% upper confidence limit (UCL) from the ITRC ISM-2 calculator; however, there were no detections in the 2021 ISM samples. For an analyte with all non-detect results, the highest LOQ was used for screening in order to inform the data gaps analysis. If a data gap is identified due to poor sensitivity, analytical alternatives that may improve sensitivity will be assessed. In general, a chemical was selected as a COPC if the screening concentration exceeded the screening value or if a screening value was not available for a potential receptor. The essential and generally non-toxic "macro elements," calcium, magnesium, potassium, and sodium were not considered COPCs.
- Groundwater and soil sample results (surface and subsurface) were compared to relevant human health screening levels on a sample-by-sample basis.
- Screening level comparison tables are presented by medium per AOC with detected concentrations exceeding screening levels highlighted (**Appendix J**). Tables presenting sample by sample comparisons are presented in **Appendix J.1** and **Appendix J.2** for groundwater and soil, respectively.

- RAGS D Table 2s (EPA, 2001) are also provided to summarize the results. Groundwater tables are presented in **Appendix J.3** and soil tables are presented in **Appendix J.4**.
- Risk characterization modeling (including blood lead modeling) and derivation of exposure point concentrations (EPCs), hazard quotients, hazard indices, and incremental lifetime cancer risks were not completed.

## 5.7 ECOLOGICAL RISK SCREENING

In general, for analytes remaining after the steps presented in **Subsections 5.1 through 5.4**, a risk-based ecological screening will be completed. Exceptions include essential nutrients and generally non-toxic "macro elements," calcium, magnesium, potassium, and sodium (Henry and Miles 2001), which are required for proper organism growth and function. If these elements are not detected at the Site at levels elevated above typical ambient conditions, they are not expected to pose any substantial ecological risk to receptors and, therefore, would not be considered constituents of potential ecological concern (COPECs) (see **Subsection 6.2.2** for results).

Other exceptions are aluminum and iron, which do not have chemical-specific bulk soil toxicity screening levels but are evaluated based on whether the soil pH is conducive to bioavailability. Site soil pH data are not available, therefore if these elements are not detected at the Site at levels elevated above typical ambient conditions, they are not expected to pose any substantial ecological risk to receptors and, therefore, would not be considered COPECs (see **Subsection 6.2.2** for results). A summary of the results of the completed steps and whether an analyte advanced to the ecological screening-level comparison is presented on a receptor basis in **Tables 5-39** through **5-42**.

The ecological screening was prepared in accordance with EPA's Risk Assessment Guidance under CERCLA and the procedures documented in the Phase 1 Risk Screening Approach (**Appendix A**). The primary guidance that used to perform the screening is EPA's *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (EPA, 1997) and the USACE's *Environmental Quality – Risk Assessment Handbook, Volume II: Environmental Evaluation* (USACE, 2010).

As specified in the UFP-QAPP (USACE, 2020; Section 10.6.4 Potential Ecological Receptors and Exposure Routes), the media of concern for the ecological screening is limited to soils (both surface and 1 to 5 ft bgs subsurface). Ecological receptor exposures to the 5 to 10 ft bgs depth interval is limited to the roots of larger plants (e.g., shrubs and trees) as the interval is deeper than the biologically active zone for invertebrates (EPA, 2015b) and deeper than what birds and burrowing mammals would be anticipated to reach. Therefore, the 5 to 10 ft bgs depth interval was not evaluated in Phase 1, but may be evaluated in Phase 2, if deemed appropriate.

The ecological screening was completed in a stepwise manner to focus the COPEC list to those chemicals that may pose a potential risk to ecological receptors. A brief description of the process is noted below. This Phase 1 Ecological Risk Screening process is also described in the attached ecological risk assessment flow chart (**Figure 5-1**). The Phase 1 Ecological Risk Screening can be seen in-context of the screening-level ecological risk assessment process when viewed with **Figure 5-2**.

- The site screening concentration was compared to conservative benchmarks. For discrete samples, the screening concentration was the maximum detected concentration regardless of the size of the

dataset. For ISM samples, 2x the maximum detected concentration would have been used as a conservative screening concentration in lieu of the recommended 95% UCL from the ITRC ISM-2 calculator; however, there were no detections in the 2021 ISM samples. Analytes with all non-detect results were not advanced to the screening level comparisons, but the LOQs were compared in **Subsection 5.1.2** to inform the data gaps analysis. If a data gap is identified due to poor sensitivity, analytical alternatives that may improve sensitivity will be assessed in a future UFP-QAPP, should the analyte be recommended for evaluation in Phase 2.

- Direct exposure to surface soil in AOC 1, AOC 4, and AOC 5 was evaluated for plants and soil invertebrates using soil screening values. Indirect exposure to bioaccumulative constituents in surface soil was evaluated using soil screening values based on food chain modeling for representative invertivorous birds and/or small mammal receptors. Receptor selection was guided by the results of the receptor resource inventory (see **Appendix K**). AOC 3 is mostly a paved parking lot for a golf course. Due to the limited area and low quality ecological habitat, AOC 3 surface soils were not considered an ecological exposure medium (see **Section 7,** Conceptual Site Model Updates).
- Direct exposure to subsurface soil (0 to 5 ft bgs only) in AOC 1, AOC 3, AOC 4, and AOC 5 was evaluated for the plants and soil invertebrates using soil screening values. Habitat within AOCs 1 and 4 is potentially suitable to support burrowing mammalian receptors (e.g., red fox); therefore, indirect exposure to bioaccumulative constituents in subsurface soil was evaluated using soil screening values based on food chain modeling for mammals (see **Section 7,** Conceptual Site Model Updates).
- Screenings were completed on a receptor basis so it can be determined which receptor categories do not need further evaluation for each constituent. The receptors evaluated in each AOC are noted below. Phase 2-based ecological risk assessments may evaluate other receptors, if deemed appropriate.
    - AOC 1
        - 0 to 1 ft bgs – plants, soil invertebrates, birds, and mammals
        - 0 to 5 ft bgs – plants, soil invertebrates, and mammals
    - AOC 3
        - 0 to 5 ft bgs – plants and soil invertebrates
    - AOC 4 – discrete
        - 0 to 1 ft bgs – plants, soil invertebrates, birds, and mammals
        - 0 to 5 bgs plants, soil invertebrates, and mammals
    - AOC 4 – ISM
        - 0 to 1 ft bgs – plants, soil invertebrates, birds, and mammals
    - AOC 5 (subareas separate)
        - 0 to 1 ft bgs – plants, soil invertebrates, birds, and mammals
        - 0 to 5 ft bgs plants, soil invertebrates, and mammals

- Screening level comparison tables are presented by medium per AOC with detected concentrations exceeding screening levels highlighted (**Appendix L**) as follow:
    - **Appendix L.1** Sample by Sample Screening – Plants;
    - **Appendix L.2** Sample by Sample Screening – Soil Invertebrates;
    - **Appendix L.3** Sample by Sample Screening – Birds; and
    - **Appendix L.4** Sample by Sample Screening – Mammals.
- RAGS D Table 2s (EPA, 2001) also are provided to summarize the results in **Appendix L** as follows:
    - **Appendix L.5** Screening Summary – Plants;
    - **Appendix L.6** Screening Summary – Soil Invertebrates;
    - **Appendix L.7** Screening Summary – Birds; and
    - **Appendix L.8** Screening Summary – Mammals.

# 6.0 RISK SCREENING RESULTS AND DISCUSSION

## 6.1 INTRODUCTION

After the comparison of media concentrations to calculated background threshold values was completed, analytes with maximum detection concentration (MDC) greater than the BTV were carried forward for further comparison to risk-based screening values (**Subsections 5.6 and 5.7**). The following sections provide the results of the risk screening results and a discussion of the media and COPCs that will be carried into subsequent Phase 2 investigations.

## 6.2 RESULTS

The results of the human health and ecological risk screenings, including constituents identified as site COPCs by media and the associated receptor populations is presented in the sections below.

### 6.2.1 Human Health

Risk screening for human health was completed in accordance with **Subsection 5.6**. Screening level comparison tables are provided by medium per AOC in **Appendix J**. The COPCs in soil were identified by comparing the maximum detected concentrations to the Residential Soil RSLs (EPA, 2022). COPCs in groundwater were identified by comparing the maximum detected concentrations to the Tap Water RSLs (EPA, 2022).

#### *6.2.1.1 AOC 1 Human Health Risk Screening*

Ten metal analytes were carried forward to the risk-based screening step for shallow groundwater at AOC 1. Aluminum, barium, iron, manganese, nickel, and vanadium had MDCs greater than their respective Tap Water RSLs and were identified as groundwater COPCs (**Table J.3-1**).

Picric acid and 17 metal analytes were carried forward to the risk-based screening step for surface soil at AOC 1. Arsenic, cadmium, cobalt, iron, and manganese had MDCs greater than the Residential Soil RSL and were identified as surface soil COPCs (**Table J.4-1**). Picric acid and 18 metal analytes were carried forward to the risk-based screening step for surface and subsurface soil (0-5 ft bgs) at AOC 1. Aluminum, arsenic, cadmium, cobalt, iron, and manganese had MDCs greater than the Residential Soil RSL and were identified as soil COPCs in the 0-5 ft bgs interval (**Table J.4-2**). Picric acid and 17 metal analytes were carried forward to the risk-based screening step for all soil (0-10 ft bgs) at AOC 1. Aluminum, arsenic, cadmium, cobalt, iron, and manganese had MDCs greater than the Residential Soil RSL and were identified as soil COPCs in the 0-10 ft bgs interval (**Table J.4-3**).

#### *6.2.1.2 AOC 3 Human Health Risk Screening*

Four VOCs (acetone, benzene, m,p-xylenes, toluene), 3 SVOCs, and seven metals were carried forward to the risk-based screening step for shallow groundwater at AOC 3. Benzene, 4-nitroaniline, arsenic, cobalt, manganese, nickel, and vanadium had MDCs greater than their respective Tap Water RSLs and were identified as groundwater COPCs (**Table J.3-2**).

Five SVOCs, 18 PAHs, Aroclor-1260, and 15 metal analytes were carried forward to the risk-based screening step for surface soil at AOC 3. Five PAHs (benzo(a)anthracene, benzo(a)pyrene,

benzo(b)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene) and five metals (aluminum, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface soil COPCs (**Table J.4-4**). Four VOCs, five SVOCs, 17 PAHs, Aroclor-1260, and 16 metal analytes were carried forward to the risk-based screening step for surface and subsurface soil (0-5 ft bgs) at AOC 3. Five PAHs (benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene) and five metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as soil COPCs for all soil (0-5 ft bgs) (**Table J.4-5**).

#### *6.2.1.3 AOC 5 Boiler House Human Health Risk Screening*

Caprolactam, 16 PAHs, and eight metals were carried forward to the risk-based screening step for shallow groundwater at the AOC 5 Boiler House area. Five PAHs (benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, and naphthalene) and five metals (antimony, arsenic, cobalt, manganese, and vanadium) had MDCs greater than the Residential Tap Water RSL and were identified as groundwater COPCs (**Table J.3-3**).

Eighteen PAHs and 18 metal analytes were carried forward to the risk-based screening step for surface soil at the AOC 5 Boiler House area. Five metals (arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface soil COPCs (**Table J.4-6**). Eighteen PAHs and 18 metal analytes were carried forward to the risk-based screening step for surface and subsurface soil (0-5 ft bgs) at the AOC 5 Boiler House area. Six metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface and subsurface soil COPCs (**Table J.4-7**). Eighteen PAHs and 18 metal analytes were carried forward to the risk-based screening step for all soil (0-10 ft bgs) at the AOC 5 Boiler House area. Six metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface and subsurface soil COPCs (**Table J.4-8**).

#### *6.2.1.4 AOC 5 Coal Aggregate Bins Area Human Health Risk Screening*

Phenol, five PAHs, and 12 metals were carried forward to the risk-based screening step for shallow groundwater at the AOC 5 Coal Aggregate Bins area. Naphthalene and seven metals (aluminum, arsenic, cobalt, iron, manganese, nickel, and vanadium) had MDCs greater than the Residential Tap Water RSL and were identified as groundwater COPCs (**Table J.3-4**).

Eighteen PAHs and 18 metal analytes were carried forward to the risk-based screening step for surface soil at the AOC 5 Coal Aggregate Bins area. Five PAHs (benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene) and six metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface soil COPCs (**Table J.4-9**). Dibenzofuran, 18 PAHs and 18 metal analytes were carried forward to the risk-based screening step for surface and subsurface soil (0-5 ft bgs) at the AOC 5 Coal Aggregate Bins area. Five PAHs (benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene) and six metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface and subsurface soil COPCs (**Table J.4-10**). Dibenzofuran, 18 PAHs and 18 metal analytes were carried forward to the risk-based screening step for all soil (0-10 ft bgs) at the AOC 5 Coal Aggregate Bins area. Five PAHs (benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene) and six metals

(aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as soil COPCs (**Table J.4-11**).

#### *6.2.1.5 AOC 5 Coal Storage Area Human Health Risk Screening*

Four PAHs (1-methylnaphthalene, 2-methylnaphthalene, naphthalene, and phenanthrene) and seven metals were carried forward to the risk-based screening step for shallow groundwater at the AOC 5 Coal Storage area. Naphthalene, antimony, arsenic, cobalt, iron, manganese, and nickel had MDCs greater than their respective Tap Water RSLs and were identified as groundwater COPCs (**Table J.3-5**).

Eighteen PAHs and 18 metal analytes were carried forward to the risk-based screening step for surface soil at the AOC 5 Coal Storage area. Two PAHs (benzo(a)pyrene and naphthalene) and five metals (arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface soil COPCs (**Table J.4-12**). Eighteen PAHs and 18 metal analytes were carried forward to the risk-based screening step for surface and subsurface soil (0-5 ft bgs) at the AOC 5 Coal Storage area. Two PAHs (benzo(a)pyrene and naphthalene) and five metals (arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface and subsurface soil COPCs (**Table J.4-13**). Eighteen PAHs and 18 metal analytes were carried forward to the risk-based screening step for all soil (0-10 ft bgs) at the AOC 5 Coal Storage area. Two PAHs (benzo(a)pyrene and naphthalene) and six metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface and subsurface soil COPCs (**Table J.4-14**).

#### *6.2.1.6 AOC 5 Electric Substation Human Health Risk Screening*

Naphthalene, arsenic, barium, cobalt, iron, and manganese were carried forward to the risk-based screening step for shallow groundwater at the AOC 5 Electric Substation. Naphthalene, arsenic, cobalt, and manganese had MDCs greater than their respective Tap Water RSLs and were identified as groundwater COPCs (**Table J.3-6**).

Eighteen PAHs, Aroclor-1260, and 18 metal analytes were carried forward to the risk-based screening step for surface soil at the AOC 5 Electric Substation. Six metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface soil COPCs (**Table J.4-15**). Eighteen PAHs, Aroclor-1260, and 18 metal analytes were carried forward to the risk-based screening step for surface and subsurface soil (0-5 ft bgs) at the AOC 5 Electric Substation. Six metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface and subsurface soil COPCs (**Table J.4-16**). Eighteen PAHs, Aroclor-1260, and 18 metal analytes were carried forward to the risk-based screening step for all soil (0-10 ft bgs) at the AOC 5 Electric Substation. Six metals (aluminum, arsenic, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface and subsurface soil COPCs (**Table J.4-17**).

#### *6.2.1.7 AOC 5 Possible Dump Area Human Health Risk Screening*

The VOC 1,2,3-trichlorobenzene, eight PAHs and seven metals were carried forward to the risk-based screening step for shallow groundwater at the AOC 5 Possible Dump area. 1,2,3-Trichlorobenzene, naphthalene, arsenic, cobalt, manganese, and nickel had MDCs greater than their respective Tap Water RSLs and were identified as groundwater COPCs (**Table J.3-7**).

Three SVOCs (benzaldehyde, dibenzofuran, and di-n-butyl phthalate), 17 PAHs, and 19 metal analytes were carried forward to the risk-based screening step for surface soil at the AOC 5 Possible Dump. Six metals (arsenic, cadmium, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface soil COPCs (**Table J.4-18**). Four VOCs (2-butanone, acetone, benzene, toluene), three SVOCs (benzaldehyde, dibenzofuran, and di-n-butyl phthalate), 17 PAHs, and 19 metal analytes were carried forward to the risk-based screening step for surface and subsurface soil (0-5 ft bgs) at the AOC 5 Possible Dump. Seven metals (aluminum, arsenic, cadmium, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as surface and subsurface soil COPCs (**Table J.4-19**). Four VOCs (2-butanone, acetone, benzene, toluene), three SVOCs (benzaldehyde, dibenzofuran, and di-n-butyl phthalate), 17 PAHs, and 19 metal analytes were carried forward to the risk-based screening step for all soil (0-10 ft bgs) at the AOC 5 Possible Dump. Seven metals (aluminum, arsenic, cadmium, cobalt, iron, manganese, and thallium) had MDCs greater than the Residential Soil RSL and were identified as soil COPCs (**Table J.4-20**).

#### *6.2.1.8 Human Health Risk Screening Discussion*

Metals were identified as COPCs in shallow groundwater in every investigation area. Manganese and arsenic were the most frequently identified groundwater COPCs and the only metals that were identified as a COPC in all areas (AOC 1, AOC 3, and each of the five AOC 5 subareas). Cobalt was identified as a COPC in every area except AOC 1. Nickel was identified as a COPC in five of the seven areas, including AOC 1, AOC 3, AOC 5 Coal Aggregate Bins, AOC 5 Coal Storage, and the AOC 5 Possible Dump. Vanadium was identified as a COPC in four of the seven areas (AOC 1, AOC3, AOC 5 Coal Aggregate Bins, and AOC 5 Boiler House). Iron was identified as a COPC in three of the seven areas (AOC 1, AOC 5 Coal Aggregate Bins, and AOC 5 Coal Storage). Antimony was identified as COPCs in two areas (AOC 5 Boiler House and AOC 5 Coal Storage,). Barium and antimony were only identified as COPCs in AOC 1 and AOC 5 Coal Aggregate Bins shallow groundwater, respectively.

Benzene at AOC 3 and 1,2,3-trichlorobenzene at the AOC 5 Possible Dump were the only VOCs detected in groundwater above their respective Tap Water RSLs and identified as groundwater COPCs. 4-Nitroanaline at AOC 3 was the only SVOC detected above the Tap Water RSL and identified as a groundwater COPC. Naphthalene was identified as a groundwater COPC in all AOC 5 subareas. The AOC 5 Boiler House was the only AOC with carcinogenic PAHs as groundwater COPCs, including benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenz(a,h)fluoranthene.

The preliminary CSMs for each AOC included potable use pathways for current and future nearby resident receptors. Based on the results of the risk screening, the ingestion and dermal contact with drinking water pathways must be retained. Inhalation of benzene and 1,2,3-trichlorobenzene are potentially complete pathways associated with potable use of groundwater and should be added to the human health CSMs for AOC 3 and the AOC 5 Possible Dump. The maximum detected benzene concentration (raised to the LOQ of 1 microgram per liter [µg/L] at multiple locations) is below the EPA Vapor Intrusion Screening Level (VISL, EPA, 2022) for groundwater set to a target cancer risk (TRC) of 1E-06 and a hazard quotient (HQ) of 0.1 (1.59 µg/L). There is no groundwater VISL for 1,2,3-trichlorobenzene because there is insufficient inhalation toxicity information. The maximum detected 1,2,3-trichlorobenzene concentration (raised to the LOQ of 1 µg/L at NYOW-05-004) is below the 1,2,4-trichlorobenzene VISL for groundwater set to a TRC of 1E-06 and an HQ of 0.1 (3.59 µg/L).

Metals were identified as COPCs in surface and subsurface soil in every investigation area. Cobalt, iron, and manganese were the most frequently identified surface and subsurface soil COPCs and the only metals

that were identified as COPCs in all areas and at all depths. Aluminum, arsenic, cadmium, and thallium were the only other metals identified as potentially site-related soil COPCs.

Carcinogenic PAHs including benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene were identified as COPCs in surface and subsurface soil at AOC 3 and the AOC 5 Coal Aggregate Bins. Benzo(a)pyrene and benzo(a)anthracene were also identified as COPCs in the AOC 5 Coal Storage subarea and in AOC 3, respectively. Naphthalene was identified as a surface and subsurface soil COPC in the AOC 5 Coal Aggregate Bins and Coal Storage areas.

The preliminary CSMs for AOC 1, AOC 3, and AOC 5 included surface soil exposure pathways for worker populations, recreators, or trespassers. Based on the results of the risk screening, the ingestion, dermal contact, and inhalation pathways associated with surface soil must be retained. The AOC 3 CSM included subsurface soil exposure for future utility workers. Based on the results of the risk screening, the ingestion, dermal contact, and dust inhalation pathways associated with surface and subsurface soil must be retained.

### 6.2.2 Ecological

Risk screening for ecological receptors was completed in accordance with **Subsection 5.7**. Screening level comparison tables are provided per receptor group and AOC in **Appendix L**. The COPECs in soil were identified by comparing the maximum detected concentrations to applicable receptor category (plants, soil invertebrates, birds and mammals) ecological screening benchmarks.

#### *6.2.2.1 AOC 1 Ecological Risk Screening*

Plants

Fifteen metal analytes and one explosive were carried forward to the risk-based screening step for surface soils at AOC 1. Eight metals: barium, chromium, copper, lead, manganese, mercury, selenium, and zinc had MDCs greater than plant-based screening value and were identified as COPECs (**Table L.5-1**). Eighteen metals and one explosive were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 1. The same eight metals had MDCs greater than the plant-based screening value and were identified as COPECs for subsurface soils (**Table L.5-2**).

Soil Invertebrates

Thirteen metal analytes and one explosive were carried forward to the risk-based screening step for surface soils at AOC 1. Five metals: arsenic, chromium, manganese, mercury, and zinc; and one explosive (picric acid) had MDCs greater than plant-based screening value and were identified as COPECs (**Table L.6-1**). Thirteen metals and one explosive were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 1. The same five metals and one explosive had MDCs greater than the soil invertebrate-based screening value and were identified as COPECs for subsurface soils (**Table L.6-2**).

Birds

Thirteen metal analytes and one explosive were carried forward to the risk-based screening step for surface soils at AOC 1. Five metals: cadmium, copper, lead, mercury, and zinc had MDCs greater than avian-based screening value and were identified as COPECs (**Table L.7-1**).

Mammals

Fifteen metal analytes and one explosive were carried forward to the risk-based screening step for surface soils at AOC 1. Six metals: antimony, cadmium, copper, lead, selenium, and zinc; and one explosive (picric acid) had MDCs greater than mammal-based screening value and were identified as COPECs (**Table L.8-1**). Sixteen metals and one explosive were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 1. The same six metals (plus manganese) and one explosive had MDCs greater than the mammal-based screening value and were identified as COPECs for subsurface soils (**Table L.8-2**).

#### *6.2.2.2 AOC 3 Ecological Risk Screening*

Plants

One VOC, two SVOCs, seven PAHs, one PCB and 16 metal analytes were carried forward to the risk-based screening step for subsurface soils at AOC 3. Two PAHs (acenaphthene and anthracene) and three metals (manganese, selenium, and thallium) had MDCs greater than plant-based screening value and were identified as COPECs (**Table L.5-3**).

Soil Invertebrates

Four VOCs, five SVOCs, HMW and LMW PAHs, one PCB and ten metal analytes were carried forward to the risk-based screening step for subsurface soils at AOC 3. One VOC (acetone), four SVOCs: benzaldehyde, carbazole, m&p cresols, and dibenzofuran; and two metals (manganese and mercury) had MDCs greater than soil invertebrate-based screening value and were identified as COPECs (**Table L.6-3**).

#### *6.2.2.3 AOC 5 Boiler House Ecological Risk Screening*

Plants

Seven PAHs and 16 metal analytes and were carried forward to the risk-based screening step for surface soils at AOC 5 (Boiler House). Four metals: arsenic, chromium, manganese, and thallium had MDCs greater than plant-based screening value and were identified as COPECs (**Table L.5-4**). The same PAHs and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 1 (Boiler House). The same four metals as the surface soils had MDCs greater than the plant-based screening value and were identified as COPECs for subsurface soils (**Table L.5-5**).

Soil Invertebrates

HMW and LMW PAHs and 13 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Boiler House). Four metals: arsenic, chromium, manganese, and mercury had MDCs greater than soil invertebrate-based screening value and were identified as COPECs (**Table L.6-4**). The same PAHs and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (Boiler House). The same four metals and zinc as the surface soils had MDCs greater than the soil invertebrate-based screening value and were identified as COPECs for subsurface soils (**Table L.6-5**).

Birds

Six metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Boiler House). No metals had MDCs greater than avian-based screening value and were identified as COPECs (**Table L.7-2**).

Mammals

HMW and LMW PAHs and eight metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Boiler House). No metals had MDCs greater than mammal-based screening value and were identified as COPECs (**Table L.8-3**). HMW and LMW PAHs and 15 metals and were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (Boiler House). Only zinc had a MDCs greater than the mammal-based screening value and were identified as COPECs for subsurface soils (**Table L.8-4**).

#### *6.2.2.4 AOC 5 Coal Aggregate Bins Area Ecological Risk Screening*

Plants

Eight PAHs and 16 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (coal aggregate bins). Three PAHs: 1-methylnaphthalene, 2-methylnapthalene and naphthalene and, four metals: chromium, manganese, selenium, and thallium had MDCs greater than plant-based screening value and were identified as COPECs (**Table L.5-6**). One SVOC and the same PAHs and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (coal aggregate bins). The same three PAHs and four metals as the surface soils had MDCs greater than the plant-based screening value and were identified as COPECs for subsurface soils (**Table L.5-7**).

Soil Invertebrates

HMW and LMW PAHs and 13 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Coal Aggregate Bins). Four metals: arsenic, chromium, manganese, and mercury had MDCs greater than soil invertebrate-based screening value and were identified as COPECs (**Table L.6-6**). One SVOC, the same PAHs and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (Coal Aggregate Bins). The same four metals as the surface soils had MDCs greater than the soil invertebrate-based screening value and were identified as COPECs for subsurface soils (**Table L.6-7**).

Birds

Five PAHs and 11 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (coal aggregate bins). Three PAHs: 1-methylnaphthalene, 2-methylnaphthalene, and naphthalene and three metals: lead, vanadium and zinc had MDCs greater than avian-based screening value and were identified as COPECs (**Table L.7-3**).

Mammals

HMW and LMW PAHs and 13 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (coal aggregate bins). HMW PAHs and two metals: antimony and selenium had MDCs greater than mammal-based screening value and were identified as COPECs (**Table L.8-5**). HMW and LMW PAHs and 15 metals and were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (coal aggregate bins). HMW PAHs and three metals: antimony, cadmium and

selenium had MDCs greater than the mammal-based screening value and were identified as COPECs for subsurface soils (**Table L.8-6**).

#### *6.2.2.5 AOC 5 Coal Storage Area Ecological Risk Screening*

Plants

Eight PAHs and 16 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Coal Storage Area). Four PAHs: 1-methylnaphthalene, 2-methylnapthalene, acenaphthene and naphthalene, and five metals: arsenic, chromium, manganese, selenium, and thallium had MDCs greater than plant-based screening value and were identified as COPECs (**Table L.5-8**). The same PAHs and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (coal storage area). The same four PAHs and five metals as the surface soils had MDCs greater than the plant-based screening value and were identified as COPECs for subsurface soils (**Table L.5-9**).

Soil Invertebrates

HMW and LMW PAHs and 13 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Coal Storage Area). LMW PAHs and three metals: arsenic, chromium and mercury had MDCs greater than soil invertebrate-based screening value and were identified as COPECs (**Table L.6-8**). The same PAHs and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (coal storage area). The same PAHs and metals (plus manganese) as the surface soils had MDCs greater than the soil invertebrate-based screening value and were identified as COPECs for subsurface soils (**Table L.6-9**).

Birds

Five PAHs and nine metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Coal Storage Area). Four PAHs: 1-methylnaphthalene, 2-methylnaphthalene, benzo(a)anthracene and naphthalene and four metals: lead, selenium, vanadium, and zinc had MDCs greater than avian-based screening value and were identified as COPECs (**Table L.7-4**).

Mammals

HMW and LMW PAHs and 11 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Coal Storage Area). HMW PAHs and three metals: antimony, selenium and thallium had MDCs greater than mammal-based screening value and were identified as COPECs (**Table L.8-7**). HMW and LMW PAHs and 15 metals and were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (coal aggregate bins). HMW PAHs and four metals: antimony, cadmium, selenium, and thallium had MDCs greater than the mammal-based screening value and were identified as COPECs for subsurface soils (**Table L.8-8**).

#### *6.2.2.6 AOC 5 Electric Substation Ecological Risk Screening*

Plants

Eight PAHs, one PCB and 16 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Electric Substation). One Aroclor and four metals: chromium, manganese, selenium, and thallium had MDCs greater than plant-based screening value and were identified as COPECs (**Table L.5-10**). The same PAHs, Aroclor, and metals were carried forward to the risk-based screening step

for subsurface soils (0-5 ft bgs) at AOC 5 (Electric Substation). The same four metals as the surface soils had MDCs greater than the plant-based screening value and were identified as COPECs for subsurface soils (**Table L.5-11**).

Soil Invertebrates

HMW and LMW PAHs, one PCB and 13 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Electric Substation). Three metals: chromium, manganese, and mercury had MDCs greater than soil invertebrate-based screening value and were identified as COPECs (**Table L.6-10**). The same PAHs and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (Electric Substation). The same three metals as the surface soils had MDCs greater than the soil invertebrate-based screening value and were identified as COPECs for subsurface soils (**Table L.6-11**).

Birds

Three PAHs, one PCB and 11 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Electric Substation). The one Aroclor and three metals: PCB-1260, lead, mercury, and zinc had MDCs greater than avian-based screening value and were identified as COPECs (**Table L.7-5**).

Mammals

HMW and LMW PAHs, one Aroclor and 13 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Electric Substation). Only cadmium had MDCs greater than mammal-based screening value and was identified as a COPEC (**Table L.8-9**). HMW and LMW PAHs, one Aroclor and 16 metals and were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (Electric Substation). Two metals: cadmium and copper had MDCs greater than the mammal-based screening value and were identified as COPECs for subsurface soils (**Table L.8-10**).

#### *6.2.2.7 AOC 5 Possible Dump Area Ecological Risk Screening*

Plants

Two SVOCs, eight PAHs and 17 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Possible Dump Area). Two SVOCs and six metals: dibenzofuran, di-n-butyl phthalate, chromium, copper, lead, manganese, thallium, and zinc had MDCs greater than plant-based screening value and were identified as COPECs (**Table L.5-12**). Two VOCs, and the same SVOCs, PAHs and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (Possible Dump Area). The same six metals and selenium had MDCs greater than the plant-based screening value and were identified as COPECs for subsurface soils (**Table L.5-13**).

Soil Invertebrates

Three SVOCs, HMW and LMW PAHs, one Aroclor and 13 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Possible Dump Area). Three SVOCs: benzaldehyde, dibenzofuran, and di-n-butyl phthalate, and six metals: arsenic, chromium, copper, manganese, mercury, and zinc had MDCs greater than soil invertebrate-based screening value and were identified as COPECs (**Table L.6-12**). Four VOCs and the same, SVOCs, PAHs, Aroclor and metals were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (Possible Dump Area). Acetone, and

the same three SVOCs and six metals as the surface soils had MDCs greater than the soil invertebrate-based screening value and were identified as COPECs for subsurface soils (**Table L.6-13**).

Birds

One SVOC, three PAHs, and ten metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Possible Dump Area). One SVOC (di-n-butyl phthalate) and four metals: cadmium, copper, lead, and zinc had MDCs greater than avian-based screening value and were identified as COPECs (**Table L.7-6**).

Mammals

Two SVOCs, HMW and LMW PAHs, and 12 metal analytes were carried forward to the risk-based screening step for surface soils at AOC 5 (Possible Dump Area). Five metals: antimony, cadmium, copper, lead and zinc had MDCs greater than mammal-based screening value and were identified as COPECs (**Table L.8-11**). Four VOCs, two SVOCs, HMW and LMW PAHs, and 17 metals and were carried forward to the risk-based screening step for subsurface soils (0-5 ft bgs) at AOC 5 (Possible Dump Area). Five metals: antimony, cadmium. copper, lead, and zinc had MDCs greater than the mammal-based screening value and were identified as COPECs for subsurface soils (**Table L.8-12**).

#### *6.2.2.8 Ecological Risk Screening Discussion*

The ecological risk screening results are summarized below. These results were considered in light of the uncertainties (**Subsection 6.3**) and AOC-specific COPEC lists are presented in **Subsection 6.4.2.2**.

Plants

Metals were identified as COPECs in surface and subsurface soils in AOC 1, AOC 3, and AOC 5 (all subareas). The most frequently encountered metal COPECs were chromium, manganese, selenium, and thallium. Of the 13 area/subarea depth intervals evaluated: chromium was a COPEC in 12, manganese was a COPEC in 13, selenium was a COPEC in ten and thallium was a COPEC in 11. PAHs were only identified as COPECs in AOC 5- Coal Aggregate Bins and Coal Storage Areas. The identification of petrogenic or pyrogenic fingerprints would be key to determining eligibility for any potential cleanup under FUDS.

Soil Invertebrates

Metals were identified as COPECs in surface and subsurface soils in AOC 1, AOC 3, and AOC 5 (all subareas). The most frequently encountered metal COPECs were arsenic, chromium, manganese, mercury, and zinc. Of the 13 area/subarea depth intervals evaluated: arsenic was a COPEC in ten, chromium was a COPEC in 12, manganese was a COPEC in 12, mercury was a COPEC in 12 and zinc was a COPEC in five. Picric acid was only detected and selected as a COPEC in AOC 1 (surface and subsurface soils). Acetone was the only VOC selected as a COPEC; it was a COPEC in AOC 3 and AOC 5 (Potential Dump Area) subsurface soils. SVOCs: benzaldehyde, carbazole, m&p cresol, and dibenzofuran were identified as COPECs in AOC 3 subsurface soils. Benzaldehyde, dibenzofuran, and di-n-butyl phthalate were identified as COPECs in AOC 5 (Potential Dump Area) surface and subsurface soils. Dibenzofuran was identified and a COPEC in AOC 5 (Coal Aggregate Area) subsurface soils. LMW PAHs were only identified as COPECs in AOC 5 (Coal Storage Area) surface and subsurface soils. The identification of petrogenic or pyrogenic fingerprints would be key to determining eligibility for any potential cleanup under FUDS.

Birds

Metals were identified as COPECs in surface and subsurface soils in AOC 1 and AOC 5 (all subareas). The most frequently encountered metal COPECs were copper, lead, and zinc. Of the six area/subarea depth intervals evaluated: copper was a COPEC in two, lead was a COPEC in five and zinc was a COPEC in five. PAHs were only identified as COPECs in AOC 5- Coal Aggregate Bins and Coal Storage Areas. The identification of petrogenic or pyrogenic fingerprints would be key to determining eligibility for any potential cleanup under FUDS. Di-n-butyl phthalate was the only SVOC identified, and it was in AOC 5 Possible Dump Area.

Mammals

Metals were identified as COPECs in surface and subsurface soils in AOC 1, AOC 3, and AOC 5 (all subareas). The most frequently encountered metal COPECs were antimony, cadmium, copper, lead, selenium, and zinc. Of the 12 area/subarea depth intervals evaluated; antimony was a COPEC in eight, cadmium was a COPEC in seven, copper was a COPEC in four, lead was a COPEC in four, selenium was a COPEC in five, and zinc was a COPEC in five. Picric acid was only detected and selected as a COPEC in AOC 1 (surface and subsurface soils). HMW PAHs were identified as COPECs in AOC 5 (Coal Aggregate Area and Coal Storage Area) surface and subsurface soils. The identification of petrogenic or pyrogenic fingerprints would be key to determining eligibility for any potential cleanup under FUDS.

### 6.2.3 Initial Conclusions – Risk Screening Results and Discussion

Based on the comparisons of Site concentrations with human health and ecological screening levels, summaries of COPCs/COPECs are provided for each AOC below. These summaries do not incorporate uncertainties or site-specific considerations aside from those presented **Sections 4 and 5**. See **Section 9** – Recommendations for a final list of COPCs/COPECs.

| AOC 1 | | | | | | | |
|---|---|---|---|---|---|---|---|
| | Groundwater | | Soil | | | | |
| COPC/COPECs | Temp. Well | ND & LOQ>SL | 0-1 ft bgs | 0-5 ft bgs | 0-10 ft bgs | ND & LOQ>SL | Detected but No SL |

## 6.3 UNCERTAINTY ANALYSIS

Uncertainties associated with the screenings and overall Phase 1 evaluation are classified as belonging to one of the four following categories and are discussed in the subsections below.

- Data and Information
- COPC Selection
- Exposure
- Toxicity

### 6.3.1 Data

Uncertainties associated with the data are grouped into one of the four following categories and are discussed in the subsections below.

- Media
- Analytes with Screening Levels Not Achieved at the LOQ
- Data Reduction
- Sample Size

#### *6.3.1.1 Media*

Turbidity of groundwater — the use of temporary wells resulted in groundwater samples with elevated turbidity. The turbid samples lead to uncertainties in the groundwater sample results due to sorption of insoluble analytes to particulate matter in the sample and clogging of SPE cartridges (**Section 3.2.3**). Turbid samples may lead to an overestimation of analyte concentrations unless the extraction efficiency is affected. It is noted that 9 of 16 groundwater samples clogged the SPE cartridge (i.e., flow rate <4mL/min) during extraction for the explosives analysis in AOC 4 and one sample (NYOW-04-WL005-A) required vacuum filtration through glass fiber filter paper prior to analysis due to turbidity. Low bias qualifiers primarily attributable to low surrogate recoveries indicative of poor extraction efficiency were identified at a frequency greater than 20% of samples for 2,4-DNCB and picric acid. The picric acid result for one groundwater sample (NYOW-04-WL080-A) was rejected based on surrogate recovery of less than 10%.

Soil heterogeneity — Soil samples exhibited heterogeneity as demonstrated by the analysis of FD and MS/MSD analysis, primarily affecting metals and PAHs (**Appendix B Section 2.2.1**). Soil heterogeneity results in measurements that are imprecise but does not affect the accuracy of individual measurements and the results are considered usable.

#### *6.3.1.2 Analytes with Screening Levels Not Achieved at the LOQ*

Non-DoD-related analytes with screening levels not achieved at the LOQ that were not detected are discussed in the bullets below.

- **Table 5-29** presents the DoD-relatedness categories for all analytes potentially screened within this Phase 1 evaluation. Analytes that were not detected in any media and are unlikely to be DoD-related are restricted to AOC 3 and AOC 5.

  - Within AOC 3, 82 analytes were not detected and considered unlikely to be DoD-related.
  - Within AOC 5, 87 analytes were not detected and considered unlikely to be DoD-related.

- **Tables 5-22 through 5-27** present a summary of non-detected analytes with LOQs all above various Phase 1 screening levels (e.g., human health and ecological).
- **Appendix E** contains the ratios used to develop **Tables 5-22 through 5-27** expressed as the LOQ divided by the screening level – ratios above one represent analytes with varying degrees of uncertainty regarding the presence of false negatives. The ratios were used to assign each chemical to the appropriate category in the **Table 5-22 through 5-27** series.
- Although these non-DoD-related analytes could represent potential false negatives, the lack of detections across media (soil and groundwater) and no historical record of DoD-relatedness minimizes the likelihood of these uncertainties.

The referral to Phase 2 of DoD-related analytes with screening levels not achieved at the LOQ that were not detected are discussed in the bullets below.

- **Table 5-28** presents DoD-related items associated with the known historical use of the Site. **Table 5-29** presents the DoD-relatedness categories for all analytes potentially screened within this Phase 1 evaluation. Analytes that were not detected in any media and potentially DoD-related are present in all AOCs.
- **Appendix E** contains the ratios used to develop **Tables 5-22 through 5-27** expressed as the LOQ divided by the screening level – ratios above one represent analytes with varying degrees of uncertainty regarding the presence of false negatives. The ratios were used to assign each chemical to the appropriate category in the **Table 5-22 through 5-27** series.
- DoD-related analytes with at least one screening level not achieved at the LOQ and were not detected for each AOC include:

  - Within AOC 1 – 2,4-DNP and 2,4-DNCB had a LOQ exceed at least one screening level.
  - Within AOC 3 – 2,4-DNP, 2,4-DNCB, picric acid, 2-nitroaniline, 2-nitrophenol, 3-nitroaniline, 4-chloroaniline, 4-nitrophenol, and all eight PCBs had a LOQ exceed at least one screening level.
  - Within AOC 4 (Discrete) – 2,4-DNP, 2,4-DNCB, and picric acid had a LOQ exceed at least one screening level.
  - Within AOC 4 (ISM) – 2,4-DNP, 2,4-DNCB, and picric acid had a LOQ exceed at least one screening level.
  - Within AOC 5 – 2-nitroaniline, 3-nitroaniline, 4-chloroaniline, 4-nitroaniline, and all eight PCBs had a LOQ exceed at least one screening level.
  - **Tables 5-22 through 5-27** present a summary of non-detected analytes with LOQs all above various Phase 1 screening levels (e.g., human health and ecological).

- The decision to carry these DoD-related analytes into Phase 2 minimizes the uncertainty for these DoD-related compounds to contribute towards potential false negatives.

Non-DoD-related analytes with screening levels not achieved at the LOQ that were detected at low frequency are discussed in the bullets below.

- **Table 5-28** presents DoD-related items associated with the known historical use of the Site. **Table 5-29** presents the DoD-relatedness categories for all analytes potentially screened within this Phase 1 evaluation. Analytes that were detected in less than 5% of samples in any media and unlikely to be DoD-related are restricted to AOC 3 and AOC 5.
    - Within AOC 3 – bis(2-ethylhexyl)phthalate and dibenzofuran had a LOQ exceed at least one screening level.
    - Within AOC 5 – benzaldehyde, dibenzofuran, and di-n-butyl phthalate had a LOQ exceed at least one screening level.
    - **Appendix E** contains a summary of ratios expressed as the LOQ divided by the screening level – ratios above one represent a LOQ exceeding the respective screening level and represent analytes with varying degrees of uncertainty regarding the presence of false negatives.
- These non-DoD-related analytes were not retained for Phase 1 screening or comparison of screening levels to LOQs due to the unlikelihood of these analytes being DoD-related and limited detections.
- Given these non-DoD-related analytes were detected at low frequencies, the uncertainties related to analytical sensitivity are unlikely to be significant.

#### *6.3.1.3 Data Reduction*

Use of "J" qualified results – Following EMCX direction, all analytical data with "J" qualifiers were assumed to be positive identifications at the LOQ which may result in high biases that can overestimate sample concentrations.

Rejected data – As noted in **Subsection 3.2**, occasionally, data are rejected due to quality control parameters not being met. Rejected data cannot be included in the risk assessment. In general exclusion of rejected data has little impact on the risk assessment; however, when the majority of results for a particular analyte are rejected, this adds uncertainty in the risk screening.

- Within the reduced analytical dataset, 627 results were "R" flagged and rejected during data validation.
- Across the AOCs, the number of results impacted were 1 in AOC 1, 521 in AOC 3, 1 in AOC 4 (Discrete), 9 in AOC 4 (ISM), 81 in AOC 5, and 14 within background (all related to grain size).
- Within AOC 3 (the most impacted), the 521 rejections are all for SVOCs across 6 sample locations. Of these, 520 analytes were resampled, thus, eliminating the uncertainty due to rejected data. Within AOC 5, 76 of the rejections were related to groundwater sampling. Analytes in AOC 5 that were unlikely to be DoD-related were largely non-detect – detected analytes did not exceed 5% across all samples for the AOC. DoD-related or potentially DoD-related analytes with rejected results were all not detected.

#### *6.3.1.4 Sample Size*

A sample size of n = 8 is typically too small to do reliable statistical background comparisons. Unless the site concentrations are demonstrated to be less than the PALs, especially if results are near but above the PALs and potentially near background concentrations, larger sample sizes (e.g., n = 20 – 30) should be

considered for the background comparisons to avoid false positives. From a statistical perspective, comparisons of grab sample maxima with screening levels when sample sizes are small do not conservatively demonstrate the population means are less than the screening levels but potentially underestimate mean concentrations.

### 6.3.2 COPC Selection

PAH and metal concentrations unrelated to historical DoD activities.

- Across all AOCs and media, only calcium, magnesium, potassium, and sodium in AOC 1 were determined to be unrelated to historical DoD activities.
- These analytes represent essential nutrients and would not be carried into Phase 1 screening regardless of DoD-relatedness.

COPCs with unknown source — The risk screening includes all detected analytes that exceed screening criteria and are not consistent with background, regardless of source. Inclusion of analytes, such as 4-nitroaniline and 1,2,3-trichlorobenzene, may result in an overestimate of the number of COPCs potentially resulting from DoD activities that are included in Phase 2 assessment activities.

### 6.3.3 Exposure

Evaluation of soils below 10 ft bgs – Deep soils collected from deeper than 10 ft bgs or below the water table are not generally considered following accepted CERCLA practice and were not collected as part of the Phase 1 investigation. It is unknown if future redevelopment would entail the excavating and redistribution of soils greater than 10 ft bgs. The lack of inclusion of deeper soils at AOC 4 and AOC 5 may lead to an underestimate of sample concentrations overall if the soils greater than 10 ft bgs are higher than the soils within 10 ft of ground surface and such deep soils are brought to the surface under a future use scenario. For much of the site (AOC 1 and AOC 3), soils below 10 ft are within the water table and not likely to be brought to the surface; therefore, excluding soils below 10 ft is not likely to contribute significant to uncertainty at this site.

Evaluation of site groundwater as drinking water — No potable wells are currently located on the site or near the source areas. Potable water is supplied to communities in Onondaga County by the Onondaga County Water Authority, which draws water from several sources, including Otisco Lake, Lake Ontario, and/or Skaneateles Lake. For the Lysander-Baldwinsville area (including the Radisson Community and Golf Course), potable water is obtained from Otisco Lake and Lake Ontario and then treated and distributed to the community. Therefore, the risk screening using the EPA Tap Water RSLs for the on-site resident scenario results in a likely overestimation of site COPCs.

### 6.3.4 Toxicity

Benchmarks do not address possible synergistic, antagonistic, or additive effects of contaminant mixtures. The risk may be over or underestimated, depending on the interactions among the various chemicals present in each AOC.

The soil conditions (soil type, pH, temperature, and % TOC) in the studies from which the benchmarks were derived may not mimic those conditions found at each AOC.

The benchmarks used do not consider factors that influence chemical bioavailability (e.g., site-specific organic carbon concentrations, redox potential [Eh], pH). Particularly for metals, the use of total concentration, rather than an estimate of the bioavailable fraction, represents a conservative estimate of exposure, and may overestimate risk. In addition, most toxicological benchmarks developed for metals in soils are based on soluble salts. In general, it is expected that soluble salts would most likely be quickly leached from soils either through rainfall infiltration to groundwater, or surface runoff to surface waters. Additionally, the Site occurs in a recently glaciated area with young soils that are not significantly weathered and soluble salts would not be anticipated at high concentrations. Consequently, it is unlikely that the form of the metal used in the toxicity study would occur to a significant degree in weathered soils.

Different species of plants and animals exhibit varying degrees of sensitivity to chemical stressors. The species used to derive the screening benchmarks do not necessarily have the same sensitivities as those found at the AOCs. Consequently, the inclusion or exclusion of those chemicals may under- or overestimated risk potential.

In general, ecological soil screening levels (Eco SSLs) developed for plants and soil invertebrates are conservative in nature as tests in which the COPC would be highly bioavailable were favored as study used to derive those SSLs. This may result in conservatively including those chemicals as potential COPCs.

Surrogate screening values — Surrogate screening values were selected for DoD-related and potentially DoD-related analytes (**Table 5-29**) as described in **Subsection 5.1.1.1** and **Tables 5-2 through 5-7.** Although surrogate values were selected on the basis of structural similarity to chemicals with known activities and properties and were verified through the use of predictive tools (i.e., EPA TEST), the toxicity information of these analytes has not been studied to the extent necessary to develop a primary screening value. For analytes that are known to be DoD-related (i.e., picric acid and 2,4-DNCB) with screening values developed in Appendix A of the UFP-QAPP (USACE, 2020), a safety factor of 10x was applied to the ecological screening levels to account for this uncertainty. **Subsection 8.2.7** presents an evaluation of potential data gaps associated with each chemical with a surrogate human health or ecological screening level.

- Analytes without surrogate plant screening values — Surrogate plant screening values could not be selected for the potentially or likely DoD-related analytes shown in **Table 5-13**. These include VOCs (1,2,3-trichlorobenzene, 2-butanone, acetone), SVOCs (nitroanilines, nitrophenols, benzaldehyde, and carbazole), and PAHs. The VOCs are primarily used as solvents or intermediates to produce other chemicals. The SVOCs are used as intermediates in various manufacturing process (e.g., dyes, pharmaceuticals) or derivative of combustion (carbazole and PAHs). Historical volatile releases are generally not an issue for phytotoxicity, as surficial VOCs would have dispersed or leached to groundwater. The lack of SVOC and PAH phytotoxicity values represents a data gap.
- Analytes without surrogate soil invertebrate screening values — Surrogate soil invertebrate screening values could not be selected for the potentially or likely DoD-related analytes shown in **Table 5-14**. These include cobalt, silver, thallium, and vanadium. Alloys that contain cobalt are used in military and industrial applications. Silver and thallium may be present in electronic equipment. Vanadium is associated with various steels, magnets, fuel oil, and coal. For invertebrates, the lack of cobalt, silver, thallium, and vanadium toxicity data represents a data gap.

- Analytes without surrogate avian screening values — Surrogate avian screening values could not be selected for the potentially or likely DoD-related analytes shown in **Table 5-15**. These include VOCs (1,2,3-trichlorobenzene and benzene), SVOCs (nitroanilines, nitrophenols, 4-chloroaniline, benzaldehyde, carbazole, and phenol), PAHs, antimony, and beryllium. The VOCs are solvents or associated with petroleum use. The SVOCs are used as intermediates in various manufacturing process (e.g., dyes, pharmaceuticals) or a derivative of combustion (carbazole and PAHs). Antimony is released by incinerators and coal-burning power plants. Beryllium is used in electronics, aerospace, and defense industries because it is a rigid, lightweight metal. Historical volatile releases are generally not an issue for avian toxicity as surficial VOCs would have dispersed or leached to groundwater and are generally not considered bioaccumulative; therefore, they would not be evaluated through food chain exposures. For birds, the lack of SVOC, PAH, and metals toxicity data represents a data gap.

Analytes without screening values — A number of detected analytes did not have screening values available and could not be assigned a surrogate value for ecological screening. In these cases, there may be evidence of low toxicity, an absence of data indicating toxicity, or insufficient toxicity data available to develop screening values. These analytes were not included as COPCs because they do not have toxicity values, and risk-based screening cannot be performed. It is possible that site COPCs are underestimated as a result. Of the analytes potentially or likely to be DoD-related, at least one of the four receptors (e.g., plant, soil invertebrate, bird, and mammal) had a screening level available, thus, minimizing this potential uncertainty.

## 6.4 DISCUSSION

A summary of the risk screening results and major uncertainties is presented below by medium.

### 6.4.1 Groundwater

As a result of the human health risk screenings, the following analytes were identified as COPCs in site groundwater:

| Analyte | COPC? | | |
|---|---|---|---|
| | AOC 1 | AOC 3 | AOC 5 |
| VOCs | | | |
| Benzene | -- | Yes | -- |
| 1,2,3-Trichlorobenzene | -- | -- | Yes(1) |
| SVOCs | | | |
| 4-Nitroaniline | -- | Yes | -- |
| PAHs | | | |
| Benzo(a)anthracene | -- | -- | Yes(2) |
| Benzo(a)pyrene | -- | -- | Yes(2) |
| Benzo(b)fluoranthene | -- | -- | Yes(2) |
| Dibenz(a,h)fluoranthene | -- | -- | Yes(2) |
| Naphthalene | -- | -- | Yes |
| Metals | | | |
| Aluminum | -- | -- | Yes(3) |
| Antimony | -- | -- | Yes(4) |

| Analyte | COPC? | | |
|---|---|---|---|
| | AOC 1 | AOC 3 | AOC 5 |
| Arsenic | Yes | Yes | Yes |
| Barium | Yes | -- | -- |
| Cobalt | -- | Yes | Yes |
| Iron | Yes | -- | Yes(5) |
| Manganese | Yes | Yes | Yes |
| Nickel | Yes | Yes | Yes(6) |
| Vanadium | Yes | Yes | Yes(7) |

(1) Only a COPC for AOC 5 Possible Dump.
(2) Only a COPC for AOC 5 Boiler House.
(3) Only a COPC for AOC 5 Coal Aggregate Bins.
(4) COPC for AOC 5 Boiler House and Coal Storage Area.
(5) COPC for AOC 5 Coal Aggregate Bins and Coal Storage Area.
(6) COPC for AOC 5 Coal Aggregate Bins, Coal Storage Area, and Possible Dump.
(7) COPC for AOC 5 Boiler House and Coal Aggregate Bins.

The relevant uncertainties described in **Subsection 6.3** that result in a potential overestimation of site COPCs for the analytes listed above include: (1) inclusion of COPCs with an unknown source (e.g., 4-nitroaniline); (2) use of the MDC of grab groundwater data for screening purposes (unknown uncertainty); (3) use of analyte concentrations with "J+" (positive bias) qualifiers that were raised to the LOQ; (4) inclusion of analytes with low FOD (e.g., benzene); (5) use of surrogate screening levels (unknown uncertainty); (6) evaluation of groundwater as potable water; (7) use of turbid groundwater data; (8) exclusion of results due to rejection during data validation (unknown uncertainty); and (9) limited sample size (unknown uncertainty). No analytes were included as COPCs based on the selection of surrogate screening levels for groundwater.

The relevant uncertainties described in **Subsection 6.3** that result in a potential underestimation of site COPCs for groundwater include: (1) exclusion of analytes with LOQs that are greater than the Tap Water RSLs that are potentially site-related (e.g., PCBs, 2,4-DNP); (2) use of the MDC of grab groundwater data for screening purposes (unknown uncertainty); (3) use of analyte concentrations with "J-" or "UJ" (negative bias) qualifiers (e.g., 2,4-DNCB, 2,4-DNP); (4) use of surrogate screening levels (unknown uncertainty); (5) exclusion of elements considered essential human nutrients; (6) exclusion of results due to rejection during data validation (unknown uncertainty); and (7) limited sample size (unknown uncertainty).

The overall direction of uncertainty is not known due to the unknown magnitude of the individual uncertainties. However, results of the screening may overestimate potential risk, particularly when analytes are recommended for inclusion in the Phase 2 sampling that are not detected with LOQs greater than human health screening levels. Exceptions to the potential overestimate include PCBs and 2,4-DNP, which were not detected with LOQs exceeding available screening levels and/or the data were affected by a negative bias (based on low surrogate and/or matrix spike recoveries). The analytes recommended to be carried forward in Phase 2 are presented in **Section 9**.

### 6.4.2 Soil

The following sections describe the analytes that were identified as COPCs in soil as a result of the human health and ecological risk screenings.

#### *6.4.2.1 Human Health*

As a result of the human health risk screenings, the following analytes were identified as COPCs in site soil:

| Analyte | COPC? AOC 1 (0-1 ft bgs) (0-5 ft bgs) (0-10 ft bgs) | AOC 3 (0-1 ft bgs) (0-5 ft bgs) | AOC 5 (0-1 ft bgs) (0-5 ft bgs) (0-10 ft bgs) |
|---|---|---|---|
| PAHs | | | |
| Benzo(a)anthracene | -- | Yes | -- |
| Benzo(a)pyrene | -- | Yes | Yes(9) |
| Benzo(b)fluoranthene | -- | Yes | Yes(10) |
| Dibenz(a,h)fluoranthene | -- | Yes | Yes(10) |
| Indeno(1,2,3-cd)pyrene | -- | Yes | Yes(10) |
| Naphthalene | -- | -- | Yes(9) |
| Metals | | | |
| Aluminum | Yes | Yes | Yes(11) |
| Arsenic | Yes | Yes(8) | Yes |
| Cadmium | Yes | -- | Yes(12) |
| Cobalt | Yes | Yes | Yes |
| Iron | Yes | Yes | Yes |
| Manganese | Yes | Yes | Yes |
| Thallium | -- | Yes | Yes |

(8) Only a COPC for the 0-5 ft bgs interval.
(9) COPC for all depths at AOC 5 Coal Aggregate Bins and Coal Storage Area.
(10) Only a COPC for all depths at AOC 5 Coal Aggregate Bins.
(11) COPC for all depths and subareas except: AOC 5 Boiler House (0-1 ft bgs), AOC 5 Coal Storage Area (0-1 and 0-5 ft bgs), and AOC 5 Possible Dump (0-1 ft bgs).
(12) Only a COPC for all depths at AOC 5 Possible Dump.

The relevant uncertainties described in **Subsection 6.3** that result in a potential overestimation of site COPCs for the analytes listed above include: (1) use of the MDC of the discrete soil data for screening purposes (unknown uncertainty); (2) use of analyte concentrations with "J+" (positive bias) qualifiers that were raised to the LOQ; (3) use of surrogate screening levels (unknown uncertainty); (4) soil heterogeneity (unknown uncertainty); (5) exclusion of results due to rejection during data validation (unknown uncertainty); and (6) limited sample size (unknown uncertainty). No analytes were included as COPCs based on the selection of surrogate screening levels for soil.

The relevant uncertainties described in **Subsection 6.3** that result in a potential underestimation of site COPCs for soil include: (1) use of the MDC of discrete soil data for screening purposes (unknown uncertainty); (2) use of analyte concentrations with "J-" or "UJ" (negative bias) qualifiers (e.g., 2,4-DNCB, 2,4-DNP, picric acid); (3) use of surrogate screening levels (unknown uncertainty); (4) exclusion of elements considered essential human nutrients; (5) exclusion of results due to rejection during data validation (unknown uncertainty); and (6) limited sample size (unknown uncertainty).

The overall direction of uncertainty is not known due to the unknown magnitude of the individual uncertainties. However, risk screenings are generally designed to be conservative (i.e., overestimate risk). Exceptions to the overestimate include 2,4-DNCB and 2,4-DNP, which were affected by a negative bias (based on low surrogate and/or matrix spike recoveries). The analytes recommended to be carried forward in Phase 2 are presented in **Section 9**.

#### *6.4.2.2 Ecological*

As a result of the ecological risk screenings, the following were identified as COPECs in AOC 1 soil:

| Analyte | COPEC? | | | |
|---|---|---|---|---|
| | **Plant (0-1 ft bgs) (0-5 ft bgs)** | **Soil Invertebrate (0-1 ft bgs) (0-5 ft bgs)** | **Bird (0-1 ft bgs)** | **Mammal (0-1 ft bgs) (0-5 ft bgs)** |
| Explosives | | | | |
| Picric acid | -- | Yes | -- | Yes |
| Metals | | | | |
| Antimony | -- | -- | NSL | Yes |
| Arsenic | -- | Yes | -- | -- |
| Barium | Yes | -- | -- | -- |
| Cadmium | -- | -- | Yes | Yes |
| Chromium | Yes | Yes | -- | -- |
| Copper | Yes | -- | Yes | Yes |
| Lead | Yes | -- | Yes | Yes |
| Manganese | Yes | Yes | -- | Yes(1) |
| Mercury | Yes | Yes | Yes | -- |
| Selenium | Yes | -- | -- | Yes |
| Zinc | Yes | Yes | Yes | Yes |

NSL = no screening level

(1) Only a COPEC for the 0-5 ft bgs interval.

As a result of the ecological risk screenings, the following were identified as COPECs in AOC 3 soil:

| Analyte | COPEC? | |
|---|---|---|
| | **Plant (0-5 ft bgs)** | **Soil Invertebrate (0-5 ft bgs)** |
| VOCs | | |
| Acetone | NSL | Yes |
| SVOCs | | |
| Benzaldehyde | NSL | Yes |
| Carbazole | NSL | Yes |
| Cresols, m- & p- | -- | Yes |
| Dibenzofuran | -- | Yes |
| PAHs | | |
| Acenaphthene | Yes | -- |
| Anthracene | Yes | -- |
| Metals | | |
| Manganese | Yes | Yes |
| Mercury | -- | Yes |
| Selenium | Yes | -- |
| Thallium | Yes | -- |

NSL = no screening level

As a result of the ecological risk screenings, the following were identified as COPECs in AOC 5 Boiler House soil:

| Analyte | COPEC? | | | |
|---|---|---|---|---|
| | **Plant (0-1 ft bgs) (0-5 ft bgs)** | **Soil Invertebrate (0-1 ft bgs) (0-5 ft bgs)** | **Bird (0-1 ft bgs)** | **Mammal (0-1 ft bgs) (0-5 ft bgs)** |
| Metals | | | | |
| Arsenic | Yes | Yes | -- | -- |
| Chromium | Yes(1) | Yes(1) | BKG | -- |
| Manganese | Yes | Yes | -- | -- |
| Mercury | -- | Yes(1) | BKG | -- |
| Thallium | Yes(1) | -- | BKG | -- |
| Zinc | -- | Yes(1) | -- | Yes(1) |

BKG = eliminated from screening based on background comparison

(1) Only a COPEC for the 0-5 ft bgs interval.

As a result of the ecological risk screenings, the following were identified as COPECs in AOC 5 Coal Aggregate Bins soil:

| Analyte | COPEC? | | | |
|---|---|---|---|---|
| | **Plant (0-1 ft bgs) (0-5 ft bgs)** | **Soil Invertebrate (0-1 ft bgs) (0-5 ft bgs)** | **Bird (0-1 ft bgs)** | **Mammal (0-1 ft bgs) (0-5 ft bgs)** |
| PAHs | | | | |
| 1-Methylnaphthalene | Yes | (2) | Yes | (2) |
| 2-Methylnaphthalene | Yes | (2) | Yes | (2) |
| Naphthalene | Yes | (2) | Yes | (2) |
| High Molecular Weight PAHs | (3) | -- | (3) | Yes |
| Metals | | | | |
| Antimony | -- | -- | NSL | Yes |
| Arsenic | -- | Yes | -- | -- |
| Cadmium | -- | -- | -- | Yes(1) |
| Chromium | Yes(1) | Yes(1) | BKG | -- |
| Lead | -- | -- | Yes | -- |
| Manganese | Yes | Yes | -- | -- |
| Mercury | -- | Yes(1) | BKG | -- |
| Selenium | Yes | -- | -- | Yes |
| Thallium | Yes | -- | -- | -- |
| Vanadium | -- | -- | Yes | -- |
| Zinc | -- | -- | Yes | -- |

BKG = eliminated from screening based on background comparison
NA = not analyzed
NSL = no screening level
(1) Only a COPEC for the 0-5 ft bgs interval.
(2) Evaluated as "Low Molecular Weight PAHs".
(3) Evaluated as individual PAHs.
(4) The one detected concentration of dibenzofuran in ten samples exceeded the soil invertebrate screening level; however, it is not considered a COPEC for the Coal Aggregate Bins. Throughout the whole of AOC 5 it was detected in only 3 of 65 soils samples, all below the LOQ, and in no groundwater samples. There are no historical data indicating dibenzofuran is DoD-related and the low frequency of detection does not indicate a release.

As a result of the ecological risk screenings, the following were identified as COPECs in AOC 5 Coal Storage Area soil:

| Analyte | COPEC? | | | |
|---|---|---|---|---|
| | **Plant (0-1 ft bgs) (0-5 ft bgs)** | **Soil Invertebrate (0-1 ft bgs) (0-5 ft bgs)** | **Bird (0-1 ft bgs)** | **Mammal (0-1 ft bgs) (0-5 ft bgs)** |
| PAHs | | | | |
| 1-Methylnaphthalene | Yes | (1) | Yes | (1) |
| 2-Methylnaphthalene | Yes | (1) | Yes | (1) |
| Acenaphthene | Yes | (1) | NSL | (1) |
| Benzo(a)anthracene | -- | (1) | Yes | (1) |
| Naphthalene | Yes | (1) | Yes | (1) |
| High Molecular Weight PAHs | (2) | -- | (2) | Yes |
| Low Molecular Weight PAHs | (2) | Yes | (2) | -- |
| Metals | | | | |
| Antimony | -- | -- | NSL | Yes |
| Arsenic | Yes | Yes | -- | -- |
| Cadmium | -- | -- | ND | Yes(3) |
| Lead | -- | -- | Yes | -- |
| Manganese | Yes(3) | Yes(3) | -- | -- |
| Mercury | -- | Yes(3) | ND | -- |
| Selenium | Yes | -- | Yes | Yes |
| Thallium | Yes | -- | -- | Yes |
| Vanadium | -- | -- | Yes | -- |
| Zinc | -- | -- | Yes | -- |

ND = not detected

NSL = no screening level

(1) Evaluated as PAH sums, either "High Molecular Weight PAHs" or "Low Molecular PAHs as appropriate.

(2) Evaluated as individual PAHs.

(3) Only a COPEC for the 0-5 ft bgs interval.

As a result of the ecological risk screenings, the following were identified as COPECs in AOC 5 Electric Substation soil:

| Analyte | COPEC? | | | |
|---|---|---|---|---|
| | **Plant (0-1 ft bgs) (0-5 ft bgs)** | **Soil Invertebrate (0-1 ft bgs) (0-5 ft bgs)** | **Bird (0-1 ft bgs)** | **Mammal (0-1 ft bgs) (0-5 ft bgs)** |
| PCBs | | | | |
| PCB-1260 (Aroclor 1260) | -- | -- | Yes | -- |
| Metals | | | | |
| Cadmium | -- | -- | -- | Yes |
| Chromium | Yes(1) | Yes(1) | BKG | -- |
| Copper | Yes(1) | -- | -- | Yes(1) |
| Lead | -- | -- | Yes | -- |
| Manganese | Yes | Yes | -- | -- |
| Mercury | -- | Yes | Yes | -- |
| Selenium | Yes | -- | -- | -- |
| Thallium | Yes | -- | -- | -- |
| Zinc | -- | -- | Yes | -- |

BKG = eliminated from screening based on background comparison

(1) Only a COPEC for the 0-5 ft bgs interval.

As a result of the ecological risk screenings, the following were identified as COPECs in AOC 5 Possible Dump soil:

| Analyte | COPEC? | | | |
|---|---|---|---|---|
| | **Plant (0-1 ft bgs) (0-5 ft bgs)** | **Soil Invertebrate (0-1 ft bgs) (0-5 ft bgs)** | **Bird (0-1 ft bgs)** | **Mammal (0-1 ft bgs) (0-5 ft bgs)** |
| VOCs | | | | |
| Acetone | NSL | Yes(1) | NA | -- |
| SVOCs | | | | |
| Benzaldehyde | NSL | Yes | NSL | -- |
| Dibenzofuran | -- | Yes | NSL | -- |
| Di-n-butyl phthalate | -- | Yes | Yes | -- |
| Metals | | | | |
| Antimony | -- | -- | NSL | Yes |
| Arsenic | -- | Yes | -- | -- |
| Cadmium | -- | -- | Yes | Yes |
| Chromium | Yes | Yes | -- | -- |
| Copper | Yes | Yes | Yes | Yes |
| Lead | Yes | -- | Yes | Yes |
| Manganese | Yes | Yes | -- | -- |
| Mercury | -- | Yes(1) | BKG | -- |
| Selenium | Yes(1) | -- | BKG | -- |
| Thallium | Yes | -- | -- | -- |
| Zinc | Yes | Yes | Yes | Yes |

BKG = eliminated from screening based on background comparison
NA = not analyzed
NSL = no screening level
(1) Only a COPEC for the 0-5 ft bgs interval.

The relevant uncertainties described in **Subsection 6.3** that result in a potential overestimation of site COPECs for the analytes listed above include: (1) inclusion of COPECs with an unknown source (e.g., benzaldehyde); (2) selection of surrogate screening values; (3) use of the MDC for screening purposes; (4) use of analyte concentrations with "J+" (positive bias) qualifiers that were raised to the LOQ; and (5) selection of conservative Eco SSLs assuming high bioavailability.

The relevant uncertainties described in **Subsection 6.3** that result in a potential underestimate of site COPECs (i.e., analytes not listed above) include: (1) non-detected analytes with LOQs greater than ecological screening levels; (2) use of analyte concentrations with "J-" or "UJ" (negative bias) qualifiers; (3) removal of results due to rejection during data validation; and (4) exclusion of analytes with no screening level or applicable surrogate.

The overall direction of uncertainty is not known due to the unknown magnitude of the individual uncertainties. However, results of the screening may overestimate potential risk, particularly when analytes are recommended for inclusion in the Phase 2 sampling that are either not detected with LOQs greater than ecological screening levels or without a screening level. Exceptions to the overestimate include 2,4-DNCB

and 2,4-DNP, which were not detected with LOQs exceeding available screening levels and/or the data were affected by a negative bias (based on low surrogate and/or matrix spike recoveries). The analytes recommended to be carried forward in Phase 2 are presented in **Section 9**.

*This page intentionally left blank.*

# 7.0 CONCEPTUAL SITE MODEL UPDATES

The following sections present updates to the CSM based on observations from the RI Phase 1 field investigations. The RI Phase 1 field investigations were completed in 2021 and were detailed in the *Final RI Phase 1 Field Report – AOC 4 and AOC 5* (USACE, 2021) and the *Final RI Phase 1 Field Report – AOCs 1, 3, 4 ISM, and Background* (USACE, 2022).

## 7.1 SURFACE GEOLOGY

Bluestone refined the distribution of the three surface geologic units previously mapped by Pair (2014) (i.e., Psc, Ps, and Pd) based on the logging of site and background soil borings advanced during the Phase 1 field investigation. As discussed in the UFP-QAPP (USACE, 2020), surface geology was more broadly mapped by Muller and Cadwell in 1986 and by Pair in 2014. While the exact level of effort applied in developing this previous mapping is not fully understood, it is assumed to be of a smaller scale as compared with Bluestone's site-specific investigation. Of these two available resources, the Pair (2014) mapping was selected as the basis for refining surface geology because it more accurately aligns with known landforms and more precisely defines the extent of various surface geologic units (USACE, 2020). Bluestone's evaluation and refinement of surface geologic distribution was informed by field observations for soil structure and gradation, photographs of the associated soil samples, and laboratory gradation test results. In instances where multiple soil types were observed in the vertical profile, the uppermost soil type identified beyond the 0 to 1 ft bgs depth interval was used for classification and mapping purposes.

The inferred distribution of the 161 site soil borings and 45 background soil borings are shown on **Figures 7-1 through 7-5** overlain on the historical soil distribution based on Pair (2014). The surface geologic unit Hw (wetland deposit) can be seen on some of the figures; however, this unit was identified by Pair (2014) adjacent to but not within AOC boundaries. The figures also show that fill was encountered in 10 of the 161 site soil borings and two of the 45 background soil borings. Also shown on the figures, there are 19 soil borings advanced along the toe of the drumlin in AOC 1 that were sampled from the 0 to 1 ft bgs depth interval only and are therefore classified as topsoil. It is noted that fill material observed in the upper 3 to 6 ft of the AOC 1, AOC 5, and background borings appears to be indicative of localized backfilling or grading activities, as opposed to landfilling or dumping activities.

The following observations were made regarding AOC 1 surface geology:

- The previously mapped Psc and Pd units along the northeastern boundary were determined to consist of Ps soils.
- The previously mapped Ps unit along the toe of the drumlin was predominantly classified as topsoil because the Phase 1 investigation in this area was limited to hand-augured borings to a depth of 1 ft bgs. Pockets of Pd and Ps soils were also observed in this area.
- The previously mapped Pd unit along the top of the drumlin was confirmed to consist of Pd soils.

Regarding AOC 3 surface geology, the previously mapped Psc unit was confirmed to consist of Psc soils.

Regarding AOC 4 surface geology, the previously mapped Psc unit was confirmed to predominantly consist of Psc soils, except for pockets of Ps soils along the northeastern and southeastern boundaries.

Regarding AOC 5 surface geology, the previously mapped Pd and Psc units in the eastern and western portions of the AOC, respectively, were determined to consist of a mix of Psc and Ps soils, as well as fill that is indicative of localized backfilling or grading activities.

The following observations were made regarding surface geology in the background areas located southwest of AOC 1 and northwest of AOC 5:

- The previously mapped Psc unit was determined to consist of both Psc and Ps soils.
- The previously mapped Ps unit was confirmed to predominantly consist of Ps soils, except for the former borrow pit area located southwest of AOC 1. The former borrow pit area was classified as fill based on field observations of recent backfilling activities in that area.
- The previously mapped Pd unit was confirmed to predominantly consist of Pd soils, except for pockets of Ps soils, Psc soils, and fill in the northern and southern extents. The fill observed in these areas is indicative of localized backfilling or grading activities.

Bluestone's field observations generally confirmed the previous understanding of site geology and depositional history at the Site. The distribution of the three known surface geologic units (i.e., Psc, Ps, and Pd) were refined by this investigation but generally aligned with previous mapping from Pair (2014). Surface geology at the Site is controlled by glacial deposition and marked by a higher relief drumlin hill spanning the southwestern edge of AOC 1, the eastern edge of the background area, and the northeast edge of AOC 5. The drumlin hill is composed of poorly-sorted diamicton (till) reflective of direct glacial deposition (i.e., Pd unit) and is flanked by coarser water-worked deposits of well-sorted sand and gravel (i.e., Ps unit) present in the northeastern edge of AOC 1 and the center of the background area. As previously mapped by Pair (2014), lacustrine beach deposits composed of finer-grained, water-worked deposits of well-sorted silt and clay (i.e., Psc unit) are predominant within AOCs 3, 4, and 5 and along the western edge of the background area.

These observations indicate a data gap for surface geology along the toe of the drumlin in AOC 1. This area should be investigated further to better understand soil types beyond the 0 to 1 ft bgs depth interval.

## 7.2 BEDROCK

The site and background soil borings that were advanced to refusal during the Phase 1 investigation provided additional insight into bedrock depth and elevation. **Table 7-1** presents depths and elevations where refusal was encountered, presumably due to bedrock. Instances where shallow refusal was encountered due to circumstances other than bedrock were omitted from this table for the purpose of evaluating bedrock depth only.

In AOC 1, a distinction can be made between investigations conducted along the top of the drumlin and the bottom of the drumlin. Along the top of the drumlin, refusal depth ranged from 7 to 18.7 ft bgs (average 12.84 ft bgs), and refusal elevation ranged from 426.33 to 489.23 ft above mean sea level (AMSL) (average 450.83 ft AMSL). Along the bottom of the drumlin, refusal depth ranged from 9.1 to 16 ft bgs (average 14.51 ft bgs), and refusal elevation ranged from 412.59 to 423.47 ft AMSL (average 418.77 ft AMSL). Investigations conducted prior to the Bluestone Phase 1 investigation indicated refusal, presumably due to bedrock, at a maximum depth of 51 ft bgs along the bottom of the drumlin (USACE, 2020). This varies significantly from the Phase 1 investigation findings; however, many of the Phase 1 borings at the bottom of the drumlin where advanced along the northeastern boundary of the AOC, as opposed to the toe of the

drumlin located approximately 500 ft to the southwest. Phase 1 investigations along the toe of the drumlin were limited to hand-augured borings to a depth of 1 ft bgs because the area could not be accessed with the drill rig due to site condition limitations. The lack of direct push borings closer to the toe of the drumlin is a data gap.

In AOC 3, refusal depth ranged from 6 to 18.9 ft bgs (average 12.96 ft bgs), and refusal elevation ranged from 384.10 to 394 ft AMSL (average 389.4 ft AMSL). These observations generally correspond with investigations conducted prior to the Phase 1 investigation, which indicated bedrock at depths of approximately 15 ft bgs and elevations ranging from 385 to 389 ft AMSL (USACE, 2020).

In AOC 4, refusal depth ranged from 10.5 to 20.5 ft bgs (average 15.49 ft bgs), and refusal elevation ranged from 389.54 to 415.64 ft AMSL (average 402.94 ft AMSL). Investigations conducted prior to the Phase 1 investigation indicated that bedrock was encountered at a depth of 9 ft bgs and an elevation of approximately 400 ft AMSL at a well location about halfway between AOC 3 and AOC 4 (USACE, 2020). The Phase 1 investigation indicates that both the depth to bedrock and bedrock elevation increase moving west-northwest from AOC 3 to AOC 4.

In AOC 5, refusal depth ranged from 19 to 29 ft bgs (average 23.39 ft bgs), and refusal elevation ranged from 420.22 to 437.07 ft AMSL (average 426.14 ft AMSL). No boreholes had been completed in AOC 5 under previous investigations for comparison with these observations (USACE, 2020). The Phase 1 investigation indicates that although the depth to bedrock increases, the bedrock elevation decreases moving south from the top of the AOC 1 drumlin to AOC 5.

Bluestone's field observations confirmed the previous understanding that surface relief at the Site is not controlled by bedrock but by glacial deposition, as discussed in the UFP-QAPP (USACE, 2020). This is evident in variations between the surface elevation and bedrock depth observed throughout the Site. It is possible that many of the refusal depths observed during the Phase 1 investigation are attributable to till or saprolite (weathered shale) as opposed to competent bedrock. Bedrock composition below refusal could not be fully characterized during the Phase 1 investigation.

## 7.3 HYDROGEOLOGY

The shallow groundwater elevations and contours observed during the Phase 1 investigation are shown on **Figures 7-6 through 7-10**. The groundwater contours shown on these figures were developed using water level data from the temporary site and background monitoring wells installed throughout the site. The groundwater depth and elevation data collected from these wells are presented in **Table 7-2**.

In AOC 1, a distinction can be made between the wells installed along the top of the drumlin and those installed along the bottom of the drumlin. Along the top of the drumlin, the depth to groundwater ranged from 1.38 to 7.07 ft bgs (average 3.19 ft bgs), and the groundwater elevation ranged from 441.64 to 475.2 ft AMSL (average 452.10 ft AMSL). Along the bottom of the drumlin, the depth to groundwater ranged from 0.89 to 9.06 ft bgs (average 3.77 ft bgs), and the groundwater elevation ranged from 426.14 to 452.82 ft AMSL (average 434.2 ft AMSL). The general direction of groundwater flow in AOC 1 is northeast; however, background wells located to the southwest of AOC 1 demonstrate flow to the southwest of the drumlin ridge that controls the direction of shallow groundwater flow in this area.

In AOC 3, the depth to groundwater ranged from 1.92 to 10.44 ft bgs (average 6.93 ft bgs), and the groundwater elevation ranged from 393.4 to 400.87 ft AMSL (average 396.02 ft AMSL). The general direction of groundwater flow in AOC 3 is northeast.

In AOC 4, the depth to groundwater ranged from 0.53 to 4.75 ft bgs (average 2.63 ft bgs), and the groundwater elevation ranged from 406.3 to 423.89 ft AMSL (average 415.79 ft AMSL). The general direction of groundwater flow in AOC 4 is northeast.

In AOC 5, the depth to groundwater ranged from 0.72 to 12.03 ft bgs (average 4.77 ft bgs), and the groundwater elevation ranged from 438.96 to 451.16 ft AMSL (average 443.56 ft AMSL). The general direction of groundwater flow in AOC 5 is west-southwest.

The Phase 1 observations confirmed the previous understanding that shallow groundwater at the site mimics the land surface and is influenced by local topography, as discussed in the UFP-QAPP (USACE, 2020). The Phase 1 observations demonstrate that the direction of shallow groundwater flow in AOC 1, AOC 3, and AOC 4 is generally northeast toward the Oswego River. The exceptions are the background areas southwest of the AOC 3 drumlin where flow is to the southwest and in AOC 5 where flow is to the west-southwest; both areas flow toward wetlands located west of the site and indicate that shallow groundwater flow is controlled by nearby surface water features, as discussed in the UFP-QAPP (USACE, 2020).

The temporary wells installed during the Phase 1 investigation are not sufficient to evaluate hydraulic properties of the shallow aquifer, such as hydraulic conductivity, which represents a data gap.

Furthermore, the Phase 1 investigation was not sufficient to provide a comprehensive understanding of deep aquifer characteristics and the hydraulic communication between the deep and shallow aquifers, which also represents a data gap.

## 7.4 SOURCES OF DRINKING WATER

As presented in the *RI Phase 1 Field Report – AOCs 1,3, 4 ISM, and Background* (USACE, 2022), Bluestone conducted a potable well survey in September 2021 to identify active public and/or private domestic wells located within a 2-mile radius of the Site for the purpose of evaluating potential impacts from any off-site migration of DoD-related contaminants. The survey included a desktop component, in addition to a windshield survey.

The desktop component identified 471 parcels with a private water supply, such as a well, according to the Onondaga and Oswego Counties' 2020 Assessment Roll (331 in Onondaga County and 140 in Oswego County). The desktop component also identified 83 water well locations according to NYSDEC Water Well Completion Reports. These parcels and water well locations are shown on **Figure 7-10**.

During the windshield survey, Bluestone attempted to view, from public roadways, each parcel with private water supply (471) and each NYSDEC well location (83) within the 2-mile site boundary radius. A total of 118 potential wells at 115 parcels were identified, as listed in **Table 7-3**.

In summary, the potable well survey identified a total of 554 potential well locations (471 parcels with private water supply and 83 NYSDEC water wells) that are available for further evaluation with respect to potential impacts from any off-site migration of DoD-related contaminants.

## 7.5 WETLANDS AND AQUATIC RESOURCES

A wetland delineation and vernal pool survey was performed at AOCs 1, 3, and 5 in 2020. The results of these field investigations are presented in the *Wetland Delineation and Vernal Pool Survey Report* (Bluestone, 2020). No formal wetland delineation was performed for AOC 4.

There are several forested wetland areas scattered throughout AOC 1, with the majority located in the lower elevation areas adjacent to residential properties. In total, 17.33 acres of Palustrine Forested Wetland (PFO) were identified across four areas. The largest wetland area (Wetland 1C, 10.81 acres) was identified along the northeast basal plain, with pockets of upland hills, between former Dryer Houses 29 and 31. Wetland 1B was identified along the southern portion of the basal plain, between former Dryer Houses 27 and 28. The remaining two wetlands were delineated along the second terrace (Wetlands 1A and 1F). See **Appendix K**, **Figure 2-1** for locations of wetlands and candidate vernal pools and the Phase 1 sampling locations at AOC 1.

In total, 0.26 acres of PFO/Palustrine Emergent Wetland (PEM) were identified within AOC 3, just north of the parking lot along the stream's floodplain. See **Appendix K**, **Figure 2-2** for locations of delineated wetlands and sampling locations at AOC 3. The only wetland areas associated with AOC 3 are closely associated with the unnamed stream and the northern stream bank.

Roughly 50% (the whole western side) of AOC 5 consists of a forested wetland habitat (see **Appendix K**, **Figure 2-4**). Similar to AOC 1, AOC 5 has highly mosaic microtopography throughout and an extensive network of drainage ditches from its previous land use. Therefore, wetland boundaries had to be averaged to mappable lines. This means in some areas there are many small wetland depressions and upland mounds on both sides of the boundary. The western portion of AOC 5 was confirmed to have 3.35 acres of PFO wetlands, which likely extends westward beyond the AOC boundary. See **Figure 2-4** for locations of wetlands and candidate vernal pools at AOC 5.

Based on the results of the wetland delineation efforts and vernal pool assessments, approximately 20.44 wetland acres were delineated across the AOCs 1, 3, and 5. Based on the observations of the field teams, vernal pool resources do not warrant additional consideration as unique or exceptional resources. However, the pools were all found to occur within, or to have nexus to, areas that are probable Jurisdictional Wetlands as defined and regulated by USACE under the Clean Water Act.

NYSDEC regulates wetlands that are 12.4 acres (5 hectares) or larger. The NYSDEC Freshwater Wetlands Act protects wetlands smaller than this if they are considered of unusual local importance. None of the wetlands delineated at the NYOW AOCs are larger than 12.4 acres; none are identified as part of a state-mapped New York State (NYS) freshwater wetland; and none contain features of unusual local importance.

According to the National Wetlands Inventory Map (see **Appendix K, Attachment A** and **Figure 2-3**), there is a small PEM in the southwestern portion on the Site and two small, PFOs adjacent to western AOC 4 boundary. There are also several larger PFO and PEM areas west of AOC 4 and numerous smaller Palustrine Forested Wetlands south and east of AOC 4.

## 7.6 AOC 3 GEOPHYSICAL SURVEY – SUSPECTED LANDFILL AREA

A geophysical survey was conducted at the AOC 3 Former Landfill Area to meet the DQOs of assessing the area for evidence of buried containerized waste or large metallic debris below the parking lot and

delineating the horizontal and vertical extents of the former landfill. The survey was conducted using a Geonics EM-61 MKII metal detector (EM-61) followed by ground penetrating radar (GPR) profiles to scan any anomalies identified by the electromagnetic (EM) survey that were not attributed to surficial features. The results of the survey are shown on **Figure 7-12** and discussed below.

The EM-61 survey identified several anomalies due to metallic surface interference from light poles, buried pipes, fences, vehicles, and scattered metallic debris. The survey also identified a suspected landfill signature between the stream and the parking lot.

The GPR profiles did not return a signature characteristic of buried metallic debris when scanning the suspected landfill anomaly. This may be because the metallic targets were deeper than the GPR signal was able to penetrate (approximately 4 ft bgs). However, a distinct signal response change (i.e., horizontal reflector) indicative of possible fill material in this area was observed in GPR Profile 173. The GPR Profile 174 confirmed that the northwestern anomaly was attributed to a buried metal pipe that conveys stream water. The GPR Profile 176 identified a buried slab of reinforced concrete where scattered metallic debris was observed north of the stream.

The geophysical survey conducted at the AOC 3 Former Landfill Area satisfied the DQO of assessing the area for evidence of buried containerized waste or large metallic debris. The survey did not indicate historic landfill below the parking lot but did indicate historic landfill north of the parking lot, between the parking lot and the stream. The survey also satisfied the DQO of delineating the horizontal extent of the former landfill; however, the vertical extent remains unknown and represents a data gap.

## 7.7 AOC 5 GEOPHYSICAL SURVEY – POSSIBLE DUMP AREA

A geophysical survey was conducted at the AOC 5 Possible Dump Area to meet the DQOs of assessing the area for evidence of demolition debris or disposal of other waste and delineating the horizontal and vertical extents of observed waste. The survey was conducted using a Geonics EM-31 MKII terrain conductivity meter (EM-31). The results of the survey are shown on **Figure 7-13** and discussed below.

The EM-31 survey indicated that the subsurface conductivity data were indicative of natural terrain and not fill material, buried metallic objects, or dissolved salts/solids that are typically associated with landfills; however, metallic responses were observed at several locations. It was confirmed in the field that the metallic responses aligned with the presence of visible, surficial metallic debris, such as discarded paint cans, drums, and tire rims, as well as the presence of a buried steel drainpipe.

It has been suggested that there is potential that the geophysical survey conducted at the AOC 5 Possible Dump Area did not entirely satisfy the DQOs of assessing the area for evidence of demolition debris or disposal of other waste and delineating the horizontal and vertical extents of observed waste. This is because it is possible that buried metallic objects beneath the surficial metallic debris may have gone undetected due to interference from the surficial metallic debris. However, the EM-31 survey covered approximately 90% of the Possible Dump area in addition to area north of the mapped footprint without any evidence of subsurface disposal activities and detected analytes and associated concentrations in the Possible Dump area are not substantially above background (**Tables I-65 through I-75**) or human health and ecological screening levels (**Tables J.1-7, J.2-7, L.1-7, L.2-7, L.3-6, and L.4-6**) and are not indicative of DoD-related disposal activities. Therefore, the DQO of assessing the area for evidence of demolition debris or disposal

of other waste has been met and the absence of such debris and waste negates the need to delineate the horizontal and vertical extent of waste.

## 7.8 AOC 5 – OTHER POTENTIAL SOURCES

### 7.8.1 Historical Drainage Ditch

While reviewing the historical photographic analysis (USACE, 2019), a drainage ditch was identified that ran parallel to and just west of the railroad spur, east of the coal piles. The ditch appears to be unlined except for where conduit was placed underneath intersecting roadways. The ditch is no longer visible and was likely filled in during Site decommissioning or reworked and regraded during roadway improvements to Willett Parkway. However, there is the potential that DoD-related contaminants leached into the soil and groundwater beneath the ditch and/or were transported downstream (south) to low-lying wetlands. The lack of data for characterization of this potential transport pathway is a data gap.

### 7.8.2 Source of PAHs and Metals

As noted in **Section 2**, five primary surface soil samples were collected at two AOC 5 subareas, the Coal Aggregate Bins and Coal Storage Area, and analyzed for coal and coal ash for a total of ten primary samples at AOC 5 (plus one duplicate sample). Coal was detected in moderate to very heavy concentrations in all samples submitted for analysis, excluding sample NYOW-05-SL022-A (in the Coal Aggregate Bins subarea). Coal ash was detected in trace to moderate concentrations in samples NYOW-05-SL022-A and NYOW-05-SL024-A in the Coal Aggregate Bins subarea. Coal, coal dust, and coal ash are not regulated under CERCLA (40 CFR Part 257), and therefore are not eligible for remediation under FUDS; however, contaminants that have leached from these materials are regulated under these policies.

PAHs were generally not detected above background in the Boiler House, Electric Substation, or Possible Dump areas (see **Appendix I**). Concentrations of PAHs in the Coal Aggregate Bins and Coal Storage Area are above background and human health screening levels in the 0 to 1 ft bgs soil interval (see **Tables I-32, I-37, I-43, I-48, J.2-4, and J.2-5**) and are markedly decreased (generally below background and often not detected) progressing through the 1-5 bgs and 5-10 bgs depth intervals (see **Tables I-33, I-34, I-38, I-39, I-44, I-45, I-49, and I-50**). Also of interest is that in sample NYOW-05-SL022-A, the only sample where coal ash was detected but coal was not, PAHs were not detected above background or human health screening levels (see **Table I-32 and J.2-4**). Lastly, boring locations -009, -010, and -024 were the only locations among the AOCs where the PAH ratios indicated a petrogenic source (see **Table F.7**). Although more data are needed to verify, it appears that PAH concentrations are associated with the coal particles and not the soil.

The patterns of metals concentrations in AOC 5 are less obvious; however, the higher concentrations tend to be at the Boiler House, Coal Aggregate Bins, and Coal Storage Area and maximum detected concentrations within a boring tend to be seen at depth. For example, the highest groundwater dissolved arsenic concentration among all of the AOCs was detected at the Boiler House in NYOW-05-WL019-A (140 µg/L) with the second highest soil concentration detected in the 5 to 10 ft bgs interval from the same location (40 mg/kg). The highest soil concentration of arsenic was detected in NYOW-05-PH010-C in the 5 to 10 ft bgs interval (79 mg/kg) where the third highest groundwater concentration was detected (7.9

µg/L) . The source of the elevated metals concentrations in the lower depths of the soil borings is likely due to leaching from coal and/or coal ash.

## 7.9 POTENTIAL RECEPTORS AND EXPOSURE PATHWAYS

As defined in *Engineer Manual 200-1-12 - Environmental Quality, Conceptual Site Models* (USACE, 2012), a CSM describes sources of impacts, as well as complete, potentially complete, or incomplete human and ecological exposure pathways; current, determined, or reasonably anticipated future use of property; and human and ecological potential receptors (USACE, 2012). A CSM is an iterative planning and communication tool that provides a structure to summarize and display information and to identify additional information needed to develop technically sound decisions. Revised CSMs for this Site are presented as **Figures 7-14a through d** (for human receptors) and **Figures 7-15a through d** (for ecological receptors). The current and future land uses and ecological settings for the four AOCs are provided below.

- AOC 1 – Ammonium Picrate Area: The Ammonium Picrate Area is currently within a primarily residential area of the Radisson Community with some undeveloped land with maintained paved walkways and recreational grassy areas. Homes are not built on areas of potential impacts; however, paved walking paths and grassy areas wind between homes and wooded areas containing the old loading ramps, storage bunkers, and loading dock structures. Old concrete structures in disrepair exist in wooded areas of varying density. Terrestrial habitats, including maintained grassy areas and woodlands (eastern deciduous forest), are present. Forested wetlands are located within AOC 1. Current residential properties are located within AOC 1 and some apartment buildings and residences in the Radisson Community appear to be constructed on the sites of former dryer houses, change houses, and other historical site features. Future residential development at AOC 1 is not currently expected in potentially impacted areas.

- AOC 3 – Former Landfill Area: The Former Landfill Area is currently within the Radisson Golf Course property. As discussed in the UFP-QAPP (USACE, 2020), golf courses and recreational use land are shown as commercial land use. Based on historical documentation, the Former Landfill Area is located under the current Radisson Golf Course club house parking lot. However, as discussed in **Subsection 7.6**, the geophysical survey of the suspected landfill area did not indicate historic landfill below the golf course parking lot but did indicate historic landfill north of the parking lot, between the parking lot and the stream. The former open storage area is located southwest of the landfill area across Potter Road and straddles one of the golf course fairways, with wooded areas to the north and south. At the landfill, a grassy strip with light poles extends along the middle and grassy landscaped areas surround the parking lot. The grassy center strip was not evaluated because it is likely reworked and above the landfill cap. Surface soils of potential concern are limited to the perimeter of the parking lot due to pavement. The area is paved so no surficial ecological habitat is present. Suitable subsurface soil habitat was found within the 1-5 ft interval, and select terrestrial ecological receptors were evaluated. The portion of the former open storage area that is located on what is the existing fairway was not investigated; however, the portions of the former open storage area that are covered by woody vegetation were evaluated for terrestrial ecological receptors. Lastly, there is a small stream north of the landfill that may be receiving runoff or groundwater recharge that should be evaluated for impacts to aquatic organisms, thus representing a data gap. Future use of this area is expected to remain the same as current use.

- AOC 4 – Bunker Area: The Bunker Area is currently located within Three Rivers Wildlife Management Area (WMA). NYSDEC is using several of the remaining bunkers for equipment and vehicle storage. The terrestrial habitat consists primarily of grassy fields and northern deciduous forest. Several small forested and emergent wetlands are located along the southeastern border of the Bunker Area. Future use of this area is likely to remain wildlife management.

- AOC 5 – Former Power Plant Area: The Former Power Plant Area is currently a mostly wooded area west of a residential area. Terrestrial habitats, primarily woodlands (eastern deciduous forest), are present. Review of the Radisson Community General Project Plan (1971) and recent amendments through November 2012, indicates potential future use of AOC 5 as commercial/ retail. During an inspection of AOC 5 on 02 October 2020, NYSDEC noted stakes, flagging, and survey pins that appeared to have been placed recently. NYSDEC inquired about the survey with Empire State Development (ESD) and ESD informed NYDEC that they are considering marketing and selling the area along Willett Parkway (USACE, 2020). No other potential future uses were identified during the Phase 1 investigation. The Town of Lysander Comprehensive Land Use Plan December 2014 draft shows the AOC 5 area on the map depicting Commercial and Industrial Sites. However, AOC 5 is in a district that includes Planned Unit Development, which provides flexibility in land use for a combination of single family homes, apartments, and higher density condominium/townhouse development.

Chemicals used or produced on-site during operations included 2,4-DNCB, 2,4-DNP, and picric acid. Historical groundwater sampling results indicated low levels of 2,4-DNCB were detected and 2,4-DNP was reported as non-detect in groundwater (USACE, 2020). Neither of the two SVOCs were detected in soil samples collected from historical borings. Picric acid was present at low concentrations in subsurface soil and historical groundwater samples collected from monitoring wells in the Former Ammonium Picrate Area and Former Administration Area (USACE, 2020). The Phase 1 analytical results for 2,4-DNCB, 2,4-DNP, and picric acid were mostly non-detect and the findings of the Phase 1 Investigation are consistent with the historical soil and groundwater sample results.

Although the sensitivity of the selected analytical methods was not able to meet project PALs as described in **Section 3.2**, picric acid and its precursors are not stable or persistent in environmental matrices; therefore, significant detections were not expected. Picric acid is soluble in water and would likely leach through soil to groundwater where it is expected to dissociate, especially when present at low concentrations (Army, 1987). Picric acid that is bound to soil may be transformed via photolysis in surface soil and is subject to anaerobic degradation in subsurface soils (Army, 1987). The leaching of 2,4-DNP and 2,4-DNCB from soils is dependent on pH and organic carbon content and some degradation may occur in both soil and groundwater by aerobic and anaerobic processes (ATSDR, 2021). The residence time of DNPs for aerobic biodegradation of soil has been measured to range between 8 to 120 days (ATSDR, 2021). Consequently, the non-detect values with LOQs greater than PALs for these site-related COCs are of minor significance.

### 7.9.1 Potential Human and Ecological Exposure Pathways

The human and ecological exposure pathways identified in the subsections below were updated from those presented in the UFP-QAPP (USACE, 2020) as appropriate based on data collected during the Phase 1 investigation. A re-assessment of potential human and ecological exposure pathways will be needed after completion of the data collection and analysis from the Phase 2 investigation. **Figures 7-14a through d**

and **Figures 7-15a through d** summarize the potential human health and ecological receptors and exposure routes.

#### *7.9.1.1 Potential Human Health Receptors and Exposure Routes*

Below is a brief summary of the currently identified potential receptors and exposure routes. All risk assessment activities will be performed during the Phase 2 investigation, based on Phase 1 investigation exceedances of residential risk-based screening levels and background levels. These receptors will be re-visited and further refined in the Phase 2 investigation. Based on Office of Solid Waste and Emergency Response (OSWER) guidance (EPA, OSWER Directive 9355.7, 2010) and Defense Environmental Restoration Program (DERP)-FUDS guidance (DERP management guidance, 4715.20 4.b.(5)(a)3.b.), receptors evaluated will be limited to current receptors and those associated with reasonably foreseeable future site uses. As noted above, future residential development at AOCs 1 and 5 are not currently expected in potentially impacted areas. If future development is indicated, future residents, future commercial/industrial workers, future construction workers, and/or future utility workers may be considered at AOCs 1 and 5.

Nearby Resident Using Groundwater as Drinking Water and Vapor Intrusion (AOCs 1, 3, 4, and 5)

A nearby resident using a domestic well for potable water could be exposed to groundwater from the Site. Exposure pathways would include ingestion of groundwater and dermal contact with groundwater (while showering or bathing), inhalation while showering, and vapor intrusion. Only benzene and 1,2,3-trichlorobenzene were identified above the EPA Tap Water RSL in AOCs 3 (Former Landfill Area) and the AOC 5 Possible Dump, respectively. The maximum detected benzene concentration (raised to the LOQ of 1 µg/L at multiple locations) is below the EPA VISL (EPA, 2022) for groundwater set to a TRC of 1E-06 and an HQ of 0.1 (1.59 µg/L). There is no groundwater VISL for 1,2,3-trichlorobenzene because there is insufficient inhalation toxicity information. The maximum detected 1,2,3-trichlorobenzene concentration (raised to the LOQ of 1 µg/L at NYOW-05-004 (2021-01-14)) is below the 1,2,4-trichlorobenzene VISL for groundwater set to a TRC of 1E-06 and an HQ of 0.1 (3.59 µg/L). Only trace levels (concentrations below the LOQ) of acetone, benzene, xylenes, toluene, and 1,2,3-trichlorobenzene were detected in groundwater at the Site and the Tap Water RSL is lower than the VISL for each chemical. Based on these results, the vapor intrusion (VI) pathway for offsite residents can be eliminated from further consideration.

On-site Recreational Visitor (AOC 1 and AOC 5)

An on-site recreational visitor could be exposed to surface soil while visiting the Ammonium Picrate Area (AOC 1) and Former Power Plant Area (AOC 5). It is assumed that exposure is occurring now and will continue to occur in the future at AOC 1 (no changes to site use). Soil exposure pathways would include incidental ingestion, dermal contact, and inhalation of dust emissions released from soil.

Utility Worker (AOC 3)

Underground utilities are common in residential and commercial areas, and often are located around roads and the areas between the roads and buildings. A utility worker could be exposed on a short-term basis to surface and subsurface soil at areas surrounding the former landfill at AOC 3. Exposure routes could include incidental soil ingestion, dermal contact with soil, and inhalation of dust emissions released from soil.

On-site Adolescent Trespasser (AOCs 1 and 3)

Adolescent Trespassers in the wooded areas of the Ammonium Picrate Area (AOC 1) could encounter site surface soil as part of their typical outdoor activities. During the Phase 1 investigation, evidence of trespassing or recreating (e.g., empty bottles) was found near the small stream in the northern portion of AOC 3 (Former Landfill Area). Potentially complete soil exposure pathways include incidental ingestion, dermal contact, and inhalation of dust emissions released from soil.

Outdoor Maintenance Worker (AOCs 1, 3, and 4)

An outdoor maintenance worker, representing WMA workers, could encounter site surface soils as part of their typical outdoor maintenance or landscaping activities. WMA employees are assumed to spend the majority of their 8-hour workday outdoors with exposure to DoD-related chemicals through incidental ingestion of surface soils, dermal contact with soils, and inhalation of airborne DoD-related chemicals because of wind erosion. Maintenance workers at AOC 4 (Bunker Area) would be visiting the grassy areas between bunkers as well as the apron areas, thus their area of exposure and associated activities is greater than the expected impacted area.

#### *7.9.1.2 Potential Ecological Receptors and Exposure Routes*

Below is a brief summary of the currently identified potential receptors and exposure routes. All risk assessment activities will be performed during Phase 2, based on Phase 1 investigation exceedances of ecological risk-based screening levels and background levels. These receptors will be re-visited and further refined in Phase 2, if necessary, based on actual or expected changes to land use and habitat. A detailed discussion of habitat conditions and potential receptors is provided in **Appendix K**.

The vegetative community and soil infaunal invertebrate community would have direct exposure to surface soil in AOC 1, AOC 4, and AOC 5; whereas avian and mammalian receptors would have indirect exposure to bioaccumulative constituents in surface soil.

Habitat within AOCs 1, 3, 4, and 5 is suitable to support plants and soil invertebrates that would be directly exposed to subsurface soils (1 to 5 ft bgs interval). Habitat within AOCs 1 and 4 is potentially suitable to support burrowing mammalian receptors (e.g., red fox) that would have indirect exposure to bioaccumulative constituents in subsurface soil.

In AOC 1, DoD-related chemicals could be migrating from groundwater into the wetlands downgradient of the Ammonium Picrate Buildings but upgradient from the Dryer Houses. Therefore, aquatic and benthic life in AOC 1 could be directly exposed to DoD-related constituents in surface water, sediment, and/or pore water. In AOC 3, the extent of the potential impacts downgradient from the former landfill area are uncharacterized, and aquatic and benthic life could be directly exposed to DoD-related constituents in surface water, sediment, and/or pore water in the unnamed stream north of the landfill. Wetland areas east and west of AOC 4 for are unlikely to be impacted by DoD-related constituents. The wetlands to the west of AOC 4 are upgradient from the bunkers and the drainage swale and the elevated roadway provide barriers to overland transport to the wetlands east. Lastly, in AOC 5, DoD-related chemicals could be migrating from groundwater into the wetlands west of the coal storage area and downgradient of the former drainage ditch; therefore, aquatic and benthic life could be directly exposed to DoD-related constituents in surface water, sediment, and/or pore water.

## 7.10 INITIAL CONCLUSIONS – CONCEPTUAL SITE MODEL UPDATES

Surface Geology

The distribution of the surface geologic units previously mapped by Pair (2014) were refined and the inferred distributions are shown on **Figures 7-1 through 7-5**. The mapped Ps unit along the toe of the drumlin was not verified due to issues with sampling below 1 ft bgs. This represents a potential data gap.

Bedrock

Refusal depth and elevation (see **Table 7-1**) compared with previous studies indicated the following for each of the AOCs.

- AOC 1 – Borings were not advanced in the same general area as previously; therefore good comparisons could not be made. The data collected during the Phase 1 sampling indicated that refusal depth ranged from 7 to 18.7 ft bgs (average 12.84 ft bgs) and refusal elevation ranged from 426.33 to 489.23 ft AMSL (average 450.83 ft AMSL) along the top of the drumlin, and refusal depth ranged from 9.1 to 16 ft bgs (average 14.51 ft bgs) and refusal elevation ranged from 412.59 to 423.47 ft AMSL (average 418.77 ft AMSL) at the bottom of the drumlin.
- AOC 3 – Observations generally correspond with investigations conducted prior to the Phase 1 investigation, with refusal depth ranging from 6 to 18.9 ft bgs (average 12.96 ft bgs), and refusal elevation ranging from 384.10 to 394 ft AMSL (average 389.4 ft AMSL).
- AOC 4 – USACE (2020) indicated that bedrock was encountered at a depth of 9 ft bgs and an elevation of approximately 400 ft AMSL at a well location about halfway between AOC 3 and AOC 4. The Phase 1 sampling indicated that refusal depth ranged from 10.5 to 20.5 ft bgs (average 15.49 ft bgs), and refusal elevation ranged from 389.54 to 415.64 ft AMSL (average 402.94 ft AMSL).
- AOC 5 – Previous investigations do not exist. Refusal depth ranged from 19 to 29 ft bgs (average 23.39 ft bgs) and refusal elevation ranged from 420.22 to 437.07 ft AMSL (average 426.14 ft AMSL).

The Phase 1 investigation indicates that although the depth to bedrock increases, the bedrock elevation decreases moving south from the top of the AOC 1 drumlin to AOC 5, confirming that surface relief at the Site is not controlled by bedrock but by glacial deposition.

Hydrogeology

The groundwater contours were developed using water level data from the temporary site and background monitoring wells installed throughout the site. The shallow groundwater flow observed during the Phase 1 investigation is shown on **Figures 7-6 through 7-9**. The groundwater depth and elevation data collected from these wells are presented in **Table 7-2**.

The Phase 1 observations support that shallow groundwater at the Site mimics the land surface and is influenced by local topography. The Phase 1 observations also support that the direction of groundwater flow in AOC 1, AOC 3, and AOC 4 is generally northeast toward the Oswego River. The exceptions are the background areas southwest of the AOC 3 drumlin where flow is to the southwest and in AOC 5 where

flow is to the west-southwest. Both of these areas flow toward wetlands located west of the site and indicate that shallow groundwater flow is controlled by nearby surface water features.

Potential data gaps are that the temporary wells installed during the Phase 1 investigation are not sufficient to evaluate hydraulic properties of the shallow aquifer or to provide a comprehensive understanding of deep aquifer characteristics and the hydraulic communication between the deep and shallow aquifers.

Sources of Drinking Water

The potable well survey identified a total of 554 potential well locations (471 parcels with private water supply and 83 NYSDEC water wells) that are available for further evaluation with respect to potential impacts from any off-site migration of DoD-related contaminants.

Wetlands and Aquatic Resources

Based on the results of the wetland delineation efforts and vernal pool assessments, approximately 20.44 wetland acres were delineated across the AOCs 1, 3, and 5 (see **Appendix K, Figures 2-1, 2-2, and 2-4**). Based on the observations of the field teams, vernal pool resources do not warrant additional consideration as unique or exceptional resources. However, the pools were all found to occur within, or to have nexus to, areas that are probable Jurisdictional Wetlands as defined and regulated by USACE under the Clean Water Act. None are identified as part of a state-mapped NYS freshwater wetland, all are under 5 hectares, and none contain features of unusual local importance. Therefore, the wetlands would not be regulated under NYSDEC Freshwater Wetlands Act.

AOC 4 was evaluated using National Wetlands Inventory Maps (see **Appendix K, Attachment A** and **Figure 2-3**). There is a small PEM in the southwestern portion on the Site and two small PFOs adjacent to western AOC 4 boundary. There are also several larger PFO and PEM areas west of AOC 4 and numerous smaller PFOs south and east of AOC 4.

AOC 3 Geophysical Survey – Suspected Landfill Area

The geophysical survey conducted at the AOC 3 Former Landfill Area satisfied the DQO of assessing the area for evidence of buried containerized waste or large metallic debris. The survey did not indicate historic landfill below the parking lot but did indicate historic landfill north of the parking lot, between the parking lot and the stream. The survey also satisfied the DQO of delineating the horizontal extent of the former landfill; however, the vertical extent remains unknown and represents a data gap.

AOC 5 Geophysical Survey – Possible Dump Area

The EM-31 survey covered approximately 90% of the Possible Dump area in addition to area north of the mapped footprint without any evidence of subsurface disposal activities and detected analytes and associated concentrations in the Possible Dump area are not substantially above background (**Tables I-65 through I-75**) or human health and ecological screening levels (**Tables J.1-7, J.2-7, L.1-7, L.2-7, L.3-6, and L.4-6**) and are not indicative of DoD-related disposal activities. Therefore, the DQO of assessing the area for evidence of demolition debris or disposal of other waste has been met and the absence of such debris and waste negates the need to delineate the horizontal and vertical extent of waste is negated and no data gap exists.

AOC 5 – Other Potential Sources

A drainage ditch was identified that ran parallel to and just west of the railroad spur, east of the coal piles. There is the potential that DoD-related contaminants leached into the soil and groundwater beneath the ditch and/or were transported downstream (south) to low-lying wetlands. The lack of data for characterization of this potential transport pathway is a data gap.

Integrating the results of the analytical chemistry and coal/coal ash microscopy data, it appears that the source of the elevated metals concentrations in the lower depths of the soil borings is due to leaching from coal and/or coal ash. Although more data are needed to verify, it appears that PAH concentrations are associated with the coal particles and not the soil.

Potential Receptors and Exposure Pathways

*Human Health*

The following are the current and reasonably foreseeable future site use human health receptors:

- Nearby residents using groundwater as drinking water (AOCs 1,3,4, and 5);
- On-site Recreational Visitor (AOC 1 and AOC 5);
- Utility Worker (AOC 3);
- On-site Adolescent Trespasser (AOCs 1 and 3); and
- Outdoor Maintenance Worker (AOCs 1, 3, and 4).

Future residential development at AOC 1 is not currently expected in potentially impacted areas. If future development is indicated, future residents, future commercial/industrial workers, future construction workers, and/or future utility workers may be considered at AOC 1.

*Ecological*

The following are the currently identified potential ecological receptors and exposure routes.

- vegetative community
    - direct exposure to surface soil in AOCs 1, 4, and 5
    - direct exposure to subsurface soils (1 to 5 ft bgs) in AOCs 1, 3, 4, and 5
- soil infaunal invertebrate community
    - direct exposure to surface soil in AOCs 1, 4, and 5
    - direct exposure to subsurface soils (1 to 5 ft bgs) in AOCs 1, 3, 4, and 5
- avian receptors
    - indirect exposure to bioaccumulative constituents in surface soil in AOCs 1, 4, and 5
- mammalian receptors
    - indirect exposure to bioaccumulative constituents in surface soil in AOCs 1, 4, and 5
    - specific to burrowing mammals (e.g., red fox) – indirect exposure to bioaccumulative constituents in subsurface soil in AOCs 1 and 4

- benthic invertebrate community
    - direct exposure to wetlands pore water and hydric soils/sediment in AOCs 1 and 5
    - direct exposure to pore water and sediments in the unnamed stream north of the landfill in AOC 3
- aquatic communities
    - direct exposure to surface water in AOCs 1 and 5 wetlands and in the unnamed stream north of the landfill in AOC 3

# 8.0 DATA GAPS ANALYSIS

Data gaps need to be determined, in part, based on whether the objectives of this report were met. As such, an evaluation of whether the objectives were met (**Subsection 8.1**) precedes the potential data gaps discussion (**Subsection 8.2**) below.

## 8.1 PHASE 1 RISK SCREENING AND DATA GAPS ANALYSIS OBJECTIVES

As presented in **Subsection 1.1,** the objectives of this report were as follows.

- Assess the usability of the analytical data collected as part of the Phase 1 field investigations.
- Assess if any CERCLA constituents related to historical DoD activities are present, and if these constituents are present above risk-based screening levels and background concentrations.
- Identify potential source areas and/or areas of higher concentrations.
- Focus additional fieldwork to collect data for an RI and to meet risk assessment-related DQOs if potential impacts from DoD-related constituents are indicated.

Whether each objective was met is described below.

### 8.1.1 Assess Data Usability

Objective met—**Appendix B** is the data usability assessment for the analytical data collected as part of the Phase 1 field investigations. **Subsection 3.2** presents a summary of the data usability assessment, with initial conclusions presented in **Subsection 3.3** and repeated below to be proximal to the data gaps discussion as well as recommendations (**Section 9**).

Based on the assessment of DQIs, the data obtained during the site investigation for all datasets except for AOC 4 ISM samples are of sufficient quantity and quality to support the Phase 1 investigation and human health and ecological risk screenings. Overarching data usability issues to be considered during the development of potential data gaps and recommendations are noted below.

The validated data are usable for the Phase 1 Risk Screening with the exception of the rejected data. The overall usability of the AOC 1 and AOC 4 discrete datasets are not affected by the rejected results. Three valid ISM replicates are considered necessary to provide information regarding the reproducibility and heterogeneity of the data; three DUs did not meet this criteria for at least one of the three analytes. The rejected results in AOC 5 are for compounds not likely to be DoD-related nor likely to be risk drivers; however, because of these rejections, analytical completeness for B/N extractable SVOCs was less than 90% for many compounds in groundwater. None of the AOC 3 results were rejected.

All groundwater samples were collected from temporary wells that were not developed or purged and samples tended to be turbid. The field team often experienced issues with slow and at times insufficient recharge while collecting samples.

All 2,4-DNP results and all but one picric acid result were non-detects, but the soil PALs for 2,4-DNP and picric acid and the groundwater PAL for 2,4-DNP are not attainable with contemporary analytical methodology and almost all ND.

Cadmium and selenium were analyzed by Method 6010C; changing to Method 6020A may be warranted for future sampling events to improve analytical sensitivity. The groundwater PALs for PCBs were not met and any future sampling of PCBs could employ concentrated extracts during sample preparation.

### 8.1.2 Determine Presence or Absence of DoD-related CERCLA Constituents Above Risk-based Screening Levels and Background Concentrations

Objective partially met—The objective of determining the presence or absence of DoD-related CERCLA constituents above risk-based screening levels and background concentrations was not obtained for every medium sampled at every AOC. Potential data gaps are presented on an AOC-basis in **Subsection 8.2**. Recommendations and rationale for either filling a data gap or considering the data gap permanent and taking no action is presented in **Section 9**.

### 8.1.3 Identify Potential Source Areas and/or Areas of Higher Concentrations

Objective partially met—The exercise to identify potential source areas and/or areas of higher concentrations was undertaken, in general, for only COPCs/COPECs presented in the **Section 6.4** summary tables, comparisons with background presented in **Appendix I**, and concentrations presented in **Appendices J and L**. Results of the exercise are presented by AOC below.

AOC 1

Sampling was biased towards potential source areas (e.g., Ammonium Picrate Buildings, Dryer Houses, Change Houses, Laboratory) and picric acid was detected in only one soil sample, 2,4-DNCB and 2,4-DNP were not detected, and metals were detected in concentrations relatively consistent with background. However, subsurface soil was not collected from any of the Ammonium Picrate Buildings and groundwater was not collected from the vicinity of 5 of the 6 Ammonium Picrate Buildings. Therefore, potential areas of release were not adequately characterized to make the determination of whether they are source areas.

AOC 3

Sample locations were placed around the perimeter of the suspected source areas, i.e., the former landfill and the open storage areas. Concentrations of a few VOCs, SVOCs, PAHs, and metals exceeded human health and/or ecological screening levels (see **Subsection 6.2.3**), but not at concentrations indicating a substantial source. However, the results from the geophysical surveys (see **Figure 7-12**) indicate that the landfill footprint extends more northwesterly than thought when samples were sited. The extended area is topographically downgradient and there were no samples located passed the most downgradient edge; therefore, the area was not adequately characterized to make the determination of whether the former landfill is a source area.

AOC 4

AOC 4 sample collection was biased towards known source areas (e.g., bunker outlets, bunker aprons, drainage swales between bunkers). The results were all non-detect for the three analytes: 2,4-DNCB, 2,4-DNP, and picric acid; therefore, no areas of higher concentrations were identified. However, the surficial ISM results from the bunker aprons had low bias for the SVOCs; therefore, the bunker aprons were not adequately characterized to make the determination of whether they remain source areas because there is no other data.

AOC 5

AOC 5 had not been investigated previously; therefore, 5 soil borings per potential source area (i.e., Boiler House, Coal Aggregate Bins, Coal Storage Area, Electric Substation, and Potential Dump) and 12 temporary groundwater wells AOC-wide were sampled. Concentrations detected in the Electric Substation and Potential Dump are not indicative of a substantial release/source area. However, metals concentrations in soil and groundwater (particularly arsenic), are greater than background and human health screening levels in the Boiler House, Coal Aggregate Bins, and Coal Storage Area. PAH concentrations are also above background and risk-based screening levels in the 0 to 1 ft bgs soil intervals in the Coal Aggregate Bins and Coal Storage Area. Coal and coal ash can be sources of PAHs and metals. Of the ten surficial soil samples in these coal areas, microscopy indicated that eight contained coal, one contained coal ash, and one contained both coal and coal ash. Coal, coal dust, and coal ash are not regulated under CERCLA (40 CFR Part 257), and therefore are not eligible for remediation under FUDS; however, contaminants that have leached from these materials are regulated under these policies. The source of the elevated metals concentrations in the soil borings is likely due to leaching from coal and/or coal ash. Elevated PAHs were not found at depth or in the sample that contained coal ash only; and the working hypothesis is that the PAH concentrations are associated with the coal particles and not the soil. Additional sampling is needed to determine the source of PAHs.

### 8.1.4 Focus Additional Fieldwork

Objective met—**Section 9** (Recommendations) presents the recommendations to focus the RI data collection to meet site characterization and risk assessment-related DQOs based on the potential impacts from DoD-related constituents indicated in the Phase 1 Risk Screening.

## 8.2 POTENTIAL DATA GAPS

The results of the data usability assessment and screening comparisons were used to identify data gaps at the Site and within each AOC, the background area, and within the sampling and analysis program. Recommendations for Phase 2 sampling to address the data gaps identified in this section are presented in **Section 9** for discussion with the PDT.

The data gaps that were identified generally resulted from:

1) Inaccessible sample locations where alternate locations to satisfy the project's DQOs were not identified and sampled. A comprehensive Data Collection Assessment is presented in **Appendix B**. Refer to the DUA for a comparison of all planned samples and collected samples, and an assessment of whether DQOs were achieved.

2) Areas of investigation or media that were not included in the scope of the Phase 1 investigation.

3) Sampling techniques (i.e., temporary well sampling, discrete soil sampling) that are not suitable to support RI or risk assessment activities.

4) Analytical techniques that require modification to meet project DQOs (i.e., precision, accuracy, or sensitivity requirements).

5) Availability of appropriate screening levels for potentially DoD-related or DoD-related analytes.

The following sections describe the potential data gaps that were identified. Discussions regarding whether the issue is considered a true data gap and whether to/how to resolve it are reserved for **Section 9**.

### 8.2.1 AOC 1

- Groundwater data were not collected from permanent wells. Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Additionally, temporary wells provide only limited hydrogeologic information; therefore, they are not sufficient to fully evaluate hydrogeologic conditions and aquifer characteristics. Lastly, human health risk assessment requires the use of total, not dissolved metals concentrations.

- A temporary well could not be installed at planned location NYOW-01-003 because Bluestone did not have ROE for the property. The planned groundwater sample could not be collected and represents a potential data gap for the evaluation of hydrogeology and potable water use for current/future nearby residents.

- Several planned soil sample locations could not be accessed due to ROE restrictions, including NYOW-01-002, NYOW-01-003, NYOW-01-004 (Change Houses), NYOW-01-005 (Laboratory Building), and NYOW-01-017 (Ammonium Picrate Magazine). These borings could not be relocated and represent a potential data gap in the evaluation of AOC 1 human and ecological receptors.

- Several planned soil and groundwater sample locations could not be accessed do to old concrete building foundations in the Ammonium Picrate Area along the toe of the drumlin. These borings could not be relocated within the building footprints and represent a potential data gap in the evaluation of AOC 1 surface geology, hydrogeology, and human and ecological receptors.

- Wetland areas in AOC 1 were not sampled to reduce the impact to sensitive habitats. Surface water runoff and groundwater seeps may have impacted low-lying wetland areas; therefore, absence of samples in the wetland areas constitutes a potential data gap.

- Soil samples were not collected from the former wastewater ditches outside of the AOC boundary along the northeastern side of the Ammonium Picrate Area and Administration Area. Much of the area of the former wastewater ditches is now residential property. The lack of sampling in the former wastewater ditches represents a potential data gap.

- Soil samples were not collected from within the Former Borrow Pit, representing a data gap in the evaluation of AOC 1 human and ecological receptors. Samples were not planned within the Former Borrow Pit because aerial photography shows excavation and later backfilling of the area post-DoD use.

### 8.2.2 AOC 3

- Groundwater data were not collected from permanent wells. Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Additionally, temporary wells provide only limited hydrogeologic information; therefore, they are not sufficient to fully evaluate hydrogeologic conditions and aquifer characteristics. Lastly, human health risk assessment requires the use of total, not dissolved metals concentrations.

- To avoid disturbance, surface and subsurface soil samples were not collected from the greens or the golf course fairway southwest of the Former Landfill where a portion of the open storage area is located, representing a potential data gap.

- Soil samples were not collected from the wooded area northeast of the parking lot. During the Phase 1 investigation, evidence of human activity indicative of receptor exposure to surface soil (e.g., empty bottles and debris) was found near the small northern stream. Therefore, a data gap exists in the northeast, wooded portion of the AOC.

- Sediments/pore water/surface water samples in the unnamed stream north of the parking lot were not planned for collection during Phase 1. However, based on the results of the Phase 1 investigation, samples in the unnamed stream north of the parking lot are needed to assess potential ecological risk. In addition, it is not known if the stream is gaining or losing in this area, the information regarding which is needed characterize fate and transport. These represent data gaps.

- The geophysical survey conducted at the AOC 3 Suspected Landfill Area satisfied the DQO of assessing the area for evidence of buried containerized waste or large metallic debris. The survey did not indicate historical landfill below the parking lot but did indicate historical landfill north of the parking lot, between the parking lot and the stream. Because the Phase 1 investigation assumed historical landfill below the parking lot, the area north of the parking lot was not fully characterized to address potential impacts from the newly identified landfill area. The absence of complete characterization of soil and groundwater in this area, as well as the unknown vertical extent of the landfill, represent a data gap.

### 8.2.3 AOC 4

- Surface water, pore water, and sediment data were not collected; therefore, ecological screenings in the wetland areas east and west of AOC 4 were not completed. Recommendations for sampling during Phase 2 will be dependent upon the results of the Phase 1 sampling, topography and/or potential groundwater flow (see **Section 9**).

- 2,4-DNCB in ISM surface soil had low bias attributable to low surrogate recoveries for 33 of 34 samples (97%). 2,4-DNP had low bias attributable to low surrogate recoveries for 27 of 29 samples (93%). Picric acid had low bias attributable to low surrogate and matrix spike recoveries at a

frequency of 9 of 36 samples (25%). The uniformly low bias of results reported as non-detect represents a data gap within the bunker areas at AOC 4.

- For ISM DU 1, all three replicates had results rejected for low bias of 2,4-DNP based on low MS/MSD recoveries. For ISM DU 5, one replicate had results rejected for 2,4-DNCB and 2,4-DNP due to holding time exceedances. For ISM DU 9, all three replicates had results rejected for low bias of 2,4-DNP due to an MSD that did not recover. For DU 10, one replicate had the result for 2,4-DNCB rejected based on a low surrogate recovery. Three valid ISM replicates are considered necessary to provide information regarding the reproducibility and heterogeneity of the data; therefore, the lack of three valid replicates represent a data gap within the bunker areas at AOC 4.

### 8.2.4 AOC 5

- Groundwater data were not collected from permanent wells. Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Additionally, temporary wells provide only limited hydrogeologic information; therefore, they are not sufficient to fully evaluate hydrogeologic conditions and aquifer characteristics. Lastly, human health risk assessment requires the use of total, not dissolved metals concentrations.

- At the time the UFP-QAPP was written (USACE, 2020), it was determined that for human health, the trespasser scenario was most appropriate based on the land use of AOC 5. However, the most recent developer Master Plan in the project files is from 2012. Projected future land use is considered a data gap.

- The background and screening level comparisons for groundwater discrete soil samples resulted in the identification of COPCs and COPECs within the surface and subsurface soil intervals in the Boiler House, Coal Aggregate Bins, and Coal Storage Area subareas (Subsection 6.2). Of particular note is that arsenic was detected in groundwater at the Boiler House at 140 µg/L. Therefore, additional sampling is necessary to characterize the extent of soil and groundwater impacts and estimate representative mean sample concentrations to conduct human health and ecological risk assessments.

  Data gaps were not identified for either the Electric Substation or the Possible Dump. At the Electric Substation detected constituents were at concentrations not substantially different from background and/or screening levels. As noted in **Subsection 7.10,** there is no evidence of subsurface disposal activities in the Possible Dump area and concentrations are not indicative of DoD-related disposal activities.

- Due to a laboratory equipment failure, all soil samples were analyzed outside the holding time period for TOC (i.e., 28 days) but within the holding time rejection threshold (56 days). Although microbial degradation is significantly reduced by storing samples at 4°C, some loss of organic material can occur, and the loss is exacerbated by prolonged storage. The TOC concentrations in AOC 5 were used to evaluate the suitability of background soil for comparison to site soil;

therefore, the uniformly low-biased TOC data obtained for the AOC 5 data may impact the risk screening and future ecological risk assessment and represents a potential data gap.

- Wetland surface soils were not sampled to reduce the impact to sensitive habitats. Surface water runoff and groundwater seeps may have impacted low-lying wetland areas; therefore, absence of samples in the wetland areas constitutes a potential data gap, predicated on land use. I.e., if the future land use is potentially residential, sampling within the wetland may be needed to provide sufficient coverage for residential-size lots.

- Coal and coal ash are not hazardous waste under CERCLA; therefore, the PAH and metal analytes that were identified as COPCs or COPECs within the AOC 5 Coal Aggregate Bins subarea may not be subject to further evaluation if it is determined that they are associated only with solid waste material. Surface soil samples were submitted for the analysis of coal and coal ash by a combination of microscopy techniques to determine presence/absence. A study would have to be designed to obtain additional data in order to evaluate the potential DoD-relatedness of COPCs/COPEC concentrations. This represents a data gap.

- There is the potential that DoD-related contaminants leached into the soil and groundwater beneath the newly identified ditch and/or were transported downstream (south) to low-lying wetlands. The lack of data for characterization of this potential transport pathway is a data gap.

### 8.2.5 Background

- Groundwater data were not collected from permanent wells. Grab groundwater samples were collected from temporary groundwater monitoring wells that were not developed prior to sampling. Temporary wells can result in concentrations both above and below the corresponding data from a permanent monitoring well; therefore, the groundwater data may not be representative of groundwater conditions. The effect of the well installation technique on the reported groundwater concentrations cannot be assessed during data validation. Filtered background data is not comparable to total metal results for future onsite groundwater sampling.

- Due to a laboratory equipment failure, 74 soil samples were analyzed outside the holding time period for TOC. The TOC concentrations in background soils were also used to evaluate the suitability of background soil for comparison to site soil; therefore, the uniformly low-biased TOC data obtained for the background data may impact the risk screening and represents a potential data gap.

- The mapped but not ground-truthed Psc surface geologic unit could not be sampled south of the edge of the wetland, resulting in significant relocation distances. Wetland avoidance results in a potential data gap for collection of spatially representative soil samples within the background reference area.

### 8.2.6 Sampling and Analytical

- Given that Aroclor-1260 was present in soil at AOC 3 and the AOC 5 Electric Substation subarea, the inability of the SW-846 Method 8082A to attain the Tap Water RSL represents a data gap for

the AOC 3 and AOC 5 groundwater investigations and assessment of potable use pathways for current/future nearby residents.

- The ISM samples for SVOC analysis for 2,4-DNP and 2,4-DNCB underwent the complete ISM processing and subsampling procedures, rather than having aliquots removed for SVOC analysis/moisture content prior to drying, as was specified in the UFP-QAPP. The decision to process ISM samples for the SVOC analysis was based on information provided in the ISM-2 guidance regarding the loss potential of SVOCs during air drying and the consideration that air exposure at the laboratory was not likely to produce analyte loss for surface soils that had been exposed to ambient air for many years (ITRC, 2020). There is no LCSSRM available that contains the SVOC analytes 2,4-DNCB and 2,4-DNP, and the explosives LCSSRM does not contain picric acid. As a result, the impact that air drying and sample milling to generate a flour-like matrix may have had on the recovery of all analytes cannot be quantified, and the potential low bias of non-detect ISM data constitutes a potential data gap.

- The PALs for all metals analytes in groundwater that were not met by LOQs were either attained by the LOD or were analyzed by the more sensitive analytical technique (i.e., ICP-MS), with the exception of cadmium and selenium, representing a data gap for the groundwater investigations and assessment of potable use pathways for current/future nearby residents.

- Mixing of a strongly aggregated soil (e.g., clay) to reduce intra-sample variability is difficult due to the presence of cohesive clumps that require mechanical disaggregation. Soil samples that were clay could not be thoroughly homogenized at the laboratory before sub-sampling was performed; non-homogeneous samples can impact the apparent method precision through elevated MS/MSD RPDs or FD RPDs. **Appendix B Section 2.2.1** describes the MS/MSD and FD RPDs that were greater than the upper warning limits for PAHs (phenanthrene, acenaphthylene, fluorene, anthracene, fluoranthene, benzo(a)anthracene, pyrene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, and benzo(g,h,i)perylene) and metals (antimony, calcium, magnesium, mercury, manganese, thallium, arsenic, barium, potassium, aluminum, cadmium, selenium, sodium, beryllium, vanadium, chromium, iron, cobalt, lead, zinc, nickel, and copper) representing an uncertainty and potential data gap.

- Universally low surrogate recoveries were associated with the ISM samples for SVOC analysis. An equivalent mass of Ottawa Sand was added to the samples before reanalysis in order to increase contact with the solvent, with the intent to improve surrogate recoveries. This approach did not typically improve surrogate recoveries, and the low bias of non-detect ISM data constitutes a potential data gap.

- The ecological PALs for 2,4-DNP and picric acid and the human health PAL for 2,4-DNP in groundwater are not attainable with contemporary analytical methodology; exceedances of these PALs were anticipated prior to sampling as documented in the UFP-QAPP (USACE, 2020) and alternative methods were not identified; therefore, analytical sensitivity represents a data gap.

- The PALs for all PAH analytes in groundwater were met by the LOQs, with the exception of benzo(a)anthracene, benzo(a)pyrene, and dibenz(a,h)anthracene. PAHs in groundwater were analyzed by the more sensitive analytical method (BNASIM), therefore, analytical sensitivity for PAHs in groundwater represents a data gap.

### 8.2.7 Surrogate Chemicals and Chemicals Without Screening Levels

- As presented in **Table 5-2**, four SVOCs, three PAHs, and two PCBs did not have an EPA Tap Water RSL, and surrogate chemicals were selected for screening purposes.
    - 2,4-DNT was selected as the surrogate for 2,4-DNCB. 2,4-DNCB was not detected in site groundwater and a significant data gap is not identified.
    - 2-Chlorophenol was selected as the surrogate for 2-nitrophenol and 4-nitrophenol. Neither 2-nitrophenol or 4-nitrophenol were detected in site groundwater; therefore, a significant data gap is not identified.
    - Fluorene was selected as the surrogate for carbazole. Carbazole was not detected in site groundwater and a significant data gap is not identified.
    - Acenaphthene was selected as the surrogate for acenaphthylene. Acenaphthylene was not detected in site groundwater and a significant data gap is not identified.
    - Benzo(g,h,i)perylene was detected in two groundwater samples from the AOC 5 Boiler House with a maximum concentration of 0.17 µg/L. Pyrene is an appropriate surrogate based on structural similarity and the low potential for benzo(g,h,i)perylene to drive risk; therefore, a significant data gap is not identified.
    - Phenanthrene was detected in six site groundwater samples from AOC 5 with a maximum concentration of 0.42 µg/L. Anthracene is an appropriate surrogate based on structural similarity and the low potential for phenanthrene to drive risk; therefore, a significant data gap is not identified.
    - Aroclor 1260 was selected as the surrogate for Aroclors 1262 and 1268. Aroclors 1262 and 1268 were not detected in site groundwater and a significant data gap is not identified.
- As presented in **Table 5-3**, five SVOCs, three PAHs, and two PCBs did not have an EPA Resident Soil RSL, and surrogate chemicals were selected for screening purposes.
    - 2,4-DNT was selected as the surrogate for 2,4-DNCB. 2,4-DNCB was not detected in surface or subsurface soil and a significant data gap is not identified.
    - 2-Chlorophenol was selected as the surrogate for 2-nitrophenol and 4-nitrophenol. Neither 2-nitrophenol or 4-nitrophenol were detected in surface or subsurface soil; therefore, a significant data gap is not identified.
    - 4-Nitroaniline was selected as the surrogate for 3-nitroaniline. 3-Nitroaniline was not detected in surface or subsurface soil; therefore, a significant data gap is not identified.
    - Fluorene was selected as the surrogate for carbazole. Carbazole was detected in three soil samples within AOC 3 with a maximum concentration of 0.55 mg/kg. Fluorene is an appropriate surrogate based on structural similarity and the low potential for carbazole to drive risk; therefore, a significant data gap is not identified.
    - Acenaphthene was selected as the surrogate for acenaphthylene. Acenaphthylene was detected in 38 soil samples within AOC 3 and the AOC 5 subareas with a maximum concentration of 1.6 mg/kg. Acenaphthene is an appropriate surrogate based on structural similarity and the low potential for acenaphthylene to drive risk; therefore, a significant data gap is not identified.
    - Benzo(g,h,i)perylene was detected in 22 surface and subsurface soil samples from AOC 3 and 34 surface and subsurface soil samples from the AOC 5 subareas with a maximum

detected concentration of 4.7 mg/kg. Pyrene is an appropriate surrogate based on structural similarity and the low potential for benzo(g,h,i)perylene to drive risk; therefore, a significant data gap is not identified.

- Phenanthrene was detected in 23 surface and subsurface soil samples from AOC 3 and 42 surface and subsurface soil samples from the AOC 5 subareas with a maximum detected concentration of 27 mg/kg in AOC 3 surface soil. Anthracene is an appropriate surrogate based on structural similarity and the low potential for phenanthrene to drive risk; therefore, a significant data gap is not identified.
- Aroclor 1260 was selected as the surrogate for Aroclors 1262 and 1268. Aroclors 1262 and 1268 were not detected in surface or subsurface soil and a significant data gap is not identified.

- As presented in **Table 5-4**, four VOCs, seven SVOCs, and 15 PAHs (including high molecular weight PAHs and low molecular weight PAHs) did not have phytotoxicity screening levels, and an attempt was made to select surrogate chemicals were selected for screening purposes (see **Subsection 5.1.1.1**).
  - 1,2,3-Trichlorobenzene, 2-nitroaniline, 2-nitrophenol, 3-nitroaniline, 4-nitroaniline, and 4-nitrophenol were not detected in the 0 to 1 ft bgs or 1 to 5 ft bgs soil intervals; therefore, a significant data gap is not identified.
  - Surrogates were selected for one VOC and three PAHs as noted below.
    - Toluene was selected as the surrogate for benzene. Toluene is an appropriate surrogate based on structural similarity and the low potential for benzene to drive phytotoxicity risk; therefore, a significant data gap is not identified.
    - Naphthalene was selected as the surrogate for both 1-methylnaphthalene and 2-methylnaphthalene. Naphthalene is an appropriate surrogate based on structural similarities; therefore, a significant data gap is not identified.
    - Benzo(b)fluoranthene was selected as the surrogate for benzo(k)fluoranthene. Benzo(b)fluoranthene is an appropriate surrogate based on structural similarities; therefore, a significant data gap is not identified.
  - Surrogates were not selected for the following detected analytes: 2-butanone, acetone, benzaldehyde, carbazole, and 12 PAHs (including high molecular weight PAHs and low molecular weight PAHs).
    - 2-Butanone was detected in the 0 to 5 ft bgs depth intervals at a frequency of five of 18 samples in AOC 3 and two of five samples in the AOC 5 Possible Dump Area; therefore, the lack of a surrogate for 2-butanone may represent a significant data gap.
    - Acetone was detected in the 0 to 5 ft bgs depth intervals at a frequency of six of 18 samples in AOC 3 and one of five samples in the AOC 5 Possible Dump Area; therefore, the lack of a surrogate for acetone may represent a significant data gap.
    - Benzaldehyde was detected in the 0 to 5 ft bgs depth intervals at a frequency of 6 of 36 samples in AOC 3 and 1 of 10 samples in the AOC 5 Possible Dump Area; therefore, the lack of a surrogate for benzaldehyde may represent a significant data gap.

- Carbazole was detected in the 0 to 5 ft bgs depth interval at a frequency of three of 36 samples in AOC 3; therefore, the lack of a surrogate for carbazole may represent a significant data gap.
- PAHs were frequently detected in AOC 3 and all five subareas of AOC 5. In addition, background comparisons indicated the potential for site-related releases. Therefore, lack of phytotoxicity surrogates for acenaphthylene, benzo(a)pyrene, benzo(g,h,i)perylene, chrysene, dibenz(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-c,d)pyrene, phenanthrene, and pyrene may represent a significant data gap.

- As presented in **Table 5-5**, four SVOCs and four metals did not have soil invertebrate screening levels, and an attempt was made to select surrogate chemicals were selected for screening purposes (see **Subsection 5.1.1.1**).
  - 2-Nitrophenol, 3-nitroaniline, and 4-nitroaniline were not detected in the 0 to 1 ft bgs or 1 to 5 ft bgs soil intervals; therefore, a significant data gap is not identified.
  - Benzyl alcohol was selected as the surrogate for benzaldehyde. Benzaldehyde is an appropriate surrogate based on structural similarity; therefore, a significant data gap is not identified.
  - Surrogates were not selected for the following detected analytes: cobalt, silver, thallium, and vanadium. In the 0 to 5 ft bgs depth interval, cobalt and vanadium were detected in every sample; silver was detected in at least 10% of the samples in AOC 1, AOC 3, and the AOC 5 Possible Dump subarea; and thallium was detected in at least 30% in each AOC/subarea. Background comparisons indicated the potential for site-related releases with the exception of thallium in AOC 1 and silver in AOC 5 subareas (excluding the Possible Dump Area). Therefore, lack of soil invertebrate surrogates for cobalt, silver, thallium, and vanadium may represent a significant data gap.

- As presented in **Table 5-6**, four VOCs, 11 SVOCs, 17 PAHs (including high molecular weight PAHs and low molecular weight PAHs), picric acid, and two metals did not have avian screening levels, and an attempt was made to select surrogate chemicals were selected for screening purposes (see **Subsection 5.1.1.1**).
  - Although surrogates were identified for 2-butanone and toluene, avian exposure was limited to the 0 to 1 ft bgs interval and VOCs were not analyzed within this interval. Therefore, the use of surrogates for VOCs or the lack thereof for 1,2,3-trichlorobenzene and benzene does not constitute a significant data gap.
  - 2-Nitroaniline, 2-nitrophenol, 3-nitroaniline, 4-chloroaniline, 4-nitroaniline, 4-nitrophenol, carbazole, and phenol were not detected in the 0 to 1 ft bgs soil interval of AOC 5; therefore, a significant data gap is not identified.
  - Surrogates were selected for two SVOCs, two PAHs, and picric acid as noted below.
    - Surrogates were identified for 2,4-DNCB and 2,4-DNP; however, these analytes were not detected in the 0 to 1 ft bgs soil interval. These analytes are site-specific COPECs and there were analytical issues in some datasets that potentially biased the concentrations low. 2,6-DNT is an appropriate surrogate for both 2,4-DNCB and 2,4-DNP based on structural similarity; therefore, a significant data gap is not identified.

        - Naphthalene was selected as the surrogate for both 1-methylnaphthalene and 2-methylnaphthalene. Naphthalene is an appropriate surrogate based on structural similarities; therefore, a significant data gap is not identified.
        - 2,4,6-Trinitrotoluene was selected as the surrogate for picric acid. 2,4,6-trinitrotoluene is an appropriate surrogate based on structural similarities; therefore, a significant data gap is not identified.
    - Surrogates were not selected for the following detected analytes: benzaldehyde, and 15 PAHs (including high molecular weight PAHs and low molecular weight PAHs), antimony, and beryllium.
        - Benzaldehyde was detected in the 0 to 1 ft bgs depth intervals at a frequency of one of five samples in the AOC 5 Possible Dump Area; therefore, the lack of a surrogate for benzaldehyde may represent a significant data gap.
        - PAHs were frequently detected in all five subareas of AOC 5. In addition, background comparisons indicated the potential for site-related releases mostly in the in the Coal Aggregate Bins and Coal Storage Area. Therefore, lack of avian surrogates for acenaphthene, acenaphthylene, anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-c,d)pyrene, and phenanthrene may represent a significant data gap.
        - Antimony and beryllium were detected in almost every sample collected in AOC 1 and AOC 5. Background comparisons indicated the potential for site-related releases; therefore, lack of avian surrogates for antimony and beryllium may represent a significant data gap.

- As presented in **Table 5-7**, one VOCs and one SVOC did not have mammal screening levels, and an attempt was made to select surrogate chemicals were selected for screening purposes (see **Subsection 5.1.1.1**).
    - Although a surrogate was identified for 1,2,3-trichlorobenzene, it was not detected in the 0 to 1 ft bgs or 1 to 5 ft bgs soil intervals; therefore, a significant data gap is not identified.
    - Benzyl alcohol was selected as the surrogate for benzaldehyde. Benzaldehyde is an appropriate surrogate based on structural similarity; therefore, a significant data gap is not identified.

- Surrogate plant screening values could not be selected for the potentially or likely DoD-related analytes shown in **Table 5-13**. These include VOCs (1,2,3-trichlorobenzene, 2-butanone, acetone), SVOCs (nitroanilines, nitrophenols, benzaldehyde, and carbazole), and PAHs. The VOCs are primarily used as solvents or intermediates to produce other chemicals. The SVOCs are used as intermediates in various manufacturing process (e.g., dyes, pharmaceuticals) or derivative of combustion (carbazole and PAHs). Historical volatile releases are generally not an issue for phytotoxicity, as surficial VOCs would have dispersed or leached to groundwater. The lack of SVOC and PAH phytotoxicity values represents a data gap.

- Surrogate soil invertebrate screening values could not be selected for the potentially or likely DoD-related analytes shown in **Table 5-14**. These include cobalt, silver, thallium, and vanadium. Alloys that contain cobalt are used in military and industrial applications. Silver and thallium may be present in electronic equipment. Vanadium is associated with various steels, magnets, fuel oil, and

coal. For invertebrates, the lack of cobalt, silver, thallium, and vanadium toxicity data represents a data gap.

Surrogate avian screening values could not be selected for the potentially or likely DoD-related analytes shown in Table 5-15. These include VOCs (1,2,3-trichlorobenzene and benzene), SVOCs (nitroanilines, nitrophenols, 4-chloroaniline, benzaldehyde, carbazole, and phenol), PAHs, antimony, and beryllium. The VOCs are solvents or associated with petroleum use. The SVOCs are used as intermediates in various manufacturing process (e.g., dyes, pharmaceuticals) or derivative of combustion (carbazole and PAHs). Antimony is released by incinerators and coal-burning power plants. Beryllium is used in electronics, aerospace, and defense industries because it is a rigid, lightweight metal. Historical volatile releases are generally not an issue for avian toxicity as surficial VOCs would have dispersed or leached to groundwater and are generally not considered bioaccumulative; therefore, they would not be evaluated through food chain exposures. For birds, the lack of SVOC, PAH, and metals toxicity data represents a data gap.

*This page intentionally left blank.*

# 9.0 RECOMMENDATIONS FOR PHASE 2

Prior to the formulation of Phase 2 recommendations, the results of the Phase 1 risk screening, assessment of uncertainties, updates to the CSM, and analysis of data gaps were considered. Recommendations for the Phase 2 RI are provided below and presented in **Table 9-1**. The sampling recommendations below are designed to fulfill the unmet Phase 1 objectives noted in **Section 8**, fill data gaps, and provide information to support an RI, including Human Health and Ecological Risk Assessment.

The recommendations below are general, with exact locations and sample numbers not specified. Generic analytical category recommendations are presented. Specific locations, sample numbers, and analytical methods are the purview of the sampling design to be presented in a future UFP-QAPP and are not within the scope of this document.

## 9.1 AOC 1

- Install permanent groundwater monitoring wells when additional groundwater sampling is recommended to; collect representative samples for total and dissolved metals, picric acid, 2,4-DNCB, and 2,4-DNP; and evaluate hydrogeologic conditions and aquifer characteristics.
- Additional information was gained regarding the DoD activities at the Change Houses. These structures were used for workers to change from street clothes to work clothes prior to their shift and change back into their street clothes prior to returning home. The contamination expected based on this activity is minimal and soil data from the Change House represented by the soil boring at NYOW-01-002 was non-detect for picric acid, 2,4-DNCB, and 2,4-DNP and concentrations of metals were not substantially different from background (see **Tables I-3, I-6, and I-9**). Therefore, it is not recommend to obtain ROE at NYOW-01-003 or identify an appropriate alternative location for installation and sampling of a groundwater monitoring well.
- Develop a soil sampling program for one of the locations that were inaccessible during Phase 1 field activities due to ROE restrictions and analyze samples for metals, picric acid, 2,4-DNCB, and 2,4-DNP. Data from only one of the inaccessible locations is necessary to meet the Phase 1 objective of characterizing a potential source area. ROE will need to be obtained to sample NYOW-01-017 (Ammonium Picrate Magazine) as proposed in the UFP-QAPP for the Phase 1 investigation (USACE, 2020). ROE does not need to be obtained for the following samples because data from the locations is deemed unnecessary at this time for the reasons noted below.
    - NYOW-01-003 and NYOW-01-004 (Change Houses) – as noted in the bullet above, The contamination expected based on the activities at the Change Houses is minimal and soil data from the boring at NYOW-01-002 was non-detect for picric acid, 2,4-DNCB, and 2,4-DNP and concentrations of metals were not substantially different from background (see **Tables I-3, I-6, and I-9**).
    - NYOW-01-005 (Laboratory Building) – A residence occupies the location of the former Laboratory Building and the soil has been reworked. Sample NYOW-01-005 was relocated from the proposed location approximately 171 feet to the northeast. Picric acid, 2,4-DNCB, and 2,4-DNP were not detected in groundwater or the three soil intervals. Metals were detected at concentrations not substantially different from

background (see **Tables I-3, I-6, I-9, I-16**) or the other locations within AOC 1. The Laboratory Building was used to quality test small quantities of the ammonium picrate product; therefore, there is no reason to suspect the area to be a source of metals contamination. In addition, the volume of ammonium picrate studied at the laboratory and the potential for release was far less than at the Ammonium Picrate Buildings and Dryer Houses where picric acid was detected in only 1 of 55 samples at a concentration below the LOD.

- Develop a soil and groundwater sampling program for metals, picric acid, 2,4-DNCB, and 2,4-DNP at locations around the former ammonium picrate buildings (near NYOW-01-007 through NYOW-01-018, along the toe of the drumlin) that were inaccessible during Phase 1 field activities. These data will be used to fill the gap in the evaluation of AOC 1 surface geology, hydrogeology, and human and ecological receptors as well as meet the objective of determining source areas.

- Develop a sampling program for wetland surface and subsurface soils for metals, picric acid, 2,4-DNCB, and 2,4-DNP to assess potential ecological risk. These samples will bridge the spatial data gap between the Ammonium Picrate Buildings and Dryer Houses where historical releases could have drained to the low lying areas. Sampling is recommended in wetlands between the Ammonium Picrate Buildings and the Dryer Houses only in the non-developed areas to avoid soils disturbed during development (i.e., areas of filling and mixing of soils). It is recommended that cribbing or a similar technique be used to mitigate potential damage to the wetlands by the drill rig.

- A soil sampling program within the former wastewater ditches along the northeastern side of the Ammonium Picrate Area and Administration Area is not recommended because the area has been heavily redeveloped and native soil cannot be identified.

- A soil sampling program within the former borrow pit is not recommended because the area was backfilled with non-native soil and is subject to active dumping by onsite workers.

## 9.2 AOC 3

- Install permanent groundwater monitoring wells when additional groundwater sampling is recommended to collect representative samples for total and dissolved metals, VOCs, SVOCs, PAHs, PCBs, and picric acid; and evaluate hydrogeologic conditions and aquifer characteristics.

- Based on the lack of any remarkable concentrations in the samples collected around the perimeter of the open storage area, additional sampling to evaluate the edges of the greens and fairway is not recommended.

- The CSM does not indicate the potential for DoD-related constituents to be present within the wooded area northeast of the parking lot where the evidence for recreator/trespasser scenarios were found. Therefore. additional sampling in the wooded area northeast of the parking lot is not recommended. The recreator/trespasser scenarios will be evaluated in a future risk assessment using the sampling results from the former landfill area.

- Develop a sampling program for sediments/pore water/surface water in the unnamed stream north of the parking lot for metals, VOCs, SVOCs, PAHs, PCBs, TOC (sediment only), and grain size (sediment only) to assess potential ecological risk. In addition, take field measurements to whether the stream is gaining or losing. These data should assist in determining if the former landfill is a source area and meet a Phase 1 objective.
- Develop a groundwater sampling program to characterize potential impacts from the newly identified landfill area north of the parking lot to evaluate if the landfill is a continuous source of contamination and meet a Phase 1 objective. A soil sampling program is not recommended because there is little to no soil present between the new boundary of landfilling and the stream. It is also not recommended to delineate the vertical extent of the landfill unless a removal action is determined to be necessary.

## 9.3 AOC 4

- Temporary well sample results indicated that picric acid, 2,4-DNCB, and 2,4-DNP were not detected, and the results were usable for their intended purpose; therefore, installation of permanent monitoring wells at AOC 4 is not necessary.
- Discrete soil sample results collected from within the AOC were non-detect for picric acid, 2,4-DNCB, and 2,4-DNP, and the results were considered usable for their intended purpose; therefore, additional discrete soil sampling outside of the AOC 4 bunkers is not recommended.
- A sampling program for sediments/pore water/surface water in the wetland areas east and west of AOC 4 for 2,4-DNCB and 2,4-DNP to assess potential ecological risk is not recommended. The wetlands to the west are upgradient from the bunkers. To the east, drainage swale and the elevated roadway provide barriers to overland transport to the wetlands and picric acid, 2,4-DNCB, and 2,4-DNP were not detected in any of the 16 groundwater (or 117 discrete soil) samples in AOC 4.
- Develop a discrete surface soil sampling program in the DUs for 2,4-DNCB and 2,4-DNP in surface soil to address the low bias that is prevalent in the analytical data seemingly due to using ISM sample processing. Analyze for picric acid from the samples for confirmation of ISM sampling results. Obtaining this data should meet the Phase 1 objectives of determining presence/absence and characterizing a potential source area.

## 9.4 AOC 5

- Install permanent groundwater monitoring wells when additional groundwater sampling is recommended to collect representative samples for total and dissolved metals, PAHs, and if the well(s) are sited directly downgradient from the Electric Substation, PCBs; and evaluate hydrogeologic conditions and aquifer characteristics.
- Contact the developer and/or the township to determine most likely anticipated future land use.

- Based on the results of the Phase 1 sampling, additional sampling in the Electric Substation and the Possible Dump area is not recommended. As noted in **Subsection 8.2.4,** detected constituents in the Electric Substation were at concentrations not substantially different from background and/or screening. As noted in **Subsection 7.10,** there is no evidence of subsurface disposal activities in the Possible Dump area and concentrations are not indicative of DoD-related disposal activities.
- Develop a surface and subsurface soil sampling program for metals, and PAHs to characterize soil impacts and estimate representative concentrations for risk assessment.
- Develop a groundwater sampling program for total and dissolved metals and PCBs (if sampling directly downgradient from the Electric Substation) to characterize groundwater impacts and estimate representative concentrations for risk assessment.
- Analyze TOC in the additional surface and subsurface samples program to support ecological risk assessment.
- If future land use indicates residential use, develop a program to sample wetland surface soils for metals and PAHs to provide sufficient coverage to assess risk based on residential-size lots. If sampling in the wetlands is undertaken, it is recommended that cribbing or a similar technique be used to mitigate potential damage to the wetlands by the drill rig.
- Further evaluation of the 1 to 5 ft bgs intervals proximal to the already sampled locations by microscopy to differentiate coal/coal ash from native soil is recommended to make a determination of DoD-relatedness and programmatic requirements for site cleanup. If new locations are sited in AOC 5, microscopy should be considered for those samples. Coal and coal ash are not hazardous waste under CERCLA; therefore, the PAH and metal analytes that were identified as COPCs within the AOC 5 Coal Aggregate Bins Area may not be subject to further evaluation where it is determined that they are associated only with the solid waste material (see additional discussion in Subsection 8.1.3). This will aid in meeting the Phase 1 objective of characterizing a potential source area.
- Develop a soil and groundwater sampling program to characterize the newly identified drainage ditch as to whether DoD-related contaminants leached into the soil and groundwater and/or were transported downstream (south) to low-lying wetlands.

## 9.5 BACKGROUND AREA

- Install permanent groundwater monitoring wells to collect representative samples for total and dissolved metals and PAHs; and obtain data comparable to the recommended AOC 1, AOC 3, and AOC 5 permanent well data. A minimum of six permanent background wells should be installed in the general vicinity of the Phase 1 temporary wells. A minimum of two rounds of sampling should be performed on the wells to account for seasonal variability and to provide a minimum of 12 data points for statistical evaluation to determine if site groundwater concentrations exceed background concentrations.
- Analyze TOC in any additional surface and subsurface samples to support ecological risk assessment.

- Develop a program to sample wetland surface soils for metals to assess potential for risk in the AOC 1 wetlands. If wetlands are sampled in AOC 5, PAHs also should be analyzed in background wetland samples. It is recommended that cribbing or a similar technique be used to mitigate potential damage to the wetlands by the drill rig.

## 9.6 SAMPLING AND ANALYTICAL

- Modify the aqueous extraction method for PCBs in future groundwater investigations to achieve Tap Water RSLs to assess potable use pathways for current/future nearby residents. Katahdin Analytical Service of Scarborough, Maine, can perform this extraction technique.

- Do not use ISM techniques to collect or prepare samples for SVOC analysis. If ISM techniques are retained, request that the laboratory pull an aliquot for SVOCs (including 2,4-DNCB and 2,4-DNP) and percent moisture analyses from ISM sample bags prior to subjecting the ISM samples to laboratory ISM methodology (e.g., drying and subsampling) in order to reduce potential loss from volatilization during air drying. For PAHs, large losses are associated with air drying samples analyzed for naphthalene. Moderate losses from air drying are associated with other PAHs that have been well-studied, including acenaphthene and acenaphthylene. The use of the drying step for PAHs should be evaluated based on the PAHs to be analyzed within an AOC. In general, ISM sample processing should be avoided for any analyte, not limited to SVOCs, for which unacceptable loss as a result of any ISM processing step is suspected based on the analyte's properties.

- If ISM techniques are retained, require that the laboratory purchase or develop LCSSRMs that contain all target analytes so that the effect of sample grinding on analyte recovery can be assessed and demonstrated to be acceptable; otherwise, exclude the analytes from ISM processing. Furthermore, unacceptably low SVOC surrogate recoveries were encountered due to poor solvent contact with the flour-like milled soil matrix during microwave-assisted extraction. If ISM techniques are retained, the selected particle size reduction and sample extraction processes must generate acceptable surrogate and target analyte recoveries.

- To improve analytical sensitivity for evaluation of potable use pathways for current/future nearby residents, it is recommended that EPA Method 6020A be used for analysis of cadmium and selenium in aqueous samples.

- To improve the heterogeneity of the soil matrix, the field team should homogenize any future discrete soil samples sequentially, first in quarter-sample segments and then in combined half-sample and full sample segments.

- More sensitive, commercially available methodology for the analysis of 2,4-DNP and picric acid (e.g., BNASIM, Gas Chromatography-Electron Capture Detector) are not currently available. Therefore, EPA SW-846 Method 8270 should be retained.

- Modification of the extraction or analytical methods for PAHs in groundwater is not recommended. PAHs are analyzed by the more sensitive technique (i.e., BNASIM).

- It is recommended that measures be taken to prevent the analytical laboratories from submitting data for which the laboratory QC samples' surrogate recoveries are outside of acceptance criteria.

## 9.7 SURROGATE CHEMICALS AND CHEMICALS WITHOUT SCREENING LEVELS

- Based on the data gap analysis performed in **Subsection 8.2.7**, no data gaps were identified on the basis of surrogate chemical selection for analytes without human health screening levels. Derivation of a site-specific screening level based on published literature values is not recommended for any analyte.
- Based on the data gap analysis performed in **Subsection 8..2.7**, the following data gaps were identified on the basis of surrogate chemical selection for analytes without ecological screening levels.
    - Plants: benzaldehyde, carbazole, and PAHs
    - Soil invertebrates: cobalt, silver, thallium, and vanadium
    - Birds: benzaldehyde, PAHs, antimony, and beryllium
    - Mammals: None.

    As noted in **Subsection 5.1.1.1,** an effort was undertaken to identify **s**urrogates for analytes without screening levels specified in the UFP-QAPP based on similarities to the COPEC in structure and functional groups. Notes regarding detected analytes for which surrogates were not selected (noted above) are as follows.
    - Benzaldehyde and carbazole – included as potentially DoD-related because of being detected at a frequency of 5% or greater and not due to knowledge of historical site use.
    - PAHs – rapidly metabolized, which precludes substantial bioaccumulation.
    - PAHs and metals – sufficient toxicity data were not available with which to calculate Eco-SSLs or EPA Region 4 screening levels and therefore, it is unlikely that appropriate data are available with which to derive robust screening levels.
- A significant data gap does not exist with respect to ecological screening values for benzaldehyde and carbazole, and it appears that a permanent data gap exists for PAHs and metals. Therefore, the derivation of a site-specific screening level based on published literature values is not recommended for any analyte. Although the derivation of screening levels is not recommended, PAHs and metals are potentially site-related and are present at AOCs 1 (metals only), 3, and 5 at concentrations greater than BTVs or toxicity values available for other ecological receptors. Therefore, it is recommended that Phase 2 sampling for AOC 1 includes metals and for AOCs 3 and 5 includes PAHs and metals.

## 9.8 CONSTITUENTS OF POTENTIAL CONCERN FOR EVALUATION DURING PHASE 2

Based on the totality of this Phase 1 Risk Screening and Data Gaps Analysis, the constituents below are noted to be of potential concern and recommended for evaluation through additional sampling and risk assessment or risk assessment alone during Phase 2. The lists were generated on an AOC- and medium-basis and include potentially DoD- and likely DoD-related constituents as follows:

- Groundwater – PAHs and metals: exceeding the BTV and the human health screening level;
- Groundwater – Other constituents: exceeding the human health screening level;
- Soil – PAHs and metals: exceeding the BTV and at least one human health or ecological screening level; and
- Soil – Other constituents: exceeding at least one human health or ecological screening level.

Also included are analytes without screening values (as noted in **Subsection 9.7)** with maximum concentrations greater than the BTV and analytes for which the LOQs were greater than the PAL as noted in **Subsection 6.3.1**. The analytes without screening values included as COPCs/COPECs likely represent permanent data gaps that would be discussed in the RI uncertainty analysis. Analytes with an LOQ greater than a PAL would be evaluated during future UFP-QAPP development to determine if a different preparatory or analytical methods could be used that would yield LOQs less than PALs.

*Anilines were not detected but the LOQs were greater than the SLs. As noted in **Subsection 9.7**, there was potential historical evidence that these constituents were associated with AOC 5. Anilines are components of pigments and dyes and were associated with AOC 5 solely because of the potential for paint cans to have been disposed of in the Possible Dump. Therefore, anilines are not considered COPCs or COPECs for the Boiler House Area and do not need to be included in future sampling associated with the Boiler House.

*Anilines were not detected but the LOQs were greater than the SLs. As noted in **Subsection 9.7**, there was potential historical evidence that these constituents were associated with AOC 5. Anilines are components of pigments and dyes and were associated with AOC 5 solely because of the potential for paint cans to have been disposed of in the Possible Dump Area. Therefore, anilines are not considered COPCs or COPECs for the Coal Aggregate Bins and do not need to be included in future sampling associated with the Coal Aggregate Bins.

As noted in **Subsection 8.2.4** detected constituents in the Electric Substation were at concentrations not substantially different from background and/or screening levels and additional sampling in the Electric Substation is not recommended. However, COPCs/COPECs for the Electric Substation are presented in the table below to indicate which analytes will be carried through to the Phase 2 risk assessments either for quantitative evaluation or qualitative discussion in the Uncertainty Analysis.

## 9.9 SUMMARY OF SUGGESTED PHASE 2 FIELD SAMPLING

The following is a summary of the suggested Phase 2 Field Sampling. Note that the number of samples, method specifications, and location siting are not within the scope of this document and will be addressed in the Phase 2 Investigation UFP-QAPP.

AOC 1

- Ammonium Picrate Buildings
  - Soil 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs– 2,4-DNCB, 2,4-DNP, picric acid, metals, and TOC
  - Groundwater (permanent wells) – 2,4-DNCB, 2,4-DNP, picric acid, and total and dissolved metals
- Wetlands between the Ammonium Picrate Buildings and the Dryer Houses
  - Soil 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs– 2,4-DNCB, 2,4-DNP, picric acid, metals, and TOC

AOC 3

- Groundwater (permanent well) – VOCs, SVOCs (including 2,4-DNCB, 2,4-DNP), PAHs, PCBs, picric acid, and total and dissolved metals
- Unnamed stream north of the historical landfill
  - Pore water and surface water – VOCs, SVOCs (including 2,4-DNCB, 2,4-DNP), PAHs, PCBs, picric acid, and total and dissolved metals
  - Sediment – Soil 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs – VOCs, SVOCs (including 2,4-DNCB, 2,4-DNP), PAHs, PCBs, picric acid, metals, TOC, and grain size

AOC 4

- Soil 0 to 1 ft bgs –2,4-DNCB, 2,4-DNP, and picric acid

AOC 5

- Groundwater (permanent wells) – PAHs, PCBs (if directly downgradient from the Electric Substation), and total and dissolved metals
- Soil 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs – PAHs, metals, TOC, and coal/coal ash microscopy (0 to 1 ft bgs, 1 to 5 ft bgs only)

Background

- Groundwater (permanent wells) – PAHs and total and dissolved metals
- Hydric soils (0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs) within the Psc surface geologic unit – PAHs (if wetlands are sampled in AOC 5), metals, and TOC.

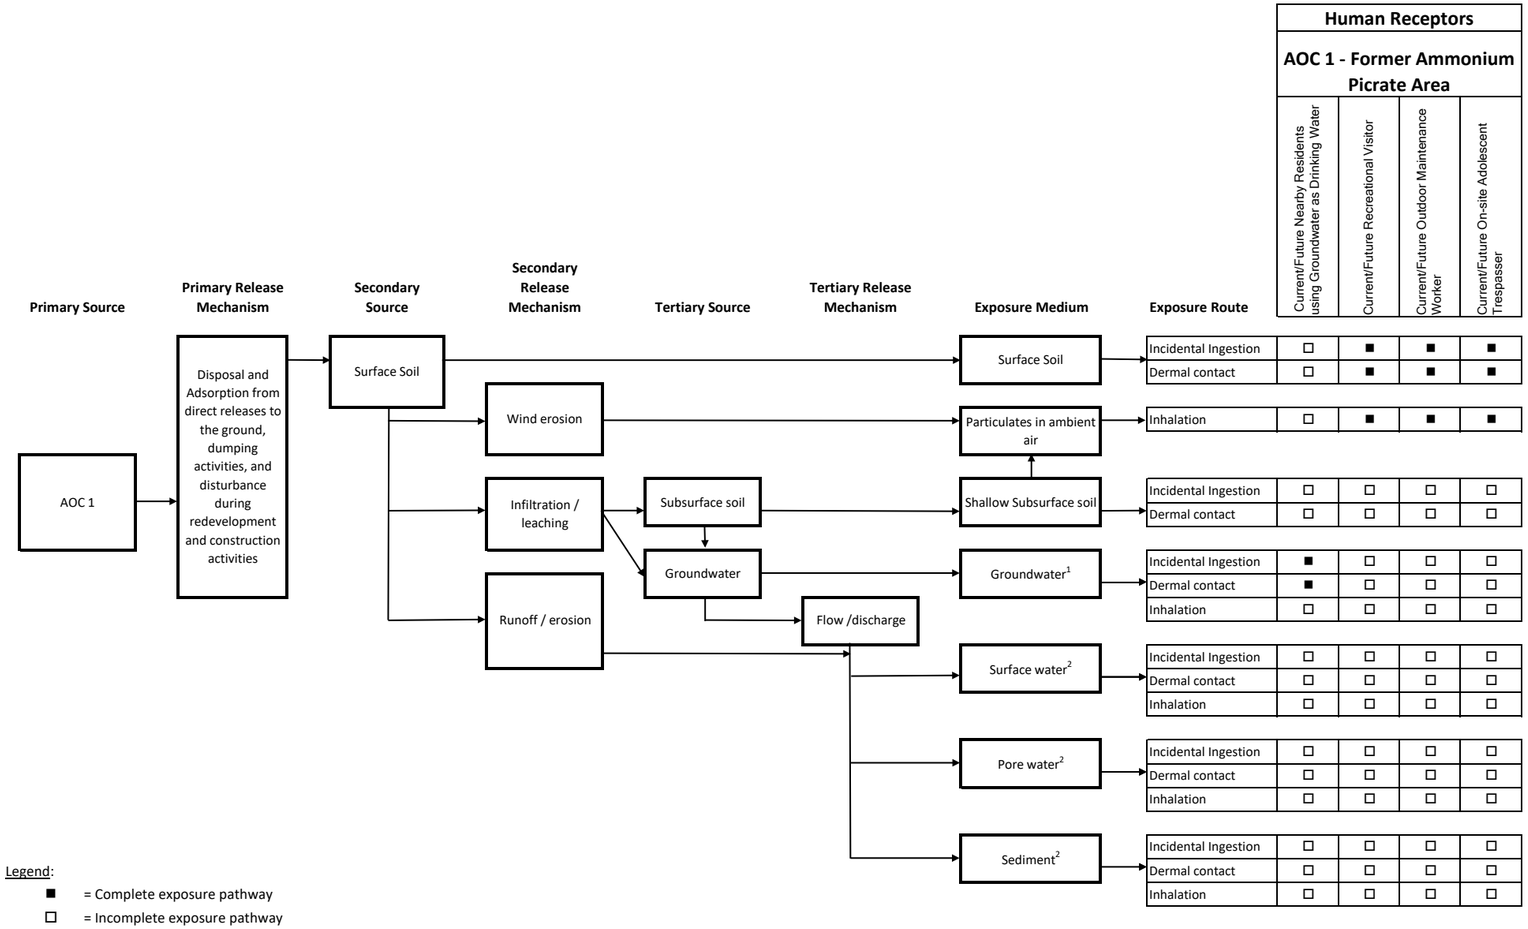
**Figure 7-14a**
**Revised Conceptual Site Model - AOC 1 - Former Ammonium Picrate Area - Human Health Receptors**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**



Notes:

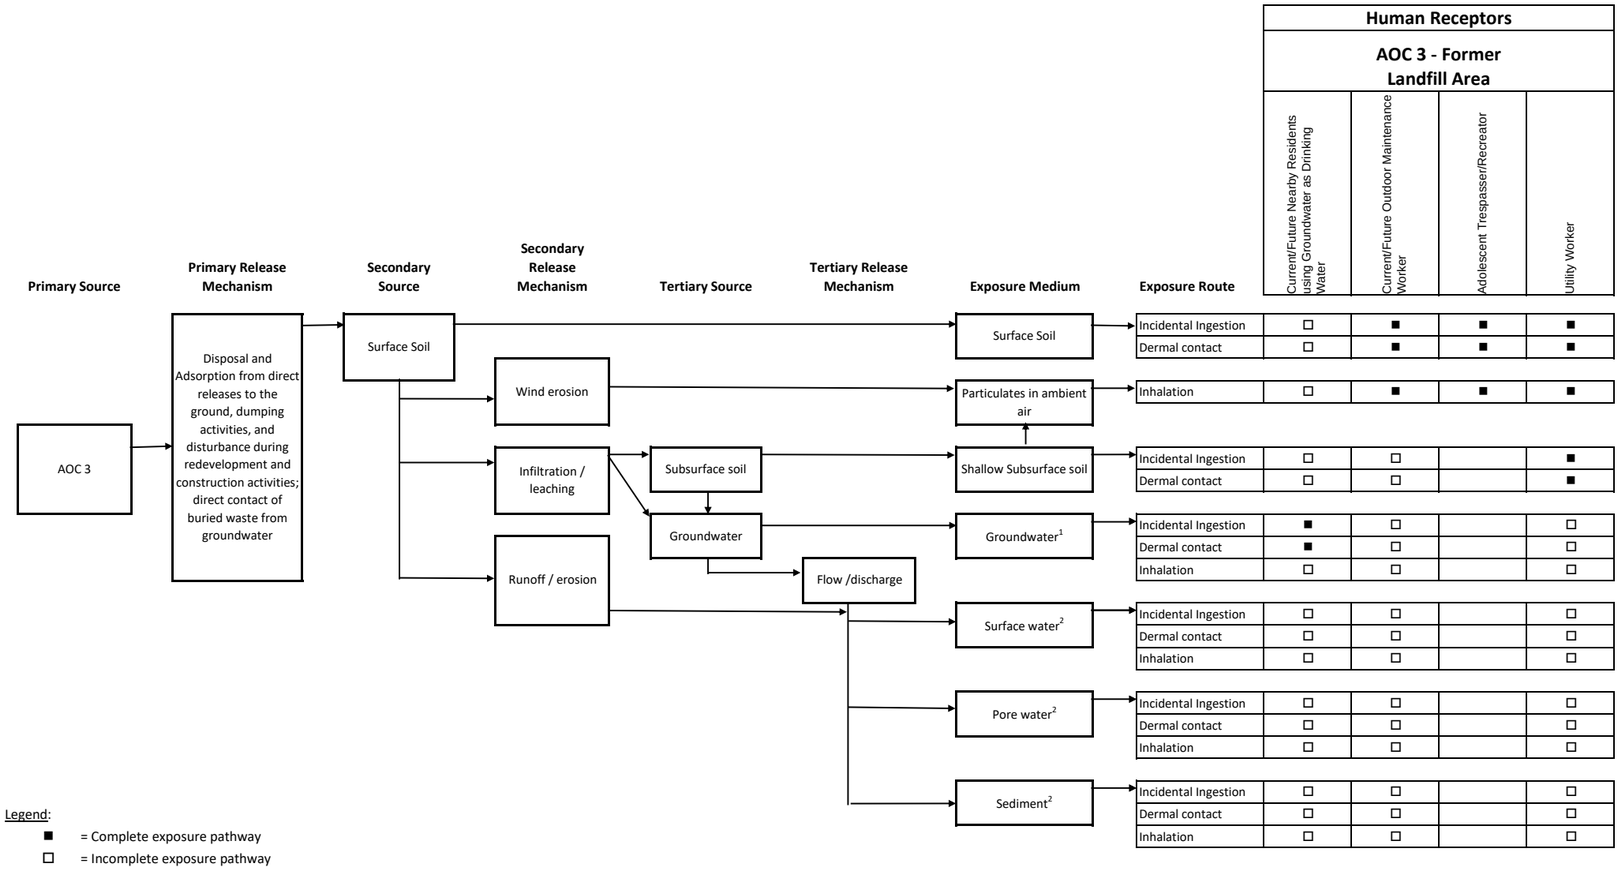
1 Groundwater on-site is not currently used as a drinking water source; therefore, groundwater exposure to on-site residents is currently considered an incomplete exposure pathway. However, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource at each of the AOCs are considered potentially complete pathways for current/future nearby residents. There are no VOCs among contaminants of concern; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater used as drinking water by current or future on-site residents or nearby residents are considered incomplete pathways.

2 Surface water, pore water, and sediment may be sampled as part of a phased assessment of groundwater contamination and potential migration. No complete human exposure pathways.

3 The following analyses were performed per medium in AOC 1 during Phase 1:

- Surface soil: TAL metals, DNCB and 2,4-DNP, picric acid; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Subsurface soil: TAL metals, DNCB and 2,4-DNP, picric acid, and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Groundwater (grab samples): TAL metals (field-filtered), DNCB and 2,4-DNP, and picric acid; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).

**Figure 7-14b**
**Revised Conceptual Site Model - AOC 3 - Former Landfill Area - Human Health Receptors**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

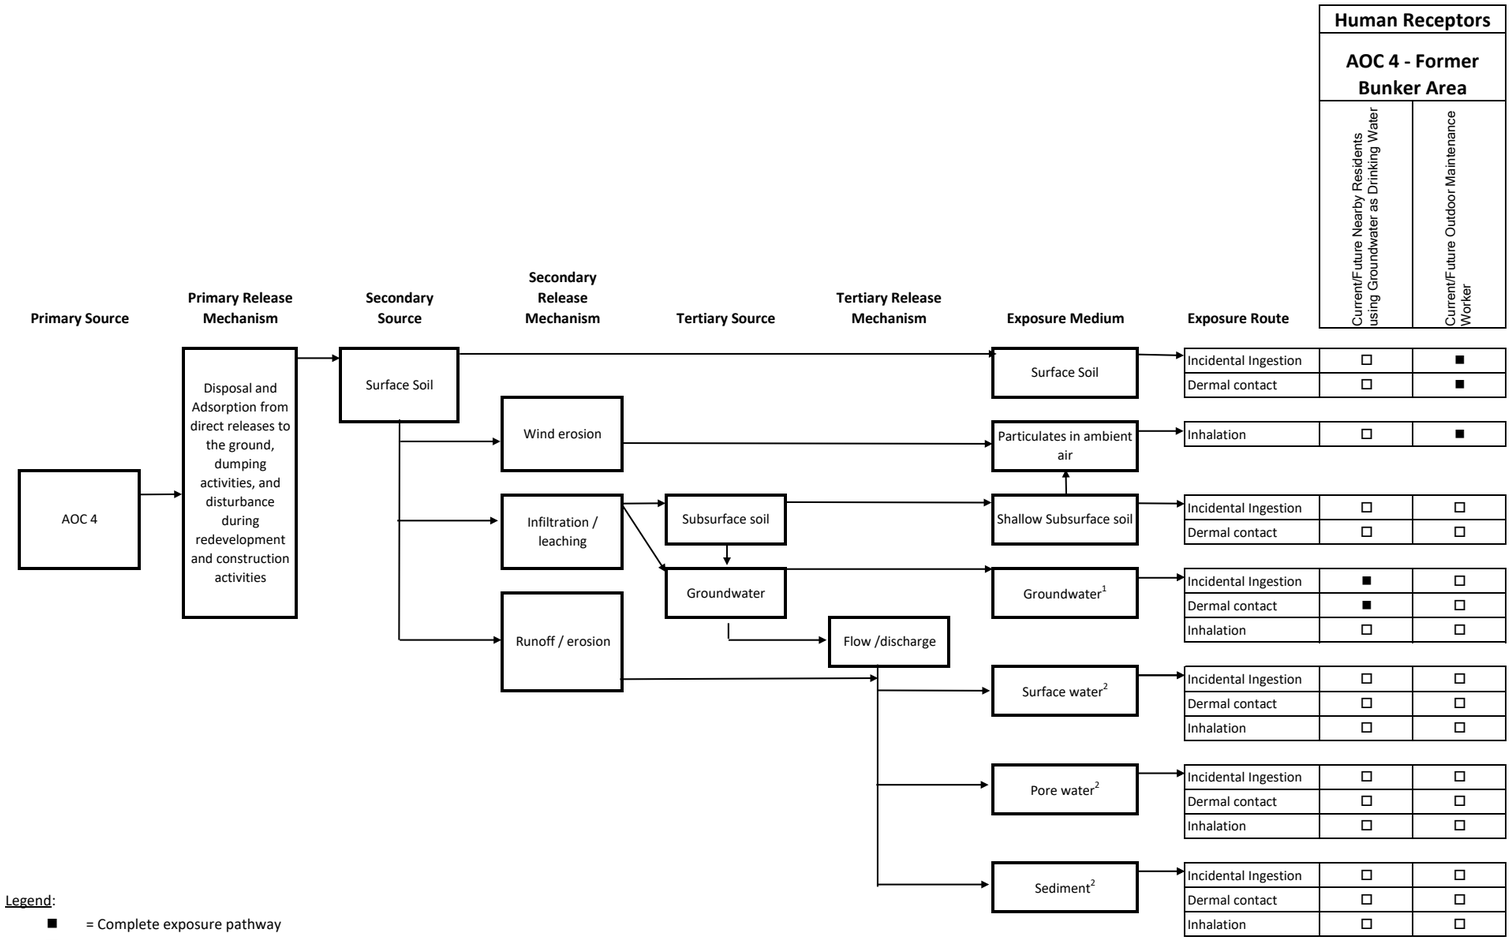


Legend:
■ = Complete exposure pathway
☐ = Incomplete exposure pathway

Notes:
1 Groundwater on-site is not currently used as a drinking water source; therefore, groundwater exposure to on-site residents is currently considered an incomplete exposure pathway. However, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource at each of the AOCs are considered potentially complete pathways for current/future nearby residents. Benzene was a COPC in AOC 3; therefore, groundwater exposure via inhalation of volatiles from groundwater used as drinking water by current or future on-site residents or nearby residents are considered potentially pathways. Benzene was not detected above the Vapor Intrusion Screening Level; therefore, groundwater exposure via vapor intrusion is considered an incomplete pathway.

2 Surface water, pore water, and sediment may be sampled during Phase 2. No complete human exposure pathways.
3 The following analyses were performed in AOC 3 during Phase 1:
*Landfill Area*
• Surface soil – TAL metals, SVOCs (including DNCB and 2,4-DNP), PAHs, picric acid, PCBs, and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
• Subsurface soil – TAL metals, VOCs, SVOCs (including DNCB and 2,4-DNP), PAHs, picric acid, PCBs, and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
• Groundwater (grab samples): TAL metals (field-filtered), VOCs, SVOCs (including DNCB and 2,4-DNP), PAHs, picric acid, and PCBs; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).
• VOCs in subsurface soil adjacent to the golf club house.
*Open Storage Area*
• Surface soil – TAL metals, SVOCs (including DNCB and 2,4-DNP), PAHs, picric acid, and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
• Subsurface soil – TAL metals, VOCs, SVOCs (including DNCB and 2,4-DNP), PAHs, picric acid, and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
• Groundwater (grab samples) – TAL metals (field-filtered), VOCs, SVOCs (including DNCB and 2,4-DNP), PAHs, and picric acid; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).

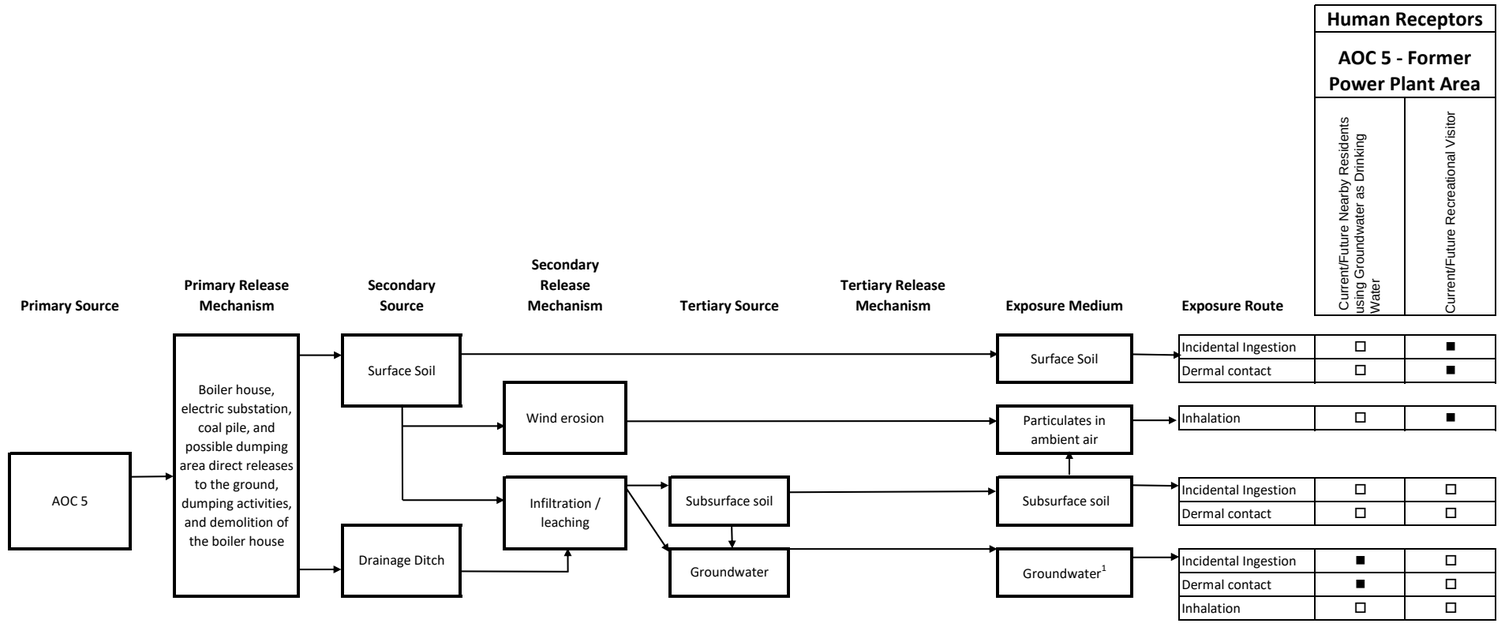
**Figure 7-14c**
**Revised Conceptual Site Model - AOC 4 - Former Bunker Area - Human Health Receptors**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**



Legend:
■ = Complete exposure pathway
☐ = Incomplete exposure pathway

Notes:
1 Groundwater on-site is not currently used as a drinking water source; therefore, groundwater exposure to on-site residents is currently considered an incomplete exposure pathway. However, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource at each of the AOCs are considered potentially complete pathways for current/future nearby residents. There are no VOCs among contaminants of concern; therefore, groundwater exposure via vapor intrusion and/or inhalation of volatiles from groundwater used as drinking water by current or future on-site residents or nearby residents are considered incomplete pathways.
2 Surface water, pore water, and sediment may be sampled as part of a phased assessment of groundwater contamination and potential migration. No complete human exposure pathways.
3 The following analyses were performed in AOC 4 during Phase 1:
- Surface soil: DNCB and 2,4-DNP, picric acid.
- Subsurface soil: DNCB and 2,4-DNP, picric acid.
- Groundwater (grab samples): DNCB and 2,4-DNP, and picric acid; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).

**Figure 7-14d**
**Revised Conceptual Site Model - AOC 5 - Former Power Plant Area - Human Health Receptors**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**



Legend:

■ = Complete exposure pathway

□ = Incomplete exposure pathway

Notes:

1 Groundwater on-site is not currently used as a drinking water source; therefore, groundwater exposure to on-site residents is currently considered an incomplete exposure pathway. However, some residences in the surrounding area may have private groundwater wells and no restrictions are in place preventing groundwater use in the area as drinking water. Therefore, ingestion and dermal exposures to groundwater used as a drinking water resource at each of the AOCs are considered potentially complete pathways for current/future nearby residents. 1,2,3-Trichlorobenzene was a groundwater COPC in AOC 5; therefore, groundwater exposure via inhalation of volatiles from groundwater used as drinking water by current or future on-site residents or nearby residents are considered incomplete pathways. 1,2,3-Trichlorobenzene was not detected above the Vapor Intrusion Screening Level; therefore, groundwater exposure via vapor intrusion is considered an incomplete pathway.

2 The following analyses were performed at AOC 5 during Phase 1:

*Boiler House*
- Surface soil: TAL metals, SVOCs, and PAHs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Subsurface soil: TAL metals, SVOCs, and PAHs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Groundwater (grab samples): TAL metals (field-filtered), SVOCs, and PAHs; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).

*Coal Storage Area*
- Surface soil: Coal Ash, TAL metals, PAHs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Subsurface soil: TAL metals, SVOCs, and PAHs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Groundwater (grab samples): TAL metals (field-filtered), SVOCs, and PAHs; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).

*Sub-Station*
- Surface soil: TAL metals, SVOCs, PAHs, and PCBs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Subsurface soil: TAL metals, SVOCs, and PAHs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Groundwater (grab samples): TAL metals (field-filtered), SVOCs, and PAHs; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).

*Possible Dump*
- Surface soil: TAL metals, SVOCs, PAHs, and PCBs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Subsurface soil: TAL metals, VOCs, SVOCs, PAHs, and PCBs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Groundwater (grab samples): TAL metals (field-filtered), VOCs, SVOCs, PAHs, and PCBs; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).

*Coal Aggregate Bins Area*
- Surface soil: Coal Ash, TAL metals, and PAHs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Subsurface soil: TAL metals, SVOCs, and PAHs; and a subset for TOC, grain size distribution (including hydrometer analysis), and CEC.
- Groundwater (grab samples): TAL metals (field-filtered), SVOCs, and PAHs; and water quality field parameters (i.e., temperature, pH, conductivity, DO, ORP, and turbidity).

**Notes:**

AOC = area of concern

CEC = cation exchange capacity

ft bgs = feet below ground surface

PAHs = polycyclic aromatic hydrocarbons

SO = soil

TOC = total organic carbon

WG = groundwater

X = Data available for method class.

AOC = area of concern

[1] Fill was observed in the shallow interval above native soil.

[2] The laboratory gradation test results for the 5 to 10 ft bgs depth interval were rejected due to melted ice water infiltrating the sample during transit between laboratories; therefore, the laboratory gradation test results were not used to inform the boring log for this depth interval. Gradation for this depth interval was estimated based on field observations.

[3] The laboratory gradation test results for the 1 to 5 ft bgs depth interval were rejected due to melted ice water infiltrating the sample during transit between laboratories; therefore, the laboratory gradation test results were not used to inform the boring log for this depth interval. Gradation for this depth interval was estimated based on field observations.

Notes:
QAPP = quality assurance project plan

List of analytes based on Phase 1 field sampling.
Shading indicates a screening value is not available for the analyte based on the hierarchy of sources presented in Subsection 5.1.1.1.

**Table 5-2**
**Groundwater Analytes without Human Health Screening Levels Identified in the UFP-QAPP with Selected Surrogates**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Analyte | Selected Surrogate | |
|---|---|---|
| | **Chemical** | **Rationale** |
| **Semi-Volatile Organic Compounds (SVOCs)** | | |
| 2,4-Dinitrochlorobenzene | 2,4-Dinitrotoluene | Analogous to approach used to derive ecological value in UFP-QAPP Appendix A. |
| 2-Nitrophenol | 2-Chlorophenol | Structural similarity; both compounds are monosubstituted phenols. |
| 4-Nitrophenol | 2-Chlorophenol | Structural similarity; both compounds are monosubstituted phenols. |
| Carbazole | Fluorene | Structural similarity; both compounds consist of two benzene rings bonded with a five membered ring between them. |
| **Polycyclic Aromatic Hydrocarbons (PAHs)** | | |
| Acenaphthylene | Acenaphthene | Classified as non-carcinogen; number of rings (2) and acenaphthene structure representative. |
| Benzo(g,h,i)perylene | Pyrene | Classified as non-carcinogen; number of rings in the pyrene structure (4) more representative than naphthalene. |
| Phenanthrene | Anthracene | Classified as non-carcinogen; number of rings (3) and anthracene structure representative. |
| **Polychlorinated Biphenyls (PCBs)** | | |
| PCB-1262 (Aroclor 1262) | Aroclor 1260 | Degree of chlorination, assigned to high risk/persistence tier. |
| PCB-1268 (Aroclor 1268) | Aroclor 1260 | Degree of chlorination, assigned to high risk/persistence tier. |

**Notes:**
UFP-QAPP = Uniform Federal Program - Quality Assurance Project Plan

1) List indicates screening value is not available for the analyte based on the hierarchy of sources presented in Section 5.1.1.1.
AND
Analytes are likely to be or potentially DoD-related as presented in Subsection 5.3.2.

**Table 5-3**
**Soil Analytes without Human Health Screening Levels Identified in the UFP-QAPP with Selected Surrogates**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Analyte | Selected Surrogate | |
|---|---|---|
| | **Chemical** | **Rationale** |
| **Semi-Volatile Organic Compounds (SVOCs)** | | |
| 2,4-Dinitrochlorobenzene | 2,4-Dinitrotoluene | Analogous to approach used to derive ecological value in UFP-QAPP Appendix A. |
| 2-Nitrophenol | 2-Chlorophenol | Structural similarity; both compounds are monosubstituted phenols. |
| 3-Nitroaniline | 4-Nitroaniline | Structural similarity; PPRTV identification of studies comparing "near equivalent" non-cancer toxicity. |
| 4-Nitrophenol | 2-Chlorophenol | Structural similarity; both compounds are monosubstituted phenols. |
| Carbazole | Fluorene | Structural similarity; both compounds consist of two benzene rings bonded with a five membered ring between them. |
| **Polycyclic Aromatic Hydrocarbons (PAHs)** | | |
| Acenaphthylene | Acenaphthene | Classified as non-carcinogen; number of rings (2) and acenaphthene structure representative. |
| Benzo(g,h,i)perylene | Pyrene | Classified as non-carcinogen; number of rings in the pyrene structure (4) more representative than naphthalene. |
| Phenanthrene | Anthracene | Classified as non-carcinogen; number of rings (3) and anthracene structure representative. |
| **Polychlorinated Biphenyls (PCBs)** | | |
| PCB-1262 (Aroclor 1262) | Aroclor 1260 | Degree of chlorination, assigned to high risk/persistence tier. |
| PCB-1268 (Aroclor 1268) | Aroclor 1260 | Degree of chlorination, assigned to high risk/persistence tier. |

**Notes:**
PPRTV = Provisional Peer-Reviewed Toxicity Values
UFP-QAPP = Uniform Federal Program - Quality Assurance Project Plan

1) List indicates screening value is not available for the analyte based on the hierarchy of sources presented in Section 5.1.1.1.
AND
Analytes are likely to be or potentially DoD-related as presented in Subsection 5.3.2.

**Table 5-4**
**Soil Analytes without Phytotoxicity Screening Levels Identified in the UFP-QAPP with Selected Surrogates**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Analyte | Selected Surrogate | |
|---|---|---|
| | Chemical | Rationale |
| **Volatile Organic Compounds (VOCs)** | | |
| 1,2,3-Trichlorobenzene | N/A | VOC phytotoxicity data limited. No appropriate surrogate. |
| 2-Butanone (MEK) | N/A | VOC phytotoxicity data limited. No appropriate surrogate. |
| Acetone | N/A | VOC phytotoxicity data limited. No appropriate surrogate. |
| Benzene | Toluene | Structural similarity; methyl functional group on benzene ring. |
| **Semi-Volatile Organic Compounds (SVOCs)** | | |
| 2-Nitroaniline | N/A | Phytotoxicity values for structurally similar compound not available. |
| 2-Nitrophenol | N/A | Phytotoxicity values for structurally similar compound not available. |
| 3-Nitroaniline | N/A | Phytotoxicity values for structurally similar compound not available. |
| 4-Nitroaniline | N/A | Phytotoxicity values for structurally similar compound not available. |
| 4-Nitrophenol | N/A | Phytotoxicity values for structurally similar compound not available. |
| Benzaldehyde | N/A | Phytotoxicity values for structurally similar compound not available. |
| Carbazole | N/A | Phytotoxicity values for structurally similar compound not available. |
| **Polycyclic Aromatic Hydrocarbons (PAHs)** | | |
| 1-Methylnaphthalene | Naphthalene | Structural similarity; lacking methyl functional group. |
| 2-Methylnaphthalene | Naphthalene | Structural similarity; lacking methyl functional group. |
| Acenaphthylene | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Benzo(a)pyrene | N/A | Phytotoxicity values for structurally similar PAHs not available. |
| Benzo(g,h,i)perylene | N/A | Phytotoxicity values for structurally similar PAHs not available. |
| Benzo(k)fluoranthene | Benzo(b)fluoranthene | Number of rings (4 six-sided and 1 five-sided) and benzo(b)fluoranthene structure representative. |
| Chrysene | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Dibenz(a,h)anthracene | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Fluoranthene | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Fluorene | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Indeno(1,2,3-c,d)pyrene | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Phenanthrene | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Pyrene | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| High Molecular Weight PAHs | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |

**Table 5-4**
**Soil Analytes without Phytotoxicity Screening Levels Identified in the UFP-QAPP with Selected Surrogates**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Analyte | Selected Surrogate | |
|---|---|---|
| | Chemical | Rationale |
| Low Molecular Weight PAHs | N/A | Phytotoxicity toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |

**Notes:**
UFP-QAPP = Uniform Federal Program - Quality Assurance Project Plan

1) List indicates screening value is not available for the analyte based on the hierarchy of sources presented in Section 5.1.1.1.
AND
Analytes are likely to be or potentially DoD-related as presented in Subsection 5.3.2.

**Table 5-5**
**Soil Analytes without Soil Invertebrate Screening Levels Identified in the UFP-QAPP with Selected Surrogates**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Analyte | Selected Surrogate | |
|---|---|---|
| | **Chemical** | **Rationale/Comment** |
| **Semi-Volatile Organic Compounds (SVOCs)** | | |
| 2-Nitrophenol | 2-Chlorophenol | Structural similarity: chlorinated functional group on benzene ring instead of nitro functional group |
| 3-Nitroaniline | 2-Nitroaniline | Structural similarity; however, will not have the same reactivity because of ortho- versus meta-substitution |
| 4-Nitroaniline | 2-Nitroaniline | Structural similarity. As noted in Table 5-3; PPRTV identification of studies comparing "near equivalent" non-cancer toxicity between 3-nitroaniline and 4-nitroaniline, implying similar reactivity. Therefore ortho- verus para-substitution would not have the same reactivity. |
| Benzaldehyde | Benzyl alcohol | Structural similarity; alcohol functional group on benzene ring instead of aldehyde functional group. Benzaldehyde will most likely degrade faster because of decarboxylation |
| **Metals** | | |
| Cobalt | N/A | Not appropriate to use another metal for a surrogate toxicity value. |
| Silver | N/A | Not appropriate to use another metal for a surrogate toxicity value. |
| Thallium | N/A | Not appropriate to use another metal for a surrogate toxicity value. |
| Vanadium | N/A | Not appropriate to use another metal for a surrogate toxicity value. |

**Notes:**
UFP-QAPP = Uniform Federal Program - Quality Assurance Project Plan

1) List indicates screening value is not available for the analyte based on the hierarchy of sources presented in Section 5.1.1.1.
AND
Analytes are likely to be or potentially DoD-related as presented in Subsection 5.3.2.

**Table 5-6**
**Soil Analytes without Avian Screening Levels Identified in the UFP-QAPP with Selected Surrogates**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Analyte | Selected Surrogate | |
|---|---|---|
| | Chemical | Rationale |
| **Volatile Organic Compounds (VOCs)** | | |
| 1,2,3-Trichlorobenzene | N/A | VOC avian toxicity data limited and generally not considered for food chain exposures. In addition, chlorinated phenols would be much more reactive so not ideal for use as surrogates. |
| 2-Butanone (MEK) | 2-Hexanone | Structural similarity; additional carbon in chain. |
| Benzene | N/A | VOC avian toxicity data limited and because EPA (2000) does not consider them persistent or bioaccumulative, VOCs generally are not considered for food chain exposures. |
| Toluene | total Xylene | Structural similarity; additional methyl functional group on ring. Toluene expected to be more reactive as the methyl group will hydrolyze and then be decarboxylated by soil microbes. |
| **Semi-Volatile Organic Compounds (SVOCs)** | | |
| 2,4-Dinitrochlorobenzene | 2,6-Dinitrotoluene | 2,4-Dinitrotoluene selected as ecological surrogate in UFP-QAPP Appendix A. The 2,4- and 2,6- ortho-/para- substitution patterns chemically show similar reactivitiy for the nitros, but the methyl substituent is not equivalent. However, avian toxicity data only exist for the 2,6-isomer. |
| 2,4-Dinitrophenol | 2,6-Dinitrotoluene | Dinitro-substituted aromatic; methyl functional group instead of hydroxyl. |
| 2-Nitroaniline | N/A | No avian toxicity data available for mono-substituted anilines. |
| 2-Nitrophenol | N/A | No avian toxicity data available for mono-substituted phenols. |
| 3-Nitroaniline | N/A | No avian toxicity data available for mono-substituted anilines. |
| 4-Chloroaniline | N/A | No avian toxicity data available for mono-substituted anilines. |
| 4-Nitroaniline | N/A | No avian toxicity data available for mono-substituted anilines. |
| 4-Nitrophenol | N/A | No avian toxicity data available for mono-substituted phenols. |
| Benzaldehyde | N/A | Avian toxicity values for structurally similar aldehyde not available. |
| Carbazole | N/A | Avian toxicity values for structurally similar aromatic compound not available. |
| Phenol | N/A | Avian toxicity values for structurally similar compound not available. |
| **Polycyclic Aromatic Hydrocarbons (PAHs)** | | |
| 1-Methylnaphthalene | Naphthalene | Structural similarity; lacking methyl functional group. |
| 2-Methylnaphthalene | Naphthalene | Structural similarity; lacking methyl functional group. |
| Acenaphthene | N/A | Avian toxicity values for structurally similar PAHs not available. |
| Acenaphthylene | N/A | Avian toxicity values for structurally similar PAHs not available. |
| Anthracene | N/A | Avian toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Benzo(a)pyrene | N/A | Avian toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Benzo(b)fluoranthene | N/A | Avian toxicity values for structurally similar PAHs not available. |

**Table 5-6**
**Soil Analytes without Avian Screening Levels Identified in the UFP-QAPP with Selected Surrogates**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Analyte | Selected Surrogate | |
|---|---|---|
| | Chemical | Rationale |
| Benzo(g,h,i)perylene | N/A | Avian toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Benzo(k)fluoranthene | N/A | Avian toxicity values for structurally similar PAHs not available. |
| Chrysene | N/A | Avian toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Dibenz(a,h)anthracene | N/A | Avian toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Fluoranthene | N/A | Avian toxicity values for structurally similar PAHs not available. |
| Fluorene | N/A | Avian toxicity values for structurally similar PAHs not available. |
| Indeno(1,2,3-c,d)pyrene | N/A | Avian toxicity values for structurally similar PAHs not available. |
| Phenanthrene | N/A | Avian toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| High Molecular Weight PAHs | N/A | Avian toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| Low Molecular Weight PAHs | N/A | Avian toxicity values for structurally similar PAHs range in values too greatly to select a surrogate with confidence. |
| **Explosives** | | |
| Picric acid | 2,4,6-Trinitrotoluene | Trinitro-substituted aromatic; methyl functional group instead of hydroxyl. |
| **Metals** | | |
| Antimony | N/A | Not appropriate to use another metal for a surrogate toxicity value. |
| Beryllium | N/A | Not appropriate to use another metal for a surrogate toxicity value. |

**Notes:**

UFP-QAPP = Uniform Federal Program - Quality Assurance Project Plan

1) List indicates screening value is not available for the analyte based on the hierarchy of sources presented in Section 5.1.1.1.
AND

Analytes are likely to be or potentially DoD-related as presented in Subsection 5.3.2.

**Soil Analytes without Mammal Screening Levels Identified in the UFP-QAPP with Selected Surrogates**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Analyte | Selected Surrogate | |
|---|---|---|
| | Chemical | Rationale/Comment |
| **Volatile Organic Compounds (VOCs)** | | |
| 1,2,3-Trichlorobenzene | 1,2,4-Trichlorobenzene | Structural similarity; both compounds are trichlorinated benzenes; however, 1,2,4 is more likely to dechlorinate dute to para- resonance. |
| **Semi-Volatile Organic Compounds (SVOCs)** | | |
| Benzaldehyde | Benzyl alcohol | Structural similarity; alcohol functional group on benzene ring instead of aldehyde functional group |

**Notes:**
UFP-QAPP = Uniform Federal Program - Quality Assurance Project Plan

**Table 5-28**
**DoD-related Items, Constituents, and Environmental Degradation Products**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Known DoD-related Constituent/Item[1] | Components and/or Breakdown Product(s) | Associated AOC | | | |
|---|---|---|---|---|---|
| | | AOC 1 | AOC 3 | AOC 4 | AOC 5 |
| Ammonia | N/A | X | | | |
| Ammonium picrate | nitrogen oxides[2] | X | | X | |
| Canvas filters | likely made from cotton | | X | | |
| Coal | carbon, hydrogen, oxygen, nitrogen ash, and sulfur[3]; PAHs[4]; VOCs and heavy metals[5] | | | | X |
| Dinitrochlorobenzene | no specific information found; expected to be the same as nitrophenols plus chloride | X | | | |
| Dinitrophenol | nitrite ions, amines, amino groups, and phenol[6] | X | | | |
| Fly ash | silica, aluminum oxide, iron oxide, calcium oxide, magnesium oxide, sulfite, sodium oxide, potassium oxide, and carbon[7] | | X | | X |
| Nitric acid | water, nitrogen dioxide, and oxygen[8] | X | | | |
| NYOW Trash | unknown | | X | | X |
| Paint | pigments (various metals[9] and nitroanilines[10]), organic solvents[9] | | X | | |
| PCBs | N/A | | | | X |
| Picric acid | nitrite ions, amines, amino groups, and phenol[11] , picramic acid eventually to complete mineralization[12] | X | | | |
| Sodium hydroxide | sodium oxide and water[13] | X | | | |
| Solid waste | Unknown | | X | | |
| Stainless steel “spiders” | iron, chromium, potentially nickel, carbon, manganese, molybdenum, nitrogen, sulfur, copper, silicon[14] | X | X | | |
| Sulfuric acid | sulfite and water[15] | X | | | |
| Wood | sugars and lignan[16] | | X | | |

Table 5-29
AOC-specific Analyte Screening for Relationship to DoD Activities
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

| AOC | Analyte | Detected | Specific Evidence for Analyte at AOC?[1] | FOD Fraction[2] | % FOD[2] | DoD-relatedness Category | Rationale |
|---|---|---|---|---|---|---|---|
| AOC 1 | 2,4-Dinitrochlorobenzene | No | Yes | 0/61 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 1 | 2,4-Dinitrophenol | No | Yes | 0/60 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 1 | Picric acid | Yes | Yes | 1/62 | 1.6 | DoD-related | Evidence of historical presence at AOC. |
| AOC 1 | Aluminum | Yes | No | 59/61 | 97 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Antimony | Yes | No | 50/61 | 82 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Arsenic | Yes | No | 59/61 | 97 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Barium | Yes | No | 61/61 | 100 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Beryllium | Yes | No | 49/61 | 80 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Cadmium | Yes | No | 53/61 | 87 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Calcium | Yes | No | 61/61 | 100 | Unlikely | Nutrient |
| AOC 1 | Chromium | Yes | Yes | 56/61 | 92 | DoD-related | Evidence of historical presence at AOC. |
| AOC 1 | Cobalt | Yes | No | 61/61 | 100 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Copper | Yes | Yes | 54/61 | 89 | DoD-related | Evidence of historical presence at AOC. |
| AOC 1 | Iron | Yes | Yes | 61/61 | 100 | DoD-related | Evidence of historical presence at AOC. |
| AOC 1 | Lead | Yes | No | 56/61 | 92 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Magnesium | Yes | No | 61/61 | 100 | Unlikely | Nutrient |
| AOC 1 | Manganese | Yes | Yes | 61/61 | 100 | DoD-related | Evidence of historical presence at AOC. |
| AOC 1 | Mercury | Yes | No | 41/61 | 67 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Nickel | Yes | Yes | 56/61 | 92 | DoD-related | Evidence of historical presence at AOC. |
| AOC 1 | Potassium | Yes | No | 61/61 | 100 | Unlikely | Nutrient |
| AOC 1 | Selenium | Yes | No | 40/61 | 66 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Silver | Yes | No | 18/61 | 30 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Sodium | Yes | No | 55/61 | 90 | Unlikely | Nutrient |
| AOC 1 | Thallium | Yes | No | 47/61 | 77 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Vanadium | Yes | No | 57/61 | 93 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 1 | Zinc | Yes | No | 55/61 | 90 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | 1,1,1-Trichloroethane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,1,2,2-Tetrachloroethane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,1,2-Trichloro-1,2,2-trifluoroethane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,1,2-Trichloroethane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,1-Dichloroethane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,1-Dichloroethene | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,2,3-Trichlorobenzene | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,2,4-Trichlorobenzene | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,2-Dibromo-3-chloropropane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,2-Dibromoethane (EDB) | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,2-Dichlorobenzene | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,2-Dichloroethane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,2-Dichloropropane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,3-Dichlorobenzene | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,3-Dichloropropane | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 1,4-Dichlorobenzene | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 2-Butanone (MEK) | Yes | No | 5/25 | 20 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | 2-Hexanone | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 4-Methyl-2-pentanone (MIBK) | No | No | 0/25 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Acetone | Yes | No | 9/25 | 36 | Potentially DoD-related | Detected in at least 5% of samples. |

| AOC 3 | 2-Chloronaphthalene | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 2-Chlorophenol | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 2-Methylphenol (o-Cresol) | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |

Table 5-29
AOC-specific Analyte Screening for Relationship to DoD Activities
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

| AOC | Analyte | Detected | Specific Evidence for Analyte at AOC?[1] | FOD Fraction[2] | % FOD[2] | DoD-relatedness Category | Rationale |
|---|---|---|---|---|---|---|---|
| AOC 3 | 2-Nitroaniline | No | Yes | 0/43 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | 2-Nitrophenol | No | Yes | 0/43 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | 3,3'-Dichlorobenzidine | No | No | 0/42 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 3-Nitroaniline | No | Yes | 0/43 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | 4,6-Dinitro-2-methylphenol | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 4-Bromophenyl phenyl ether | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 4-Chloro-3-methylphenol | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 4-Chloroaniline | No | Yes | 0/43 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | 4-Chlorophenyl phenyl ether | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | 4-Nitroaniline | Yes | Yes | 1/43 | 2.3 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | 4-Nitrophenol | No | Yes | 0/43 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | Acetophenone | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Atrazine | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Benzaldehyde | Yes | No | 7/43 | 16 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Benzyl butyl phthalate | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Biphenyl (Diphenyl) | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Bis(2-chloroethoxy)methane | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Bis(2-chloroethyl) ether (2-Chloroethyl ether) | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Bis(2-ethylhexyl)phthalate | Yes | No | 2/43 | 4.7 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Caprolactam | Yes | No | 1/43 | 2.3 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Carbazole | Yes | No | 3/43 | 7.0 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Cresols, m- & p- | Yes | No | 1/43 | 2.3 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Dibenzofuran | Yes | No | 2/43 | 4.7 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Diethyl phthalate | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Dimethyl phthalate | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | di-n-Butyl phthalate | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | di-n-Octyl phthalate | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Hexachlorobenzene | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Hexachlorobutadiene | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Hexachlorocyclopentadiene | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Hexachloroethane | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Isophorone | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Nitrobenzene | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | N-Nitrosodi-n-propylamine | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | N-Nitrosodiphenylamine | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Pentachlorophenol | No | No | 0/43 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 3 | Phenol | No | Yes | 0/43 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | 1-Methylnaphthalene | Yes | No | 17/39 | 44 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | 2-Methylnaphthalene | Yes | No | 18/39 | 46 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Acenaphthene | Yes | No | 10/39 | 26 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Acenaphthylene | Yes | No | 18/39 | 46 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Anthracene | Yes | No | 22/39 | 56 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Benzo(a)anthracene | Yes | No | 24/39 | 62 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Benzo(a)pyrene | Yes | No | 24/39 | 62 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Benzo(b)fluoranthene | Yes | No | 24/39 | 62 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Benzo(g,h,i)perylene | Yes | No | 22/39 | 56 | Potentially DoD-related | Detected in at least 5% of samples. |

Table 5-29
AOC-specific Analyte Screening for Relationship to DoD Activities
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

| AOC | Analyte | Detected | Specific Evidence for Analyte at AOC?[1] | FOD Fraction[2] | % FOD[2] | DoD-relatedness Category | Rationale |
|---|---|---|---|---|---|---|---|
| AOC 3 | Benzo(k)fluoranthene | Yes | No | 22/39 | 56 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Chrysene | Yes | No | 24/39 | 62 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Dibenz(a,h)anthracene | Yes | No | 14/39 | 36 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Fluoranthene | Yes | No | 24/39 | 62 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Fluorene | Yes | No | 20/39 | 51 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Indeno(1,2,3-c,d)pyrene | Yes | No | 22/39 | 56 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Naphthalene | Yes | No | 19/39 | 49 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Phenanthrene | Yes | No | 23/39 | 59 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Pyrene | Yes | No | 24/39 | 62 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Picric acid | No | Yes | 0/39 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | PCB-1016 (Aroclor 1016) | No | No | 0/30 | 0 | Potentially DoD-related | Aroclor 1260 detected in at least 5% of the AOC samples. |
| AOC 3 | PCB-1221 (Aroclor 1221) | No | No | 0/30 | 0 | Potentially DoD-related | Aroclor 1260 detected in at least 5% of the AOC samples. |
| AOC 3 | PCB-1232 (Aroclor 1232) | No | No | 0/30 | 0 | Potentially DoD-related | Aroclor 1260 detected in at least 5% of the AOC samples. |
| AOC 3 | PCB-1242 (Aroclor 1242) | No | No | 0/30 | 0 | Potentially DoD-related | Aroclor 1260 detected in at least 5% of the AOC samples. |
| AOC 3 | PCB-1248 (Aroclor 1248) | No | No | 0/30 | 0 | Potentially DoD-related | Aroclor 1260 detected in at least 5% of the AOC samples. |
| AOC 3 | PCB-1254 (Aroclor 1254) | No | No | 0/30 | 0 | Potentially DoD-related | Aroclor 1260 detected in at least 5% of the AOC samples. |
| AOC 3 | PCB-1260 (Aroclor 1260) | Yes | No | 6/30 | 20 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | PCB-1262 (Aroclor 1262) | No | No | 0/30 | 0 | Potentially DoD-related | Aroclor 1260 detected in at least 5% of the AOC samples. |
| AOC 3 | PCB-1268 (Aroclor 1268) | No | No | 0/30 | 0 | Potentially DoD-related | Aroclor 1260 detected in at least 5% of the AOC samples. |
| AOC 3 | Aluminum | Yes | Yes | 39/39 | 100 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | Antimony | Yes | No | 29/39 | 74 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Arsenic | Yes | No | 34/39 | 87 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Barium | Yes | No | 39/39 | 100 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Beryllium | Yes | No | 32/39 | 82 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Cadmium | Yes | No | 32/39 | 82 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Calcium | Yes | Yes | 39/39 | 100 | DoD-related | Constituent of fly ash. |
| AOC 3 | Chromium | Yes | Yes | 32/39 | 82 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | Cobalt | Yes | No | 38/39 | 97 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Copper | Yes | Yes | 32/39 | 82 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | Iron | Yes | Yes | 36/39 | 92 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | Lead | Yes | Yes | 36/39 | 92 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | Magnesium | Yes | Yes | 39/39 | 100 | DoD-related | Constituent of fly ash. |
| AOC 3 | Manganese | Yes | Yes | 39/39 | 100 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | Mercury | Yes | No | 31/39 | 79 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Nickel | Yes | Yes | 36/39 | 92 | DoD-related | Evidence of historical presence at AOC. |
| AOC 3 | Potassium | Yes | Yes | 39/39 | 100 | DoD-related | Constituent of fly ash. |
| AOC 3 | Selenium | Yes | No | 31/39 | 79 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Silver | Yes | No | 4/39 | 10 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Sodium | Yes | Yes | 35/39 | 90 | DoD-related | Constituent of fly ash. |
| AOC 3 | Thallium | Yes | No | 21/39 | 54 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Vanadium | Yes | No | 38/39 | 97 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 3 | Zinc | Yes | No | 33/39 | 85 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 4 - Discrete | 2,4-Dinitrochlorobenzene | No | Yes | 0/133 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 4 - Discrete | 2,4-Dinitrophenol | No | Yes | 0/133 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 4 - Discrete | Picric acid | No | Yes | 0/132 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 4 - ISM | 2,4-Dinitrochlorobenzene | No | Yes | 0/34 | 0 | DoD-related | Evidence of historical presence at AOC. |

Table 5-29
AOC-specific Analyte Screening for Relationship to DoD Activities
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

| AOC | Analyte | Detected | Specific Evidence for Analyte at AOC?[1] | FOD Fraction[2] | % FOD[2] | DoD-relatedness Category | Rationale |
|---|---|---|---|---|---|---|---|

| AOC 4 - ISM | Picric acid | No | Yes | 0/36 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | 1,1,1-Trichloroethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,1,2,2-Tetrachloroethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,1,2-Trichloro-1,2,2-trifluoroethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,1,2-Trichloroethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,1-Dichloroethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,1-Dichloroethene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,2,3-Trichlorobenzene | Yes | No | 1/13 | 7.7 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | 1,2,4-Trichlorobenzene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,2-Dibromo-3-chloropropane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,2-Dibromoethane (EDB) | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,2-Dichlorobenzene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,2-Dichloroethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,2-Dichloropropane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,3-Dichlorobenzene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,3-Dichloropropane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 1,4-Dichlorobenzene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 2-Butanone (MEK) | Yes | No | 2/13 | 15 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | 2-Hexanone | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | 4-Methyl-2-pentanone (MIBK) | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Acetone | Yes | No | 1/13 | 7.7 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Benzene | Yes | No | 1/13 | 7.7 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Bromochloromethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Bromodichloromethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Bromoform | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Bromomethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Carbon disulfide | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Carbon Tetrachloride | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Chlorobenzene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Chloroethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Chloroform | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Chloromethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | cis-1,2-Dichloroethene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | cis-1,3-Dichloropropene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Cumene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Cyclohexane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Dibromochloromethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Dichlorodifluoromethane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Ethylbenzene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | m,p-Xylene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Methyl acetate | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Methyl tert-butyl ether (MTBE) | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Methylcyclohexane | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | Methylene chloride | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |
| AOC 5 | o-Xylene | No | No | 0/13 | 0 | Unlkely | No evidence of historical presence at AOC and less than 5% detects. |

| AOC 5 | Fluoranthene | Yes | Yes | 51/87 | 59 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | Fluorene | Yes | Yes | 20/87 | 23 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | Indeno(1,2,3-c,d)pyrene | Yes | Yes | 36/87 | 41 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | Naphthalene | Yes | Yes | 70/87 | 80 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | Phenanthrene | Yes | Yes | 48/87 | 55 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | Pyrene | Yes | Yes | 52/87 | 60 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1016 (Aroclor 1016) | No | Yes | 0/23 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1221 (Aroclor 1221) | No | Yes | 0/23 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1232 (Aroclor 1232) | No | Yes | 0/23 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1242 (Aroclor 1242) | No | Yes | 0/23 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1248 (Aroclor 1248) | No | Yes | 0/23 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1254 (Aroclor 1254) | No | Yes | 0/23 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1260 (Aroclor 1260) | Yes | Yes | 4/23 | 17 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1262 (Aroclor 1262) | No | Yes | 0/23 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | PCB-1268 (Aroclor 1268) | No | Yes | 0/23 | 0 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | Aluminum | Yes | Yes | 81/87 | 93 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | Antimony | Yes | No | 69/87 | 79 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Arsenic | Yes | No | 87/87 | 100 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Barium | Yes | No | 87/87 | 100 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Beryllium | Yes | No | 75/87 | 86 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Cadmium | Yes | No | 75/87 | 86 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Calcium | Yes | Yes | 87/87 | 100 | DoD-related | Constituent of fly ash. |
| AOC 5 | Chromium | Yes | No | 77/87 | 89 | Potentially DoD-related | Detected in at least 5% of samples. |

Table 5-29
AOC-specific Analyte Screening for Relationship to DoD Activities
Phase 1 Risk Screening and Data Gaps Analysis
Former New York Ordnance Works, Baldwinsville, NY

| AOC | Analyte | Detected | Specific Evidence for Analyte at AOC?[1] | FOD Fraction[2] | % FOD[2] | DoD-relatedness Category | Rationale |
|---|---|---|---|---|---|---|---|
| AOC 5 | Cobalt | Yes | No | 87/87 | 100 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Copper | Yes | No | 76/87 | 87 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Iron | Yes | Yes | 83/87 | 95 | DoD-related | Evidence of historical presence at AOC. |
| AOC 5 | Lead | Yes | No | 76/87 | 87 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Magnesium | Yes | Yes | 87/87 | 100 | DoD-related | Constituent of fly ash. |
| AOC 5 | Manganese | Yes | No | 87/87 | 100 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Mercury | Yes | No | 57/87 | 66 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Nickel | Yes | No | 79/87 | 91 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Potassium | Yes | Yes | 87/87 | 100 | DoD-related | Constituent of fly ash. |
| AOC 5 | Selenium | Yes | No | 51/87 | 59 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Silver | Yes | No | 1/87 | 1.1 | Potentially DoD-related | Althought there is bo evidence of historical presence at AOC there are less than 5% detects, metals are not being eliminated at this stage of the risk screenings. |
| AOC 5 | Sodium | Yes | Yes | 44/87 | 51 | DoD-related | Constituent of fly ash. |
| AOC 5 | Thallium | Yes | No | 43/87 | 49 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Vanadium | Yes | No | 77/87 | 89 | Potentially DoD-related | Detected in at least 5% of samples. |
| AOC 5 | Zinc | Yes | No | 76/87 | 87 | Potentially DoD-related | Detected in at least 5% of samples. |

AOC = Area of Concern.
DoD = Department of Defense.
FOD = Frequency of detection.

[1]See Table 5-28 for AOC-specific DOD-related items, constituents, and environmental degradation products.
[2]Based on analytical data from Phase 1 field sampling.

**Table 5-30**
**Site to Background Comparability Scoring**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Geologic Unit and Depth (ft bgs)[1] | Overall[2] | | | | | | | | | | Final | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Cation Exchange Capacity | Total Organic Carbon | Grain Size Box Plot | | | Grain Size Ternary Chart | Cluster Analysis (Al/Fe) | HMW PAHs | LMW PAHs | Pryogenic/ Petrogenic PAHs | + | 0 | − | Total |

| Pd 0-1 | + | − | − | + | − | 0 | + | N/A | N/A | + | 4 | 1 | -3 | **1.5** |
| Pd 1-5 | + | + | + | 0 | 0 | + | + | N/A | N/A | + | 6 | 2 | 0 | **7** |
| Pd 5-10 | + | + | + | + | 0 | + | + | N/A | N/A | + | 7 | 1 | 0 | **7.5** |

**Notes**

(1) Each row represents a different geologic unit/depth interval combination used to compare background and site data (e.g., Psc 0-1 only compares lacustrine silt and clay from 0-1 ft bgs).

(2) Similarity determinations were conducted based on the results of multiple statistical tests (as described in **Section 5.4**) and assessment of box plots, Q-Q plots, and overall summary statistics for site and background data.

**Scoring Definitions**

"+" = Highly similar = 1 point

0 = Moderately similar = 0.5 points

"-" = Dissimilar = -1 points

Al = Aluminum
Fe = Iron
ft bgs = feet below ground surface
HMW = High Molecular Weight
LMW = Low Molecular Weight
N/A = Not Applicable
PAH = Polycyclic Aromatic Hydrocarbons
Pd = Diamicton (Till)
Ps = Sorted Sand and Gravel
Psc = Lacustrine Silt and Clay

Notes

(1) All depth intervals (for example, 0 - 1, 1 - 5) expressed in feet below ground surface
(2) Comparisons for AOC 5 subareas are provided only for informational purposes and not used to eliminate analytes from further screening.
(3) "Yes/No" designation summarized from Appendix I. "Yes" indicates a potential site-related release and that Site concentrations were not determined to be comparable with Background concentrations.

Notes

(1) All depth intervals (for example, 0 - 1, 1 - 5) expressed in feet below ground surface
(2) Comparisons for AOC 5 subareas are provided only for informational purposes and not used to eliminate analytes from further screening.
(3) "Yes/No" designation summarized from Appendix I. "Yes" indicates a potential site-related release and that Site concentrations were not determined to be comparable with Background concentrations.

-- Not Analyzed within the AOC
CASRN = Chemical Abstracts Service Registry Number
WG = Groundwater

Surface Soil Geologic Unit Definitions

Ps = Sorted Sand and Gravel
Psc = Lacustrine Silt and Clay
Pd = Diamicton (Till)

**Table 5-37**
**Analytes Advancing to Sample by Sample Screening Level Comparisons and Exposure Summary Tables - Human Health - Groundwater Exposure**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| AOC/Analyte | No Screening Level[1] | | All Non-detects[2] | | | Background Comparison Result Potential for Site-related Release[3] | Advance to Sample by Sample Screening Level Comparison and Summary Table[4] |
|---|---|---|---|---|---|---|---|
| | Unlikely DoD-related | Likely or Potentially DoD-related | LOQ < SL | LOQ > SL | Mixed | | |
| Zinc | -- | -- | X | -- | -- | No | No |

[1]As presented in Subsection 5.1.1.1, analytes without screening levels do not advance to the screening level comparison step.
Analytes without screening levels that are "unlikely" to be DoD-related are noted in Table 5-16.
There are no groundwater analytes that are "likely to be" or "potentially" DoD-related without human health screening levels.

[2]As presented in Subsection 5.2, analytes that were never detected in a medium within an AOC/Subarea do not advance to the screening level comparison step. A summary of non-detected analytes and the relationship of the LOQ to the SLs is presented in Table 5-22.

[3]The "potential for site-related release" is based on the background comparisons presented in Subsection 5.4.2.

[4]The analyte does not advance to the sample by sample screening level comparison if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the aggregate results from the exposure interval background comparisons.

[5]The analyte is not presented on the screening summary tables if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release.

[1]As presented in Subsection 5.1.1.1, analytes without screening levels do not advance to the screening level comparison step.
Analytes without screening levels that are "unlikely" to be DoD-related are noted in Table 5-17.
There are no soil analytes that are "likely to be" or "potentially" DoD-related without human health screening levels.

[2]As presented in Subsection 5.2, analytes that were never detected in a medium within an AOC/Subarea do not advance to the screening level comparison step. A summary of non-detected analytes and the relationship of the LOQ to the SLs is presented in Table 5-23.

[3]The "potential for site-related release" is based on the background comparisons presented in Subsection 5.4.2. The result noted in this table is for all geologic units within the AOC/Subarea combined. If at least one of the geologic unit background comparisons within the interval showed the potential for site-related release, the potential for such was considered "yes".

[4]The analyte does not advance to the sample by sample screening level comparison if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the aggregate results from the exposure interval background comparisons.

[5]The analyte is not presented on the screening summary tables if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the results from the exposure interval-specific background comparisons.

[1]As presented in Subsection 5.1.1.1, analytes without screening levels do not advance to the screening level comparison step.
Analytes without screening levels that are "unlikely" to be DoD-related are noted in Table 5-18.
Analytes without screening levels that are "likely to be" or "potentially" DoD-related are noted in Table 5-13.

[2]As presented in Subsection 5.2, analytes that were never detected in a medium within an AOC/Subarea do not advance to the screening level comparison step. A summary of non-detected analytes and the relationship of the LOQ to the SLs is presented in Table 5-24.

[3]The "potential for site-related release" is based on the background comparisons presented in Subsection 5.4.2. The result noted in this table is for all geologic units within the AOC/Subarea combined. If at least one of the geologic unit background comparisons within the interval showed the potential for site-related release, the potential for such was considered "yes".

[4]The analyte does not advance to the sample by sample screening level comparison if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the aggregate results from the exposure interval background comparisons.

[5]The analyte is not presented on the screening summary tables if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the results from the exposure interval-specific background comparisons.

[1]As presented in Subsection 5.1.1.1, analytes without screening levels do not advance to the screening level comparison step.
Analytes without screening levels that are "unlikely" to be DoD-related are noted in Table 5-19.
Analytes without screening levels that are "likely to be" or "potentially" DoD-related are noted in Table 5-14.

[2]As presented in Subsection 5.2, analytes that were never detected in a medium within an AOC/Subarea do not advance to the screening level comparison step. A summary of non-detected analytes and the relationship of the LOQ to the SLs is presented in Table 5-25.

[3]The "potential for site-related release" is based on the background comparisons presented in Subsection 5.4.2. The result noted in this table is for all geologic units within the AOC/Subarea combined. If at least one of the geologic unit background comparisons within the interval showed the potential for site-related release, the potential for such was considered "yes".

[4]The analyte does not advance to the sample by sample screening level comparison if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the aggregate results from the exposure interval background comparisons.

[5]The analyte is not presented on the screening summary tables if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the results from the exposure interval-specific background comparisons.

[6]If screening levels for low molecular weight PAHs and high molecular weight PAHs, the PAH category is evaluated as the sum and not as individual PAHs.

[1]As presented in Subsection 5.1.1.1, analytes without screening levels do not advance to the screening level comparison step.
Analytes without screening levels that are "unlikely" to be DoD-related are noted in Table 5-20.
Analytes without screening levels that are "likely to be" or "potentially" DoD-related are noted in Table 5-15.

[2]As presented in Subsection 5.2, analytes that were never detected in a medium within an AOC/Subarea do not advance to the screening level comparison step. A summary of non-detected analytes and the relationship of the LOQ to the SLs is presented in Table 5-26.

[3]The "potential for site-related release" is based on the background comparisons presented in Subsection 5.4.2. The result noted in this table is for all geologic units within the AOC/Subarea combined. If at least one of the geologic unit background comparisons within the interval showed the potential for site-related release, the potential for such was considered "yes".

[4]The analyte does not advance to the sample by sample screening level comparison if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the aggregate results from the exposure interval background comparisons.

[5]The analyte is not presented on the screening summary tables if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the results from the exposure interval-specific background comparisons.

[1]As presented in Subsection 5.1.1.1, analytes without screening levels do not advance to the screening level comparison step.
Analytes without screening levels that are "unlikely" to be DoD-related are noted in Table 5-21.
There are no soil analytes that are "likely to be" or "potentially" DoD-related without mammal screening levels.

[2]As presented in Subsection 5.2, analytes that were never detected in a medium within an AOC/Subarea do not advance to the screening level comparison step. A summary of non-detected analytes and the relationship of the LOQ to the SLs is presented in Table 5-27.

[3]The "potential for site-related release" is based on the background comparisons presented in Subsection 5.4.2. The result noted in this table is for all geologic units within the AOC/Subarea combined. If at least one of the geologic unit background comparisons within the interval showed the potential for site-related release, the potential for such was considered "yes".

[4]The analyte does not advance to the sample by sample screening level comparison if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the aggregate results from the exposure interval background comparisons.

[5]The analyte is not presented on the screening summary tables if there is no screening level, if it is never detected, or if it is a PAH or metal and is not considered to be potentially resulting from a site-related release based on the results from the exposure interval-specific background comparisons.

[6]If screening levels for low molecular weight PAHs and high molecular weight PAHs, the PAH category is evaluated as the sum and not as individual PAHs.

**Table 9-1**
**Data Gaps/DQOs/Problem Statement Summary - Recommended Sampling - AOC 1**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Area of Concern | Problem Statement/Data Gaps | Media | Goals | Type of Sampling and Analytes or Analytical Methods | Study Boundaries |
|---|---|---|---|---|---|
| AOC 1<br>Ammonium Picrate Area | Planned soil sample location, NYOW-01-017 (Ammonium Picrate Magazine), could not be accessed due to ROE restrictions. This boring could not be relocated and represents a data gap in the evaluation of AOC 1 human and ecological receptors.<br><br>ROE will need to be obtained, where possible, to sample NYOW-01-017 (Ammonium Picrate Magazine) as proposed in the UFP-QAPP for the Phase 1 investigation (USACE, 2020). | Soil | Meet the Phase 1 objective of characterizing a potential source area.<br><br>Collect additional data for calculating representative exposure unit concentrations for risk assessment. | Discrete soil boring at 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals.<br><br>2,4-DNCB, 2,4-DNP, picric acid, metals, and TOC | Vicinity of NYOW-01-017 |
| | Several planned soil and groundwater sample locations could not be accessed do to old concrete building foundations in the Ammonium Picrate Area along the toe of the drumlin. These borings could not be relocated within the building footprints and represents a potential data gap in the evaluation of AOC 1 surface geology, hydrogeology, and human and ecological receptors. | Soil and Groundwater | These data will be used to fill the gap in the evaluation of AOC 1 surface geology, hydrogeology, and human and ecological receptors as well as meet the objective of determining source areas.<br><br>Collect additional data for calculating representative exposure unit concentrations for risk assessment. | Discrete soil boring at 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals.<br><br>Grab groundwater samples from permanent wells.<br><br>Soil: 2,4-DNCB, 2,4-DNP, picric acid, metals, and TOC<br><br>Groundwater: 2,4-DNCB, 2,4-DNP, picric acid, and total and dissolved metals | Around or within the footprint of the former Ammonium Picrate Buildings. |
| | Wetland areas in AOC 1 were not sampled to reduce the impact to sensitive habitats. Surface water runoff and groundwater seeps may have impacted low-lying wetland areas; therefore, absence of samples in the wetland areas constitutes a potential data gap. | Soil | Bridge the spatial data gap between picrate buildings and dryer house where historical releases could have drained to the low lying areas.<br><br>Collect samples using procedures to mitigate impacts to the wetlands.<br><br>Collect additional data for calculating representative exposure unit concentrations for risk assessment. | Discrete soil borings at 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals.<br><br>2,4-DNCB, 2,4-DNP, picric acid, metals, and TOC | The three non-developed wetland areas between the Ammonium Picrate Buildings and the Dryer Houses. |

Note: See Section 9 for discussion of potential data gaps for which additional sampling was not recommended.

**Table 9-2**
**Data Gaps/DQOs/Problem Statement Summary - Recommended Sampling - AOC 3**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Area of Concern | Problem Statement/Data Gaps | Media | Goals | Type of Sampling and Analytes or Analytical Methods | Study Boundaries |
|---|---|---|---|---|---|
| AOC 3<br>Former Landfill Area | Sediments/pore water/surface water samples in the unnamed stream north of the parking lot were not planned for collection during Phase 1. However, based on the results of the Phase 1 investigation (e.g., analytes detected above soil invertebrate screening levels and groundwater with detections of VOCs, SVOCs, and metals flowing towards the stream), samples in the unnamed stream north of the parking lot are needed to assess potential ecological risk. In addition, it is not known if the stream is gaining or losing in this area, the information regarding which is needed characterize fate and transport. These represent data gaps. | Sediment, Pore Water, and Surface Water | Develop a sampling program for sediments/pore water/surface water in the unnamed stream north of the parking lot to assess potential ecological risk. Include sediment TOC and grain size to evaluate similarities/dissimilarities among sampling locations.<br><br>Take field measurements to determine whether the stream is gaining or losing.<br><br>These data should assist in determining if the former landfill is a source area, and meet a Phase 1 objective. | Grab sediment, pore water, and surface water samples for VOCs, SVOCs, PAHs, PCBs, picric acid, total and dissolved metals, TOC (sediment only), and grain size (sediment only).<br><br>Field measurements to determine whether groundwater is recharging the stream. | Stream channel upstream of, adjacent to, and downstream of AOC 3 as far as but not into the ponded area. |
| | The geophysical survey did not indicate historical landfilling below the parking lot but did indicate historical landfill north of the parking lot, between the parking lot and the stream. Because the Phase 1 investigation assumed historical landfill below the parking lot, the area north of the parking lot was not fully characterized to address potential impacts from the newly identified landfill area. The absence of complete characterization of groundwater in this area represents a data gap.<br><br>In addition, Aroclor-1260 was present in soil at AOC 3 and the SW-846 Method 8082A used to analyze for PCBs could not attain the Tap Water RSL. This represents a data gap for the AOC 3 groundwater investigation and assessment of potable use pathways for current/future nearby residents. | Groundwater | Develop a groundwater sampling program to characterize potential impacts from the newly identified landfill area north of the parking lot to evaluate if the landfill is a continuous source of contamination and meet a Phase 1 objective. | Grab groundwater samples from permanent wells.<br><br>VOCs, SVOCs, PAHs, PCBs, picric acid, and total and dissolved metals. | The wooded area north of the stream but south of the fairway and greens across from the newly identified landfill area. |

Note: See Section 9 for discussion of potential data gaps for which additional sampling was not recommended.

**Table 9-3**
**Data Gaps/DQOs/Problem Statement Summary - Recommended Sampling - AOC 4**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Area of Concern | Problem Statement/Data Gaps | Media | Goals | Type of Sampling and Analytes or Analytical Methods | Study Boundaries |
|---|---|---|---|---|---|
| AOC 4<br>Bunker Area | For ISM data, four DUs (1, 5, 9, and 10) had at least one replicate result for at least one COPC rejected. Three valid ISM replicates are considered necessary to provide information regarding the reproducibility and heterogeneity of the data. In addition, of the valid ISM results, 97% of the 2,4-DNCB, 93% of the 2,4-DNP, and 25% of the picric acid results had low bias attributable to low surrogate recoveries and/or low matrix spike recoveries. The lack of three valid replicates and the uniformly low bias of the non-detected results represent a data gap within the bunker areas at AOC 4.<br><br>However, discrete soil data associated with the 16 gw wells (0-1, 1-5, and 5-10 bgs) and the 24 outlet/45 swale (1-5 bgs) are good data and all non-detect. Therefore, the data gap is limited to the surface soil within the bunker aprons. | Soil | Meet the Phase 1 objectives of determining presence/absence and characterizing a potential source area. | Discrete surface soil samples at the 0 to 1 ft bgs interval.<br><br>2,4-DNCB, 2,4-DNP, and picric acid | The bunker aprons just downgradient of the bunker outlets. |

Note: See Section 9 for discussion of potential data gaps for which additional sampling was not recommended.

**Table 9-4**
**Data Gaps/DQOs/Problem Statement Summary - Recommended Sampling - AOC 5**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Area of Concern | Problem Statement/Data Gaps | Media | Goals | Type of Sampling and Analytes or Analytical Methods | Study Boundaries |
|---|---|---|---|---|---|
| AOC 5 | At the time the UFP-QAPP was written (USACE, 2020), it was determined that for human health, the trespasser scenario was most appropriate based on the land use of AOC 5. However, the most recent developer Master Plan in the project files is from 2012. Projected future land use is considered a data gap. | Not Applicable | Determine whether residential development is a reasonable future land use for AOC 5. | Not Applicable | AOC 5 |
| | The background and screening level comparisons for discrete soil samples resulted in the identification of COPCs and COPECs within the surface and subsurface soil intervals in the Boiler House, Coal Aggregate Bins, and Coal Storage Area subareas (**Subsection 6.2**); therefore, additional sampling is necessary to characterize soil the extent of soil and groundwater impacts, estimate representative mean sample concentrations, and to conduct human health and ecological risk assessments. | Soil and Groundwater | Characterize soil the extent of soil and groundwater impacts, estimate representative mean sample concentrations, and to conduct human health and ecological risk assessments. | Discrete soil boring at 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals.<br><br>Grab groundwater samples from permanent wells.<br><br>Soil: PAHs and metals<br><br>Groundwater: PAHs and total and dissolved metals and PCBs (if sampling directly downgradient from the Electric Substation) | Boiler House, Coal Aggregate Bins, and Coal Storage Area |
| | Due to a laboratory equipment failure, all soil samples were analyzed outside the holding time period for TOC (i.e., 28 days) but within the holding time rejection threshold (56 days). While microbial degradation is significantly reduced by storing samples at 4°C, some loss of organic material can occur, and the loss is exacerbated by prolonged storage. The TOC concentrations in AOC 5 were used to evaluate the suitability of background soil for comparison to site soil; therefore, the uniformly low-biased TOC data obtained for the AOC 5 data may impact the risk screening and future ecological risk assessment and represents a potential data gap. | Soil | Obtain TOC data for any additional soil samples with sufficient quality to support risk assessment. | Discrete soil boring at 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals.<br><br>TOC | Wherever soil samples are collected for other parameters in AOC 5. |
| | Wetland surface soils were not sampled to reduce the impact to sensitive habitats. Surface water runoff and groundwater seeps may have impacted low-lying wetland areas; therefore, absence of samples in the wetland areas constitutes a potential data gap, predicated on land use. I.e., if the future land use is potentially residential, sampling within the wetland may be needed to provide sufficient coverage for residential-size lots. | Soil | If a reasonably foreseeable future use of AOC 5 is residential, sample within the wetland to provide sufficient coverage to evaluate risks based on residential-size lots. | Discrete surface soil samples at the 0 to 1 ft bgs interval.<br><br>PAHs and metals | Wetlands on the west side of AOC 5 |

**Table 9-4**

**Former New York Ordnance Works, Baldwinsville, NY**

| Area of Concern | Problem Statement/Data Gaps | Media | Goals | Type of Sampling and Analytes or Analytical Methods | Study Boundaries |
|---|---|---|---|---|---|
| AOC 5, Continued | Coal and coal ash are not hazardous waste under CERCLA; therefore, the PAH and metal analytes that were identified as COPCs or COPECs within the AOC 5 Coal Aggregate Bins subarea may not be subject to further evaluation if it is determined that they are associated only with solid waste material. Surface soil samples were submitted for the analysis of coal and coal ash by a combination of microscopy techniques to determine presence/absence. A study would have to be designed to obtain additional data in order to evaluate the potential DoD-relatedness of COPCs/COPEC concentrations. This represents a data gap. | Soil | Further evaluation of the 1 to 5 ft bgs intervals proximal to the already sampled locations by microscopy to differentiate coal/coal ash from native soil is recommended to make a determination of DoD-relatedness and programmatic requirements for site cleanup. If new locations sited in AOC 5, microscopy should be considered for those samples also. This will aid in meeting the Phase 1 objective of characterizing a potential source area. | Discrete soil borings at locations where surface soil was submitted for microscopy at the 1 to 5 ft bgs interval.<br><br>Discrete soil boring at 0 to 1 ft bgs and 1 to 5 ft bgs at any new locations.<br><br>PAHs, metals, and microscopy for coal and coal ash | Boiler House, Coal Aggregate Bins, and Coal Storage Area |
| | There is the potential that DoD-related contaminants leached into the soil and groundwater beneath the newly identified ditch and/or were transported downstream (south) to low-lying wetlands. The lack of data for characterization of this potential transport pathway is a data gap. | Soil and Groundwater | To characterize the newly identified drainage ditch as to whether DoD-related contaminants leached into the soil and groundwater and/or were transported downstream (south) to low-lying wetlands | Discrete soil boring at 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals.<br><br>Grab groundwater samples from permanent wells.<br><br>Soil: PAHs and metals<br><br>Groundwater: PAHs and total and dissolved metals | Area of the former drainage ditch to the west of and parallel to the railway on AOC 5. |

Note: See Section 9 for discussion of potential data gaps for which additional sampling was not recommended.

**Table 9-5**
**Data Gaps/DQOs/Problem Statement Summary - Recommended Sampling - Background**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Area of Concern | Problem Statement/Data Gaps | Media | Goals | Type of Sampling and Analytes or Analytical Methods | Study Boundaries |
|---|---|---|---|---|---|
| Background | Phase 1 groundwater metals data are dissolved concentrations obtained from filtered samples from temporary wells. Phase 2 sampling includes the installation of permanent wells and sampling including total metals. Data from the two phases will not be comparable and the lack of permanent groundwater well data is a data gap. | Groundwater | Install permanent groundwater monitoring wells to collect representative samples for total and dissolved metals and PAHs; and obtain data comparable to the recommended AOC 1, AOC 3, and AOC 5 permanent well data. | Grab groundwater samples from permanent wells.<br><br>PAHs and total and dissolved metals | Upgradient of AOC groundwater influence |
| | Due to a laboratory equipment failure, 74 soil samples were analyzed outside the holding time period for TOC. The TOC concentrations in background soils were also used to evaluate the suitability of background soil for comparison to site soil; therefore, the uniformly low-biased TOC data obtained for the background data may impact the risk screening and represents a data gap. | Soil | For any additional soil samples, obtain TOC data with sufficient quality to support risk assessment. | Discrete soil boring at 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals.<br><br>TOC | Wherever soil samples are collected for other parameters in background. |
| | The mapped but not ground-truthed Psc surface geologic unit could not be sampled south of the edge of the wetland, resulting in significant relocation distances. Wetland avoidance results in a data gap for collection of spatially representative soil samples within the background reference area. | Soil | To assess potential for DoD-related COPC exposure risk in the AOC 1 wetlands. If wetlands are sampled in AOC 5, PAHs should also be analyzed in background wetland samples. It is recommended that cribbing or a similar technique be used to mitigate potential damage to the wetlands by the drill rig. | Discrete soil boring at 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs soil intervals.<br><br>Metals and if wetlands are sampled in AOC 5, PAHs | Psc geologic unit outside of AOC-related influence |

Note: See Section 9 for discussion of potential data gaps for which additional sampling was not recommended.

**Table 9-6**
**Data Gaps/DQOs/Problem Statement Summary - Recommended Sampling and Analytical Changes**
**Phase 1 Risk Screening and Data Gaps Analysis**
**Former New York Ordnance Works, Baldwinsville, NY**

| Area of Concern | Problem Statement/Data Gaps | Media | Goals | Type of Sampling and Analytes or Analytical Methods | Study Boundaries |
|---|---|---|---|---|---|
| AOCs 3 and 5 | Aroclor-1260 was present in soil at AOCs 3 and 5 and the SW-846 Method 8082A used to analyze for PCBs in groundwater could not attain the Tap Water RSL. This represents a data gap for the AOCs 3 and 5 groundwater investigations and assessment of potable use pathways for current/future nearby residents. | Groundwater | Use an extraction method with SW-846 Method 8082A that will achieve the Tap Water RSL at the LOQ. | Grab groundwater samples from permanent wells.<br><br>PCBs with low level extraction | Permanent groundwater wells wherever sampled for PCBs |
| All AOCs and Background | The PALs for all metals analytes in groundwater that were not met by LOQs were either attained by the LOD or were analyzed by the more sensitive analytical technique (i.e., ICP-MS), with the exception of cadmium and selenium, representing a data gap for the groundwater investigations and assessment of potable use pathways for current/future nearby residents. | Groundwater | Use EPA Method 6020A to analyze of cadmium and selenium in aqueous samples to achieve the Tap Water RSL at the LOQ (and if not, at the LOD). | Grab groundwater samples from permanent wells.<br><br>Total and dissolved metals by EPA Method 6020A | Permanent groundwater wells wherever sampled for metals |
| All AOCs and Background | Soil samples that were clay could not be thoroughly homogenized at the laboratory before sub-sampling was performed; non-homogeneous samples may have impacted the apparent method precision through elevated MS/MSD RPDs or FD RPDs. | Soil | The field team should homogenize any future discrete soil samples sequentially, first in quarter-sample segments and then in combined half-sample and full sample segments to more thoroughly homogenize soil samples to increase apparent method precision. | Discrete soil sampling - all methods | Discrete soil wherever sampled |

Note: See Section 9 for discussion of potential data gaps for which additional sampling was not recommended.

## 1.0 INTRODUCTION

The Phase 1 Risk Screening approach has been developed in conjunction with the New York Ordnance Works (NYOW) site U.S. Army Corps of Engineers (USACE) project delivery team (PDT) and Environmental and Munitions Center of Expertise (EMCX). The approach is organized as follows:

- Section 2 – Phase 1 Risk Screening Objectives
- Section 3 – Background Threshold Values
- Section 4 – Site Data Set
- Section 5 – Risk Screenings
- Section 6 – References

## 2.0 PHASE 1 RISK SCREENING OBJECTIVES

The objectives of the Phase 1 Risk Screening are:

- To assess if there are any Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) constituents present and related to historical Department of Defense (DoD) activities, as well as present above risk-based screening levels and background concentrations.
- To identify potential source areas and/or areas of higher concentrations.
- To focus additional fieldwork to collect data for an RI and to meet risk assessment-related Data Quality Objectives (DQOs) if potential impacts from DoD-related constituents are indicated.

## 3.0 BACKGROUND THRESHOLD VALUES

### 3.1 INTRODUCTION

Background threshold values (BTVs) are being developed for use in the phased site assessment process. Additional sampling may need to occur prior to commencing the risk screenings if there are data gaps in the background soil data set(s) that would prohibit the development of appropriate BTVs for areas of concern (AOCs) 1, 3, and 5 at the NYOW site. Therefore, the section regarding BTVs is presented in this Technical Memorandum before the comprehensive risk screening approach (Section 5).

Prior to developing soil BTVs for use in determining whether polycyclic aromatic hydrocarbon (PAH) and metal concentrations at AOCs 1, 3, and 5 are within background concentrations, the background data set must be compiled. To date, AOC 4 soil and groundwater samples have been analyzed only for site-specific constituents of potential concern (COPCs), i.e., picric acid, dinitrochlorobenzene, and 2,4-dinitrophenol. Therefore, BTVs for AOC 4 are not required.

In order to determine that the background data set is both robust and appropriate to the site, the following objectives must be achieved:

1) Determine if data from differing soil sampling intervals (0 to 1 foot below ground surface [ft bgs], 1 to 5 ft bgs, and 5 to 10 ft bgs) within the assigned surface geologic units (diamicton [Pd], lacustrine deposits of silt and clay [Psc], and beach deposits of stratified silt, sand, and gravel [Ps]) for the background locations can be combined.
2) Determine if surface geologic units within the background locations can be combined.
3) Determine whether background location geophysical/geochemical characteristics are representative of site location characteristics.
4) Determine if there are data gaps in the background soil data set(s) that would prohibit the development of appropriate background threshold values for AOCs 1, 3, and 5 at the NYOW site.

If data gaps exist after these four evaluation steps, a sampling program would need to be developed and executed. Resulting data would be combined with existing data as appropriate and the exercise in Background Data Set Objectives 1-4 would be repeated.

The data set for calculating groundwater BTVs is less complicated in that data from all wells located outside the area of influence of the site may be combined regardless of geologic units. Therefore, Sections 3.2 and 3.3 below are not applicable to groundwater. All nine of the wells will be used to calculate groundwater BTVs as described in Section 3.4.

## 3.2 INTRA-BACKGROUND SOIL CONCENTRATION COMPARISONS

The intra-background comparison will satisfy Background Data Set Objectives 1 and 2.

### 3.2.1 Background Soil Data Set

Background data consists of discrete soil samples collected from 0 to 10 ft bgs (i.e., 0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs). Figures showing all sample locations will be provided. The surface soil interval (i.e., 0 to 1 ft bgs) is categorized as top soil. Geologic units assigned to the soil borings are presented in Table 1 below. The significance of the geology will be discussed in a future document.

**Table 1: Soil Boring Surface Geologic Units**

| NYOW-B-040** | NYOW-B-020 | NYOW-B-028 | NYOW-B-050*** | NYOW-B-044 | |
| **n=8** | **n=24** | | | **n=11** | |

**Notes:**
*Psc observed above Ps in boring profile
**Psc observed above Pd in boring profile
***Ps observed above Psc in boring profile
****Ps observed above Pd in boring profile

Two background sample borings (NYOW-B-047 and NYOW-B-048) were determined to be fill due to the presence of non-native materials, such as brick and concrete fragments, in the shallow interval above the native soil. Samples from borings in fill will be excluded from the BTV data set as they may contain concentrations not representative of native soil.

Deposition from anthropogenic sources are more likely to remain bound to organic matter at the surface, resulting in a potential accumulation of metals and PAHs in the 0 to 1 ft bgs soil interval. Although it is anticipated that the 0 to 1 ft bgs soil interval will have differing PAH and metal concentrations from the subsurface intervals, the statistical comparisons among all three intervals will be undertaken in order to compile the most robust data set for the calculation of BTVs. During the Phase 1 Risk Screening, exposure interval specific data sets will be compared with BTVs.

### 3.2.2 Data Reduction

Field duplicates and associated discrete primary samples will be reduced to obtain only one result per location/depth/analyte combination using the following approach.

- When two non-detections are reported, the non-detection with the lowest limit of detection (LOD) (to reduce data censoring), will be selected.
- When a detection and a non-detection are reported, the detection (to reduce data censoring) will be selected.
- When two detections are reported, the mean of the two values will be selected.

PAHs sums (total, high molecular weight [HMW], and low molecular weight [LMW]) will be calculated as follows:

- Low molecular weight PAHs will be considered those with ≤ 3 benzene rings and high molecular weight PAHs will be considered those with ≥ 4 benzene rings (EPA, 2007 – Eco Guidance for Developing Ecological Soil Screening Levels (Eco-SSLs), Attachment 4-1; https://www.epa.gov/sites/default/files/2015-09/documents/ecossl_attachment_4-1.pdf )

**Table 2: PAH Categories**

| LMW PAHs | HMW PAHs |
|---|---|
| 1-Methylnaphthalene | Benzo(a)anthracene |
| 2-Methylnaphthalene | Benzo(a)pyrene |
| Acenaphthene | Benzo(b)fluoranthene |

| Anthracene | Benzo(k)fluoranthene |
| Fluoranthene | Chrysene |
| Fluorene | Dibenz(a,h)anthracene |
| Naphthalene | Indeno(1,2,3-c,d)pyrene |
| Phenanthrene | Pyrene |

- Within a sample, if all of the analytes within a PAH category are detected, the total will be the sum of the results for the category.
- Within a sample, if any of the analytes within a PAH category are non-detect, the total will be the Kaplan-Meier (KM) sum for the PAH category. This approach is after Helsel (2009) Summing Nondetects: Incorporating Low-level Contaminants in Risk Assessment. *Integrated Environmental*

*Assessment and Management*. 6(3):361-366. The use of the LMW PAH and HMW PAH categories are based on ecological risk assessment; therefore, there are no relative toxicity weighting factors to consider.

### 3.2.3 Comparisons

Initial comparisons (Background Data Set Objective 1) will be based on the chemistry (i.e., PAHs and metals) from 0 to 1 ft bgs, 1 to 5 ft bgs, and the 5 to 10 ft bgs intervals within a surface geologic unit to determine if the depth intervals can be combined. The second set of comparisons (Background Data Set Objective 2) will be between surface geologic units using the data sets resulting from the Background Data Set Objective 1 exercise. Comparisons will be made by using a combination of box plots and statistical tests. Standard side-by-side box plots will be presented only for analytes that have at least five samples within the data set and that meet the following criteria:

- n = 5 – at least 3 detects;
- n = 6 to 10 – at least 4 detects;
- n = 11 to 20 – at least 5 detects; and
- n > 20 – greater than 20% detects.

If an analytes does not have at least five samples within the data set, scatter plots will be used to qualitatively compare data sets.

Multiple comparison tests for centrality will be used initially to determine whether or not data can be grouped because they are more effective in controlling false positives than multiple pairwise tests alone. False positive and false negative error rates are inversely related. Controlling false positives (i.e., rejecting the null hypothesis incorrectly) is more desirable in this context so that the most robust data sets may be compiled.

Data distributions will be determined using Q-Q plots and goodness of fit tests performed in ProUCL and interpreted in accordance with guidance provided in the ProUCL Technical Guide (EPA, 2015). Normally and non-normally distributed datasets will be treated in accordance with guidance provided in the ProUCL Technical Guide (EPA, 2015) as follows. For normally distributed data sets with equal variance, the Tukey's test will be run. For data sets without a normal distribution, the nonparametric Dunn's test will be run. When a significant difference is detected using a multiple comparison test, pairwise tests will be done to determine which data sets significantly differ.

Pairwise statistical tests will be dependent upon the distribution and the frequency of detection as follows:

- Means of datasets exhibiting normal distributions will be compared using a Student's t-test using the most recent version of EPA's ProUCL software (assuming a null hypothesis of the data set 1 mean is less than or equal to the data set 2 mean at $p \leq 0.05$). Assumptions associated with the execution of the Student's t-test include: normally distributed populations and equal population variances. If variances are unequal, the t-test for unequal variances (Welch-Satterthwaite t-test) will be done and associated p-values presented.
- Means of datasets exhibiting non-normal distributions and containing at least 50% detects will be compared using a Permutation test. The only assumption associated with the permutation test is population equivalence [i.e., data from the two groups being compared are exchangeable (Helsel et al., 2020)]. If the dataset does not contain at least 50% detects, the Mann-Whitney test will be used.

If the null hypothesis is rejected during a pairwise test, the Benjamini-Hochberg (BH) method will be used to reduce the overall false discovery rate (FDR; i.e., the expected proportion of incorrect rejections of the null hypothesis) for the pairwise tests. The BH approach is implemented as described below. For k groups there are c = k(k-1)/2 possible pairwise (combinations) comparisons.

- Set the FDR rate to the desired p-value (i.e., 0.05).
- Order the observed p-values the c pairwise hypothesis tests from high to low.
- Compare each p-value with the product (i/c)FDR, where i = c, c-1, c-2,…1.

A pairwise difference is significant if the observed p-value < (i/c)FDR. Data groupings that are statistically significantly different will not be combined.

### 3.3 SITE VERSUS BACKGROUND SURFACE GEOLOGIC UNIT COMPARISON

Exploratory graphics will be created and hypothesis testing will be performed as noted below for each of the site surface geologic units for each of the following parameters in each of the three collected soil intervals (0 to 1 ft bgs, 1 to 5 ft bgs, and 5 to 10 ft bgs) for the site discrete sample data (all AOCs combined) versus the background data set(s) resulting from the comparisons in Subsection 3.2.3.

- Grain size (table with sample name, corresponding textural classes, and sand/silt/clay data; ternary charts and box plots)
    - Sand
    - Silt
    - Clay
- Total organic carbon (TOC; box plots)
- Cation exchange capacity (CEC; box plots)
- Geochemical ratios – Al to Fe (cluster analysis; see EPA's 2019 *Summary Report. Separating Anthropogenic Metals Contamination from Background, A Critical Review of Geochemical Evaluations and Proposal of Alternative Methodology*. at https://cfpub.epa.gov/ncea/erasc/recordisplay.cfm?deid=347774 )
- HMW and LMW PAHs (hypothesis testing)
- Pyrogenic PAHs and Petrogenic PAHs (hypothesis testing)

The three site soil sample intervals will be kept separate for this exercise to align with the exposure intervals for the receptors to be evaluated in the Phase 1 Risk Screening.

The site data set reduction will follow the same procedure outlined in Subsection 3.2.2.

Data summary tables will be presented in an augmented RAGS D Table 2 format (EPA, 2001) that includes the following:

- Frequency of detection;
- Range of detects;
- Range of LODs for non-detects;
- Mean;
- Median; and
- Standard deviation.

Note that the KM method will be used to calculate the mean and standard deviation for data sets that contain non-detects.

Exploratory graphics and hypothesis tests also will be evaluated to determine if site and background data sets are similar. The exploratory graphics evaluation will be conducted using the guidelines below.

- Box plots – similarity indicated when there is substantial (approximately 50% or more) overlap in the interquartile ranges and the median concentrations are similar. Scatter plots may be used to qualitatively compare highly censored data sets.
- Ternary graphs – similarity indicated for ternary graph evaluation when background plots within the general density patterns of the site.

Comparisons made with hypothesis testing will use the same procedure as presented in Subsection 3.2.3.

The Phase 1 Screening will present the use for/significance of each of the data types compared (i.e., grain size, TOC, CEC, geochemical ratios, HMW and LMW PAHs, and pyrogenic and petrogenic PAHs). Best professional judgment will be used to determine if site and background locations are similar based on the magnitude of differences and utility of the parameters. Q-Q plots and box plots will be used to identify locations that are potentially different between site and background. Background locations that are deemed potentially different from the site will be removed from the data set and the graphics and hypothesis testing will be re-run as often as necessary to obtain a background data set representative of site soil conditions. The rationale for removing any location from the background data set will be described in detail.

As noted in Subsection 3.2.1, ProUCL guidance (EPA, 2015) indicates that background data sets should have a minimum of 10 observations (i.e., samples) and that 8 to 10 observations are needed to perform statistical inference. Ground-truthing of the geologic units resulted in the following number of locations within units for which BTVs will be developed:

- top soil – n = 45;
- Psc – n = 8;
- Ps – n = 24; and
- Pd – n = 11.

After a background data set is considered representative, if there are not at least eight samples within the data set, recommendations regarding additional sampling will be developed. If eight or more samples remain in a data set, BTVs will be calculated.

## 3.4 BACKGROUND THRESHOLD VALUE CALCULATION

Background soil data sets determined in Subsections 3.2 and 3.3 and data from the nine background wells will be used to calculate soil and groundwater BTVs, respectively. As noted in Subsection 3.1, all of the background groundwater wells were located outside the area of influence of the site and data from the nine wells may be used to calculate groundwater BTVs.

For the purposes of the Phase 1 Risk Screening, soil BTVs will be calculated for each data set determined in Subsections 3.2 and 3.3. If the project proceeds to Phase 2, background soil may need to be collected via incremental sampling methodology (ISM) techniques for comparability with anticipated additional site data.

For the BTV calculations, non-detects will be included in the ProUCL input at the LOD and potential outliers will not be removed. BTVs will be calculated in ProUCL assuming a 95 percent confidence limit

to develop 95 percent Upper Tolerance Limits (UTLs) or Upper Probability Limits (UPLs), depending upon sample size. UPLs are more effective for reducing false positives in small (< 25 samples) data sets. BTVs will be selected as follows.

- If all of the detections for an analyte are less than the limit of quantitation (LOQ), the BTV will be judgmentally set as less than the LOQ.
- If the data set contains less than 3 detects that are also above the LOQ, the BTV will be a non-parametric BTV.
- If the data set contains at least 3 detects above the LOQ and has < 50 samples, parametric KM BTVs will be selected preferentially over non-parametric BTVs.
- If the data set contains at least 3 detects above the LOQ and has ≥ 50 samples, the data distribution will be used to determine if the parametric or non-parametric KM BTVs will be selected.

95% UCLs also will be calculated and presented alongside the BTVs.

If an analyte within a background data set does not have any detections, a BTV will be calculated as the 95$^{th}$ percentile of the LODs that are less than the project action level (PAL) identified in the quality assurance project plan (QAPP) (USACE, 2020). If none of the LODs are less than the PAL, the issue will be discussed with the PDT. Any BTVs developed using a non-detected data set will be discussed in the uncertainty analysis.

## 3.5 COMPARING SITE CONCENTRATIONS TO BTVS

Comparisons between site and background will be made for AOCs 1, 3, and AOC 5 subareas separately. (To date, AOC 4 soil and groundwater samples have been analyzed only for site-specific COCs; therefore, a background comparison is not appropriate.) Site soil data sets will be compiled based on the depth intervals for the AOC-specific exposure scenarios and sample geologic unit. If the exercise outlined in Subsection 3.2 indicates that geologic units may be combined for the background data set, the site soils will be combined likewise.

Depending upon how the soil depth intervals are combined for BTV calculation and site exposure units (EUs), there could be a few variations on how comparisons to BTVs are made. If BTVs are not available for an EU depth interval, the approach will be to either:

- compare the concentrations in the EU depth interval to BTVs that span the EU depth interval (e.g., a 0 to 1 ft bgs EU might be compared with a BTV that was developed by combining data from 0 to 10 ft bgs), or
- compare the concentrations in the EU depth interval to the most conservative BTV developed for depth intervals within the EU depth interval range (e.g., a 0 to 5 ft bgs EU might be compared to the lower of the BTVs developed for 0 to 1 ft and 1 to 5 ft bgs).

As noted in Subsection 3.1, BTVs will not be developed for fill material. Based on the site history, it is assumed that on-site fill is related to DoD activities. Therefore, in order to not be considered a potential source, site fill should not contain concentrations of metals and PAHs exceeding native soil background concentrations. As such, site sample concentrations located in fill will be compared with the BTV developed for the geologic unit identified for the surrounding site locations. If the fill is surrounded by site locations from more than one geologic unit, the most conservative BTV (i.e., lowest) for the applicable units will be used in the comparison.

A conclusion of a potential site-related release will be made for soil if the maximum concentration for site data sets with ≤ 20 samples is greater than the BTV or if more than 5% of the results for site data sets > 20 samples are greater than the BTV. Only one round of groundwater data is available from temporary wells located mainly to determine groundwater flow direction. At this time there are no identifiable plumes. As such, the conclusion of a potential site-related release will be made if the maximum detected groundwater concentration for AOC 1, AOC 3, or the AOC 5 subarea exceeds the BTV.

# 4.0 SITE DATA SET

The Phase 1 field collection efforts were completed in 2021. Figures showing all sample locations will be provided. With the exception of ISM) samples collected from surface soil (0 to 1 ft bgs) in the bunker aprons of AOC 4, all samples collected were discrete. ISM data were not collected from the same sampling units as discrete samples and will be grouped and screened, as described below, independently of data collected using conventional discrete samples. If, in the future, based on the Phase 1 Risk Screening and data gaps analysis, ISM samples were to be collected from a sampling unit (SU) overlapping existing discrete samples used in the Phase 1 risk screening, only the ISM results would be evaluated in the risk assessment.

The site data groupings will include only data collected as part of the Phase 1 sampling. Each of the following four AOCs will be screened, as described below, separately:

- Ammonium Picrate Area (AOC 1);
- Former Landfill Area (AOC 3);
- Bunker Area (AOC 4); and
- Former Power Plant Area (AOC 5).

The sample by sample presentation of the data will be AOC-, medium-, and depth interval-specific (i.e., surface soil, subsurface soil – 1 to 5 ft bgs, subsurface soil – 5 to 10 ft bgs, and groundwater) for each AOC, with the exception of AOC 4. For AOC 4, the surface soil data from the discrete and ISM samples will be presented on separate tables.

The data summary tables and comparisons with BTVs will be presented by AOC for groundwater and for EUs per geologic unit for surface soil exposure at 0 to 1 ft bgs, and subsurface soil exposures at 0 to 5 ft bgs and 0 to 10 ft bgs. For AOC 4, statistics for the surface soil discrete data and for each of the twelve ISM decision units (DUs) will be calculated and presented separately, for a total of at least 13 AOC 4 surface soil data sets. As noted in Subsection 3.5, if geologic units may be combined for the background data set, the site soils will be combined likewise.

# 5.0 RISK SCREENINGS

Several steps in the human health and ecological risk screenings are essentially the same. Where specific details of the similar steps differ, the more conservative of the two was selected to streamline and provide uniformity in the Phase 1 risk screenings. The common steps are presented in Subsections 5.1 through 5.4. The remainder of the human health and ecological risk screenings will be performed in parallel, with approaches specific each presented in Subsections, 5.5 and 5.6, respectively.

## 5.1 ANALYTES WITHOUT SCREENING VALUES OR FOR WHICH THE LOQ IS GREATER THAN THE PAL

There are almost always analytes without screening values or for which the LOQ is greater than the PAL. Worksheet #15 of the *Uniform Federal Policy Quality Assurance Project Plan, Former New York Ordnance Works, Baldwinsville, New York, Final* (USACE, 2020) indicates the analytes for which it was known that PALs do not exist or for which PALs would not be achieved at the LOQ. During the QAPP development, ecological PALs were either available or derived for all of the known COPCs (i.e., picric acid, 2,4-dinitrochlorobenzene [DNCB], and 2,4-dinitrophenol [2,4-DNP]) in AOCs 1 and 4. The analyte lists for AOCs 3 and 5 were longer than for AOCs 1 and 4 based on their historical uses. The selection of surrogates for PALs for additional AOCs 3 and 5 analytes was not performed during the QAPP development phase. Research to determine DoD-related COPCs other than the ammonium picrate-related analytes (i.e., picric acid, DNCB, and 2,4-DNP) was not within the QAPP task scope. That research is within the Phase 1 Risk Screening task scope and is described in Subsection 5.2.

The approaches for evaluating analytes without screening values and for which the LOQ is greater than the PAL are discussed in Subsections 5.1.1 and 5.1.2, respectively.

### 5.1.1 Analytes Without Screening Values

Screening values are medium-specific (i.e., soil or groundwater) and are needed for each of the AOC-specific receptors for the Phase 1 Risk Screening. During QAPP development, routine analytes for which there is no PAL and which were not related to the manufacture of ammonium picrate were considered for elimination from the analysis unless there was a PAL for that analyte in another matrix. Based on these criteria, no analytes were eliminated. VOCs without PALs were retained at AOC 3 and AOC 5 because they are frequently associated with landfills and therefore will allow for a more comprehensive assessment of potential risk.

The approach for evaluating analytes without screening values is dependent upon whether it is DoD-related/potentially DoD-related or unlikely to be DoD-related as described in Subsections 5.1.1.1 and 5.1.1.2, respectively.

#### *5.1.1.1 DoD-related and Potentially DoD-related Analytes*

Analytes without a screening value that are either DoD-related or potential DoD-related will be discussed with the PDT risk assessors to determine if a surrogate screening value may be used for risk screening; and if so, what value should be used. Human health surrogate screening values will be limited to regional screening levels (RSLs) current at the time of the screening as appropriate for the medium. Ecological surrogate screening values will be limited to the hierarchy of benchmarks for use in the Phase 1 Ecological Risk Screening noted in Subsection 5.6.

Surrogates are generally selected based on similarities to the COPC in structure and functional groups. Justification for each of the surrogates will be provided for transparency and for input as needed in the uncertainty analysis. Screening values will not be derived. Derivation of screening values is beyond the current scope of the Phase 1 Risk Screening but may be considered in Phase 2.

Uncertainties regarding the use of surrogates will be discussed in the Phase 1 Risk Screening Uncertainty section.

#### *5.1.1.2 Analytes that are Unlikely to be DoD-related*

As noted in Subsection 5.2.3, with the exception of PAHs and metals, analytes that are unlikely to be DoD-related will be noted as such and not evaluated further.

### 5.1.2 Analytes for Which the LOQ is Greater than the PAL

To meet measurement quality objectives for sensitivity, the LOQs for detections and LODs for non-detections must be less than the PALs. When MQOs for sensitivity are not met, the results are typically unusable for reliably determining whether concentrations are above or below the PALs.

As noted in Subsection 5.1, the analytes for which it was known that PALs would not be achieved at the LOQ were presented in the QAPP. Prior to the finalization of the QAPP, methods were changed for known constituents of potential concern when possible to meet PALs; however, many analytes did not have alternatives to achieve lower limits. Any additional analytes that did not achieve the PAL at the LOQ based on analytical issues associated with the Phase 1 sample collection effort (conducted in 2021) will be identified in the Data Usability Assessment. If the data gaps analysis identifies COPCs for analysis during Phase 2 sampling for which the LOQ did not meet PALs during the Phase 1 analyses, analytical method, laboratory, and laboratory location options will be explored in an attempt to lower the LOQs below PALs.

The approach for evaluating an analyte that did not achieve the PAL at the LOQ is dependent upon whether it is DoD-related/potentially DoD-related or unlikely to be DoD-related as described in Subsections 5.1.2.1 and 5.1.2.2, respectively.

#### *5.1.2.1 DoD-related and Potentially DoD-related Analytes*

Analytes with PALs not achieved at the LOQ that were not detected within a medium on an AOC-basis in the Phase 1 samples collected in 2021 and are potentially site-related (see Subsection 5.2) are typically unusable for reliably determining whether concentrations are above or below the PALs and will not proceed through the remaining screening steps. These analytes will be discussed in the uncertainty analysis with respect to any historical use, analytical, or toxicological reasons as to why the analyte is believed to be site-related and subsequently presented in the data gaps analysis for potential investigation during Phase 2.

#### *5.1.2.2 Analytes that are Unlikely to be DoD-related*

As noted in Subsection 5.2.3, with the exception of PAHs and metals, analytes that are unlikely to be DoD-related will be noted as such and not evaluated further.

## 5.2 ANALYTES NOT RELATED TO DOD ACTIVITIES

Prior to the specific human health and ecological risk screenings, it will be determined if detected analytes or non-detected analytes with LOQs greater than the PAL may be present as a result of historical DoD-related activities. Non-detected analytes for which the LOQ is less than the PAL for each of the appropriate receptors will be noted as such and not evaluated further.

Site chemistry will be tabulated and evaluated on an AOC-specific basis because each of the four AOCs had different uses. AOCs 1 and 4 likely have similar and constituents and the analytical methods were limited as to what was expected based on the manufacture of picric acid. AOCs 3 and 5 are different in that AOC 3 was a landfill and AOC 5 was a power plant and had not been investigated previously; therefore, sufficient information regarding the site-specific constituents of concern was not available to cull the

analyte lists. Given the site history and AOC-specific uses, it is not likely that constituents will be eliminated from either AOC 3 or AOC 5.

With the exception of PAHs and metals, analytes unlikely to be associated with historical DoD-related activities at the former NYOW will be discussed with the PDT and potentially eliminated from the risk screenings, as well as additional sampling efforts and risk assessment. If PAHs and metals are unlikely to be site-related, they will be carried through the remaining screening steps as appropriate and discussed in the uncertainty section.

The identification of analytes as DoD-related, potentially DoD-related, and unlikely to be DoD-related is described below.

### 5.2.1 DoD-related Analytes

Research for identifying DoD-related analytes will be limited to DoD-produced site-specific documents provided by the PDT (e.g., Industrial Waste Surveys). Analytes noted as being used at the site will be considered DoD-related.

### 5.2.2 Potentially DoD-related Analytes

If an analyte is not confirmed in the reviewed literature as site-related, but is detected in at least 5% of the AOC-specific samples, the analyte will be considered potentially DoD-related.

### 5.2.3 Analytes Unlikely to be DoD-related

If an analyte is not confirmed in the reviewed literature as site-related and is detected in less than 5% of the AOC-specific samples, the analyte will be considered unlikely to be DoD-related. Analytes that are unlikely to be DoD-related will be noted as such and not evaluated further.

## 5.3 BACKGROUND COMPARISONS

For each AOC, site and background concentrations will be compared as detailed in Subsection 3.5. For AOCs 1 and 3, PAHs and metals with concentrations considered to be within background will not be evaluated further.

In the case of AOC 5 where the investigation is an initial Site Investigation (SI), any comparisons with background would be for informational purposes and not used to eliminate analytes from further investigation because insufficient site data are available to perform a robust statistical comparison. Further sampling may be proposed for AOC 5 for analytes detected above screening levels or with uncertainties surrounding the relationship between the PAL and LOQ.

Given how BTVs are defined (i.e., the null hypothesis is that the site concentrations are consistent with background concentrations), false positives (Type I error or the incorrect rejection of the null hypothesis) overestimate contamination and false negatives (Type II error or failure to reject the null hypothesis) underestimate contamination. BTVs typically control false positives only. From a statistical perspective, results greater than BTVs demonstrate likely site-related releases but results less than BTVs are inconclusive. PDT concurrence will be achieved prior to eliminating contaminants less than BTVs from further Phase 1 evaluation. Stakeholder concurrence will be sought prior to Phase 2 sampling activities. Hypothesis testing for centrality can simultaneously control Type I and Type II errors for background comparisons and may be undertaken during Phase 2.

### 5.4 NATURE, FREQUENCY OF DETECTION, MAGNITUDE, AND SPATIAL DISTRIBUTION

Evaluate the nature, frequency of detection, magnitude, and spatial distribution. If a chemical has a frequency of detection (FOD) ≤ 5% across media and depth intervals, the nature, frequency, magnitude, and spatial clustering of exceedances will be evaluated to determine if there is a decision point surrounding the data (e.g., does it elucidate a data gap or where additional sampling is needed). All analytes, regardless of FOD, will continue to the next step in the initial risk screening.

If any frequently detected constituents are associated with sampling/laboratory procedures (e.g., detected in blanks), then they will be evaluated during data validation according to the procedures detailed in the QAPP (2020). If analytical results cannot be used for the COPC screening evaluation (e.g., rejected results) because of data quality issues documented during data validation, then they will be discussed in the data usability assessment and the uncertainty section of the risk screening.

### 5.5 HUMAN HEALTH RISK SCREENING

For analytes remaining after the steps presented in Subsections 5.1 through 5.4, a risk-based human health screening will be completed. The human health screening will be conducted in accordance with CERCLA guidance. Published guidance from USACE and New York State Department of Environmental Conservation (NYSDEC) will also be considered. Sources include but are not limited to:

- United States Army Corps of Engineers (USACE) Risk Assessment Handbook, Volume I: Human Health Evaluation (EM 200-1-4) (USACE, 1999)
- EPA RAGS Volume I:
- Human Health Evaluation Manual, Part A (EPA, 1989)
- Human Health Evaluation Manual, Part E, Supplemental Guidance for Dermal Risk Assessment (EPA, 2004)
- Human Health Evaluation Manual, Part F, Supplemental Guidance for Inhalation Risk Assessment (EPA, 2009)
- EPA Child Exposure Factors Handbook (EPA, 2008)
- EPA Exposure Factors Handbook: 2011 Edition (EPA, 2011) and relevant chapter updates
- EPA Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens (EPA, 2005)
- EPA RSL Table (EPA, 2021, or latest version)
- EPA Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors (EPA, 2014)
- USACE Environmental Quality, Standard Scopes of Work for Environmental Risk Assessments (EP 200-1-15) (USACE, 2016)
- Input from NYSDEC

The media of concern for the human health screening will be limited to groundwater and soils (both surface and subsurface).

The human health screening will be completed stepwise to focus the COPC list to those chemicals that may pose a potential risk to human receptors. A brief description of the process is noted below.

- Compare the site screening concentrations to the most recent versions of the residential soil and tap water screening values identified in the QAPP. For discrete samples, the screening concentration

will be the maximum detected concentration regardless of the size of the data set. For ISM samples, 2x the maximum detected concentration would be used as a conservative screening concentration in lieu of the recommended 95% UCL from the ITRC ISM-2 calculator; however, there were no detections in the 2021 ISM samples. For an analyte with all non-detect results, the highest LOQ will be used for screening in order to inform the data gaps analysis. If a data gap is identified due to poor sensitivity, analytical alternatives that may improve sensitivity will be assessed. In general, a chemical will be selected as a COPC if the screening concentration exceeds the screening value or if a screening value is not available for a potential receptor. The essential and generally non-toxic "macro elements," calcium, magnesium, potassium, and sodium will not be considered COPCs.

- Groundwater and soil (surface and subsurface) will be compared to relevant human health screening levels on a sample-by-sample basis.
- The groundwater data does not account for leaching potential in the future (i.e., constituent mass that has not mobilized to the aquifer yet); therefore, the soil to groundwater values will be used to evaluate potential future groundwater COPCs to support the refinement of any Phase 2 sampling.
- Screening level comparison tables will be presented by medium per AOC with detected concentrations exceeding screening levels highlighted. RAGS D Table 2s (EPA, 2001) will also be provided to summarize the results.
- Modeling and calculation of exposure point concentrations, hazard quotients, hazard indices, incremental lifetime cancer risks are not included.
- Blood lead modeling is not included in the Phase 1 deliverable.

## 5.6 ECOLOGICAL RISK SCREENING

For analytes remaining after the steps presented in Subsections 5.1 through 5.4, a risk-based ecological screening will be completed. The ecological screening will be prepared in accordance with EPA's Risk Assessment Guidance under CERCLA. The primary guidance that will be used to perform the screening is EPA's *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (EPA, 1997) and the USACE's *Environmental Quality – Risk Assessment Handbook, Volume II: Environmental Evaluation* (USACE, 2010).

The media of concern for the ecological screening will be limited to soils (both surface and 1 to 5 ft bgs subsurface). Ecological receptor exposures to the 5 to 10 ft bgs depth interval is limited and, therefore, will not be evaluated in Phase 1, but may be evaluated in Phase 2, if deemed appropriate.

Ecological receptors to be evaluated in the Phase 1 Risk Screening will be AOC-specific; limited to plants, soil invertebrates invertivorous small mammals and birds, and if suitable subsurface soil habitat exists, burrowing mammals (e.g., red fox); and will be guided by the results of the receptor resource inventory. Phase 2-based ecological risk assessments may evaluate other receptors, if deemed appropriate.

The results of the Phase 1 ecological resource and receptor inventory will be presented. This inventory will include updated natural heritage database searches and a US Fish and Wildlife Services (USFWS) Information for Planning and Consultation (IPaC) review. A comprehensive table of receptors identified as possibly present (including common name, Latin name, and Federal and State listing categories) will be compiled as the result of literature surveys. All species observations made during the wetland delineation and vernal pool surveys, as well as incidental observations during other Phase 1 field investigations and discussions with the Three Rivers Wildlife Management Area staff will be identified on the comprehensive table developed during the literature surveys.

The ecological screening will be completed in a stepwise manner to focus the constituent of potential ecological concern (COPEC) list to those chemicals that may pose a potential risk to ecological receptors. A brief description of the process sequence is noted below. This Phase 1 Ecological Risk Screening process is also described in the attached ecological risk assessment flow chart (Figure 1). The Phase 1 Ecological Risk Screening can be seen in-context of the screening-level ecological risk assessment process when viewed with Figure 2.

- Compare the site screening concentration to conservative benchmarks. For discrete samples, the screening concentration will be the maximum detected concentration regardless of the size of the data set. For ISM samples, 2x the maximum detected concentration would be used as a conservative screening concentration in lieu of the recommended 95% UCL from the ITRC ISM-2 calculator; however, there were no detections in the 2021 ISM samples. For an analyte with all non-detect results, the highest LOQ will be used for screening in order to inform the data gaps analysis. If a data gap is identified due to poor sensitivity, analytical alternatives that may improve sensitivity will be assessed. Toxicity benchmark references will be limited to those used in QAPP Worksheet 15 for PAL selection. Toxicity benchmarks will not be derived during the Phase 1 Ecological Risk Screening; however, derived values for site-specific analytes presented in QAPP Appendix A.1 will be used. For analytes without site-specific derived values, the hierarchy of benchmarks for use in the Phase 1 Ecological Risk Screening is as follows:

    - EPA Eco-SSLs (Eco-SSLs; various dates) (https://www.epa.gov/chemical-research/interim-ecological-soil-screening-level-documents),
    - EPA Region 4 Ecological Risk Assessment Supplemental Guidance (2018) –Soil Screening Values for Hazardous Waste Sites (https://www.epa.gov/sites/production/files/2018-03/documents/era_regional_supplemental_guidance_report-march-2018_update.pdf),
    - EPA Region 5 (2003) RCRA Ecological Screening Levels (ESLs) (https://archive.epa.gov/region5/waste/cars/web/pdf/ecological-screening-levels-200308.pdf), and
    - Los Alamos National Laboratory (LANL) ECORISK Database Ecological Screening Levels (2017) (accessed at https://www.lanl.gov/environment/protection/eco-risk-assessment.php - no longer available on-line).

    In general, a chemical will be selected as a COPEC if the screening concentration exceeds the screening benchmark or if a screening benchmark is not available for a potential receptor. The essential nutrients and generally non-toxic "macro elements," calcium, chloride, magnesium, potassium, and sodium, as well as the "micro" or "trace" element, iron (Henry and Miles 2001), are required for proper organism growth and function. If these elements are not detected at the site at levels elevated above typical ambient conditions, they are not expected to pose any substantial ecological risk to receptors and, therefore, will not be considered COPECs.

- Direct exposure to surface soil in AOC 1, AOC 4, and AOC 5 will be evaluated for plants and soil invertebrates using soil screening values. Indirect exposure to bioaccumulative constituents in surface soil will also be evaluated using soil screening values based on food chain modeling for representative invertivorous birds and/or small mammal receptors. Receptors selected will be guided by the results of the receptor resource inventory. AOC 3 is mostly a paved parking lot for a golf course. Due to the limited area and low quality ecological habitat, AOC 3 surface soils will not be considered an ecological exposure medium. As noted in the previous bullet, toxicity benchmark references will be limited to those used in QAPP Worksheet 15 for PAL selection.

Toxicity benchmarks will not be derived during the Phase 1 Ecological Risk Screening; however, derived values for site-specific analytes presented in QAPP Appendix A.1 will be used. As noted in the previous bullet, if a screening benchmark is not available for a potential receptor, the chemical will be retained as a COPEC.

- Direct exposure to subsurface soil (1 to 5 ft bgs only) in AOC 1, AOC 3, AOC 4, and AOC 5 will be evaluated for the plants and soil invertebrates using soil screening values. If suitable habitat is present within an AOC, indirect exposure to bioaccumulative constituents in subsurface soil will also be evaluated using soil screening values based on food chain modeling for representative burrowing mammalian receptors (e.g., red fox).
- Screenings will be done on a receptor basis so it can be determined which receptor categories do not need further evaluation for each constituent.
- Refined screenings, exposure point concentrations, baseline risk assessment, and food-chain modeling are not included in the Phase 1 deliverable.

### 5.7 RESULTS AND DISCUSSION

After both of the risk screenings, details regarding what media/constituents/receptors may be eliminated from further study for each AOC will be presented.

Uncertainties associated with the screenings also will be provided. Topics will include uncertainties associated with the following, if applicable:

- non-DoD-related analytes with PALs not achieved at the LOQ that were not detected;
- the referral to Phase 2 of DoD-related analytes with PALs not achieved at the LOQ that were not detected;
- non-DoD-related analytes with PALs not achieved at the LOQ that were detected at low frequency;
- PAH and metal concentrations unrelated to historical DoD activities;
- analytical results unable to be used for the risk screening evaluation (e.g., rejected results) because of data quality issues documented during data validation; and
- surrogate toxicity values and analytes for which surrogate values were not identified.

The results of the data usability assessment and screening comparisons will be used to inform the data gaps analysis. The data gaps analysis will present recommendations for Phase 2 sampling (if needed) for discussion with the PDT.

## LIST OF APPENDICES

**Appendix A** Data Validation Reports

**Appendix B** SDG List

**Appendix C** Summary Statistics

# 1.0 DATA VALIDATION

Data validation establishes that the data generated by the field sampling and laboratory analyses are complete, compliant with the required methods and standard operating procedures, within accepted Quality Assurance (QA)/Quality Control (QC) limits, usable for established data quality objectives (DQOs), and properly documented.

Data validation was performed in accordance with the U.S. Department of Defense (DoD) General Data Validation Guidelines (September 16, 2019), the DoD Data Validation Guidelines Module 1 (May 11, 2020), the U.S. Environmental Protection Agency's (EPA) National Functional Guidelines for Organic Superfund Methods Data Review (January 2017), the EPA's National Functional Guidelines for Inorganic Superfund Methods Data Review (January 2017), the Uniform Federal Policy Quality Assurance Project Plan (UFP-QAPP) (USACE, 2020), and the specifics of the methods employed. Data validation reports were generated for all laboratory analytical data upon completion of the review. Data validation reports are included in **Appendix A**.

Bluestone's data validation was performed to conform with Stage 2B guidelines as defined by EPA in "Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use, EPA 540-R-08-005" for combined automated and manual data verification and validation. Automated data review was performed using the Automated Data Review (ADR) module in FUDSChem for all quality control summary results as provided by the Laboratory in the Staged Electronic Data Deliverable (SEDD) files submitted with the data packages. No calibration information is included in this file format; therefore, all calibrations (initial and continuing) were evaluated manually. Sample results for grain size and cation exchange capacity (CEC) underwent Stage 1 manual validation.

# 2.0 DATA USABILITY ASSESSMENT

The purpose of the data usability assessment report is to determine if the DQOs outlined in the Uniform Federal Policy-Quality Assurance Project Plan (USACE, 2020) were met. The laboratory sample delivery groups (SDGs) that are included in the data usability assessment for each investigation are listed in **Appendix B**. In accordance with Worksheet #37 (Data Usability Assessment) of the UFP-QAPP, this assessment will include the following elements:

- Data Collection Objective and Sampling Design – determine whether the collected data are of the right type and quantity to support decision-making for the project.
- Data Quality Indicator (DQI) Evaluation – evaluate data quality indicators (precision, accuracy/bias, representativeness, comparability, completeness, and sensitivity).
- Statistical Method Evaluation – verify whether the underlying assumptions for the selected statistical method are valid; consider the consequences for selecting the incorrect alternative and/or the tolerance for uncertainty in measurements.
- Conclusions – describe how data quality issues will be addressed and how limitations of the use of the data will be handled.

## 2.1 DATA COLLECTION ASSESSMENT

The overall project objective was to determine if Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) constituents related to DoD operations at the Site may have been released to

the environment (USACE, 2020). If the Phase 1 sampling results indicate that further investigation is necessary, then additional sampling will be conducted during Phase 2. The following subsections detail Phase I investigation objectives for the Areas of Concern (AOCs) at the Site.

### 2.1.1 AOC 5

The Phase 1 investigation objectives for AOC 5 (Former Power Plant) are summarized below:

| Activity/Objective | Data Needs |
|---|---|
| Activity: Collect surface soil samples (0-1 feet below ground surface [ft bgs]) in the Coal Storage Area and around the Coal Aggregate Bins. Characterize soil lithology within soil borings.<br><br>Objective: To determine if coal ash is present and characterize soil constituent concentrations. To determine soil types within the AOC. | Data Planned: 25 surface soil samples planned.<br><br>Data Collected: 25 surface soil samples collected. Soil boring logs completed.<br><br>Soil samples analyzed for:<br>• Semi-volatile organic compounds (SVOCs) by SW-846 Method 8270D<br>• Polycyclic aromatic hydrocarbons (PAHs) by SW-846 Method 8270D with Selected Ion Monitoring (SIM)<br>• Polychlorinated biphenyls (PCBs) by SW-846 Method 8082A<br>• Metals by Inductively Coupled Plasma (ICP) SW-846 Method 6010C and by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) Method 6020A<br>• Mercury (Hg) by SW-846 Method 7471B,<br>• Percent moisture (%M) by American Society for Testing and Materials (ASTM) Method D2216,<br>• Total organic carbon (TOC) by Method 9060A,<br>• Cation exchange capacity (CEC) by SW-846 Method 9081<br>• Grain Size Distribution by ASTM Method D422 |
| Activity: Advance direct push technology (DPT) soil borings to collect 50 subsurface soil samples. Characterize soil lithology within soil borings.<br><br>Objective: To determine if coal ash is present and characterize soil constituent concentrations. To determine soil types within the AOC. | Data Planned: 50 subsurface soil samples, including ten samples analyzed for volatile organic compounds (VOCs).<br><br>Data Collected: 50 subsurface soil samples collected. Soil boring logs completed.<br><br>Soil samples analyzed for:<br>• VOCs by SW-846 Method 8260C<br>• SVOCs by SW-846 Method 8270D<br>• PAHs by SW-846 Method 8270D with SIM<br>• PCBs by SW-846 Method 8082A |

| Activity/Objective | Data Needs |
|---|---|
| | • Metals by ICP SW-846 Method 6010C and by ICP-MS Method 6020A<br>• Hg by SW-846 Method 7471B,<br>• %M by ASTM Method D2216,<br>• TOC by Method 9060A,<br>• CEC by SW-846 Method 9081<br>• Grain Size Distribution by ASTM Method D422 |
| Activity: Collect grab groundwater samples from temporary monitoring wells. Collect water quality parameters (WQP) to demonstrate groundwater stabilization.<br><br>Objective: To assess whether DoD-related chemicals associated with the former power plant operations (i.e., Boiler House, Coal Storage Area, Electrical Substation, Possible Dump Area, and Coal Aggregate Bins) are present above human health risk-based screening levels in groundwater. To collect representative groundwater samples. | Data Planned: 12 grab groundwater samples collected from within the Electrical Substation, Boiler House, Coal Storage Area and Possible Dump Area. Water quality field parameters (pH, oxidation reduction potential [ORP], turbidity, temperature, dissolved oxygen [DO], and specific conductivity) to be collected at each location.<br><br>Data Collected: 12 groundwater samples collected. WQP were collected until stabilization.<br><br>Groundwater samples analyzed for:<br>• VOCs by SW-846 Method 8260C<br>• SVOCs by SW-846 Method 8270D<br>• PAHs by SW-846 Method 8270D with SIM<br>• PCBs by SW-846 Method 8082A<br>• Dissolved metals by ICP SW-846 Method 6010C and ICP-MS Method 6020A<br>• Dissolved Hg by SW-846 Method 7470A |

Deviations from the UFP-QAPP

The sampling procedures for the Phase 1 investigation are presented in Worksheet #17 (Sampling Design and Rationale) of the UFP-QAPP and the required frequency of sample collection is presented in Worksheet #18 (Sampling Locations and Methods). Field QC samples (field duplicate [FD]) and matrix spike [MS]/matrix spike duplicate [MSD]) were collected by Bluestone during the Phase I investigation at AOC 5 at the frequency shown in **Table 1**. As presented in Worksheet #20 (Field QC Summary) in the UFP-QAPP, the minimum FD sampling frequency (10%) and MS/MSD frequencies (5%) for aqueous and solid samples were met at AOC 5.

Table 1 – Field QC Sample Frequency – AOC 5

| Matrix/Analysis | FD | | MS | | MSD | |
|---|---|---|---|---|---|---|
| **Aqueous** | **Count** | **%** | **Count** | **%** | **Count** | **%** |

| SW8082A/SW3546 | 2 | 10% | 3 | 15% | 3 | 15% |
| SW8270D/ SW3546 | 7 | 11% | 6 | 9.2% | 6 | 9.2% |
| SW9060A | -- | -- | 2 | 13% | 2 | 13% |
| SW6010C/3050B | 8 | 11% | 8 | 11% | 8 | 11% |
| SW6020A/3050B | 8 | 11% | 8 | 11% | 8 | 11% |
| SW8260C/SW5035 | 1 | 10% | 1 | 10% | 1 | 10% |

Two soil sample locations were modified from the proposed locations as described in the Phase 1 Field Report (USACE, 2021a). The soil samples (NYOW-05-006 and NYOW-05-010) were relocated to avoid mapped wetland areas. Sample NYOW-05-006 was relocated 20 feet south; however, the revised sample location remained in the north-central portion of the Coal Storage Area. Sample NYOW-05-010 was relocated 35 feet north-east. The revised sample location remained in the south-central portion of the Coal Storage Area and the intended spatial coverage and sample size were achieved.

The proposed monitoring well location NYOW-05-017 (soil and groundwater location) hit shallow refusal at 5 ft bgs; therefore, the location was offset 5 feet to the north, designated NYOW-05-017-1, and advanced to 29 ft bgs. As this new location falls within the footprint of the former Boiler House, the DQO was achieved.

The proposed monitoring well location NYOW-05-015 hit refusal at 25.5 ft bgs (above the saturated zone). Soil samples were collected from this boring, but no monitoring well was installed. Instead, a monitoring well was installed at the NYOW-05-016 location in the saturated zone at a depth of 28 ft bgs. Both soil and groundwater samples were collected from location NYOW-05-016. NYOW-05-015 was intended to evaluate groundwater conditions, in conjunction with NYOW-05-012, at the former substation. Relocation of the temporary monitoring well to NYOW-05-016, adjacent to the former Boiler House, maintained the DQO of evaluating groundwater at AOC 5. Groundwater samples were obtained from both the former substation at NYOW-05-012 and from the former boiler house at NYOW-05-016.

NYOW-05-018 was installed to 6 ft bgs after three attempts (shallow refusal was due to concrete). A soil sample was collected from the 5–6-foot interval instead of the 5–10-foot interval. Soil was collected from the 5–10-foot interval in the four other soil borings associated with the former boiler house. The AOC-5 preliminary conceptual site model (CSM) (USACE, 2020) indicates that recreational visitors potentially exposed to surface soil are the only human receptor population identified. Therefore, subsurface soil

exposure is not anticipated. The subsurface soil sample collected at NYOW-05-018 is sufficient to assess vertical delineation of soil impacts and the soil-to-groundwater pathway; therefore, adequate information was obtained to achieve the DQO at the Boiler House.

### 2.1.2 AOC 4

The Phase 1 investigation objectives for AOC 4 (Former Bunker Area) are summarized below:

| Activity/Objective | Data Needs |
|---|---|
| Activity: Advance 16 DPT soil borings along three transects and collect a discrete surface soil (0-1 ft bgs) sample from each DPT. Characterize soil lithology within soil borings.<br><br>Objective: To determine soil constituent concentrations. To determine soil types within the AOC. | Data Planned: 16 surface soil samples planned.<br><br>Data Collected: 16 surface soil samples collected. Soil boring logs completed.<br><br>Soil samples analyzed for:<br>• SVOCs dinitrochlorobenzene (DNCB) and 2,4- dinitrophenol (DNP) by SW-846 Method 8270D<br>• Picric acid by SW-846 Method 8330A<br>• %M by ASTM Method D2216. |
| Activity: Collect subsurface soil (1-5 ft bgs and 5-10 ft bgs) samples from each DPT. Collect subsurface (1-5 ft bgs) soil samples from discharge points of the bunker trench drains and from locations spaced along the length of the drainage swales.<br><br>Objective: To determine soil constituent concentrations. To determine soil types within the AOC. | Data Planned: 101 subsurface soil samples planned.<br><br>Data Collected: 101 subsurface soil samples collected. Soil boring logs completed.<br><br>Soil samples analyzed for:<br>• SVOCs DNCB and 2,4-DNP by SW-846 Method 8270D<br>• Picric acid by SW-846 Method 8330A<br>• %M by ASTM Method D2216. |
| Activity: Collect groundwater grab samples from the DPT soil borings. Collect WQP to demonstrate groundwater stabilization.<br><br>Objective: To assess the quality of groundwater in the vicinity of the bunkers. To collect representative groundwater samples. | Data Planned: Up to 16 grab groundwater samples were planned. Water quality field parameters (pH, ORP, turbidity, temperature, DO, and specific conductivity) to be collected at each location.<br><br>Data Collected: 16 groundwater samples collected. WQP were collected until stabilization.<br><br>Groundwater samples analyzed for:<br>• SVOCs DNCB and 2,4-DNP by SW-846 Method 8270D<br>• Picric acid by SW-846 Method 8330B |

Deviations from the UFP-QAPP

The sampling procedures for the remedial investigation (RI) are presented in Worksheet #17 (Sampling Design and Rationale) of the UFP-QAPP and the required frequency of sample collection is presented in Worksheet #18 (Sampling Locations and Methods). Field QC samples (FD and MS/MSD) were collected by Bluestone during the Phase I investigation at AOC 4 at the frequency shown in **Table 2**. As presented in Worksheet #20 (Field QC Summary) in the UFP-QAPP, the minimum FD sampling frequency (10%) and MS/MSD frequencies (5%) for aqueous and solid samples were achieved at AOC 4.

Table 2 – Field QC Sample Frequency – AOC 4, Discrete

| **Matrix/Analysis** | **FD** | | **MS** | | **MSD** | |
|---|---|---|---|---|---|---|
| **Aqueous** | **Count** | **%** | **Count** | **%** | **Count** | **%** |
| SW8330B/SW3535 | 2 | 13% | 1 | 6.3% | 1 | 6.3% |
| SW8270D/SW3520C | 2 | 13% | 1 | 6.3% | 1 | 6.3% |
| **Solid** | **Count** | **%** | **Count** | **%** | **Count** | **%** |
| SW8330A/METHOD | 13 | 11% | 10 | 8.5% | 10 | 8.5% |
| D2216 | 13 | 11% | -- | -- | -- | -- |
| SW8270D/SW3546 | 13 | 11% | 9 | 7.7% | 9 | 7.7% |

A total of ten AOC 4 boring locations were modified from the proposed locations as described in the Phase 1 Field Report (USACE, 2021a).

Five boring locations (NYOW-04-080, NYOW-04-081, NYOW-04-082, NYOW-04-084 and NYOW-04-085) were relocated to avoid mapped swallow-wort areas. NYOW-04-080 was relocated 20 feet west, NYOW-04-081 was relocated 40 feet northwest, NYOW-04-082 was relocated 20 feet west, NYOW-04-084 was relocated 15 feet west and NYOW-04-085 was relocated 35 feet west. The revised locations were sufficiently close to the original locations along the Eastern Transect to achieve the DQOs.

Two boring locations (NYOW-04-003 and NYOW-04-005) were relocated to avoid mapped wetland areas. NYOW-04-003 was relocated 75 feet north and NYOW-04-005 was relocated 20 feet northeast. The revised locations were sufficiently close to the original locations along the Western Transect to achieve the DQOs.

One boring location (NYOW-04-083) was relocated approximately 30 feet northwest along East Igloo Road to avoid a gravel pile that was present in the original location. The revised location was sufficiently close to the original location along the Eastern Transect to achieve the DQO.

One boring location (NYOW-04-036) was relocated approximately 70 feet northwest to add a buffer between the boring location and a nearby red-tailed hawk nest. The revised location was sufficiently close to the original location along the Middle Transect to achieve the DQO.

One monitoring well location (NYOW-04-006) was shifted 30 feet southwest to a location closer to the road, to avoid a roadside drainage swale that the drill rig was unable to traverse. The rig was also unable to access the original location from the north along the service road between West Igloo and East Igloo Roads due to soft ground beneath the snowpack. This DPT location was originally sited at the southern end of the Western Transect to determine if groundwater discharges to the surface water body to the southwest. The new location was sufficiently close to the original to achieve the DQO.

Insufficient recharge was encountered at three monitoring well locations (NYOW-04-037, NYOW-04-082, and NYOW-04-038). As a result, only the minimum required volume of water was collected for SW-846

Method 8270D (one liter) and SW-846 Method 8330B (one-half liter). The reduced volume did not cause an elevation in reporting limits for Method 8270D, and the reporting limits for Method 8330B remained below the project action limit (PAL); thus, the DQO was achieved.

### 2.1.3 AOC 1

The Phase 1 investigation objectives for AOC 1 (Former Ammonium Picrate Area) are summarized below:

| **Activity/Objective** | **Data Needs** |
|---|---|
| Activity: Collect discrete surface soil (0-1 ft bgs) samples. Characterize soil lithology within soil borings.<br><br>Objective: To assess whether DoD-related chemicals associated with the production area are present above risk-based human health and ecological screening and background levels. To determine soil types within the AOC. | Data Planned: 22 surface soil samples were planned.<br><br>Data Collected: 30 surface soil samples collected. Soil boring logs completed.<br><br>Surface soil samples analyzed for:<br>• Metals by ICP SW-846 Method 6010C and ICP-MS Method 6020A<br>• Hg by SW-846 Method 7471B<br>• SVOCs DNCB and 2,4-DNP by SW-846 Method 8270D<br>• Picric acid by SW-846 Method 8330A<br>• %M by ASTM Method D2216.<br>A subset of samples was analyzed for:<br>• TOC by Method 9060A<br>• CEC by SW-846 Method 9081<br>• Grain Size Distribution by ASTM Method D422 |
| Activity: Advance DPT soil borings and collect subsurface soil (1-5 ft bgs and 5-10 ft bgs) samples. Characterize soil lithology within soil borings.<br><br>Objective: To assess whether DoD-related chemicals associated with the production area are present above risk-based human health and ecological screening and background levels. To determine soil types within the AOC. | Data Planned: 44 subsurface soil samples were planned.<br><br>Data Collected: 22 subsurface soil samples collected. Soil boring logs completed.<br><br>Subsurface soil samples analyzed for:<br>• Metals by ICP SW-846 Method 6010C and ICP-MS Method 6020A<br>• Hg by SW-846 Method 7471B<br>• SVOCs DNCB and 2,4-DNP by SW-846 Method 8270D<br>• Picric acid by SW-846 Method 8330A<br>• %M by ASTM Method D2216.<br>A subset of samples was analyzed for:<br>• TOC by Method 9060A<br>• CEC by SW-846 Method 9081<br>• Grain Size Distribution by ASTM Method D422 |

| Activity/Objective | Data Needs |
|---|---|
| Activity: Collect grab groundwater samples from temporary monitoring wells Collect WQP to demonstrate groundwater stabilization.<br><br>Objective: To assess whether DoD-related chemicals associated with the production area are present above risk-based human health screening and background levels in groundwater. To collect representative groundwater samples. | Data Planned: ten grab groundwater samples were planned. Note: The QC frequencies for AOC 1 and AOC 3 are of the combined data sets as imported to the FUDSChem database

A total of fourteen AOC 1 boring locations were modified from the proposed locations as described in the Phase 1 Field Report (USACE, 2021a). One boring location (NYOW-01-019) was relocated approximately 10 feet northwest to avoid an area of wetlands and surface water. The revised location was sufficiently close to the original location near a former dryer house structure to achieve the DQO.

Four boring locations (NYOW-01-005, NYOW-01-022, NYOW-01-023, and NYOW-01-024) were relocated based on field observations prior to installation to be within the Radisson Community green space. NYOW-01-005 was relocated 171 feet northeast, NYOW-01-022 was relocated 60 feet east, NYOW-01-023 was relocated 12 feet southwest, and NYOW-01-024 was relocated 36 feet southeast. The revised locations were sufficiently close to the original locations to achieve the DQOs.

Eight boring locations (NYOW-01-001, NYOW-01-006, NYOW-01-007, NYOW-01-009, NYOW-01-011, NYOW-01-013, NYOW-01-015, and NYOW-01-018) were relocated to avoid areas with steep slopes that the DPT rig was unable to access. NYOW-01-001 was relocated 46 feet northeast, NYOW-01-006 was relocated 266 feet east, NYOW-01-007 was relocated 21 feet northeast, NYOW-01-009 was relocated 20 feet northeast, NYOW-01-011 was relocated 23 feet northeast, NYOW-01-013 was relocated 31 feet east, NYOW-01-015 was relocated 24 feet northeast, and NYOW-01-018 was relocated 84 feet east. The revised locations were sufficiently close to the original locations along the Eastern Transect to achieve the DQOs. Subsurface samples were not collected from NYOW-01-007, NYOW-01-009, NYOW-01-011, and NYOW-01-013.

One boring location (NYOW-01-002) was relocated, due to a right-of-entry concern, 67 feet northeast to be within the Radisson Community property. The revised location was sufficiently close to the original location near a former change house structure to achieve the DQO.

Insufficient recharge was encountered at NYOW-01-021. As a result, only the minimum required volume of water was collected for SW-846 Method 8270D (one liter). The reduced volume did not cause an elevation in reporting limits for Method 8270D.

Samples were not collected at two locations (NYOW-01-003 and NYOW-01-004) because Bluestone did not have a right of entry (ROE) for either property. These borings could not be relocated onto Radisson Community property because the former change houses that these borings were proposed to characterize are located at the top of a near-vertical slope. The only safe, accessible locations within the Radisson Community property that these borings could have been relocated to would not have satisfied the DQOs because these locations would have been at the base of a 25-foot tall, steep (approximately 60 to 70 degree) slope. In addition, one location (NYOW-01-017), proposed at a former magazine (No. 107), was not installed because this location is located on private property and ROE was not agreed to by the property owner. Therefore, these three borings have been postponed until ROE can be acquired and represent an existing and potentially permanent data gap.

The existing concrete building foundations and steep slopes prompted a change in the sampling plan to collect shallow (0-1 ft bgs) samples biased to potential receptors (i.e., downgradient areas and beneath

existing drain discharges). Borings at four locations (NYOW-01-008, NYOW-01-010, NYOW-01-012, and NYOW-01-014) were not installed because these borings were proposed in the center of the concrete floors and were not accessible by the DPT rig due to the presence of sidewalls. Instead, surface soil samples were collected from NYOW-01-025 through NYOW-01-039 using hand augers. Around each former manufacturing building, a hand auger surface soil sample was collected from the nearest downgradient point along the northeast side of the concrete footprint. In support of the DQO to determine presences/absence, these unplanned discrete samples were located in areas where the preliminary site conceptual model indicates site-related constituents, if present, should be found in higher concentrations, decreasing the possibility of incorrectly eliminating a constituent from further evaluation. Additional samples were collected near observed drain discharge points on the northwest and southeast sides of each former manufacturing building. Hand auger sample collection was conducted at these locations as DPT rig access was limited by steep slopes to the northwest, west, and south, and by wetlands to the north, east, and southeast.

Groundwater samples at two locations (NYOW-01-WL022-A and NYOW-01-WL023-A) were recollected for explosives and SVOC analyses because the original samples were received at the laboratory outside of the required temperature criteria due to shipment delays. Because the compromised samples were recollected, data usability is not impacted.

### 2.1.4 AOC 3

The Phase 1 investigation objectives for AOC 3 (Former Landfill) are summarized below:

| Activity/Objective | Data Needs |
|---|---|
| Activity: Advance 16 DPT soil borings and collect discrete a discrete surface soil (0-1 ft bgs) sample from each DPT location. Characterize soil lithology within soil borings.<br><br>Objective: To assess whether DoD-related chemicals associated with the former landfill and former open storage areas are present above risk-based human health and ecological screening and background levels. To determine soil types within the AOC. | Data Planned: 16 surface soil samples were planned.<br><br>Data Collected: 16 surface soil samples collected. Soil boring logs completed.<br><br>Surface soil samples analyzed for:<br>• Metals by ICP SW-846 Method 6010C and ICP-MS Method 6020A<br>• Hg by SW-846 Method 7471B<br>• SVOCs by SW-846 Method 8270D<br>• PAHs by SW-846 Method 8270D with SIM<br>• Picric acid by SW-846 Method 8330A<br>• PCBs by SW-846 8082A (former landfill area samples only)<br>• %M by ASTM Method D2216.<br><br>A subset of samples was analyzed for:<br>• TOC by Method 9060A<br>• CEC by SW-846 Method 9081<br>• Grain Size Distribution by ASTM Method D422 |

| Activity/Objective | Data Needs |
|---|---|
| Activity: Advance DPT soil borings and collect a subsurface soil (1-5 ft bgs) sample from each DPT boring. Characterize soil lithology within soil borings.<br><br>Objective: To assess whether DoD-related chemicals associated with the former landfill and former open storage areas are present above risk-based human health and ecological screening and background levels. Deviations from the QAPP

The sampling procedures for the RI are presented in Worksheet #17 (Sampling Design and Rationale) of the UFP-QAPP and the required frequency of sample collection is presented in Worksheet #18 (Sampling Locations and Methods). Field QC samples (FD and MS/MSD) were collected by Bluestone during the Phase I investigation at AOC 3 (and AOC 1) at the frequency shown in **Table 3,** below. As presented in Worksheet #20 (Field QC Summary) in the UFP-QAPP, the minimum FD sampling frequency (10%) and MS/MSD frequencies (5%) for aqueous and solid samples were met at AOC 3 and AOC 1.

Table 3 – Field QC Sample Frequency – AOCs 1 and 3

| **Matrix/Analysis** | **FD** | | **MS** | | **MSD** | |

Note: The QC frequencies for AOC 1 and AOC 3 are of the combined data sets as imported to the FUDSChem database

A total of 14 AOC 3 boring locations were modified from the proposed locations as described in the Phase 1 Field Report (USACE, 2021a).

Five boring locations (NYOW-03-011, NYOW-03-012, NYOW-03-013, NYOW-03-014, and NYOW-03-015) were relocated based on geophysical survey findings, which indicated that the former landfill is located north of the golf course parking lot. NYOW-03-011 was relocated 25 feet northwest, NYOW-03-012 was relocated 16 feet northwest, NYOW-03-013 was relocated 140 feet north, NYOW-03-014 was relocated 137 feet north, and NYOW-03-015 was relocated 184 feet north. The revised locations were sufficient to characterize subsurface soil conditions adjacent to the former landfill and achieve the DQOs.

Three boring locations (NYOW-03-009, NYOW-03-010, and NYOW-03-018) were relocated based on field observations prior to installation. NYOW-03-009 (relocated 183 feet southwest) and NYOW-03-010 (relocated 27 feet southwest) were relocated due to proximity to the property line based on field observations of the fence line. NYOW-03-018 was relocated 178 feet northeast to be a potential soil vapor

intercept location between the former landfill and the existing clubhouse building. The revised locations were still located within the footprint of the former landfill area of concern and therefore achieve the DQOs.

One boring location (NYOW-03-016) was relocated 12 feet to the southwest to avoid underground utilities that were located during the private utility clearance. The revised location was sufficiently close to the original location to achieve the DQO.

Five boring locations (NYOW-03-001, NYOW-03-002, NYOW-03-005, NYOW-03-007, and NYOW-03-008) were relocated to avoid areas with steep slopes that the DPT rig was unable to access. NYOW-03-001 was relocated 39 feet east, NYOW-03-002 was relocated 12 feet east, NYOW-03-005 was relocated 44 feet southeast, NYOW-03-007 was relocated 27 feet northeast, and NYOW-03-008 was relocated 40 feet southwest. The revised locations were sufficiently close to the original locations to achieve the DQOs.

The proposed monitoring well location NYOW-03-011 (soil and groundwater location) hit shallow refusal at 10.5 ft bgs and water was not encountered; therefore, no well was installed at location NYOW-03-011. A well was installed at NYOW-03-010 instead, which provides sufficient groundwater information on the eastern extent of AOC 3 to achieve the DQO.

A total of 11 surface and subsurface soil samples (NYOW-03-PH008-B, NYOW-03-PH009-B, NYOW-03-PH013-B, NYOW-03-PH014-B, NYOW-03-PH015-B, NYOW-03-SL008-A, NYOW-03- SL009-A, NYOW-03- SL013-A, NYOW-03- SL014-A, NYOW-03- SL015-A, and SL-DUP-001_210405) were recollected for the SVOC analysis because the original samples were received at the laboratory outside of the required temperature criteria due to shipment delays. Because the compromised samples were recollected, data usability is not impacted.

Seven subsurface soil samples (NYOW-03-PH005-B, NYOW-03-PH006-B, NYOW-03-PH007-B, NYOW-03-PH016-B, NYOW-03-PH017-B, NYOW-03-PH018-B, and PH-DUP-001_210401) were recollected for the VOC analysis because a sample control technician inadvertently place the original sample vials in the refrigerator instead of the freezer. Because the compromised samples were recollected, data usability is not impacted.

Four subsurface soil samples (NYOW-03-PH005-B, NYOW-03-PH006-B, NYOW-03-PH007-B, and NYOW-03-PH016-B) were inadvertently recollected for SVOC analysis due to a transcription error where both VOCs and SVOCs, instead of VOCs only, were marked in the matrix provided to the field sampling team. Because both sets of analytical results represent valid, discrete soil data collected from unique soil boring locations, the SVOC results from both samples (original and re-sample) have been reported and uploaded to FUDSChem.

### 2.1.5 AOC 4 Incremental Sampling Methodology (ISM)

The Phase 1 investigation objectives for ISM sampling at AOC 4 (Former Bunker Area) are summarized below:

| Activity/Objective | Data Needs |
|---|---|
| Activity: Identify 12 DUs that correspond to each of the ammonium picrate bunkers. Collect three ISM samples, each comprised of 30 surface soil (0-1 ft bgs) increments, at each DU. Characterize soil lithology and complete a boring log for each DU. | Data Planned: 36 surface soil ISM samples were planned. |

| Activity/Objective | Data Needs |
|---|---|
| Objective: To generate a versatile data suite that may be applied to risk-based objectives and to provide opportunities to evaluate total concentrations of any contaminants. To characterize soil within each DU. | Data Collected: 36 surface soil ISM samples were collected. Soil description and boring logs completed.<br><br>ISM samples were analyzed for:<br>• SVOCs (DNCB and 2,4-DNP) by SW-846 Method 8270D<br>• Picric acid by SW-846 Method 8330B |

Deviations from the QAPP

The sampling procedures for the RI are presented in Worksheet #17 (Sampling Design and Rationale) of the UFP-QAPP and the required frequency of sample collection is presented on Worksheet #18 (Sampling Locations and Methods). ISM field replicates (FR) were collected by Bluestone at each of the 12 DUs during the Phase I investigation at AOC 4. Four MS samples were aliquoted by the laboratory after ISM processing was complete (**Table 4**). As presented in Worksheet #20 (Field QC Summary) in the UFP-QAPP, the minimum MS sampling frequency (10%) was met for ISM samples at AOC 4.

Table 4 – Field QC Sample Frequency – AOC 4, ISM

| Matrix/Analysis | FD | | MS | | MSD | |
|---|---|---|---|---|---|---|
| **Solid** | **Count** | **%** | **Count** | **%** | **Count** | **%** |
| SW8330A/METHOD | -- | -- | 4 | 11% | 4 | 11% |
| SW8270D/SW3546 | -- | -- | 4 | 11% | 4 | 11% |

A total of 21 ISM increments within seven decision units (DU001, DU002, DU006, DU007, DU011, DU012, and DU013) were relocated to be outside of their respective bunker driveway aprons due to the presence of gravel that was preventing sample collection by hand tools. The relocated increments were still collected from within their respective DUs, and the DQOs were achieved.

The ISM samples for SVOC analysis underwent the complete ISM processing and subsampling procedures, rather than having aliquots removed for SVOC analysis/moisture content prior to drying, as was specified in the UFP-QAPP. The decision to process ISM samples for the SVOC analysis was based on information provided in the ISM-2 guidance regarding the loss potential of SVOCs during air drying and the consideration that air exposure at the laboratory was not likely to produce analyte loss for surface soils that had been exposed to ambient air for many years (ITRC, 2021).

While only MS samples were included in the QAPP in accordance with programmatic requirements, both MS and MSDs were inadvertently performed for ISM samples in the SVOC and explosives analyses by the laboratory.

### 2.1.6 Background

The Phase 1 investigation objectives for Background are summarized below:

| Activity/Objective | Data Needs |
|---|---|
| Activity: Select 15 background sample locations. Advance DPT soil borings and collect a discrete surface soil (0-1 ft bgs) sample from each location. Characterize soil lithology within soil borings.<br><br>Objective: To assess background threshold values at locations not impacted by DoD operations. To determine soil types for background. | Data Planned: 45 surface soil samples were planned.<br><br>Data Collected: 45 surface soil samples were collected. Soil boring logs completed.<br>Surface soil samples were analyzed for:<br>• Metals by ICP SW-846 Method 6010C and ICP-MS Method 6020A<br>• Hg by SW-846 Method 7471B<br>• PAHs by SW-846 Method 8270D with SIM<br>• %M by ASTM Method D2216<br>• TOC by Method 9060A<br>• CEC by SW-846 Method 9081<br>• Grain Size Distribution by ASTM Method D422 |
| Activity: Collect discrete subsurface soil (1-5 ft bgs and 5-10 ft bgs) samples from each DPT location for each of the three major soil types (Ps, Pd, and Psc). Characterize soil lithology within soil borings.<br><br>Objective: To assess background threshold values at locations not impacted by DoD operations. To determine soil types for background. | Data Planned: 90 subsurface soil samples were planned.<br><br>Data Collected: 90 subsurface soil samples were collected. Soil boring logs completed.<br><br>Subsurface soil samples were analyzed for:<br>• Metals by ICP SW-846 Method 6010C and ICP-MS Method 6020A<br>• Hg by SW-846 Method 7471B<br>• PAHs by SW-846 Method 8270D with SIM<br>• %M by ASTM Method D2216<br>• TOC by Method 9060A<br>• CEC by SW-846 Method 9081<br>• Grain Size Distribution by ASTM Method D422 |
| Activity: Collect upgradient groundwater samples from DPT soil borings. Collect WQP to demonstrate groundwater stabilization.<br><br>Objective: To compare background concentrations to the concentrations of DoD-related constituents measured in site groundwater samples. To collect representative groundwater samples. | Data Planned: nine background groundwater samples were planned. Water quality field parameters (pH, ORP, turbidity, temperature, DO, and specific conductivity) to be collected at each location.<br><br>Data Collected: nine background groundwater samples were collected. WQP were collected until stabilization.<br>Background groundwater samples were analyzed for:<br>• Dissolved metals by ICP SW-846 Method 6010C and ICP-MS Method 6020A |

| Activity/Objective | Data Needs |
|---|---|
| | • Dissolved Hg by SW-846 Method 7470A<br>• PAHs by SW-846 Method 8270D with SIM |

Deviations from the UFP-QAPP

Soil background samples must represent regional surficial geology to the respective AOC surface and subsurface media. TOC, CEC, and grain size were used to evaluate subsurface soil lithology to establish the number of viable soil samples for each soil type (Ps, Pd, and Psc). The following sample sizes were obtained during the subsurface soil sampling event:

- Ps (sand and gravel), *n = 24*
- Pd (diamicton), *n = 11*
- Psc (lacustrine silt and clay), *n = 8*

The objective of the subsurface soil sampling to obtain 15 samples for each soil type was not achieved; however, the sample size is sufficient (i.e., n ≥ 8) to compare site soil to background using summary statistics (e.g., ranges, means, medians, standard deviations), exploratory graphical displays (e.g., side-by-side box plots, histograms, and quantile-quantile plots), and to calculate BTVs (Bluestone, 2022). In the case of AOC 5, where the investigation is an initial Site Investigation (SI), any comparisons with background is for informational purposes and not used to eliminate methods and/or analytes from further investigation (Bluestone, 2022).

The sampling procedures for the RI are presented in Worksheet #17 (Sampling Design and Rationale) of the UFP-QAPP and the required frequency of sample collection is presented in Worksheet #18 (Sampling Locations and Methods). Field QC samples (FD and MS/MSD) were collected by Bluestone during the Phase I investigation for Background at the frequency shown in **Table 5**. As presented in Worksheet #20 (Field QC Summary) in the UFP-QAPP, the minimum FD sampling frequency (10%) and MS/MSD frequencies (5%) for aqueous and solid samples were met for background sampling.

Table 5 – Field QC Sample Frequency – Background

| Matrix/Analysis | FD | | MS | | MSD | |
|---|---|---|---|---|---|---|
| **Aqueous** | **Count** | **%** | **Count** | **%** | **Count** | **%** |
| BNASIMD/SW3510C | 1 | 11% | 1 | 11% | 1 | 11% |
| SW7470A/FLDFLT | 1 | 11% | 1 | 11% | 1 | 11% |
| SW6010C/FLDFLT | 1 | 11% | 1 | 11% | 1 | 11% |
| SW6020A/FLDFLT | 1 | 11% | 1 | 11% | 1 | 11% |
| **Solid** | **Count** | **%** | **Count** | **%** | **Count** | **%** |
| SW9081/METHOD | 14 | 10% | -- | -- | -- | -- |
| BNASIMD/SW3546 | 14 | 10% | 15 | 11% | 15 | 11% |
| SW7471B/TOTAL | 14 | 10% | 14 | 10% | 14 | 10% |
| D2216 | 14 | 10% | -- | -- | -- | -- |
| SW9060A | 14 | 10% | 14 | 10% | 14 | 10% |
| SW6010C/3050B | 14 | 10% | 15 | 11% | 15 | 11% |
| SW6020A/3050B | 14 | 10% | 15 | 11% | 15 | 11% |

A total of 21 Background boring locations were modified from the proposed locations to avoid areas of wetlands and surface water as described in the Phase 1 Field Report (USACE, 2021a) and presented below in **Table 6**.

**Table 6**: Relocated Background Boring Locations

| Sample ID | Relocation Distance and Direction | Sample ID | Relocation Distance and Direction |
|---|---|---|---|
| NYOW-B-003 | 47 feet north | NYOW-B-009 | 300 feet southeast |
| NYOW-B-010 | 132 feet northeast | NYOW-B-011 | 586 feet south |
| NYOW-B-012 | 185 feet north | NYOW-B-014 | 233 feet north |
| NYOW-B-015 | 652 feet northwest | NYOW-B-016 | 912 feet northwest |
| NYOW-B-018 | 451 feet north | NYOW-B-019 | 1281 feet northwest |
| NYOW-B-020 | 217 feet northwest | NYOW-B-025 | 115 feet northeast |
| NYOW-B-026 | 685 feet north | NYOW-B-027 | 700 feet south |
| NYOW-B-028 | 753 feet north | NYOW-B-029 | 611 feet southeast |
| NYOW-B-030 | 913 feet southeast | NYOW-B-031 | 88 feet west |
| NYOW-B-033 | 503 feet southeast | NYOW-B-040 | 52 feet southwest |
| NYOW-B-047 | 37 feet southeast | | |

Each of the background soil borings was relocated to an area still within the historic soil units. The Psc unit could not be sampled south of the edge of the wetland, resulting in the greatest overall relocation distances (e.g., NYOW-B-019, NYOW-B-016). The background soil sampling yielded the lowest sample size for Psc.

## 2.2 DATA QUALITY INDICATOR EVALUATION

### 2.2.1 Precision

Precision measures the agreement among a set of replicate measurements. Analytical precision is estimated using laboratory control spike (LCS)/laboratory control spike duplicate (LCSD) pairs or MS/MSD pairs. Field and analytical precision are evaluated using FD sample pairs. The most commonly used estimates of precision when only two samples are available is the relative percent difference (RPD). The RPD is calculated as the absolute value of the difference between two results divided by the arithmetic mean of the results. The RPDs for QC sample pairs were within the precision limits presented in the UFP-QAPP (USACE, 2020), with the exceptions noted below.

#### *2.2.1.1 AOC 5*

Surface Soil

**Table 7** summarizes the number of surface soil results that were qualified due to parent/FD RPD exceedances:

| **Table 7:** AOC5 Surface Soil Summary – Analytical and Field Precision (3 parent/FD pairs) | |
|---|---|
| Total number of Surface Soil results for parent/FD pairs | 470 |
| Surface Soil results qualified for parent/FD RPD exceedances | 24 (5.1%) |

The notable surface soil parent/FD RPD exceedances are as follows:

- NYOW-05-SL002-A: FD RPDs > 50% for phenanthrene (157%), fluoranthene (141%), benzo(a)anthracene (137%), pyrene (137%), benzo(a)pyrene (133%), indeno(1,2,3-cd)pyrene (123%), benzo(b)fluoranthene (116%), chrysene (115%), calcium (78%), and magnesium (57%).
- NYOW-05-SL023-A: FD RPD > 50% for calcium (136%).

Surface soils are inherently heterogeneous; therefore, elevated RPDs for PAH and metal analytes are commonly encountered.

**Table 8** summarizes the number of surface soil results that were qualified due to MS/MSD RPD exceedances:

| **Table 8:** AOC5 Surface Soil Summary – Analytical Precision (MS/MSD pairs) | |
|---|---|
| Total Number of Surface Soil Results | 2134 |
| Surface Soil results qualified for MS/MSD RPD exceedances | 16 (<1%) |

The notable surface soil MS/MSD RPD exceedances are as follows:

- NYOW-05-SL003-A: MS/MSD RPD > 20% for magnesium (43%) and dibenzofuran (21%).
- NYOW-05-SL010-A: MS/MSD RPDs > 20% for manganese (57%), calcium (33%), aluminum (25%), antimony (25%), and magnesium (24%).
- NYOW-05-SL022-A: MS/MSD RPDs > 20% for manganese (109%), calcium (92%), magnesium (37%), iron (30%), potassium (26%), and barium (23%).
- NYOW-05-SL025-A: MS/MSD RPDs > 40% for benzo(a)anthracene (52%), chrysene (40%), and pyrene (40%).

There were no surface soil results qualified for LCS/LCSD RPD exceedances, indicating acceptable laboratory precision.

Subsurface Soil

**Table 9** summarizes the number of subsurface soil results that were qualified due to parent/FD RPD exceedances:

| **Table 9:** AOC 5 Subsurface Soil Summary – Analytical and Field Precision (5 parent/FD pairs) | |
|---|---|
| Total number of Subsurface Soil results for parent/FD pairs | 1040 |
| Subsurface Soil results qualified for parent/FD RPD exceedances | 25 (2.4%) |

The notable subsurface soil parent/FD RPD exceedances are as follows:

- NYOW-05-PH001-C: FD RPDs > 50% for arsenic (103%), barium (93%), potassium (77%), aluminum (74%), vanadium (69%), chromium (67%), magnesium (63%), iron (58%), and cobalt (52%).
- NYOW-05-PH022-B: FD RPDs > 50% for benzo(g,h,i)perylene (172%), calcium (67%), and lead (62%).

**Table 10** summarizes the number of subsurface soil results that were qualified due to MS/MSD RPD exceedances:

| **Table 10:** AOC5 Subsurface Soil Summary – Analytical Precision (MS/MSD pairs) | |
|---|---|
| Total number of Subsurface Soil results | 5736 |
| Subsurface Soil results qualified for MS/MSD RPD exceedances | 12 (<1%) |

The notable surface soil MS/MSD RPD exceedances are as follows:

- NYOW-05-PH003-B: MS/MSD RPDs > 20% for manganese (123%), thallium (38%), selenium (36%), antimony (35%), cadmium (35%), and arsenic (28%).
- NYOW-05-PH011-B: MS/MSD RPD > 20% for antimony (29%).
- NYOW-05-PH021-C: MS/MSD RPDs > 20% for zinc (50%), manganese (36%), cadmium (23%), thallium (23%), and selenium (22%).

There were no subsurface soil results qualified for LCS/LCSD RPD exceedances.

Groundwater

**Table 11** summarizes the number of groundwater results that were qualified due to parent/FD RPD exceedances:

| **Table 11:** AOC 5 Groundwater Summary – Analytical and Field Precision (2 parent/FD pairs) | |
|---|---|
| Total number of groundwater (GW) results for parent/FD pair | 484 |
| GW results qualified for parent/FD RPD exceedances | 2 (<1%) |

The notable groundwater parent/FD RPD exceedances are as follows:

- NYOW-05-WL012-A: FD RPD > 30% for dissolved iron (61.8%).

There were no groundwater results qualified for MS/MSD or LCS/LCSD RPD exceedances.

#### *2.2.1.2 AOC 4*

Surface Soil

There were no target analytes detected in any of the surface soil samples; therefore, there were no surface soil results qualified for parent/FD RPD exceedances. There were no surface soil results qualified for MS/MSD or LCS/LCSD RPD exceedances. The DQOs for the project were achieved regarding precision for AOC 4 surface soil sampling.

Subsurface Soil

There were no target analytes detected in any of the subsurface soil samples; therefore, there were no subsurface soil results qualified for parent/FD RPD exceedances. There were no subsurface soil results qualified for MS/MSD or LCS/LCSD RPD exceedances. The DQOs for the project were achieved regarding precision for AOC 4 subsurface soil sampling.

Groundwater

There were no target analytes detected in any of the groundwater samples; therefore, there were no groundwater results qualified for parent/FD RPD exceedances. There were no groundwater results qualified for MS/MSD or LCS/LCSD RPD exceedances. The DQOs for the project were achieved regarding precision for AOC 4 groundwater sampling.

#### *2.2.1.3 AOC 1*

Surface Soil

**Table 12** summarizes the number of surface soil results that were qualified due to parent/FD RPD exceedances:

| **Table 12:** AOC 1 Surface Soil Summary – Analytical and Field Precision (2 parent/FD pairs) | |
|---|---|
| Total number of Surface Soil results for parent/FD pairs | 112 |
| Surface Soil results qualified for parent/FD RPD exceedances | 22 (19.6%) |

The notable surface soil parent/FD RPD exceedances are as follows:

- NYOW-01-SL005-A: FD RPD > 50% for zinc (165%).
- NYOW-01-SL019-A: FD RPDs > 50% for TOC (139%), aluminum (84%), nickel (82%), chromium (77%), copper (69%), barium (64%), vanadium (62%), cobalt (59%), potassium (57%), and lead (57%).

**Table 13** summarizes the number of surface soil results that were qualified due to MS/MSD RPD exceedances:

| **Table 13:** AOC 1 Surface Soil Summary – Analytical Precision (MS/MSD pairs) | |
|---|---|
| Total number of Surface Soil results | 897 |
| Surface Soil results qualified for MS/MSD RPD exceedances | 6 (<1%) |

The notable surface soil MS/MSD RPD exceedances are as follows:

- NYOW-01-SL002-A: MS/MSD RPD > 20% for TOC (48%).
- NYOW-01-SL021-A: MS/MSD RPDs > 20% for zinc (70%), calcium (59%), and magnesium (23%).
- NYOW-01-SL029-A: MS/MSD RPD > 20% for TOC (20.03%).

There were no surface soil results qualified for LCS/LCSD RPD exceedances. Surface soil sample NYOW-01-SL026-A exhibited dual column RPD greater than the control limit (40%) for picric acid at 194%. No obvious chromatographic interference was identified. Consistent with the Quality System Manual and SW-846 Method 8000D, the lower result from the primary column was reported.

Subsurface Soil

**Table 14** summarizes the number of subsurface soil results that were qualified due to parent/FD RPD exceedances:

| **Table 14:** AOC 1 Subsurface Soil Summary – Analytical and Field Precision (5 parent/FD pairs) | |
|---|---|
| Total number of Subsurface Soil results for parent/FD pairs | 282 |
| Subsurface Soil results qualified for parent/FD RPD exceedances | 16 (5.7%) |

The notable subsurface soil parent/FD RPD exceedances are as follows:

- NYOW-05-PH019-C: FD RPDs > 50% for TOC (152%), copper (58%), and zinc (57%).
- NYOW-05-PH023-C: FD RPDs > 50% for calcium (83%), cobalt (65%), magnesium (61%), and nickel (60%).

**Table 15** summarizes the number of subsurface soil results that were qualified due to MS/MSD RPD exceedances:

| **Table 15:** AOC 1 Subsurface Soil Summary – Analytical Precision (MS/MSD pairs) | |
|---|---|
| Total number of Subsurface Soil results | 755 |
| Subsurface Soil results qualified for MS/MSD RPD exceedances | 23 (3.0%) |

The notable subsurface soil MS/MSD RPD exceedances are as follows:

- NYOW-01-PH002-B: MS/MSD RPDs > 20% for calcium (58%), TOC (30%), cobalt (23%), cadmium (21%), beryllium (21%), sodium (21%) and nickel (21%).
- NYOW-01-PH019-B: MS/MSD RPDs > 20% for iron (40%), antimony (24%), and cadmium (22%).
- NYOW-01-PH023-B: MS/MSD RPDs > 20% for TOC (61%), sodium (29%), beryllium (28%), silver (26%), chromium (26%), nickel (26%), lead (26%), vanadium (25%), cobalt (25%), zinc (24%), copper (21%), potassium (21%), and calcium (21%).

There were no subsurface soil results qualified for LCS/LCSD RPD exceedances.

Groundwater

**Table 16** summarizes the number of groundwater results that were qualified due to parent/FD RPD exceedances:

| **Table 16:** AOC 1 Groundwater Summary – Analytical and Field Precision (1 parent/FD pair) | |
|---|---|
| Total number of GW results for parent/FD pair | 52 |
| GW results qualified for parent/FD RPD exceedances | 4 (7.7%) |

The notable groundwater parent/FD RPD exceedances are as follows:

- NYOW-01-WL005-A: FD RPDs > 30% for dissolved aluminum (137%) and dissolved iron (79%).

There were no groundwater results qualified for MS/MSD or LCS/LCSD RPD exceedances.

#### *2.2.1.4 AOC 3*

Surface Soil

**Table 17** summarizes the number of surface soil results that were qualified due to parent/FD RPD exceedances:

| **Table 17:** AOC 3 Surface Soil Summary – Analytical and Field Precision (3 parent/FD pairs) | |
|---|---|
| Total number of Surface Soil results for parent/FD pairs | 422 |
| Surface Soil results qualified for parent/FD RPD exceedances | 48 (11.4%) |

The notable surface soil parent/FD RPD exceedances are as follows:

- NYOW-03-SL006-A: FD RPD > 50% for calcium (161%), magnesium (112%), benzo(a)anthracene (103%), cadmium (97%), fluoranthene (84%), pyrene (84%), benzo(k)fluoranthene (81%), benzo(a)pyrene (72%), chrysene (70%), indeno(1,2,3-cd)pyrene (67%), benzo(b)fluoranthene (60%), benzo(g,h,i)perylene (51%), and percent solids (20.1%).
- NYOW-03-SL013-A: FD RPDs > 50% for anthracene (73%), chrysene (70%), acenaphthylene (69%), TOC (67%), benzo(g,h,i)perylene (65%), benzo(a)anthracene (63%), CEC (63%), benzo(a)pyrene (61%), benzo(b)fluoranthene (59%), fluoranthene (59%), and benzo(k)fluoranthene (54%).

**Table 18** summarizes the number of surface soil results that were qualified due to MS/MSD RPD exceedances:

| **Table 18:** AOC 3 Surface Soil Summary – Analytical Precision (MS/MSD pairs) | |
|---|---|
| Total number of Surface Soil results | 1859 |
| Surface Soil results qualified for MS/MSD RPD exceedances | 20 (1.1%) |

The notable surface soil MS/MSD RPD exceedances are as follows:

- NYOW-03-SL004-A: MS/MSD RPDs > 20% for thallium (35%), cadmium (33%), selenium (32%), and arsenic (30%).
- NYOW-03-SL009-A: MS/MSD RPD > 20% for phenanthrene (42%), sodium (41%), beryllium (40%), calcium (40%), barium (39%), cobalt (39%), chromium (38%), copper (38%), potassium (38%), nickel (37%), lead (37%), magnesium (35%), vanadium (35%), antimony (31%), zinc (30%), and manganese (22%).

**Table 19** summarizes the number of surface soil results that were qualified due to LCS/LCSD RPD exceedances:

| **Table 19:** AOC 3 Surface Soil Summary – Analytical Precision (LCS/LCSD pairs) | |
|---|---|
| Total number of Surface Soil results | 1859 |
| Surface Soil results qualified for LCS/LCSD RPD exceedances | 5 (<1%) |

The notable surface soil LCS/LCSD RPD exceedances are as follows:

- LCS/LCSD RPDs > 20% for carbazole (70% and 27%), benzaldehyde (52%), *m,p*-cresols (33%), and dibenzofuran (24%).

Surface soil samples NYOW-03-SL008-A, NYOW-03-SL010-A, NYOW-03-SL013-A, and NYOW-03-SL015-A exhibited dual column RPDs for PCB-1260 greater than the control limit (40%) at 68%, 64%, 52%, and 104%, respectively.

Subsurface Soil

**Table 20** summarizes the number of subsurface soil results that were qualified due to parent/FD RPD exceedances:

| **Table 20:** AOC 3 Subsurface Soil Summary – Analytical and Field Precision (3 parent/FD pairs) | |
|---|---|
| Total number of Subsurface Soil results for parent/FD pairs | 616 |
| Subsurface Soil results qualified for parent/FD RPD exceedances | 41 (6.7%) |
