6. Based upon client requirements, a MSD is prepared and analyzed under the same conditions as the MS. The acceptance criteria and corrective action are the same as the MS. The relative percent difference between the MS and MSD is statistical and can be found in the LIMS. If the RPD is outside of these criteria, consult your group leader to determine if reanalysis is necessary.

7. A Total Inorganic Carbon (TIC) check standard must be prepared daily to determine the efficiency of inorganic carbon removal when performing the total organic carbon analysis. This standard is prepared by adding 1.25 ml of the TOC QC stock and 1.25 ml of the TIC QC stock to a 25 ml volumetric and bringing to volume with reagent water.

Uncontrolled Copy

8. Daily a TOC carryover check must be analyzed. This is preformed by analyzing the highest calibration point and immediately following with a blank. the result of the blank must be less than half the reporting limit.

*QC Frequency and Acceptance criteria*

| QC Check | Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|---|
| CCV | Beginning and end of batch and after every 10 samples and if instrument is idle for more than 4 hours. | CCV(high and mid): 85 - 115%<br><br>CCVL: 50 - 150% | Re-calibrate instrument, perform maintenance if needed. |
| CCB | Beginning and end of batch and after every 10 samples | <MDL | Re-calibrate instrument, perform maintenance if needed. |
| TOC Carryover Check | Daily, immediately after the highest calibration point | <MDL | Re-calibrate instrument, perform maintenance if needed. |
| TIC Check | Daily | 80 - 120% | Re-analyze check, perform maintenance if needed. |
| LCS<br>LCSD (if required by client) | Each batch of samples. Analyze the 50mg/L QC standard. | waters: Statistical, see LIMS. No wider than 85 - 115%<br>LCSD RPD: 15% | Repeat all samples in batch |
| MB | Each batch of samples | <MDL | B-flag data >MDL. Repeat all samples in batch >1/2RL |
| MS<br>MSD (if required by client) | Every 10 samples, at least 1 per batch | waters: 85 - 115%<br>MS RPD: Statistical, see LIMS. | Data are qualified |
| DU | Every 10 samples, at least 1 per batch | RPD: 15% | Data are qualified |

## Scope

This method is suitable for the determination of target compounds listed and maintained in the Laboratory Information Management System (LIMS) for soil and solid matrices. Samples consist of soils/solids collected or submitted in bulk in glass containers with Teflon-lined screw-caps or in field core sampling/storage containers (i.e., EnCore or equivalent). Associated MDLs/LOQs are listed in the LIMS under the analysis numbers and/or Project Information lists. A list of analytes listed under the method is included in the Appendix, as well as the Reagent Formulary Reports for the compounds in the method (Figures 1-2). Non-target volatile compounds in the sample can be tentatively identified (TIC) using a mass spectral reference library comparison. This analysis must be performed by or under the direct supervision of an operator experienced in the analysis of volatile organics by purge and trap GC/MS methodologies and skilled in mass spectral interpretation. Using this method, the TICs are quantitated with an estimated concentration.

Compounds other than those listed in the LIMS for this group of master scans may be analyzed using USEPA SW-846 Method 8260C. Selected Ion Monitoring (SIM) parameters can be used to detect, identify and quantitate volatile organic compounds in methanol extracts of soils/solids, if lower quantitation limits are required (project- or client-specified) and/or matrix interferences are anticipated. Attachment I describes the proper analysis procedure for Gasoline Range Organics in soils and solids. Due to poor purging efficiency or poor chromatography, some analytes require calibration at higher levels and/or higher practical quantitation limits (PQLs). Standards containing additional analytes must be prepared as described in the Standards section of this document. Both secondary stock solutions and matrix spike solutions must be prepared for use in analyzing additional compounds.

## Basic Principles

The soil sample is prepared according to analysis *S-SS-WI10682* and *S-SS-WI11170* for 8260C. The sample is purged with an inert gas and the effluent gas passed through a sorbent trap where the volatile organics are trapped. After purging, the sorbent trap is rapidly heated and backflushed onto the head of a gas chromatographic column held at the appropriate initial temperature for the column in use. The gas chromatographic column is temperature programmed to separate the volatile compounds, which are subsequently detected and identified using mass spectrometric techniques.

Uncontrolled Copy

When a compound reaches the MS, it is bombarded by high energy electrons (70 eV). This causes the compound to fragment and form ions. The positive ions are focused into a quadrupole mass analyzer, where the ions are separated according to their mass/charge ratios during rapid repetitive scans. These ions are then amplified and detected with an electron multiplier.

The resulting time/intensity/mass spectra data are stored and processed by a computer. Target compounds are identified on the basis of relative retention times and mass spectral matches to standards, which are injected every 12 hours on the same system. The internal standard method is used for quantitation.

The GRO analysis is typically performed in conjunction with the analysis of other volatile target compounds by SW-846 Method 8260C. The GRO quantitation range is 0.1 minutes before the peak apex of C6 (hexane) to 0.2 minutes after the peak apex of C12 (dodecane); however, other ranges can be established. By establishing a (C12) GRO window to 0.2 minutes following the elution of dodecane, the areas from a trio of unresolved peaks eluting near to the upper limit of the range must consistently be included in the total GRO area. In addition, the range remains tight enough to ensure that no C13 or greater compounds can be included in the total GRO area. The C4 range retention time is determined by selecting the first peak after the air and/or artifact peak minus 0.1 minutes in the first level of standard analyzed with the ICAL. The C5 range retention time is 0.1 minutes before the peak apex of pentane.This analysis must be performed by or under the direct supervision of an operator experienced in the analysis of volatile organics by GC/MS purge and trap methodologies. The area of the total ion chromatogram for the GRO range is determined. The area of the internal standards and surrogate standards are found and subtracted from the total area of the chromatogram within the desired time range. The resulting area is then quantitated versus the internal standard, fluorobenzene.

## Interferences

Contaminant sources are volatile compounds in the laboratory environment, impurities in the inert purging gas, carryover from samples containing high concentrations of volatile organic compounds and dirty glassware. The analyst must demonstrate that the system is free from interferences (by producing acceptable method blank data) before analyzing a batch of samples. Matrix effects from heavily contaminated soils and solids can interfere with the internal standard responses, target analytes and surrogate recoveries, thereby hindering accurate quantitation. See Section 4.0 of SW-846 Method 8260C for further discussion.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

The toxicity of each reagent used has not been precisely determined. However, each reagent must be treated as a potential health hazard. Safety measures would include the use of fume hoods, safety glasses, lab coats, and gloves when working directly with reagents. Refer to the *Chemical Hygiene Plan* for specific details.

## Personnel Training and Qualifications

Education Requirement: A 4–year Baccalaureate Degree from an accredited College or University in one of the physical sciences and/or 1 – 3 years of relevant gas chromatography experience.

Analysts must be trained in the proper method of volatile organic sample preparation and analysis as determined by the supervisor(s). All training and education relating to volatile organic sample preparation and analysis must be documented by each analyst in their training record. Specifically, each new chemist must train with an experienced chemist for the first 12 weeks depending on the individual and their previous experience. The first 12 weeks are spent working one-on-one with the trainer. This time may be less if the new chemist has prior relevant experience in GC/MS and analytical chemistry background.

During the training period, the new chemist must learn daily maintenance, calibration techniques, data and library search review, and forms generation. They are also required to read all relevant SOPs and EPA methods. All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP. Each analyst must perform an Initial Demonstration of Capability to measure proficiency. Thereafter, an annual Demonstration of Capability is performed and maintained in the analyst's training records.

**NOTE:** A separate Demonstration of Capability for GRO is required.

## Sample Collection, Preservation, and Handling

Soils are either collected/submitted in bulk in glass containers with Teflon-lined screw-caps, in field core sampling/storage containers (i.e., EnCore or equivalent), or preserved in the field before submittal to the laboratory. Samples for low level volatiles analysis are frozen with reagent water at ≤ 10 °C, and may be preserved with sodium bisulfate. Samples for high level volatiles analysis are preserved in methanol. Refer to the volatiles preservation SOPs *S-SS-WI10682* and *S-SS-WI11170* for further information. All samples must be analyzed within 14 days of collection.

Uncontrolled Copy

## Apparatus and Equipment

1. Gastight micro syringes – 10-µL and larger

2. 5-mL gastight syringes

3. Analytical balance, capable of accurately weighing ±0.0001 g

4. Top-loading balance capable of weighing ±0.01 g

5. Glassware

   a. Class A Volumetric flasks with ground-glass stopper

   b. Vials, 1.5-mL, 15-mL, and 40-mL screw cap, with Teflon/silicone septa

   c. Mininert vials, 1-mL, 2-mL, and 5-mL

6. Purge and trap device – Consisting of the sample purger, the trap, and desorber; the OI Analytical 4560, OI Analytical 4660, or equivalent meets the requirements of this method. The purging chamber must have the purge gas passing through the sample as finely divided bubbles and minimize the headspace between the sample and the trap to <15 mL.

7. Autosampler – OI Analytical 4551, Archon, or equivalent meets the requirements of this method. The Archon has the capability to purge solid samples directly in the 40-mL vial (needed for samples prepared by analysis 8389).

8. Spiker units (optional) – OI Analytical Model 4551 SIM/Spiker or equivalent. One or two automated syringe spikers can be added to the OI Analytical Model 4551 autosampler to automatically introduce 10 µL of internal standard (ISTD), surrogate standard, and/or matrix spiking solutions to the sample as it is being transferred to the sparge vessel. The Archon has a groove that can deliver 1 µL of appropriate standards.

9. GC/MS system – The HP 5890GC/5972 MSD, HP 6890GC/5973MSD, HP 6890GC/5975MSD, and Shimadzu GC/MS QP5000 meet the requirements for this method.

10. Data System/Computer/Software– this is interfaced to the GC/MS system, which continuously acquires and stores data during the analysis, and can process/reduce data to generate the appropriate forms and supporting data. The software used for acquisition is HP Chemstation®, and data reduction is accomplished using Target® software.

11. GC Columns

   a. Column 1 – 30M × 0.25 mm ID DB624 capillary column with a 1.4-µm film thickness from Agilent, or equivalent (to be used with the Shimadzu QP5000 or the Agilent 5972, 5973 and 5975 MSDs)

   b. Column 2 – 20M × 0.18 mm ID DB624 capillary column with a 1.0-µm film thickness from Agilent, or equivalent (to be used with the Shimadzu QP5000 or the Agilent 5972, 5973 and 5975 MSDs)

Different sampling/analysis combinations are used based on how the sample was collected, expected level of VOCs in the sample, possible matrix interferences, list of target compounds, whether TICs were requested, the required quantitation limits and the type of equipment/instrumentation available.

**NOTE:** Refer to *T-VOA-WI7619* for instrumentation maintenance and troubleshooting.

## Reagents and Standards

A. Reagents

1. Reagent water is defined as water in which an interferant is not observed at or above the reporting limit for parameters of interest. In general, the deionized water supplied at the taps in the laboratory must meet these criteria. If the reagent water does not meet the requirements, see your supervisor for further instructions.

2. Purge and Trap grade Methanol or equivalent

3. Sodium bisulfate – ACS grade

4. Sand- Ottawa Standard

B. Standards

See *T-VOA-WI7629* for standards traceability.

1. Stock standard solutions – Stock solutions must be prepared in methanol. Standards are prepared from ampulated and neat compounds obtained from suppliers that indicate the purity of the compound. No correction for purity is made if the purity is listed as ≥96%. Pre-made solutions can be used if the supplier documents the

Uncontrolled Copy

concentrations of the solutions. All ampulated standards are stored at ≤-10°C until the expiration date indicated by the vendor or for 1 year if no expiration date is provided.

**NOTE:** For most of the target compounds, the stock standard solutions are purchased from a vendor as custom mixes (V for calibration and Q for separate source quality control). The internal and surrogate standards are purchased from a vendor, as well as the target compounds that are gases at room temperature. These gaseous standards have a 1-week expiration date, starting from the date they are opened.

2. Surrogate stock standard solution (for high level soils) – a 2500 µg/mL stock standard solution of dibromofluoromethane, toluene-d8, 4-bromofluorobenzene, and 1,2-dichloroethane-d4 is prepared in methanol by a commercial supplier

3. 8260A Internal standard spiking solution (8260IS) – a 2500 µg/mL stock standard solution of fluorobenzene, chlorobenzene-d5, 1,4-dichlorobenzene-d4, and 12500 µg/mL deuterated tertiary butyl alcohol (tBA-d10) is prepared in methanol by a commercial supplier. Deuterated tertiary butyl alcohol (tBA-d10) is used sometimes as an auxiliary ISTD. If an autosampler is used, dilute the stock to 250 µg/mL (1250 µg/mL for tBA-d10) in methanol. This is assuming a 1-µL groove in the autosampler. If the groove is determined to be other than 1 µL, the standard preparation must be adjusted so that appropriate final concentration is obtained (50 µg/kg).

4. GRO calibration standard – a 5500-µg/mL stock unleaded gasoline composite prepared in methanol by a commercial supplier.

5. GRO QC standard – a 20,000-µg/mL stock unleaded gasoline composite prepared in methanol by a commercial supplier

6. To prepare stock standards from neat compounds:

a. Place about 9.8 mL methanol or an equivalent solvent into a tared 10.0-mL glass-stoppered volumetric flask. Weigh the flask to the nearest 0.1 mg.

b. Add the liquids using a syringe or pipette by adding 2 or more drops of the assayed material to the flask, being careful that no drop hits the side of the flask. Reweigh the flask, record/note the amount, dilute to volume, stopper, and mix by inverting the flask at least 3 times. Calculate the concentration of the standard.

c. The stock standard solutions are stored in Teflon-sealed screw-capped vials at ≤-10°C. The compound name, concentration, date prepared, expiration date, preparer name and storage conditions must appear on the bottle.

d. Replace in house prepared stock standard solutions every 6 months.

7. Secondary dilution standards – Using the stock standard solutions, prepare secondary stock solutions in methanol containing the desired compounds. These standards are prepared by calculating the volume of each stock standard required producing a given volume of a mixed working standard with a known concentration of each analyte. When custom mixes are used, these may be diluted down individually, or combined together with other mixes. The working standard is tested according to *T-VOA-WI7629*. The verified working standard is poured into Teflon-lined screw-capped GC vials or mininert vials and stored at ≤-10°C. A designator indicating the standard, month, and preparation date must be on the standard vials. The designator and all data pertaining to the working standard preparation are to be recorded in the standards logbook. Replace secondary dilution standards every 2-4 weeks (1 week for standards containing gases) unless otherwise indicated.

a. 1,4-Bromofluorobenzene (BFB) standard – Prepare a 50-µg/mL solution of BFB in methanol by diluting the stock standard (prepared from neat material) with methanol to a final volume of 100 mL. The volume of stock standard used varies, depending on the actual stock concentration.

b. Surrogate standard spiking solution (high level only) – Prepare the surrogate standard spiking solution from the stock standard solutions at a concentration of 25 or 250 µg/mL in methanol. The requested soil preparation method dictates what concentration of surrogates are required for analysis.

c. Internal standard (IS) solution (high level only) – fluorobenzene, chlorobenzene-d5, 1,4-dichlorobenzene-d4, and tert-Butyl Alcohol-d10. One mL of 8260IS is diluted with methanol to a total volume of 10 mL to give a final concentration of 250 µg/mL (1250 µg/mL for tBA-d10). This is assuming a 1-µL groove in the autosampler. If the groove is determined to be other than 1 µL, the standard preparation must be adjusted so that appropriate final concentration is obtained (50 µg/kg).

d. IS/SS spiking solution (low level only)– Dilute 1 mL of 8260IS and 1 mL of 8260SS with methanol to 10-mL final volume (resulting in a concentration of 250 µg/mL, 1250 µg/mL for tBA-d10). This is assuming a 1-µL groove in the autosampler. If the groove is determined to be other than 1 µL, the standard preparation must be adjusted so that appropriate final concentration is obtained 50 µg/kg).

e. Calibration spiking solution – Prepare solutions in methanol that contain the compounds of interest at known concentrations. Suggested calibration levels are 4, 10, 20, 50, 100, and 300 (µg/kg). Replace the calibration spiking solution every 2-4 weeks (1 week for standards containing gases).

f. Matrix spiking solution – Prepare solutions in methanol that contain the compounds of interest at known concentrations. These solutions serve as both the matrix spiking solution and the laboratory control sample solutions. Matrix spikes also serve as duplicates; therefore, two aliquots of the same sample need to be spiked for analysis with these solutions. Replace the matrix spiking solution every 2-4 weeks (1 week for standards containing gases).

Uncontrolled Copy

g. Store all standard solutions at ≤-10°C and protected from light.

## Calibration

A. Instrument Conditions:

1. The purge and trap device must have the trap conditioned for at least 10 minutes at 180° to 220°C at a flow rate of 20 to 60 mL/min prior to initial use.

2. An example of purge and trap conditions are listed below:

| | |
|---|---|
| Purge gas | Helium |
| Purge flow | 35 – 40 mL/min |
| Purge temperature | 40°C for low level soils and ambient temp. for medium/high level soils |
| Purge time | 11 min |
| Desorb temperature | 190°-220°C |
| Desorb time | 0.5 to 4 minutes ** |
| Bake temperature | 180°-220°C |
| Bake time | 8 min (±3 min) |

** - Range as suggested by the purge and trap instrument manufacturer

**NOTE:** Purge and trap conditions may be changed to optimize instrument operations. A record of actual purge and trap conditions for each instrument may be found in the appropriate instrument maintenance log.

3. The suggested gas chromatographic operating conditions are listed in the table below, depending on the column used:

| | Column 1 | Column 2 |
|---|---|---|
| Column liquid phase | DB-624 | DB-624 |
| Carrier gas | Helium | Helium |
| Carrier gas flow | 0.8 mL/min | 0.6 mL/min |
| Make-up gas flow | None | None |
| Initial temperature | 45°C | 45°C |
| Initial hold time | 4.5 min | 2.5 min |
| Temperature ramp | 12°/min to 100°C then 25°/min to 240°C | 12°/min to 100°C then 25°/min to 235°C |
| Final temperature | 240°C | 235°C |
| Final hold time | None | .02 min |

4. Recommended mass spectrometer (MS) operating conditions:

| | |
|---|---|
| Ions | Positive |
| Electron energy | 70 volts |
| Mass range | 35 – 300 amu |

H-P systems Scan time:

| | |
|---|---|
| Number A/D Samples | 22 (4) |
| Integration Time/Sample | 50 microsec |
| Total Scan Time | 0.6 sec |

B. Tuning:

Tune the GC/MS system to meet the criteria in Table 1 following a 50-ng injection of BFB. The chromatographic conditions must be the same as those under which the samples are analyzed except that the temperature ramp may be increased and the initial temperature and flow rate may be different. The BFB tune must be verified every 12 hours.

The tune must be evaluated by taking the average of the three scans across the BFB peak apex with a background subtraction of a scan within 20 scans prior to the start of the BFB peak.

**NOTE:** All standards, samples, and associated quality control samples must be analyzed with the same mass spectrometer parameters as those used to obtain a successful tune.

C. Initial Calibration:

1. Perform the initial calibration by analyzing at least six distinct levels of analyte concentration. For high level soils, the surrogates are also analyzed at each distinct level. Response factors for each analyte are determined from these levels. Six levels are required if second order regression fits are used. Calibration for GRO consists of analyzing

Uncontrolled Copy

six distinct levels of GRO area in order to produce a response factor for the GRO quantitation range of interest using the internal standard, fluorobenzene. The relative standard deviation of the response factor determines the suitability of the average relative response factor for calculation of the GRO concentration. The relative standard deviation of the response factors determines the suitability of the average relative response factor for calculation of the analyte or GRO concentration. Prior to the analysis of any calibration level, retention time markers must be run for the GRO range of interest. The retention time markers are hexane (C6) and Dodecane (C12). Other markers can be used if different ranges are required by a project.

**NOTE:** 5 levels are required by the method.

2. A method detection limit (MDL) standard must be analyzed with each initial calibration. This standard is prepared at or near the departmental MDL and is not to be included in the calibration curve. All compounds must be detected at or below MDL standard.

3. For medium/high level soils, methanol is added to all calibration standards. For low-level soils prepared according to EPA Method 5035, 1 scoop (approximately .50 -.75 grams) of sodium bisulfate is added to all calibration standards.

4. When using an autosampler, blanks and standards are prepared and poured into 40-mL vials with Teflon-lined septa. For the high-level method, 5 mL is withdrawn from the vial and transferred to the sparge vessel along with the appropriate amount of the internal standard spiking solution. For the low-level method, the autosampler transfers 5 mL of reagent water along with the appropriate amount of IS/SS spiking solution to the 40-mL vial.

5. Purge and desorb according to conditions listed in Calibration A.2.

6. Collect GC/MS data until the end of the GC run.

7. Empty and rinse the purging chamber at least twice with reagent water prior to loading another sample into the vessel, to minimize the possibility of carryover contamination.

8. Each level is analyzed as described above. Next, tabulate the area response of the characteristic ions (Table 2) against concentration for each analyte, surrogate standard, and internal standard and calculate relative response factors (RRF) for each compound (see Calculation section). The following table describes the guidelines for an acceptable initial calibration:

| Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Initially and then when analytes in the daily calibration standard fail criteria. | 1. % RSD of ≤20% is required for all analytes. 10% of the analytes may fail this criteria.<br><br>2. All compounds of interest must be detected in the MDL standard.<br><br>3. The relative retention times of the target compounds must agree within 0.06 relative retention time (RRT) units. The exception would be in the case of system maintenance.<br><br>4. Minimum response factors must be met for select compounds. See Table 3. | 1. Any target analyte with a %RSD of ≤20% must use the average RRF for quantitation. For any analyte in which the %RSD >20%, a first-degree linear regression can be used (providing that the correlation coefficient [CC] is ≥0.995). A quadratic fit ** (using 6 stds) can also be used (provided the coefficient of determination [CD] is >0.99). If the linear fit and quadratic fit pass the criteria for any given analyte, then use the line/curve with the smallest positive y-intercept. If the y-intercept quantifies to be greater than the LOQ, consult your supervisor immediately or recalibrate. If CC or CD is <0.995 for linear or <0.99 for quadratic, recalibrate. Supervisory approval is required for exceptions to these guidelines. If >10% target analytes fail, recalibration is required. If a linear or quadratic curve fit is used for a target analyte, the calibration data must be refit back into the calibration model for all calibration levels. Percent error between the calculated and expected amounts of an analyte should be ≤ 30% for all standards. For some data uses, ≤ 50% may be acceptable for the lowest calibration point.<br>NOTE: Quadratic regression cannot be used for South Carolina compliance samples.<br><br>2. If a compound is not detected in the MDL standard, then report to the level of the lowest standard detected.<br><br>3,4. Perform system maintenance and recalibrate. |

**Consult USEPA method 8000D for non-linear curve fitting techniques/guidelines

9. Each GRO level is analyzed as described above. Next, tabulate the area response for the GRO quantitation range minus the peak areas for the internal and surrogate standards that elute within the GRO range. Calculate the relative response factor (RRF) for GRO (see Calculation section) using the internal standard peak area for Fluorobenzene. Although four internal standard compounds are spiked for the 8260C analysis, only Fluorobenzene, is used for the quantitation of the GRO result.

10. Calculate the average relative response factors for the GRO quantitation range of interest. The calibration levels are evaluated on the basis of the relative standard deviation of the RRF values (%RSD). The %RSD for the GRO range of interest must be ≤20%. If the calibration meets this requirement, then the average RRF is used to calculate

sample concentrations. If the %RSD is >20% then re-analysis of one or more levels can be necessary before the calibration is valid.

D. Initial Calibration Verification:

Following the calibration, an Initial Calibration Verification (ICV) standard must be run. The ICV acts as a second source standard to check against the initial calibration. All analytes must meet ICV acceptance windows of 70%-130%. If the ICV does not meet the aforementioned criteria, a second ICV is analyzed before invalidating the initial calibration. Upon failure of the second ICV, the system must be recalibrated after proper corrective action is taken.

For the GRO analysis, the ICV acts as a second source standard to check against the initial calibration. Results must quantitate within the 70-130% window. If the ICV does not meet the aforementioned criteria, a second ICV can be run before invalidating the initial calibration. Upon failure of the second ICV, the system must be recalibrated after proper corrective action is taken.

E. Continuing Calibration:

Continuing Calibration Verification (CCV) – The CCV is performed by analyzing a 50-ppb calibration standard (prepared daily due to aqueous nature) in subsequent tune periods after an initial calibration. The CCV is considered valid when the criteria listed below are met:

| Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Every 12 hours. | 1. % Drift of ≤20% is required for all analytes. No more than 20% of analytes may fail this criteria if not detected in proceeding samples.<br><br>2. The relative retention times (RRT) of the target compounds must agree within 0.06 RRT units. The exception would be in the case of system maintenance.<br><br>3. The extracted ion current profile (EICP) area for each internal standard must fall within the window of –50 % to +100 % from the mid-level standard area produced during the last initial calibration.<br><br>4. Minimum response factors must be met for select compounds. See Table 3. | 1. - 4. In the event that the continuing calibration verification (CCV) standard fails any of these criteria, sample analysis must be suspended and the CCV must be re-analyzed. If the re-analysis fails any of the criteria then adjustments are to be made to the analytical system to return it to its original condition, followed by the analyses of 2 consecutive CCVs at the same level that failed. If both CCVs pass the criteria, then sample analysis can continue. Otherwise, the system must be recalibrated and the samples reanalyzed, or the data can be qualified. |

A 1100-ppb standard is analyzed for the GRO analysis. The calibration is considered valid if the percent drift is ≤20%. Also, the internal standard peak area of fluorobenzene for the CCV is monitored against the mid-point standard of the initial calibration and must be –50% to +100% of the area counts. If any criteria listed above fails, the CCV is considered invalid. In the case where two consecutive CCVs fail, corrective action must be taken which can include re-analysis of the calibration check, instrument maintenance, and/or recalibration. If the criteria are met, the selected quantitation method from the initial calibration is used for blank and sample calculations until the end of the 12-hour period.

F. MDL Sensitivity Check- A MDL Sensitivity Check must be analyzed in cases where compounds fail to meet the % drift criteria in the CCV and have decreased sensitivity (-20% drift or greater). Affected compounds can be reported as non-detects if it is demonstrated that there is adequate sensitivity to detect the compound at the MDL. If the failed compound is detected, the concentration must be reported as an estimated value.

## Calibration Calculations

1. Calculation of the relative response factor (RRF):

Uncontrolled Copy

$$RRF = \frac{[A(x) \times C(is)]}{[A(is) \times C(x)]}$$

**Where:**

A(x) = Characteristic ion area for the compound being measured

A(is) = Characteristic ion area for the specific internal standard

C(x) = Concentration of the compound being measured

C(is) = Concentration of specific internal standard

2. Regression equations:

1st Order (linear) regression: $Y = Mx + B$

2nd order (quadratic) regression: $Y = Cx2 + Mx + B$

**Where:**

x = Area(Std) /Area(Istd)

Y = Conc.(Std)/Conc.(Istd)

M = 1st degree slope

C = 2nd degree slope

B = Y-intercept

3. Percent relative standard deviation (%RSD):

$$\% \ RSD = \frac{Standard\ Deviation}{Mean} \times 100$$

4. Calculation of the percent drift:

$$\% \ Drift = \frac{C(i) - C(c)}{C(i)} \times 100$$

**Where:**

C(i) = Calibration check compound standard concentration

CI = Measured concentration using selected quantification method

## Procedure

A. Method Blank:

Analyze the method blank as described above for the initial calibration standards using reagent water. Refer to table in QA/QC section for specific requirements. The method blank is examined for interfering peaks. Any target compound peaks are calculated as described under the Calculations section of this procedure. All compounds must be less than the reporting limit for the associated samples. If the blank values exceed these values, corrective action must be taken and the method blank reanalyzed until the criteria are met. The method blank must be analyzed before processing any samples.

Controlled copy

B. Laboratory Control Sample/ Duplicate and Matrix Spike/Duplicate: Refer to table in QA/QC section for specific requirements.

**NOTE**: Per client request, the analyst may perform a compositing procedure prior to analysis. See Attachment 3, or the specific procedure provided by the client for this process.

C. Qualitative Analysis:

Sample analysis for soil, solids, and nonaqueous matrices proceeds as described in the Calibration section. The aqueous matrix is replaced by the soil sample, which is prepared according to *S-SS-WI10682* and *S-SS-WI11170*. A compound is identified by comparison of the following parameters with those of a standard of this target compound (standard reference spectra). In order to verify identification, the following criteria must be met:

1. The intensities of the characteristic ions of the compound must maximize in the same scan or within one scan of each other.

2. The compound relative retention time must compare within ±0.06 RRT units of the RRT of the standard.

3. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 30% relative intensity if less than three such ions occur in the reference spectrum.

4. The relative intensities of the characteristic ions must agree within 30% of the relative intensities of these ions in the reference spectrum. Analyst discretion is used to determine compound identification. (Example: for an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%).

5. The above criteria apply to hits greater than or equal to the LOQ. For hits between the MDL and the LOQ, both the above criteria and analyst discretion are used to determine compound identification.

6. The analyst must account for peaks that are greater than 10% relative intensity in the sample mass spectrum, but not present in the standard mass spectrum. Also, if a compound fails any of the criteria listed above but in the judgment of the mass spectral interpretation specialist is a correct identification, the identification is used and the quantitation of the peak is performed. The primary and secondary ions can be found in Table 2.

7. For the GRO analysis, the Total Ion Chromatogram (TIC) is reviewed to insure proper integration around the 8260 surrogates and internal standards. Also the TIC is checked to make sure all major peaks are integrated.

D. Quantitative Analysis:

Once a compound has been identified, quantitation of identified priority pollutant compounds is performed using the equations listed in the Calculations section of this SOP. The primary ions listed in Table 2 are used for quantitation. A secondary ion may be used if there is interference with the primary ion. All calculations must report concentrations in values of µg/kg. Any analyte with a calculated concentration above the highest standard must be reanalyzed at a dilution that brings the concentration in the solution within the calibration curve. It is desirable to have the dilution fall within the top half of the calibration curve, but it is not required.

The quantitation of the GRO range is performed using the equations listed in the Calculations section of this procedure. All calculations must report concentrations in values of µg/L. In the case where the total GRO concentration exceeds the calibration range, the sample is re-analyzed at a dilution that brings the GRO concentration within the calibration range of the GC/MS system.

## Calculations

A. Analyte Concentration

1. Low level

$$\text{Concentration } (\mu g/kg) \frac{(Ax)(Is)}{(Ais)(RRF)(Ws)}$$

**Where:**

Ax = Area of the quantitation ion peak for the compound to be measured
Ais = Area of the quantitation ion peak for the appropriate internal standard
Is = Amount of internal standard added in nanograms
Ws = Weight of sample purged
RRF = Relative response factor from the initial calibration

2. Medium/high level

Uncontrolled copy

$$Concentration\ (\mu g/kg) \frac{(Ax)\,(Is)\,(Vt)}{(Ais)\,(RRF)\,(Ws)\,(Vi)}$$

**Where:**

Ax = Area of the quantitation ion peak for the compound to be measured
Ais = Area of the quantitation ion peak for the appropriate internal standard
Is = Amount of internal standard added in nanograms
Vt = Volume of the total extract in microliters
Vi = Volume of the extract used for purging in microliters
Ws = Weight of sample extracted
RRF = Relative response factor from the initial calibration

B. QC Calculations:

$$\%\ Recovery = \frac{SSR - SR}{SA} \times 100$$

**Where:**

SSR = Spiked sample result

SR = Sample result

SA = Spike added

C. Relative percent difference (RPD)

$$RPD = \frac{MSR - MSDR}{(1/2)\ (MSR + MSDR)} \times 100$$

**Where:**

MSR = Matrix spike measured concentration

MSDR = Matrix spike duplicate measured concentration

## Statistical Information/Method Performance

The LCS must contain 80% to100% of the compounds in the calibration mix. LCS, MS, and surrogate recoveries and RPD are compared to the limits stored on the LIMS. These limits are statistically derived but must fall within 70% to 130% recovery for South Carolina compliance samples. Historical data for MS/Ds, LCS/Ds, measurement of uncertainty, is reviewed at least annually. Reporting limits including method detection limits (MDLs) and limits of quantitation (LOQs) are set according to EPA method requirements and are evaluated on an annual basis in accordance with 40 CFR Part 136. Updates to the LIMS are made as needed by the QA Department and only as directed by the supervisor. The department database is updated via a download from the LIMS.

## Quality Assurance/Quality Control

Each analysis batch must contain a method blank, a laboratory control sample (LCS), and either an unspiked background sample (US), a matrix spike (MS), a matrix spike duplicate (MSD), or a laboratory control sample/laboratory control sample duplicate (LCS/LCSD). Additional QC samples may be required to meet project or state certification requirements. For South Carolina, an LCS duplicate (LCSD) is only necessary per client request, or when adequate sample volume is not provided to prepare a matrix spike and matrix spike duplicate (MS/MSD). It is not appropriate to prepare and analyze an LCSD with each batch of samples if adequate sample volume has been provided for a MS/DUP or MS/MSD. Every sample or QC analysis must contain internal standards and surrogate compounds.

The laboratory will establish the Lower Limit of Quantitation (LLOQ) at concentrations where both quantitative and qualitative requirements can consistently be met for 8000D. The LLOQ is the lowest concentration at which the laboratory has demonstrated target analytes can be reliably measured and reported with a certain degree of confidence, which must be ≥ the lowest point in the calibration curve. The LLOQ/LLOQVs (Limit of Quantitation Verifications) are analyzed once per instrument per quarter. See SOP *QA-SOP11892*.

The GC/MS system must be tuned to meet the criteria in Table 1 following BFB injection. The chromatographic conditions must be the same as those under which the samples are analyzed except that the rate of temperature

ramping may be increased and the initial temperature and column flow may be different. The BFB tune must be verified every 12 hours.

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Internal Standards<br>• Added to every sample, standard, method blank or QC sample | 1. Peak areas within -50% to +100% of the area in the associated reference standard.<br><br>2. Retention time (RT) within 30 seconds of RT for associated reference standard. | 1. Check instrument for possible problems and then reanalyze samples.<br><br>2. If re-injecting meets the criteria, report this analysis.<br><br>3. If this reanalysis still shows the same problem, report results from first analysis and qualify data with a comment. |
| Surrogates<br>• Added to every sample, standard, method blank or QC sample | All % recoveries must fall within statistically derived QC limits, which are reviewed and updated on a semi-annual basis. | If non-compliant, check for calculation or preparation errors. If no errors are found, check system for problems and reanalyze. If this reanalysis still shows the same problem, report first analysis and qualify data with a comment. If recoveries are outside of specification high and no target compounds are detected then a reanalysis or comment is not required. |
| Method Blank (MB)<br>Performed during each tune period after the initial calibration or CCV (minimum of 1 MB per 20 samples)<br>• 1 scoop of Sodium Bisulfate is added if the preservative was added to the initial calibration.<br>• Approximately 5 grams of sand is required for low level analysis. | 1. Must meet internal standard criteria.<br><br>2. Must meet surrogate criteria.<br><br>3. Quantitative results for all target compounds must be less than the reporting limit for the associated samples. | 1,2. Inspect system for possible problems and reanalyze.<br><br>3. If the MB contains target analytes and the associated samples do not, then no corrective action is required. If the target compounds in the MB are also in the associated samples, then they must be reanalyzed after a clean MB is obtained (certain projects may allow some exceptions for common laboratory contaminants like methylene chloride and acetone up to 5X the LOQ) |
| Laboratory Control Sample/Laboratory Control Sample Duplicate (LCS/LCSD)<br>• LCS analyzed with each batch of ≤ 20 samples<br>• LCSD analyzed if MS/MSD unavailable<br>• Approximately 5 grams of sand is required for low level analysis.<br>• 1 scoop of Sodium Bisulfate is added if the preservative was added to the initial calibration. | 1. Must meet internal standard criteria.<br><br>2. Must meet surrogate criteria.<br><br>3. All % recoveries must fall within statistically derived QC limits, which are reviewed and updated on a semi-annual basis. | 1,2. If non-compliant, check for calculation or preparation errors. If no errors found, check system for problems and reanalyze.<br><br>3. If LCS/LCSD re-analysis still fails, perform appropriate system maintenance and restart the tune period. Only with an LCS % recovery failing high (for the requested target compounds) with targets non-detected in the sample, can the results be reported. Otherwise, the sample must be analyzed with a compliant LCS. |
| Matrix Spike/Matrix Spike Duplicate (MS/MSD)<br>• MS/MSD analyzed with each batch of ≤ 20 samples (if sufficient sample volume available) | 1. % Recoveries must fall within statistically derived QC limits, which are reviewed and updated on a semi-annual basis<br><br>2. RPDs within QC limits. | 1. If LCS within QC limits, proceed with sample analysis.<br><br>2. If most recoveries and/or RPDs outside of QC limits, consult the supervisor. |

The method blank must meet all the above criteria for internal standard recoveries and surrogate recoveries. In addition, the method blank may not contain any target compound above the reporting limit for the associated samples. All method blanks must meet these criteria; otherwise, the system is considered out of control and corrective action must be taken.

If sufficient sample volume is not available to perform MS/MSD, LCS/LCSD are prepared and analyzed and must meet the above-mentioned criteria.

**NOTE:** Prior to release from the analytical laboratory, all data is reviewed in accordance with *T-VOA-WI8373*.

Uncontrolled Copy

The sample is analyzed using the same instrumental conditions as the standard (whether ICAL or CCV), tune and method blank. If the QA criteria are satisfied and no target compounds are detected at concentrations above the calibration range, the results can be reported. To avoid possible matrix effects, sample carryover and re-analyses, an initial dilution may be performed if:

1. Prescreening indicates a high volatile organic content in the sample
2. Historical data (or lack thereof) and/or sample appearance indicate a need for dilution

If target compounds are detected in the sample at concentrations above the calibration range, a dilution must be performed (see *T-VOA-WI7692* for information on when cleaning blanks must be run). See method SW-846 8260C for the recommended dilution procedures.

**Table 1**

**BFB Key Ion Abundance Criteria**

| Mass | Ion Abundance Criteria |
|---|---|
| 50 | 15% to 40% of mass 95 |
| 75 | 30% to 60% of mass 95 |
| 95 | base peak, 100% relative abundance |
| 96 | 5% to 9% of mass 95 |
| 173 | less than 2% of mass 174 |
| 174 | greater than 50% of mass 95 |
| 175 | 5% to 9% of mass 174 |
| 176 | greater than 95% but less than 101% of mass 174 |
| 177 | 5% to 9% of mass 176 |

**Client-Specific Volatile Compositing**

1. Samples are collected using pre-tared methanol vials.
2. The client defines the decision unit and provides compositing instructions to the laboratory.
3. The Volatiles prep technician weighs each vial and records the initial weight of soil collected for each vial.
4. The Volatiles prep technician enters the initial combined weight and total methanol extract volume as the initial and final volumes in LIMS.
5. The Volatiles analyst removes an equal amount of methanol from each discrete sample vial, composited in an appropriately sized container and mixed well.

NOTE: Caution must be used to minimize handling time to avoid the loss of volatiles.

6. The initial combined weight and total methanol extract volume is used to calculate the results of the composited sample.

## Scope

This method is suitable for the determination of the target compounds listed and maintained in the LIMS (Laboratory Information Management System) for aqueous matrices. Associated MDLs/LOQs are also listed in the LIMS under the analysis number and/or Project Information lists. Non-target volatile compounds in the sample can be tentatively identified (TIC) using a mass spectral reference library comparison. This analysis must be performed by or under the direct supervision of an operator experienced in the analysis of volatile organics by purge and trap GC/MS methodologies and skilled in mass spectral interpretation. Using this method, the TICs are quantitated with an estimated concentration. Compounds other than those listed in the LIMS for this group of master scans are analyzed using USEPA SW-846 Method 8260C. A list of analytes listed under the method is included in the Appendix, as well as the Reagent Formulary Reports for the compounds in the method (Figures 1-2). Due to poor purging efficiency or poor gas chromatographic performance, some analytes require calibration at higher levels and higher practical quantitation limits (PQLs). Standards containing additional analytes must be prepared as described in the Standards section of this document. Both secondary stock solutions and matrix spike solutions must be prepared for use in analyzing additional compounds.

## Basic Principles

A 5-mL or 25-mL sample or a dilution of a sample is placed in a specially designed purge vessel. The sample is purged with an inert gas and the effluent gas passed through a sorbent tube where the volatile organics are trapped. After purging, the sorbent trap is rapidly heated and backflushed on to the head of a gas chromatographic (GC) capillary column. The GC column is temperature programmed to separate the volatile compounds, which are subsequently detected and identified using mass spectrometric techniques.

When a compound reaches the Mass Spectrometer, it is bombarded by high-energy electrons (70 eV). This causes the compound to fragment and form ions. The positive ions are focused into a quadrupole mass analyzer, where the ions are separated according to their mass/charge ratios during rapid repetitive scans. These ions are then amplified and detected with an electron multiplier.

The resulting time/intensity/mass spectra data are stored and processed by a computer. Target compounds are identified on the basis of relative retention times and mass spectral matches to standards, which are injected every 12 hours on the same system. The internal standard method is used for quantitation.

Uncontrolled Copy

The GRO analysis is typically performed in conjunction with the analysis of other volatile target compounds by SW-846 Method 8260C. The GRO quantitation range is 0.1 minutes before the peak apex of C6 (hexane) to 0.2 minutes after the peak apex of C12 (dodecane); however, other ranges can be established. By establishing a (C12) GRO window to 0.2 minutes following the elution of dodecane, the areas from a trio of unresolved peaks eluting near to the upper limit of the range must consistently be included in the total GRO area. In addition, the range remains tight enough to ensure that no C13 or greater compounds can be included in the total GRO area. The C4 range retention time is determined by selecting the first peak after the air and/or artifact peak minus 0.1 minutes in the first standard analyzed in the ICAL. The C5 range retention time is 0.1 minutes before the peak apex of pentane. This analysis must be performed by or under the direct supervision of an operator experienced in the analysis of volatile organics by GC/MS purge and trap methodologies. The area of the total ion chromatogram for the GRO range is determined. The area of the internal standards and surrogate standards are found and subtracted from the total area of the chromatogram within the desired time range. The resulting area is then quantitated versus the internal standard, fluorobenzene.

## Interferences

Contaminant sources are volatile compounds in the laboratory environment, impurities in the inert purging gas, carryover from samples containing high concentrations of volatile organic compounds and dirty glassware. The analyst must demonstrate that the system is free from interferences (by producing acceptable method blank data) before analyzing a batch of samples. Matrix effects from heavily contaminated waters can interfere with the internal standard responses, target analytes and surrogate recoveries, thereby hindering accurate quantitation. See Section 4.0 of SW-846 Method 8260C for further discussion.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

The toxicity or carcinogenicity of each reagent used in this method has not been precisely defined; therefore, each chemical compound must be treated as a potential health hazard. Exposure to these chemicals must be reduced to the lowest possible level by whatever means available, such as the use of fume hoods, safety glasses, lab coats, and gloves. Neat compound sources and stock solutions must be collected into a lab pack upon expiration. The lab pack is delivered to Safety personnel for appropriate disposal. Expired secondary standard solutions in methanol must be disposed of as solvent waste. Pour expired secondary standard solutions into the appropriate solvent waste collection container. Aqueous calibration standard mixes are disposed of as nonhazardous aqueous waste due to the low concentration. Samples with a pH ≤2 are taken to storage until disposal in an acid waste container.

## Personnel Training and Qualifications

Education Requirement: A 4-year Baccalaureate Degree from an accredited College or University in one of the physical sciences and/or one to three years of relevant gas chromatography experience.

Analysts must be trained in the proper method of volatile organic sample preparation and analysis as determined by the supervisor(s). All training and education relating to volatile organic sample preparation and analysis must be documented by each analyst in his/her training record. Specifically, each new chemist trains with an experienced chemist for the first 12 weeks depending on the individual and his/her previous experience. The first 12 weeks are spent working one-on-one with the trainer. This time is less if the new chemist has prior relevant experience in GC/MS and/or analytical chemistry background.

During the training period, the new chemist learns daily maintenance, calibration techniques, data and library search review, and forms generation. He/she is also required to read all relevant SOPs and EPA methods. All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP.

Each analyst must perform an Initial Demonstration of Capability <(IDOC) to measure proficiency. The IDOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation (per EPA 8000D the criteria are the statistical LCS window, and RPD ≤ 20%). Various options are available for a DOC and can include four laboratory control samples or one blind sample. Thereafter, an annual Demonstration of Capability is performed annually and is maintained in the analyst's training records.

**NOTE:** A separate Demonstration of Capability for GRO is required.

## Sample Collection, Preservation, and Handling

The samples to be analyzed with this method must be stored in a refrigerator at 0°C to 6°C, not frozen. Samples are collected in 40-mL vials with no headspace. Preserve samples to a pH of <2 in order to prevent degradation of aromatic compounds that are present in the sample. 1:1 HCL is the recommended preservative. Preserved samples must be analyzed within 14 days of collection; those that are not preserved must be analyzed within 7 days of

collection. Samples to be tested for Acrolein and Acrylonitrile must be collected without headspace in vials that are preserved to a pH range of 4.0 to 5.0 and must be analyzed within 7 days of collection. Samples may also be submitted in unpreserved vials for Acrolein and Acrylonitrile, but must be analyzed within 3 days of collection. Unpreserved samples from South Carolina for Acrolein and Acrylonitrile do not meet RCRA requirements and must be qualified. Samples submitted outside of the pH range or analyzed outside of the specified holding time windows will be reported with a comment on the final analytical report.

## Apparatus and Equipment

1. Gastight micro-syringes – 1 to 1000 µL (various sizes)

2. 5-mL gastight syringes

3. Analytical balance, capable of accurately weighing ±0.0001 g

4. Glassware

   a. Class-A Volumetric flasks with ground-glass stopper

   b. Vials, 1.5-mL, 15-mL, and 40-mL screw cap, with Teflon™/silicone septa

   c. Mininert vials, 1 mL, 2 mL, and 5 mL

5. Purge and trap device – Consisting of the sample purger, the trap, and desorber; the OI Analytical 4560, OI Analytical 4660, or equivalent meets the requirements of this method. The purging chamber must have the purge gas passing through the sample as finely divided bubbles and minimize the headspace between the sample and the trap to <15 mL.

6. Autosampler – OI Analytical 4551, OI Analytical 4552, Archon, or equivalent meets the requirements of this method.

7. Spiker unit – OI analytical Model 4551/4552 SAM/Spiker or equivalent. One or two automated syringe spikers can be added to the OI Analytical Model 4551/4552 autosampler to automatically introduce 1 µL of internal standard (ISTD), surrogate standard, and/or matrix spiking solutions to the sample as it is being transferred to the sparge vessel. The Archon has a groove that can deliver 1 µL of appropriate standards.

8. GC/MS system – The Agilent 5890GC/5972 MSD, Agilent 6890GC/5973MSD, Agilent 6890GC/5975MSD and Shimadzu GC/MS QP5000 meet the requirements for this method.

9. Data System/Computer/Software – this is interfaced to the GC/MS system that continuously acquires and stores data during the analysis, and can process/reduce data to generate the appropriate forms and supporting data. The software used for acquisition is HP Chemstation®, and data reduction is accomplished using Target® software.

10. GC Columns

   a. Column 1 – 30M × 0.25 mm ID DB624 capillary column with a 1.4-µm film thickness from Agilent, or equivalent (to be used with the Shimadzu QP5000 or the Agilent 5972, 5973 and 5975 MSDs)

   b. Column 2 – 20M × 0.18 mm ID DB624 capillary column with a 1.0-µm film thickness from Agilent, or equivalent (to be used with the Shimadzu QP5000 or the Agilent 5972, 5973 and 5975 MSDs)

   c. Column 3 – 20M × 0.18 mm ID DB-VRX capillary column with a 1.0-µm film thickness from Agilent, or equivalent (to be used with the Shimadzu QP5000 or the Agilent 5972, 5973 and 5975 MSDs)

   **NOTE:** Refer to *T-VOA-WI7619* for instrumentation maintenance and troubleshooting.

## Reagents and Standards

A. Reagents

   1. Reagent water is defined as water in which an interferent is not observed at or above the reporting limit for parameters of interest. In general, the deionized water supplied at the taps in the laboratory meets these criteria. If the reagent water does not meet the requirements, see your supervisor for further instructions.

   2. Methanol, Purge and Trap Grade or equivalent.

B. Standards

See *T-VOA-WI7629* for standards traceability.

   1. Stock standard solutions – Stock solutions must be prepared in methanol. Standards are prepared from ampulated and neat compounds obtained from suppliers that indicate the purity of the compound. No correction for purity is made if the purity is listed as ≥96%. Pre-made solutions can be used if the supplier documents the

Uncontrolled Copy

concentrations of the solutions. All ampulated standards are stored at ≤-10°C until the expiration date indicated by the vendor or for 1 year if no expiration date is provided.

a. For most of the target compounds, the stock standard solutions are purchased from a vendor as custom mixes (V for calibration and Q for separate source quality control). The internal and surrogate standards are purchased from a vendor, as well as the target compounds that are gases at room temperature. These gaseous standards have a 1-week expiration date, starting from the date they are opened.

b. 8260A Surrogate standard spiking solution (8260SS) – a 2500 µg/mL stock standard solution of dibromofluoromethane, toluene-d8, 4-bromofluorobenzene, and 1,2-dichloroethane-d4 is prepared in methanol by a commercial supplier.

c. 8260A Internal standard spiking solution (8260IS) – a 2500 µg/mL stock standard solution of fluorobenzene, chlorobenzene-d5, 1,4-dichlorobenzene-d4, and 12500 µg/mL deuterated tertiary butyl alcohol (tBA-d10) is prepared in methanol by a commercial supplier. Deuterated tertiary butyl alcohol (tBA-d10) is used sometimes as an auxiliary ISTD.

d. GRO calibration standard – a 5500-µg/mL stock unleaded gasoline composite prepared in methanol by a commercial supplier.

e. GRO QC standard – a 20,000-µg/mL stock unleaded gasoline composite prepared in methanol by a commercial supplier

To prepare stock standards from neat compounds:

(1) Place about 9.8 mL methanol or an equivalent solvent into a tared 10.0-mL glass-stoppered volumetric flask. Weigh the flask to the nearest 0.1 mg.

(2) Add the liquids using a syringe or pipette by adding 2 or more drops of the assayed material to the flask, being careful that no drop hits the side of the flask. Reweigh the flask, record/note the amount, dilute to volume, stopper, and mix by inverting the flask at least 3 times. Calculate the concentration of the standard.

(3) The stock standard solutions are stored in Teflon™-sealed screw-capped vials at ≤-10°C. The compound name, concentration, date prepared, expiration date, preparer name and storage method must appear on the bottle.

(4) Replace in-house prepared stock standard solutions every 6 months.

2. Secondary dilution standards - Using the stock standard solutions, prepare secondary stock solutions in methanol containing the desired compounds. These standards are prepared by calculating the volume of each stock standard required to produce a given volume of a mixed working standard with a known concentration of each analyte. When custom mixes are used, these are diluted down individually or combined together with other mixes. The working standard is tested according to *T-VOA-WI7629*. The verified working standard is poured into Teflon-lined screw-capped GC vials or mininert vials and stored at ≤-10°C. A designator indicating the standard name, month, and day of preparation and expiration date must be on the standard vials. The designator and all data pertaining to the working standard preparation are to be recorded in the standards logbook. Replace secondary dilution standards every 2-4 weeks (1 week for standards containing gases) unless otherwise indicated.

a. 1,4-Bromofluorobenzene (BFB) standard – Prepare a 50-µg/mL solution of BFB in methanol by diluting the stock standard (prepared from neat material) with methanol to a final volume of 100 mL. The volume of stock standard used varies depending on the actual stock concentration.

b. IS/SS spiking solution – Dilute 1 mL of 8260IS and 1 mL of 8260SS with methanol to 10-mL final volume (resulting in a concentration of 250 µg/mL, 1250 µg/mL for tBA-d10). This is assuming a 1-µL groove in the autosampler. If the groove is determined to be other than 1 µL, the standard preparation must be adjusted so that appropriate final concentration is obtained.(50& µg/L for 5-mL purge, 10 µg/L for 25-mL purge).

c. Calibration spiking solution – Prepare solutions in methanol that contain the compounds of interest at known concentrations. Suggested calibration levels are 1, 4, 10, 20, 50, 100, and 300 ppb for 5-mL purge analysis. Suggested calibration levels are 0.2, 0.5, 1, 2, 5, 10, and 25 ppb for 25-mL purge analysis. Replace calibration spiking solution every 2-4 weeks (1 week for standards containing gases).

d. Matrix spiking solution – Prepare second source solutions in methanol that contain the compounds of interest at known concentrations. These solutions serve as both the matrix spiking solution and the laboratory control sample solutions. Matrix spikes also serve as duplicates. Therefore, two aliquots of the same sample need to be spiked for analysis with these solutions. Replace matrix spiking solution every 2-4 weeks (1 week for standards containing gases).

Store all standard solutions at ≤-10°C and protected from light.

## Preparation of Glassware

All glassware is cleaned according to *T-VOA-WI7691*.

Uncontrolled Copy

## Calibration

A. Instrument conditions

1. The purge and trap device must have the trap conditioned for at least 10 minutes at 180° to 220°C at a flow rate of 20 to 60 mL/min prior to initial use.

2. An example of purge and trap conditions are listed below:

| | |
|---|---|
| Purge Gas | Helium |
| Purge Flow | 35 - 45 mL/min |
| Purge Temperature | 40°C for 8260C waters |
| Purge Time | 11 minutes |
| Desorb Temperature | 190°- 220°C |
| Desorb Time | 0.5 to 4 minutes ** |
| Bake Temperature | 180°-220°C |
| Bake Time | 5 – 16 min |

**Range as suggested by the purge and trap instrument manufacturer

**NOTE:** Purge and trap conditions are changed to optimize instrument operations. A record of actual purge and trap conditions for each instrument is found in the appropriate instrument maintenance log.

3. The suggested gas chromatographic operating conditions are listed in the table below, depending on the column used:

| | Column 1 | Column 2 | Column 3 |
|---|---|---|---|
| **Column liquid phase** | DB-624 | DB-624 | DB-VRX |
| **Carrier gas** | Helium | Helium | Helium |
| **Carrier gas flow** | 0.8 mL/min | 0.6 mL/min | 0.6 mL/min |
| **Make-up gas flow** | None | None | None |
| **Initial temperature** | 45°C | 45°C | 45°C |
| **Initial hold time** | 4.5 min | 2.5 min | 4 min |
| **Temperature ramp** | 12°/min until 100°C<br>then<br>25°/min until 240°C | 12°/min until 100°C<br>then<br>25°/min until 235°C | 25°/min until 60°C<br>then<br>36°/min until 240°C |
| **Final temperature** | 240°C | 235°C | 240°C |
| **Final hold time** | None | .02 min | 1 min |

4. The recommended mass spectrometer operating conditions are listed below:

| | |
|---|---|
| **Mass range:** | 35 – 300 amu |
| **Scan time:** | One scan cycle per second or less and resulting in at least five scans per chromatographic peak |

**NOTE:** It is not necessary to use the exact parameters listed above. Equivalent columns and conditions that give the performance required by the method are acceptable.

B. Tuning

Tune the GC/MS system to meet the criteria in Table 1 following a 50-ng injection of BFB. The chromatographic conditions must be the same as those under which the samples are analyzed except that the temperature ramp is increased and the initial temperature and flow rate is different. The BFB tune must be verified every 12 hours.

The tune must be evaluated by taking the average of the three scans across the BFB peak apex with a background subtraction of a scan within 20 scans prior to the start of the BFB peak.

**NOTE:** All standards, samples, and associated quality control samples must be analyzed with the same MS parameters as those used to obtain a successful tune.

C. Initial calibration

1. The initial internal standard calibration consists of analyzing seven distinct levels of analyte concentrations and producing response factors for each compound (six levels are required if second order regression fits are used). Calibration for GRO consists of analyzing six distinct levels of GRO area in order to produce a response factor for the GRO quantitation range of interest using the internal standard, fluorobenzene. The relative standard deviation of the response factor determines the suitability of the average relative response factor for calculation of the GRO concentration. The relative standard deviation of the response factors determines the suitability of the average relative

Uncontrolled Copy

response factor for calculation of the analyte concentration. Prior to the analysis of any calibration level, retention time markers must be run for the GRO range of interest. The retention time markers are hexane (C6) and Dodecane (C12). Other markers can be used if different ranges are required by a project.

**NOTE:** 5 levels of standard are required by the method.

a. When using an OI 4552 or OI 4551 autosampler, the standards (including target and surrogate compounds) are prepared and poured into 40-mL vials with Teflon™-lined septa. A 5-mL or 25-mL aliquot is withdrawn from the vial by the autosampler. The aliquot is transferred through the spiker unit to add the IS/SS spiking solution and then transferred to the sparge vessel.

b. Purge and desorb according to instrument conditions listed in Calibration A.

c. Collect GC/MS data until the end of the GC run.

d. Empty and rinse the purging chamber at least twice with reagent water prior to loading another sample into the vessel, to minimize the possibility of carryover contamination.

e. Each level is analyzed as described above. Next, tabulate the area response of the characteristic ions (Table 2) against concentration for each analyte, surrogate standard, and internal standard and calculate relative response factors (RRF) for each compound (see Calculation section). The calibration is valid for 12 hours from the injection of the BFB tune standard, at which time a new tune check and a continuing calibration check standard are evaluated prior to the analysis of additional samples. The following table describes the guidelines for an acceptable initial calibration:

| Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Initially and then when analytes in the daily calibration standard fail criteria. | 1. % RSD of≤20% is required for all analytes. 10% of the analytes may fail this criteria.<br><br>2. The relative retention times of the target compounds must agree within 0.06 relative retention time (RRT) units. The exception would be in the case of system maintenance.<br><br>3. Minimum response factors must be met for select compounds. See Table 3. | 1. Any target analyte with a %RSD of ≤20% must use the average RRF for quantitation. For any analyte in which the %RSD >20%, a first-degree linear regression can be used (providing that the correlation coefficient [CC] is ≥0.995). A quadratic fit ** (using 6 stds) can also be used (provided the coefficient of determination [CD] is >0.99). If the linear fit and quadratic fit pass the criteria for any given analyte, then use the line/curve with the smallest positive y-intercept. If the y-intercept quantifies to be greater than the LOQ, consult your supervisor immediately or recalibrate. If CC or CD is <0.995 for linear or <0.99 for quadratic, recalibrate. Supervisory approval is required for exceptions to these guidelines. If >10% target analytes fail, recalibration is required. If a linear or quadratic curve fit is used for a target analyte, the calibration data must be refit back into the calibration model for all calibration levels. Percent error between the calculated and expected amounts of an analyte should be ≤30% for all standards. For some data uses, ≤50% may be acceptable for the lowest calibration point.<br>NOTE: Quadratic regression cannot be used for South Carolina compliance samples.<br>2.-3. Perform system maintenance and recalibrate. |

**Consult USEPA method 8000D for non-linear curve fitting techniques/guidelines

f. Each level is analyzed as described above. Next, tabulate the area response for the GRO quantitation range minus the peak areas for the internal and surrogate standards that elute within the GRO range. Calculate the relative response factor (RRF) for GRO (see Calculation section) using the internal standard peak area for fluorobenzene. Although four internal standard compounds are spiked for the 8260C analysis, only one, fluorobenzene, is used for the quantitation of the GRO result.

Calculate the average relative response factors for the GRO quantitation range of interest. The calibration levels are evaluated on the basis of the relative standard deviation of the RRF values (%RSD). The %RSD for the GRO range of interest must be ≤20%. If the calibration meets this requirement then the average RRF is used to calculate sample concentrations. If the %RSD is >20% then re-analysis of one or more levels can be necessary before the calibration is valid.

D. Following the calibration, an Initial Calibration Verification (ICV) standard must be run. The ICV acts as a second source standard to check against the initial calibration. All analytes must meet ICV acceptance windows of 70%-130%. If the ICV does not meet the aforementioned criteria, a second ICV is analyzed before invalidating the initial calibration. Upon failure of the second ICV, the system must be recalibrated after proper corrective action is taken. For the GRO analysis, the ICV acts as a second source standard to check against the initial calibration. Results must quantitate within the 70-130% window. If the ICV does not meet the aforementioned criteria, a second ICV can be run before invalidating the initial calibration. Upon failure of the second ICV, the system must be recalibrated after proper corrective action is taken.

E. Continuing calibration verification (CCV) – The CCV is performed by analyzing a CCV standard in subsequent tune periods after an initial calibration. The CCV (prepared daily due to aqueous nature) is analyzed at 50 ppb for 5-mL purge waters and 10 ppb for 25-mL purge waters. The CCV is considered valid when the criteria listed below are met:

| Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Every 12 hours. | 1. % Drift of ≤20% is required for all analytes. No more than 20% of analytes may fail this criteria if not detected in proceeding samples.<br><br>2. The relative retention times (RRT) of the target compounds must agree within 0.06 RRT units. The exception would be in the case of system maintenance.<br>3. The extracted ion current profile (EICP) area for each internal standard must fall within the window of –50 % to +100 % from the mid-level standard area produced during the last initial calibration.<br>4. Minimum response factors must be met for select compounds. See Table 3. | 1.-4. In the event that the continuing calibration verification (CCV) standard fails any of these criteria, sample analysis must be suspended and the CCV must be re-analyzed. If the re-analysis fails any of the criteria then adjustments are to be made to the analytical system to return it to its original condition, followed by the analyses of 2 consecutive CCVs at the same level that failed. If both CCVs pass the criteria, then sample analysis can continue. Otherwise, the system must be recalibrated and the samples reanalyzed, or the data can be qualified. |

A 1100-ppb standard (prepared daily due to aqueous nature) is analyzed for the GRO analysis. The calibration is considered valid if the percent drift is ≤20%. Also, the internal standard peak area of fluorobenzene for the CCV is monitored against the mid-point standard of the initial calibration and must be –50% to +100% of the area counts. If any criteria listed above fails, the CCV is considered invalid. In the case where two consecutive CCVs fail, corrective action must be taken which can include re-analysis of the calibration check, instrument maintenance, and/or recalibration. If the criteria are met, the selected quantitation method from the initial calibration is used for blank and sample calculations until the end of the 12-hour period.

F. MDL Sensitivity Check- A MDL Sensitivity Check must be analyzed in cases where compounds fail to meet the % drift criteria in the CCV and have decreased sensitivity (-20% drift or greater). Affected compounds can be reported as non-detects if it is demonstrated that there is adequate sensitivity to detect the compound at the MDL. If the failed compound is detected, the concentration must be reported as an estimated value.

## Procedure

A. Method Blank

Analyze the method blank as described above for the initial calibration standards using reagent water. Refer to table in QA/QC section for specific requirements. The method blank is examined for interfering peaks. Any target compound peaks are calculated as described under the Calculations section of this procedure. All compounds must be less than the reporting limit for the associated samples. If the blank values exceed these values, corrective action must be taken and the method blank reanalyzed until the criteria are met. The method blank must be analyzed before processing any samples.

B. Laboratory Control Sample/ Duplicate and Matrix Spike/Duplicate: Refer to table in QA/QC section for specific requirements.

C. Qualitative analysis

A compound is identified by comparison of the following parameters with those of a standard of this suspected compound (standard reference spectra). In order to verify identification, the following criteria must be met:

1. The intensities of the characteristic ions of the compound must maximize in the same scan or within one scan of each other.

2. The compound relative retention time must compare within ±0.06 RRT units of the RRT of the standard.

3. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 30% relative intensity if less than three such ions occur in the reference spectrum.

4. The relative intensities of the characteristic ions must agree within 30% of the relative intensities of these ions in the reference spectrum. Analyst discretion is used to determine compound identification. Example: for an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%).

5. The above criteria apply to hits greater than or equal to the LOQ. For hits between the MDL and the LOQ, both the criteria listed above and the analyst's discretion is used to determine compound identification.

6. The analyst must account for peaks that are greater than 10% relative intensity in the sample mass spectrum, but not present in the standard mass spectrum. Also, if a compound fails any of the criteria listed above but in the

Uncontrolled Copy

judgment of the mass spectral interpretation specialist is a correct identification, the identification is used and the quantitation of the peak is performed.

The primary and secondary ions for the target compounds can be found in Table 2.

7. For GRO, the Total Ion Chromatogram (TIC) is reviewed to insure proper integration around the 8260 surrogates and internal standards. Also the TIC is checked to make sure all major peaks are integrated.

D. Quantitative analysis

Once a compound has been identified, quantitation is based on the internal standard technique and the integrated area from the extracted ion current profile (EICP) of the primary characteristic ion. The list of primary characteristic ions is listed in Table 2.

The quantitation of the GRO range is performed using the equations listed in the Calculations section of this procedure. All calculations must report concentrations in values of µg/L. In the case where the total GRO concentration exceeds the calibration range, the sample is re-analyzed at a dilution that brings the GRO concentration within the calibration range of the GC/MS system.

E. Sample Analysis

A 5-mL or 25-mL aliquot of the sample is analyzed using the same instrumental conditions as the standard (whether ICAL or CCV), tune and method blank. If the QA criteria are satisfied and no target compounds are detected at concentrations above the calibration range, the results can be reported. To avoid possible matrix effects, sample carryover and re-analyses, an initial dilution is performed if:

1. Prescreening indicates a high volatile organic content in the sample

2. Historical data (or lack thereof) and/or sample appearance indicate a need for dilution

If target compounds are detected in the sample at concentrations above the calibration range, a dilution must be performed (See *T-VOA-WI7692* for information on when cleaning blanks must be run). See Section 11.5.6 in method SW-846 8260C for recommended dilution procedures.

## Calculations

A. Calibration calculations

1. Calculation of the relative response factor (RRF):

$$RRF = \frac{[A(x) \times C(is)]}{[A(is) \times C(x)]}$$

**Where:**

A(x) = Characteristic ion area for the compound being measured

A(is) = Characteristic ion area for the specific internal standard

C(x) = Concentration of the compound being measured

C(is) = Concentration of specific internal standard

2. Regression Equations:

1st Order (linear) regression: Y = MX + B

2nd order (quadratic) regression: Y = CX2 + MX + B

**Where:**
x = Area(Std) /Area(Istd)
Y = Conc.(Std)/Conc.(Istd)
M = 1st degree slope
C = 2nd degree slope
B = Y-intercept

Uncontrolled copy

3. Percent relative standard deviation (%RSD):

$$\%\ RSD = \frac{Standard\ Deviation}{Mean} \times 100$$

4. Calculation of the percent drift:

$$\%\ Drift = \frac{C(i) - C(c)}{C(i)} \times 100$$

**Where:**
C(i) = Calibration check compound standard concentration
C(c) = Measured concentration using selected quantification method

B. QA Calculations

1. Calculation of percent recovery

$$\%\ Recovery = \frac{SSR - SR}{SA} \times 100$$

**Where:**

SSR = Spiked sample result

SR = Sample result

SA = Spike added

2. Relative percent difference (RPD):

$$RPD = \frac{MSR - MSDR}{(1/2)\ (MSR + MSDR)} \times 100$$

**Where:**

MSR = Matrix spike measured concentration

MSDR = Matrix spike duplicate measured concentration

3. Analyte Concentration

$$Concentration\ (\mu g/L) = \frac{(Ax)\ (Is)}{(Ais)\ (RRF)}$$

**Where:**

Ax = Area of the quantitation ion peak for the compound to be measured

Ais = Area of the quantitation ion peak for the appropriate internal standard

Is = Concentration of internal standard added in µg/L

RRF = Relative response factor from the initial calibration

**Statistical Information/method Performance**

Uncontrolled copy

The LCS must contain 80% to100% of the compounds in the calibration mix. LCS, MS, and surrogate recoveries and RPD are compared to the limits stored on the LIMS. These limits are statistically derived but must fall within 70% to 130% recovery for South Carolina compliance samples. Historical data for MS/Ds, LCS/Ds, measurement of uncertainty, is reviewed at least annually. Reporting limits including method detection limits (MDLs) and limits of quantitation (LOQs) are set according to EPA method requirements and are evaluated on an annual basis in accordance with 40 CFR Part 136. The MDLs are maintained in the LIMS. Updates to the LIMS are made as needed by the QA Department and only as directed by the supervisor. The department database is updated via a download from the LIMS.

## Quality Assurance/Quality Control

Each analysis batch (consisting of no more that 20 samples) must contain a method blank, a laboratory control sample (LCS), and either an unspiked background sample (US), a matrix spike (MS), a matrix spike duplicate (MSD), a laboratory control sample/laboratory control sample duplicate (LCS/LCSD) or a duplicate (DUP). The LCS serves as a 2nd source standard verification of the initial calibration (ICAL). Additional QC samples are required to meet project or state certification requirements. Every sample or QC analysis must contain internal standards and surrogate compounds at a concentration of 50 µg/L for a 5-mL purge or 10 µg/L for a 25-mL purge. For South Carolina samples, an LCS duplicate (LCSD) is only necessary per client request, or when adequate sample volume is not provided to prepare a matrix spike and matrix spike duplicate (MS/MSD). It is not appropriate to prepare and analyze an LCSD with each batch of samples if adequate sample volume has been provided for a MS/DUP or MS/MSD.
The laboratory will establish the Lower Limit of Quantitation (LLOQ) at concentrations where both quantitative and qualitative requirements can consistently be met for 8000D. The LLOQ is the lowest concentration at which the laboratory has demonstrated target analytes can be reliably measured and reported with a certain degree of confidence, which must be ≤ the lowest point in the calibration curve. The LLOQ/LLOQVs (Limit of Quantitation Verifications) are analyzed once per instrument per quarter. See SOP *QA-SOP11892*.

The GC/MS system must be tuned to meet the criteria in Table 1 following BFB injection. The chromatographic conditions must be the same as those under which the samples are analyzed except that the rate of temperature ramping may be increased and the initial temperature and column flow may be different. The BFB tune must be verified every 12 hours.

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| 1. Internal Standards<br><br>Added to every sample, standard, method blank and QC sample | 1. Peak areas within -50% to +100% of the area in the associated reference standard.<br><br>2. Retention time (RT) within 30 seconds of RT for associated reference standard. | 1. Check instrument for possible problems and then reanalyze samples.<br><br>2. If re-injecting meets the criteria, report this analysis.<br><br>3. If this reanalysis still shows the same problem, report results from first analysis and qualify data with a comment. |
| 2 Surrogates<br><br>Added to every sample, standard, method blank and QC sample | All % recoveries must fall within statistically derived QC limits, which are evaluated on a semi-annual basis. | If non-compliant, check for calculation or preparation errors. If no errors are found, check system for problems and reanalyze. If this reanalysis still shows the same problem, report first analysis and qualify data with a comment. If recoveries are outside of specification high and no target compounds are detected, then a reanalysis or comment is not required. |
| 3 Method Blank (MB)<br><br>Performed during each tune period after the initial calibration or CCV (minimum of 1 MB per 20 samples) | 1. Must meet internal standard criteria.<br><br>2. Must meet surrogate criteria.<br><br>3. Quantitative results for all target compounds must be less than the reporting limit for the associated samples. | 1.-2.Inspect system for possible problems and reanalyze.<br><br>3. If the MB contains target analytes and the associated samples do not, then no corrective action is required. If the target compounds in the MB are also in the associated samples, then they must be reanalyzed after a clean MB is obtained (certain projects may allow some exceptions for common laboratory contaminants like methylene chloride and acetone up to 5X the LOQ) |

Uncontrolled Copy

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Laboratory Control Sample/Laboratory Control Sample Duplicate (LCS/LCSD)<br><br>LCS analyzed with each batch of ≤ 20 samples<br>LCSD analyzed if MS/MSD unavailable. | 1. Must meet internal standard criteria.<br><br>2. Must meet surrogate criteria.<br><br>3. All % recoveries must fall within statistically derived QC limits, which are evaluated on a semi-annual basis. | 1.-2. If non-compliant, check for calculation or preparation errors. If no errors found, check system for problems and reanalyze.<br><br>3. If LCS/LCSD re-analysis still fails, perform appropriate system maintenance and restart the tune period. Only with a LCS % recovery failing high (for the requested target compounds) with targets non-detected in the sample, can the results be reported. Otherwise, the sample must be analyzed with a compliant LCS. |
| Matrix Spike/Matrix Spike Duplicate (MS/MSD)<br><br>MS/MSD analyzed with each batch of ≤ 20 samples (if sufficient sample volume available). | 1. % Recoveries must fall within statistically derived QC limits, which are evaluated on a semi-annual basis<br><br>2. RPDs within QC limits. | 1. If LCS within QC limits, proceed with sample analysis.<br><br>2. If most recoveries and/or RPDs outside of QC limits, consult the supervisor. |

**NOTE:** Prior to release from the analytical laboratory, all data is reviewed in accordance with *T-VOA-WI8373* or *T-VOA-WI8400* (dual purge and trap).

**Table 1**

**BFB Key Ion Abundance Criteria**

| Mass | Ion Abundance Criteria |
|---|---|
| 50 | 15% to 40% of mass 95 |
| 75 | 30% to 60% of mass 95 |
| 95 | base peak, 100% relative abundance |
| 96 | 5% to 9% of mass 95 |
| 173 | less than 2% of mass 174 |
| 174 | greater than 50% of mass 95 |
| 175 | 5% to 9% of mass 174 |
| 176 | greater than 95% but less than 101% of mass 174 |
| 177 | 5% to 9% of mass 176 |

| Type: | ASTD | Expiration Date: | 03/01/2023 |
| Description: | A0184815 Custom Gases Primary Standa | Laboratory: | Eurofins Lancaster Laboratories Envir |
| No. of Bottles: | 5 | Prepared By: | Long, Jason M |
| Storage Location: | VOA-C148-F | Vendor: | Restek |
| Reagent Volume: | 1.000 mL | Vendor Lot #: | A0184815 |
| Creation Date: | 11/02/2022 | Vendor Cat #: | 577488 |
| Open Date: | 02/22/2023 | | |
| Container(s): | 3514559, 3909488, 3909489, 3909490, 3909491 | | |
| Comment: | | | |

MSV_DME_00051

# Reagent ID: MSV_DME_00051

| | | | |
|---|---|---|---|
| Type: | ASTD | Expiration Date: | 12/12/2023 |
| Description: | V DME Lot A0190883 | Laboratory: | Eurofins Lancaster Laboratories Envir |
| No. of Bottles: | 1 | Prepared By: | Long, Jason M |
| Storage Location: | VOA-C148-F | Vendor: | Restek |
| Reagent Volume: | 1.000 mL | Vendor Lot #: | A0190883 |
| Creation Date: | 11/07/2022 | Vendor Cat #: | 564156 |
| Open Date: | 11/12/2023 | | |
| Container(s): | 3514299 | | |
| Comment: | Exp: 08/19/2025 | | |

## Reagent Analyte Information

| Analyte | Source ID | Source Exp. Date | Source Conc. | Source Conc. Units | Final Conc. | Final Conc. Units |
|---|---|---|---|---|---|---|
| Dimethyl ether | | | | | 1000.00000 | ug/mL |

## Scope

This SOP describes analysis of the parameters noted below and the instrument maintenance and operating conditions for the ManTech system. The ManTech Multi-Parameter System is an instrument used for the determination of the following analytes (see table below) in drinking waters, surface waters, and wastewater samples.
The table below lists the name and LIMS ID number of the analyses that are included in this SOP and the method references associated with each.

**Table of Analyses and Reference Methods**

| Analysis Name | LIMS ID | Analysis Method |
|---|---|---|
| Acidity to pH 3.7 and pH 8.3 (titrimetric) | 305.2 | EPA 305.2 |
| Fluoride | 340.2<br>4500_F_C | See *T-WC-WI53655* |

## Basic Principles
Samples are analyzed using the ManTech Multi-Parameter System, which has been designed to test for specific analytes. The system is able to be configured in different ways to optimize sample volumes required, and analysis times. The ManTech system is able to analyze for one parameter or multi-parameters at the same time.

## Reference Modifications
The following analyses have reference modifications:

1. Method 2340C - Total Hardness:

   a. The procedures listed in SM 2340C and Method 130.2 are modified by using potassium cyanide (KCN) as the inhibitor instead of sodium cyanide (NaCN).

   b. SM2340C and EPA 130.2 state to dilute 25 mL of sample to 50 mL with reagent water prior to titration. This procedure uses 50 mL sample.

2. Method SM4500NH#_D, 350.3 – Ammonia-Nitrogen and Distilled Ammonia-Nitrogen
Instead of using NaOH in order to pH adjust the samples during the ammonia analysis, this procedure uses alkaline reagent. Alkaline reagent is a purchased reagent containing NaOH that is currently recommended by the manufacturer of the ammonia electrode.

## Interferences
Sample matrix is likely to be the largest cause of interference for each analysis.

Samples containing oily layers, soaps, suspended solids, or precipitates may impede the electrode response. The electrode must be cleaned according to the manufacturer's instructions.

Total Hardness – excessive amounts of heavy metals can interfere, causing a faded or indistinct endpoint by the stoichiometric consumption of EDTA. If this interference is not resolved after multiple dilutions on the ManTech automated procedure, then the sample must be analyzed using the manual procedure. See SM 2340C for more discussion on interferences and how to treat them.

Ammonia Nitrogen – volatile amines are a positive interference. Mercury and Silver also interfere with this procedure. Electrode responds slowly at levels <1 mg NH3-N/L; use longer electrode immersion times.

See individual analytical SOPs for interferences.

## Safety Precautions and Waste Handling
All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

## Personnel Training and Qualifications
All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is

maintained in the analyst's training records.

Initially, each technician performing these techniques must work with an experienced technician for a period of time until they can independently perform the procedure. Proficiency is measured through an Initial Demonstration of Capability (IDOC).

The IDOC consists of four aliquots spiked at 1-4X the RL that are carried through all steps of the procedure. The criteria include the calculation of mean accuracy of 50 - 150% and standard deviation of less than 20%.

The DOC consists of four laboratory control spikes (or alternatively, one blind sample for the DOC) that are carried through all steps of the procedure and meet the LCS acceptance criteria and standard deviation of less than 20%.

## Sample Collection, Preservation, and Handling

Samples for Total Acidity, and Acidity to pH 3.7 and pH 8.3 are to be collected with minimum aeration and analyzed within 14 days of collection.

Samples for Ammonia must be collected in a glass container, preserved with concentrated sulfuric acid to a pH < 2. Analyze within 28 days of collection.

Samples for Total Hardness must be collected in a glass or plastic container, preserved with nitric acid to a pH < 2. Analyze within 6 months of collection.

All samples must be stored at 0° to 6°C, not frozen. Prior to analysis, samples must be brought to room temperature.

See individual analytical SOPs for sampling and preservation requirements.

## Apparatus and Equipment

1. ManTech Multi-Parameter System instrument:

   The instrument is equipped and programmed to analyze for pH, temperature of pH, alkalinity, acidity, conductivity, fluoride, ammonia and total hardness.

   Each test can be performed individually or in tandem with others. The analyst will determine the combination of analyses for each run.

   a. pH Electrode

   b. Fluoride ion selective electrode

   c. Interface

   d. Burivar I/2 (25 mL burette)

   e. TitraRinse pump

   f. TitraRinse slow speed reagent addition pump

   g. Reversible Peri-Max pump

   h. ManTech photometric detector with a 620nm filter

   i. Conductivity/TDS Meter, Model 4510

   j Ammonia electrode

   k. Autosampler - MEGA, 197 sample locations

2. Ammonia Distillation LIMS ID SM4500NH3_B

a. Kjeldahl distillation rack

b. Refrigerated recirculator (Coolflow) with a recirculating pressure set at 20 psi and the temperature adjustment set at 10°C, or equivalent.

c. Glass distillation apparatus with connector and 800 mL Kjeldahl flask

d. pH indicator strips, purchased

e. Porous boiling chips, purchased

f. 500 mL class A graduate

g. 400 mL (approx.) distillation collection cups

h. 800 mL (approx.) sample collection cups

i. Kjeldahl flasks

j. 5 mL class A pipette

3. Total Acidity Preparation LIMS ID SM2310B_Prep

a. pH meter with pH electrode and automated temperature compensator (ATC) probe that reads to 0.05 pH units

b. Magnetic stir bar and stir plate

c. Hot plate

d. 150-mL glass beakers and plastic cups

## Reagents and Standards

Alternative weights and volumes are acceptable as long as final concentrations remain the same.

A. Reagents and Standards needed for ManTech Analyses

1. Standardized Sulfuric acid, 0.02 N

a. Dilute 0.6 mL of concentrated sulfuric acid to 1000 mL with reagent water.

b. Store at room temperature in glass or plastic container and re-evaluate yearly.

c. Standardize according to *T-WC-WI10362*.

d. Re-standardize titrant before use if more than 30 days have passed since the last standardization date.

2. Sodium hydroxide, 10 N - Purchased; see container for shelf life information. Or prepare:

a. Dissolve 400 ± 0.5 g NaOH pellets in 1000 mL volumetric flask containing approximately 800 mL reagent water. Solution becomes very warm.

b. Cool to room temperature and dilute to 1000 mL with reagent water.

c. Store at room temperature in plastic or glass container and re-evaluate yearly.

3. Sodium hydroxide, 1.0 N

a. In a 1-L glass volumetric flask containing approximately 500 mL reagent water, dissolve 40.00 ± 0.05 g NaOH.

b. Cool and dilute to volume.

c. Store at room temperature in plastic or glass container and re-evaluate yearly.

4. Standardized Sodium Hydroxide, 0.02 N

a. In a 1-L glass volumetric flask, add approximately 500 mL reagent water.

b. Add 20 mL of 1 N NaOH to the flask and dilute to volume with reagent water.

c. Store at room temperature in glass or plastic container and re-evaluate yearly.

d. Standardize using instructions as per *T-WC-WI11585*.

e. Re-standardize titrant before use if more than 30 days have passed since the last standardization date.

5. Total alkalinity standard (9400 mg/L as $CaCO_3$)

a. Dry sodium carbonate ($Na_2CO_3$) for at least 4 hours at approximately 250°C.

b. Desiccate approximately 2 hours.

c. Dissolve 9.954g ± 0.002g $Na_2CO_3$ in reagent water and dilute to 1000 mL in a volumetric flask.

d. Solution expires 3 months from the date of preparation.

e. Store in a glass container at 0º to 6ºC, not frozen.

f. Dilute for other concentrations.

6. TISAB III, purchased. See container for storage conditions.

7. Ammonia nitrogen standard (100 m/L $NH_3$-N)

a. Dry ammonium chloride (NH4Cl) at 103°C to 105°C for approximately 2 hours.

b. Desiccate approximately 1 hour.

c. Dissolve 0.3819 ± 0.0002 g $NH_4Cl$ in approximately 800 mL reagent water.

d. Once dissolved, preserve the solution with concentrated sulfuric acid to a pH < 2. Dilute to 1000 mL in a volumetric flask.

e. Stable for 6 months.

f. Store at 0º - 6º C, not frozen in a glass or plastic container.

g. Dilute as needed for other concentrations.

**NOTE**: The Ammonia nitrogen standard used to prepare the calibration curve must be prepared using a **different source** of NH4Cl.

8. Ammonia electrode storage solution- purchased. See container for shelf life information.

9. Standard EDTA titrant (0.02N) - Purchased; see container for shelf life information.

10. pH 10 hardness buffer solution – purchased; see container for shelf life information. Or prepare:

a. Dissolve 16.9 g ammonia chloride ($NH_4Cl$) in 143 mL of concentrated ammonium hydroxide ($NH_4OH$).

b. Separately, dissolve 1.179 ± 0.0005 g of disodium EDTA and 0.78 ± 0.005 g of ($MgSO_4 \cdot 7$ H2O) in 50 mL of reagent water (this solution becomes turbid).

c. Combine the above two solutions and dilute to 250 mL with reagent water in a volumetric flask.

d. Solution is stable 30 days.

e. Store at room temperature in plastic container.

11. Calmagite indicator solution (0.1 % w/v) – Purchased; Store at room temperature. See manufacturer's label for expiration date.

12. Calcium reference standard (1000 mg/L Ca = 2497 mg/L $CaCO_3$) – Purchased; store at room temperature. See manufacturer's label for expiration date.

13. 1000 mg/L $CaCO_3$ intermediate calcium standard

a. Pipette 20.0 mL of purchased reference standard into 50 mL volumetric flask and dilute to volume with reagent water.

b. Stable for 6 months.

c. Store at room temperature in glass or plastic container.

14. 15% w/v Sodium Acetate Solution – Add 85 mL of reagent water to a 150 mL beaker. Dissolve 15.0 g ± 0.01 g of sodium acetate anhydrous into the reagent water. Prepare fresh before use.

15. Total acidity standard (5000 mg/L as $CaCO_3$)

a. In a 1-L glass volumetric flask containing approximately 500 mL of reagent water; add 20.4000 ± 0.0005 g potassium hydrogen phthalate, dried at 120 degrees C for 2 hours. Cool in desiccator for approximately 1 hour.

b. Allow to dissolve and dilute solution to volume.

c. Store at 0°to 6°C, not frozen, in a glass container.

d. Solution expires 6 months from the date of preparation.

16. Hydrogen peroxide ($H_2O_2$, 30% solution) – purchased. Store at room temperature. See label for expiration date.

17. pH 8.00 buffer Solution; purchased. Store at room temperature. See container for shelf life information.

B. **Reagents needed for LIMS ID SM4500NH3_B – Ammonia distillation:**

1. Borate buffer solution – Dissolve 19.0 ± 0.1 g sodium borate, 10-hydrate ($Na_2B_4O_7 \cdot 10\ H_2O$) in approximately 1000 mL of reagent water. Add 176 mL of 0.1N NaOH to the solution and dilute to 2000 mL with reagent water in a volumetric flask. Store at room temperature in a glass container. Solution stable for 6 months.

2. 0.1N $H_2SO_4$ – Dilute 3.0 mL of concentrated sulfuric acid to 1000 mL with reagent water in a volumetric flask. Store at room temperature in a glass or plastic container and re-evaluate yearly.

3. 4% $H_2SO_4$ Solution – Dilute 380 mL of 0.1N $H_2SO_4$ to 1000 mL with reagent water in a volumetric flask. Store at room temperature in a plastic container and re-evaluate yearly.

4. Antifoam B; purchased. Store at room temperature. See manufacturer's label for expiration date.

5. Sodium hydroxide, 5N – Dissolve 200 ± 0.5 g sodium hydroxide (NaOH) pellets in approximately 800 mL of reagent water. Solution becomes very warm. Cool to room temperature and dilute to 1000 mL with reagent water in a volumetric flask. Store at room temperature in plastic container and re-evaluate yearly. (This is used to pH adjust samples.)

6. Sodium hydroxide, 0.1N – Dilute 40 mL of 5N NaOH solution to 2000 mL with reagent water in a volumetric flask. Store at room temperature in a plastic container and re-evaluate yearly. (This is used in

borate buffer solution.)

7. Dilute Hydrochloric (HCl) acid – Add 50 mL of concentrated HCl to approximately 3.5 liters of reagent water. Slowly invert. Store at room temperature in a plastic container. (This is used to rinse tubing prior to steam cleaning the distillation apparatus.)

8. Ammonia-nitrogen standard, 500 mg/L $NH_3$-N – In a 1 L volumetric flask containing approximately 500 mL reagent water, dissolve 1.9095 ± .0002 g $NH_4Cl$ (which has been dried at 105° ± 2°C for at least 2 hours). Dilute to 1 L using reagent water. Preserve the solution with concentrated sulfuric acid to a pH <2. Store the standard at 0º to 6ºC, not frozen in a glass or plastic container. Standard expires 6 months from the date of preparation.

**C. Standards Preparation Needed for Linearity Check for LIMS ID 2510B, 120.1 and 9050A**

1. 0.1 M KCl (12,900 µhoms/cm) [Solution I]

   a. In a 1 L glass volumetric flask, dissolve 7.4555 ± .0001 g predried KCl (2 hours at 105° ± 2°C) in approximately 500 mL reagent water.

   b. Dilute to volume with reagent water.

   c. Solution expires 3 months from the date of preparation.

   d. Store at room temperature in a glass or plastic

2. 0.01 M KCL (1413 µhoms/cm) [Solution II

   a. In a 1-L volumetric flask, dissolve 0.7456 ± 0.0001 g predried KCl (2 hours at 105° ± 2°C) in approximately 500 mL reagent water.

   b. Dilute to volume with reagent water.

   c. Solution expires 3 months from the date of preparation.

   c. Store at room temperature in a glass or plastic container.

2. Prepare the following 8 standards in 100-mL volumetric flasks using Solutions I or II as indicated in the table below. Bring to volume with reagent water. Prepare fresh before use.

| Solution to use | Standard | mL of Solution | umhos/cm |
|---|---|---|---|
| Solution II | 0.0001 M | 1 | 14.94 |
| Solution II | 0.0005 M | 5 | 73.9 |
| Solution II | 0.001 M | 10 | 147 |
| Solution II | 0.005 M | 50 | 717.8 |
| Solution II | 0.01 M | 100 | 1,413 |
| Solution I | 0.02 M | 20 | 2,767 |
| Solution I | 0.05 M | 50 | 6,668 |
| Solution I | 0.1 M | 100 | 12,900 |

## Calibration

Calibration is performed daily. It is only necessary to calibrate for analyses that will be performed on that day.

Balances must be calibrated each day before use.

**NOTE:** For all calibrations, 50 mL of standard is poured into a sample tube. For each analysis, a predetermined and programmed sample volume is used (to be taken from the 50 mL in the sample tube).

**NOTE:** Recalibration is necessary for each analysis if acceptance criteria is not met.

A. LIMS ID SM4500NH3_D, 350.3 Ammonia Calibration

1. Curve: Prepare a calibration curve daily using the concentrations listed below.

The curve must be analyst specific.

| Conc. (mg/L NH3-N) | mL 100 mg/L ® 100 mL |
|---|---|
| 0.1 | 0.1 |
| 0.5 | 0.5 |
| 2.5 | 2.5 |
| 5.0 | 5.0 |
| 10.0 | 10.0 |

a. Ensure electrode is filled to line with appropriate fill solution (NH4Cl).

b. Dilute stock standard to obtain the following concentrations: 0.1, 0.5, 2.5, 5.0, 10.0 mg/L and place calibration standards into the sampler rack in ascending order, and pH 4 buffer into dip rinse (second rinse) position.

c. Sampler moves to flowing rinse station where electrode is rinsed with reagent water.

d. Sampler moves to dip station and electrode remains immersed in pH 4 buffer for 15 seconds.

e. Sampler moves to flowing rinse station where electrode is rinsed again with reagent water.

f. Sampler moves to first calibration standard position and stirrer is turned on.

g. 0.45 mL of ISA (10 N NaOH) is added to sample to adjust pH to 11 or greater, ensuring all NH4 is converted to NH3.

h. Ammonia electrode is allowed to stabilize and reading is recorded.

i. Steps c. - h. are repeated for remaining calibration standards.

j. Acceptance criteria: The slope of the curve must be between -54.0 to -60.0 mV. When linear fits are used, the % error is measured between the calculated and expected amounts to determine the calibration function acceptability. The % error must be ≤50% for the low calibration point and ≤10% for all other points of the calibration curve. This calculation is kept on file with the raw calibration data.

k. Record pH electrode ID, instrument ID, Employee ID, and date on calibration print out. Store in designated calibration folder.

l. Export and attach the curve to the analytical batch in LIMS.

B. Conductivity Meter Linearity Check (for Specific Conductivity analyses 2510B, 120.1, 9050A):

a. Linearity check of the conductivity meter must be performed on the instrument at least once per year using the following concentrations below. Refer to Reagents and Standards section for preparation instructions.

0 .0001M, 0.0005M, 0.001M, 0.005M, 0.01M, 0.02M, 0.05M, 0.1M

b. Fill tubes with standards in accending order by concentration and schedule the Mantech instrument to perform conductivity on all the standards.

c. Print out data from standards and keep in designated calibration folder for Conductivity.

d. Correlation Coefficient must be = 0.995. If this acceptance criteria is not met, the linearity check must be repeated.

## Procedure

### I. Preparation Procedures: Ammonia Distillation

A. LIMS ID SM4500NH3_B - Ammonia Distillation (for use with LIMS ID SM4500NH3_D)

1. Before each distillation, rinse tubes with dilute HCl. Add approximately 500 mL of reagent water to an 800-mL Kjeldahl flask to steam clean the distillation apparatus.

2. Connect Kjeldahl flask to glass adapter and hose. Turn on the Coolflow. Turn on the temperature control and distill until approximately 150 mL of water is collected in the beaker at the bottom of the setup. Remove distillate from delivery tube immediately after turning off heat source to avoid back wash during the cool-down phase.

3. Measure 500 mL of sample (or an aliquot diluted to 500 mL with reagent water) using a Class A graduated cylinder. Pour into a beaker and adjust the pH of the sample to 9.5 with 5N NaOH. Check pH of adjusted sample with purchased pH strips to ensure the pH is 9.5, and then add 25 mL of borate buffer solution.

4. Transfer the solution to an 800-mL Kjeldahl flask. Add a pinch of boiling chips and approximately 5 mL of antifoam B to the solution. Connect flask to glass adapter and hose. Turn on the Coolflow.

5. Measure 50 mL of 4% H2SO4 solution into a 400-mL beaker. Make sure the delivery tube is below the level of the 4% H2SO4 solution (receiving solution).

6. Begin heating. Collect approximately 220 mL of distillate. Distill at a rate of 6 - 10mL/min. Turn off heat and immediately remove the distillate beakers from the delivery tube. Turn off the Coolflow.

7. Pour the distillate into a 500-mL Class A graduated cylinder and dilute to final volume of 500 mL with reagent water. Store distillate at 0°C - 6°C; not frozen, prior to analyzing

8. Analyze distillate for NH3-N according to Method SM4500NH3_D procedure.

B. LIMS ID SM2310B_Prep - Total Acidity Preparation (for use with LIMS ID SM2310B)

1. Calibrate the pH electrode prior to use. Refer to *T-WC-WI11519* for instructions on calibration.
2. Pour 100 mL of the sample into a 150-mL beaker. Read the initial pH of the sample and record the result.

3. If the pH is above 4.0, add standard sulfuric acid in 5 mL increments to lower the pH to 4.0 or less. If the initial pH is less than 4.0, addition of sulfuric acid is not required.

4. Add 5 drops of 30% $H_2O_2$ .

5. Heat the sample to boiling and boil for 3 minutes.

6. Cool the sample to room temperature. Analyze for Total Acidity, LIMS ID SM2310B.

**II. ManTech Procedure:**

NOTE: Before operating the analyst must ensure that all required reagents and reagent water containers needed for each test are in adequate supply and are not expired.

A. To operate the instrument, open the PC-titrate software menu from the computer desktop.

Each day before any analysis is performed; the daily calibration associated with each analysis must be completed and evaluated to ensure that the acceptance criteria are met. (See the calibration section for the required concentrations and acceptance criteria for each calibration). Daily calibration schedules are created and saved. If a specific analysis is not being performed that day, the calibration can be removed from the schedule for that day.

B. Performing daily calibration:

Open the daily start up tab and load the standards according to the schedule for each calibration. Click on the start button and the instrument will proceed with the calibration. Once the calibration is complete the

calibration data is automatically sent to the assign printer and is printed. Ensure the calibration data meets requirements before proceeding. See the calibration section for the required concentrations and acceptance criteria for each calibration. Store calibration sheets in designated ManTech folders.

C. Analyzing samples:

**NOTE**: specific instructions are found in the analytical method SOPs.

To analyze samples, select “Run titration” from the PC-titrate menu. A blank schedule will appear.

1. Click on the add row buttons to add the required number of rows for that run.

2. Double click on the blank space under the schedule header. The menu of analyses will appear. Select the analyses to be performed and click ok.

3. When completing the schedule, each analysis must be bracketed by its own Continuing Calibration Verification standard (CCV) of alternating concentrations and a Continuing Calibration Blank (CCB). The CCV’s and CCB’s ID’s are pre–programmed and are to be scanned in from the charts provided at each instrument. Barcodes are provided for each CCV and CCB. See Table I.

4. The Laboratory Control Standard (LCS) for each analysis is pre-programmed and is to be scanned in from the charts provided at each instrument. See Table I.

5. Scan the sample numbers directly from the label of the container. Sample numbers and QC identifiers can be typed. Use a "^" to designate the dilution factor. 410-12345-A-6^10 indicates a 10 times dilution.

6. Fill the sample tubes with Method Blank, LCS, each CCV, CCB and samples. Ensure the sample tubes are loaded according to the order on the schedule.

7. Click on the auto-generate order number to add the order number to the schedule.

8. Once the schedule is completed, click start and the instrument will proceed with the analysis until the entire schedule of samples is complete.

9. Save the data and send to the PC –Titrate export file before importing to the LIMS system.

10. Create PDFs of all calibrations and raw data associated with the batch. Attach the PDFs to the "Docs" tab in the batch in the LIMS.

D. Routine Maintenance of ManTech multi-parameter system

1. Calibration of Titrasip Pumps: Flow Rate Check:

a. Manual Control of Autosampler

(1) From the PC-Titrate main menu, click on Titrator, then on Manual Control (autosampler tab)

(2) Next, click on Load Tray From Folder button and then double click on Automax 197 Tube Sampler file

(3) Then, under Zone select tubes. Under Tubes select tube position and place a tube in that position on the autosampler tray.

(4) Click on Home Sampler

(5) Click on Go To This Location XYZ button. The autosampler will then move to the tube position.

(6) Click OK button in order to get back to the PC-Titrate main menu

b. Flow Rate Check:

(1) From the PC-Titrate menu select the pump to be calibrated (Click on Pump Cal button) and follow the prompts.

(2) Calibration must be performed monthly and documented in the maintenance logbook.

**NOTE:** When completed, Home sampler (follow instructions under II. ManTech Procedure D1a. steps 1-4)

2. Calibration of Zero and Span for the Hardness detector and monthly buffer volume check for Hardness Detector

**NOTE:** Turn on Hardness Detector in order for the detector to warm up before calibration.

**NOTE:** Ensure reagent water is in titration vessel cup containing the photo cell

a. Accessing Zero and Span Check screen and set-up:

(1) From the PC-Titrate main menu, click on Titrator, then on Manual Control

(2) Click on Analog

(3) Click on Scan Analog, making sure the continuous button is checked

(4) The Hardness Detector is on Monitor Electrode # 4

b. Zero Check/Calibration:

(1) Unscrew the Zero (careful not to look directly into the bright light). The Zero must be as close as possible to 0 mV.

(2) If not, adjust the screw for Zero on the hardness detector until reading is as close as possible to 0 mV.

(3) Check/Calibration must be performed monthly and documented in the maintenance logbook.

c. Span Check/Calibration:

(1) The Span reading must be -400 mV ± 25 mV.

(2) If not, adjust the screw for Span on the hardness detector until reading is within range.

(3) Check/Calibration must be performed monthly and documented in the maintenance logbook.

d. Monthly buffer volume check on Hardness Detector:

**Perform two trials:

(1) Place buffer dispenser titrant line into a 10 mL graduated cylinder.

(2) From the PC-titrate main menu, click on run titration.

(3) Following steps outlined in procedure section C above, schedule a vial of reagent water to be analyzed for Hardness and click on START.

(4) Once the buffer has been dispensed into the graduated cylinder, click on STOP on the computer screen.

(5) Record the amount of buffer solution collected in the graduated cylinder in the maintenance logbook for the instrument. Repeat steps 1-5 once more.

(6) Average two trials and record average result in maintenance logbook

(7) Acceptance criteria is 2.0 mL +/- 0.1 mL.

(8) If averaged amount falls outside the acceptance range, then repeat the buffer volume check. If the check fails again then seek guidance from supervisor.

3. Changing and Entering Acid Normalities on ManTech:

a. Changing Titrant –Purging titrant: Titrant must be changed each time a new stock of titrant is prepared.

**NOTE:** Disconnect acid titrant bottle from dispenser line

(1) Click on PC-Titrate, Titrator, Manual Control, Serial Devices

(2) Click on Burivar II TIS1 tab; Titrasip pump#1/Burette #1

(3) Purge Buret one time (empty cup-use manual button on side of pump #1 at the top of cup)

(4) Fill titrant bottle with new standardized 0.02N H2SO4 titrant and connect dispenser line to bottle

(5) Purge system two more times

(6) Click OK

b. Entering Acid Normalities: Acid Normalities must be updated in ManTech software each time the acid is standardized and the standardization yields a new normality.

(1) Click on PC-Titrate, Set-up, Titration Method, Load

(2) Click Alkalinity

(3) Under Titrant Information-Concentration, change Normality to current value.

(4) Click Save

(5) Click Alkalinity-Low and follow steps (3) and (4) above

E. Maintenance of all other systems:

1. Maintenance of the Ammonia Ion-Selective Electrode – See manufactures instruction manual for maintenance and operation of electrode

2. Maintenance of pH electrodes- refer to *T-WC-WI11519* for maintenance of pH electrodes

3. Perform Maintenance on all other systems as needed.

F. Retrieving Historical Raw Data on ManTech:

1. Find run number of sample in question.

2. Open PC-titrate software menu from computer desktop

3. Click on Titrator, Replay Titration, Load, Sort by order and sample name

4. Click on sample (go by time), Select, Print, Equation Result Report (rplyeqn.srw), Print.

## Calculations

A. Free Carbon Dioxide Calculation (LIMS ID SM4500_CO2_D)

The calculation assumes that the total alkalinity of the sample is due almost entirely to hydroxides, carbonates or bicarbonates.

The total dissolved solids of the sample may not be greater than 500 mg/L for this calculation.

mg/L CO2 = 2.0 x B x 10^(6-pH)

**Where:**
B = bicarbonate alkalinity (from LIMS ID 2320B)

**NOTE**: Total carbon dioxide can be calculated, if requested, according to the calculations found in SM 4500 CO2 D-2011

B. Total Hardness (LIMS ID 2340C, 130.2):

Hardness (EDTA) as mg $CaCO_{3/L}$ =

A x B x 1000 / mL of sample

where:
A = mL titration for sample
B = mg CaCO3 equivalent to 1.00 ml of 0.01 M EDTA titrant (B = 1.00088)

B is calculated as follows:

$$B = \left(\frac{0.01\ \text{mol}}{\text{L}}\right) \times \left(\frac{0.001\ \text{L}}{1}\right) \times \left(\frac{100.088\ \text{g}}{\text{mol}}\right)\left(\frac{1000\ \text{mg}}{\text{g}}\right)$$

B = (Molarity of titrant) x (1 mL of titrant) x (molecular weight of CaCO3)

C. Total Acidity (LIMS ID SM2310B, 305.1)

$$\text{Acidity as mg / mL } CaCO_3 \quad \frac{[(A \times B) - (C \times D)] \times 50{,}000}{\text{mL of sample}}$$

**Where:**
A = Vol. of std. NaOH used in titration
B = Normality of std. NaOH
C = Vol. of std. H2SO4 used to reduce pH to less than 4
D = Normality of std. H2SO4

I. Acidity to pH 3.7 and pH 8.3 (LIMS ID 305.2)

mg/L as CaCO3 = (Normality)(50,000)(mL of titrant) / ( mL of sample volume)

## Statistical Information/Method Performance

The method detection limit (MDL) is determined annually by following the procedure outlined in *QA-SOP11892*.

The quality control acceptance windows are generated annually by following the procedure outlined in *QA-SOP11896*.

## Quality Assurance/Quality Control

Before independent analysis is allowed, an Initial Demonstration of Capability (IDOC) consisting of a Method Blank (MB) and 4 Laboratory Control Standards (LCS) with acceptable results must be analyzed. This must be followed up with an Ongoing DOC containing 4 LCS samples annually.

The batch size is limited to 20 samples or less. For analyses with more than 10 samples on a batch, two duplicates are needed (excluding ammonia and fluoride – only one duplicate is needed per batch 20 samples – unless a batch contains an NPDES sample(s) from South Carolina and the batch contains more than 10 samples, then two duplicates are needed).

A Laboratory Control Standard (LCS) must be analyzed for each analysis per batch. See Table I for each analysis LCS concentration.

A Method Blank (MB) must be analyzed for each analysis per batch. MB > MDL are qualified. If the MB is > RL, non-detected samples may be reported with qualification. Any samples in the batch with detections > MDL must be re-analyzed.

For alkalinity, Total Acidity and total hardness one matrix spike (MS) must be analyzed per batch of 20 samples or less.

For ammonia, fluoride and Acidity to pH 3.7 and 8.3 (total acidity spikes only), a matrix spike (MS) and a matrix spike duplicate (MSD) must be analyzed per batch of 20 samples or less.

When sample volume does not permit the analysis of either a sample matrix duplicate or an MS and MSD, then a LCSD must be analyzed to demonstrate method precision.

For Ammonia by ISE a Certified Reference Material (CRM) must be analyzed annually. The acceptance range for the CRM is 90% to 110% of the true value.

Total Acidity samples with results > 600 mg/L as CaCO3 must be diluted and reanalyzed.

For Total Hardness, samples that are designated NPDES require digestion. Confirm whether this analysis is appropriate for samples designated NPDES.

Every Total Hardness batch containing drinking water samples must analyze a 10mg/L MRL sample.

For each analysis, a continuing calibration verification (CCV) standard must be analyzed at the beginning of each batch, after every 10 samples and at the end of each batch. The concentration of the CCV must at or below the mid-point of the calibration. All CCVs must have an acceptance criteria of 90% to 110%. If any CCV's are outside this range, then the samples bracketed by the out of specification CCV must be repeated. Refer to Table I for CCV concentrations for each analysis.

A continuing calibration verification blank (CCB – a reagent water blank) must be analyzed after each CCV standard on the batch. The CCB must be less than the MDL for the analysis. If the CCB is above the MDL, then the samples bracketed by the out of specification CCB must be repeated.

See LIMS for current quality control (QC) acceptance windows.

**Table I**

**Cross Reference**

| Document | Document Title |
|---|---|
| *T-WC-WI10610* | Fixed Suspended Solids (Gravimetric) Volatile Suspended Solids (Gravimetric) by SM 2540 E - 2011 or EPA 160.4 in Water |
| *QA-SOP11892* | Determining Method Detection Limits and Limits of Quantitation |
| *QA-SOP11896* | Establishing Control Limits |

**Scope**
Methods 2540D and 2540D_SingleDry are used for the determination of total suspended solids (TSS) in potable, surface and saline water, domestic and industrial wastewater in a range up to 20,000 mg/L. The reporting limit for this analysis varies with the sample volume. LIMS may round the reporting limit during the calculation routine.

**Basic Principles**
For Methods 2540D and 2540D_SingleDry, a well-mixed sample is filtered through a glass fiber filter and the residue on the filter is dried in an oven at 103° to 105°C. The increase in weight of the filter represents the TSS.

The start time for the analysis is the time the samples are initially placed in the oven to dry.

Method 2540D requires repeat drying, cooling, desiccating and weighing cycles until the weight change is less than 4% of the previous weight or ≤ 0.0005g, whichever is less.

Method 2540D_SingleDry records only one weight after a 16 hour drying cycle.

The appropriate analysis scan is typically determined by the sample state of origin.

**Interferences**
Samples high in dissolved solids may yield positive interferences. If the sample is over the residue limit of 0.2 g, the sample is reanalyzed at a reduced volume.

**Safety Precautions and Waste Handling**
All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

**Personnel Training and Qualifications**
All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each technician performing these techniques must work with an experienced technician for a period of time until they can independently perform the procedure. Proficiency is measured through an Initial Demonstration of Capability (IDOC).

The IDOC and the DOC consists of four laboratory control spikes (or alternatively, one blind sample for the DOC) that are carried through all steps of the procedure and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation.

**Sample Collection, Preservation, and Handling**
Samples must be unpreserved, collected in glass or plastic containers and refrigerated at 0° to 6°C, not frozen.

Analyze samples within 7 days of collection to minimize microbiological decomposition of the solids.

Exclude non-representative, nonhomogeneous materials, such as leaves and sticks, from the analysis if their inclusion is not desired in the final result.

## Apparatus and Equipment

1. ProWeigh Filters from Environmental Express – pre-weighed 47 mm glass fiber filters or equivalent
2. ProWeigh Filters from Environmental Express – pre-weighed **volatile** 47 mm glass fiber filters or equivalent
3. Filtration apparatus
4. Desiccators.
5. Oven maintained at 104° ± 1°C. Adjust as needed to stay in this range.
6. Analytical balance.

## Reagents and Standards

Alternate weights and volumes are acceptable as long as final concentrations remain the same.

A. 1,8 Naphthalimide, 98%, Thermo Fisher Scientific, Cas#A18856.18 or equivalent .See COA for storage conditions and expiration.

B. TSS Working Standard (150 mg/L)

1. Dry 1,8 Naphthalimide, 98%, for approximately 1 hour at 104° ± 1°C.
2. Desiccate approximately 1 hour.
3. Dissolve 0.1500 ± 0.005 g Naphthalimide in approximately 700-mL of reagent water in a 1000-mL volumetric flask.
4. Mix very well.
5. Dilute to 1000 mL with reagent water.
6. Store at room temperature.
7. Stable 30 days.
8. Prior to use, Naphthalimide can be weighed out and stored in small glass vials at room temperature.

## Calibration

A balance calibration check and leveling check must be performed each day before use.

## Procedure

1. Batch samples for analysis in the LIMS.
2. Assemble filtration apparatus.
3. Assign a pre-washed, pre-weighed filter to each client sample and each QC sample on the batch. If fixed or volatile suspended solids are to be performed use a pre-weighed **volatile** filter and follow instructions in *T-WC-WI10610*.
4. Remove the assigned filter from its aluminum carrying dish and place on the filtration unit.
5. Apply vacuum to the filtration apparatus.
6. Wet filter with small amount of reagent water to seat it.
7. Quality Control samples preparation
    a. Analyze the method blank by using 1000 mL of reagent water.

b. Analyze the LCS/LCSD using 1000 mL of the 150 mg/L TSS working standard for each QC standard.

c. Prepare duplicates by analyzing equal portions of sample.

8. Sample filtration

a. Shake sample vigorously.

**NOTE:** If the sample does not maintain a homogeneous state until the aliquot is taken, then magnetically stir the sample while pipetting the appropriate aliquot onto the filter.

b. Using a graduated cylinder or wide mouth pipette, measure 1000 mL of sample or a smaller portion if the sample matrix dictates.

**Note:** 1000ml of sample should be used whenever possible.

c. Rapidly transfer an aliquot of the sample to the filtration unit.

d. Still under vacuum, filter the sample and record the time. Filtration time is the "Start Time" in the TALS Lims program.

e. Repeat steps 8b-d until the appropriate total volume for the sample matrix has been filtered.
Record each volume filtered in the 'Notes' column.

f. After all of the sample's volumes have been filtered, rinse the graduated cylinder. Rinse sufficiently to ensure all of the solids inside the graduated cylinder are transferred to the filtration apparatus.

(1) If the entire volume was used for the analysis, then rinse the inside of the sample container with at least three 10-mL portions of reagent water and transfer the rinses to the filtration apparatus. Rinse sufficiently to ensure all of the solids inside the bottle are transferred to the filtration apparatus.

g. Wash the filter with at least three 10 mL portions of reagent water. Allow complete drainage between washings. If complete filtration takes more than 10 minutes, reanalyze the sample decreasing the sample volume.

h. If necessary, perform a final rinse to remove any residue from the sides of the filtration unit.

i. Continue suction at least 3 minutes after filtration is complete.

**NOTE:** This step is important to ensure that dissolved solids are rinsed through, and not dried in the filter.

9. The total sample volume filtered ('initial Amount' column on the raw data worksheet) is calculated by adding all the volumes from the 'Notes' column. Record the total sample volume used in the 'Initial Amount' column on the worksheet.

10. Transfer the filter back into its aluminum carrying dish and place in an oven maintained at 104° ± 1°C.

11. Record the oven temperature and the time the samples were placed in the oven in the batch information window.

12. Dry the filter for the appropriate amount of time according to the analysis selected.

a. Method 2540D - dry the filter for at least one hour.

b. Method 2540D_SingleDry - dry the filter for at least 16 hours.

13. After the drying time, transfer the aluminum dish into a desiccator and cool to balance temperature. Record the time and the temperature.

14. After cooling, weigh the filter and record the oven dried weight of the filter.

a. Method 2540D - repeat this drying desiccating and weighing cycle until weight change is less than 4% of the previous weight or ≤ 0.0005g, whichever is less.

b. Method 2540D_SingleDry - require only one weight after a 16-hour drying cycle.

**Calculations**

$$mg\ Total\ Suspended\ Solids\ /\ L = \frac{(A - B) \times 1000 \times 1000}{Sample\ Volume\ (mL)}$$

**Where:**

A = Weight of filter, (in grams) after drying

B = Tare weight of filter (in grams)

## Statistical Information/Method Performance

Generate the method detection limit (MDL) and limit of quantitation (LOQ) annually by following the procedure in *QA-SOP11892* . The department maintains annual study data and updates to LIMS are made as needed by the QA department.

Generate the quality control acceptance windows by following the procedure outlined in *QA-SOP11896*. The limits are evaluated annually and updated as needed. These limits are maintained in LIMS for the relevant analysis number(s).

## Quality Assurance/Quality Control

1. Batch size - a batch contains up to 20 samples, analyzed within a 24 hour period.

2. See Table I for QC acceptance criteria. If acceptable results cannot be obtained and the client requests that the data be reported, the data must be qualified to note that the method criteria were not met.

3. For every batch, a MB LCS, and a DU must be analyzed. A DU must be analyzed with each group of up to 10 samples. When there is not enough sample to perform a DU, a LCSD must be performed.

4. The maximum residue limit for samples is 0.2 g. If sample results are > 200 mg/L re-analyze using a smaller initial volume.

5. Follow Project Notes in the LIMS for any additional unique client requirements.

6. See LIMS for current quality control acceptance windows.

*Table I - QC Frequency and Acceptance Criteria*

| QC Check | Minimum Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|---|
| Method Blank (MB) | 1 per batch | <RL | B qualifier if MDL<MB<RL. Re-analyze samples if MB>RL. |
| Laboratory Control Sample (LCS) 150mg/L | 1 per batch | See LIMS for current QC acceptance windows | If reanalysis cannot be performed, data must have an NCM explaining the LCS qualification. |
| LCSD 150mg/L | Per Client or regulatory requirement, OR insufficent sample for DU | RPD <20% | If reanalysis cannot be performed, data must have an NCM explaining the LCS qualification. |
| Sample Duplicate (DU) | 1 per batch | RPD <5% | Data are qualified |

## 1.0 Scope and Application

**1.1** This standard operating procedure (SOP) describes the determination of nitroaromatic and nitroamine explosive residues by high performance liquid chromatography (HPLC) using dual columns and dual UV wavelengths. This includes analysis in water, soil, and sediment matrices. The instrumental analysis is based on EPA Methods 8330A and 8330B.

**1.2** This SOP does not include the extraction procedures. For those details, please refer to DV-OP-0017 *Solid Phase Extraction of Nitroaromatic and Nitroamine Explosive Compounds and Picric Acid from Water Samples by SW-846 3535A* and DV-OP-0018 *Extraction of Nitroaromatic and Nitroamine Explosive Compounds and Picric Acid from Soil Samples by SW-846 8330A and 8330B*.

### 1.3 Application of 8330A versus 8330B

**1.3.1** This procedure is for analysis by either Method 8330A or 8330B. EPA Method 8330B includes Appendix A which describes sample collection and preparation procedure using Incrementing Sampling Methodology (ISM) (see details in DV-OP-0018 *Extraction of Nitroaromatic and Nitroamine Explosive Compounds and Picric Acid from Soil Samples*).

**1.3.2** For soil analysis a sample size of 2 g is used for 8330A and a sample size of 10 grams is used for 8330B.

**1.3.3** 8330A only describes the cyano (CN) column for confirmation. 8330B gives the option of either cyano (CN) or phenyl-hexyl columns for confirmation. Eurofins Denver uses the Phenomenex Luna Phenyl-Hexyl column for confirmation on both methods, as it provides better sensitivity and peak resolution.

### 1.4 Analytes, Matrix(s), and Reporting Limits

**1.4.1** The list of analytes, CAS numbers, abbreviations are found in Attachment I. Reporting limits and Method Detection Limits for individual analytes are stored in TALS.

**1.4.2** The working ranges of this method are as follows:

| Analytes | 8330A Soil (2 g prep) | 8330B Soil (10 g prep) | Water |
|---|---|---|---|
| All Analytes except nitroglycerin and PETN | 0.2 µg/g – 100 µg/g | 0.08 µg/g – 10 µg/g | 0.2 µg/L - 25 µg/L |
| Nitroglycerin and PETN | 2.0 µg/g – 250 µg/g | 0.80 µg/g – 100 µg/g | 2.0 µg/L - 250 µg/L |

## 2.0 Summary of Method

**2.1** Instrument calibration is performed by external standardization using a minimum of five concentration levels.

**2.2** An acetic acid and phosphate buffer in water / methanol gradient program is used for HPLC separation (see details in Section 7.8.10 and Attachment 5). Compounds are tentatively identified based on retention time and detection by the UV detector using the primary Agilent Poroshell 120 EC-C18 column. Confirmation is performed by the UV detector using a Phenomenex Luna Phenyl-Hexyl column (see Attachment 5 for instrument conditions).

## 3.0 Definitions

**3.1** **Explosives**: As used in this SOP, the term "explosives" refers specifically to the analytes listed in Attachment 1. These include compounds that can be readily detonated with heat, shock, or ignition, such as nitroglycerin, RDX, and TNT. It also includes production by-products and degradation products of true explosives.

**3.2** Refer to DV-QA-003P *Quality Control Program* for definitions of general analytical and QA/QC terms.

## 4.0 Interferences

**4.1** Solvents, reagents, glassware, and other sample processing hardware may yield discrete artifacts and/or elevated baselines, causing misinterpretation of the chromatograms. All of these materials must be demonstrated to be free from interferences, under the conditions of the analysis, by running method blanks.

**4.2** Contamination by carryover can occur when a low-concentration sample is analyzed immediately following a high-concentration sample. This potential is minimized by continuously flushing the needle with solvent. If contamination is suspected, the sample should be re-aliquoted and re-analyzed.

**4.3** Co-elution of target analytes with non-target analytes can occur, resulting in false positives or biased high results.

**4.4** Co-elution between target analytes can occur when high concentrations of individual compounds are present in samples, see Section 12.3 for details.

**4.5** The inclusion of vegetation is not recommended per QSM 5.4 and 6.0

**4.6** Per EPA Method 8330B Section 4.3: "Tetryl decomposes rapidly in methanol/water solutions, as well as with heat. All aqueous samples expected to contain tetryl should be diluted with acetonitrile prior to filtration and acidified to pH <3 with aqueous sodium bisulfate. All samples expected to contain tetryl should not be exposed to temperatures above room temperature."

## 5.0 Safety

Employees must abide by the policies and procedures in the Environmental Health and Safety Manual (CW-E-M-001), Radiation Safety Manual (RSM) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

### 5.1 Specific Safety Concerns or Requirements

**5.1.1** Eye protection that satisfies ANSI Z87.1, laboratory coat, and nitrile or latex gloves must be worn while handling samples, standards, solvents, and reagents. Disposable gloves that have been contaminated will be removed and discarded; non-disposable gloves must be cleaned immediately.

**5.1.2** If a sample is expected to have an explosive concentration $\geq$ 2% (but less than 10%), the EH&S Coordinator and Group Leader shall be notified before any work is performed. Additional safety precautions may be implemented as required due to high concentrations of explosives.

**WARNING:** Soil samples with explosive concentrations greater than 2% cannot be accepted by the laboratory unless they have a moisture content of 25% or greater. Under no circumstances shall a soil sample with an explosive concentration greater than 10% be accepted by the laboratory.

**5.1.3** Soil samples with high concentrations (between 2 and 10%) of explosives should not be ground using a mortar and pestle. Visual observation of a soil samples is important prior to grinding samples. Any samples containing metal fragments, powders, waxy appearing pieces, or other suspicious material should be brought to the attention of the Group Leader and the EH&S Coordinator before proceeding with the procedure. Bypassing the grinding step and proceeding to solvent dilution is an alternative for samples that are determined to be unsafe to grind.

**5.2 Primary Materials Used**

The following is a list of materials used in this method, which have a serious or significant hazard rating.

**NOTE:** This list does not contain all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table.

A complete list of materials used in the method can be found in the reagent and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

| MATERIAL [(1)] | HAZARDS | EXPOSURE LIMIT [(2)] | SIGNS AND SYMPTOMS OF EXPOSURE |
|---|---|---|---|
| Acetonitrile | Flammable Poison | 40 ppm – TWA | Early symptoms may include nose and throat irritation, flushing of the face, and chest tightness. Prolonged exposure to high levels of vapors may cause formation of cyanide anions in the body. |
| Glacial Acetic Acid | Corrosive Poison Flammable Liquid and Vapor | 10 ppm - TWA | Inhalation of concentrated vapors may cause serious damage to the lining of the nose, throat, and lungs. Breathing difficulties may occur. Can cause serious damage to skin, including redness, pain, and burns. Contact with eyes may cause severe damage followed by loss of sight. |
| Methanol | Flammable Poison Irritant | 200 ppm - TWA | A slight irritant to the mucous membranes. Toxic effects are exerted upon the nervous system, particularly the optic nerve. Symptoms of overexposure may include headache, drowsiness, and dizziness. Methyl alcohol is a defatting agent and may cause the skin to be become dry and cracked. Skin absorption can occur, symptoms may parallel inhalation exposure. Irritant to the eyes. |
| Phosphoric Acid | Corrosive | 1 ppm - TWA | Ingestion can cause severe burns to the throat, mouth, and stomach, abdominal pain and nausea. Severe exposures by ingestion can lead to shock, circulatory collapse, and death. Inhalation is not an expected hazard unless misted. Corrosive, contact with skin or eyes can |

| MATERIAL [1] | HAZARDS | EXPOSURE LIMIT [2] | SIGNS AND SYMPTOMS OF EXPOSURE |
|---|---|---|---|
| | | | cause redness, pain, severe burns, blurred vision, and permanent eye damage. |
| Sodium hydroxide | Corrosive Poison | 2 mg/m$^3$ | Effects from inhalation of dust or mist vary from mild irritation to serious damage of the upper respiratory tract, depending on severity of exposure. Symptoms may include sneezing, sore throat, runny nose. Contact with skin can cause irritation or severe burns and scarring with greater exposures. Causes irritation of eyes and can cause burns that may result in permanent impairment of vision, even blindness with greater exposures. |

(1) Always add acid to water to prevent violent reactions.
(2) Exposure limit refers to the OSHA regulatory exposure limit.

## 6.0 Equipment and Supplies

### 6.1 Instrumentation

**6.1.1 HPLC System**
HPLC, equipped with a pump capable of achieving 6,000 psi, a 100 µL loop injector, and a Diode Array Detector (DAD) or Multi-Wavelength Detector (MWD), Hewlett Packard Model 1100, or equivalent.

**6.1.2** Primary Column: Reverse phase HPLC column, Agilent Poroshell 120, EC-C-18, 4.6 mm x 150 mm (2.7 µm) or equivalent.

**6.1.3** Confirmation Column: Phenomenex Luna Phenyl-Hexyl reverse phase HPLC column, 15 cm x 4.6 mm (3 µm) or equivalent.

**6.1.4** Hewlett Packard HPLC Chem Station for instrument control.

### 6.2 Supplies

**6.2.1** Glass vials, various sizes.

**6.2.1.1** Amber glass, 8.0 mL and 12.0 mL, with Teflon-lined screw caps, for the storage of standards.

**6.2.1.2** Crimp-top vial with caps for analysis, 1.8 mL.

**6.2.2** Disposable pipettes, used for non-quantitative transfers only.

**6.2.3** Volumetric flasks, various sizes.

**6.2.4** Hamilton syringes, various sizes.

### 6.3 Computer Software and Hardware
A list of computer software and hardware used for analysis and data processing is maintained by the QA department at \\Tacorp\corp\QA\QA_Facilities\Denver-QA\Equipment: Master Equipment List.

## 7.0 Reagents and Standards

### 7.1 Stock Standards

**7.1.1** Stock standards are purchased as certified solutions or prepared from 100%, neat materials. Stock standard solutions are stored at -10 °C to -20 °C, or per vendor

instructions. All stock standards must be protected from light and should be brought to room temperature before using.

**7.1.2** Stock standard solutions must be replaced after 1 year or sooner if comparison with check standards prepared from an independent source indicates a problem. Expiration times for all standards are measured from the time the standard is prepared or from the time that the standard ampoule is opened, if the standard is supplied in a sealed ampoule.

**7.1.3** 3,5-Dinitroaniline is purchased at a concentration of 100 µg/mL in acetonitrile, equivalent to the High-Level Calibration Mix. This standard is added directly to the Intermediate Level Calibration Standard. (Section 7.4).

**7.1.4** PETN and Nitroglycerin are purchased as separate individual standards at a concentration of 1,000 µg/mL in acetonitrile. These standards are added directly to the Intermediate Level Calibration Standard (Section 7.4).

**7.1.5** 2,4-diamino-6-nitrotoluene and 2,6-diamino-4-nitrotoluene are purchased as separate individual standards at a concentration of 100 µg/mL in acetonitrile, equivalent to the High-Level Calibration Mix. These standards are added directly to the Intermediate Level Calibration Standard (Section 7.4).

**7.1.6** MNX, DNX, TNX are purchased from Ultra Scientific as a custom standard at 100 µg/mL. These compounds are in a separate standard called 8330 DMT in TALS. This is the only known source of MNX, DNX, and TNX and we do not currently have a second-source standard for these compounds.

**7.2 Volume Measurements for all Standards Preparation**

The volume of stock and intermediate standard solutions used in subsequent dilutions is measured using Hamilton syringes appropriate for the volume being measured and accurate to ± 2%. Standards are prepared either by (1) using a syringe to measure the standard solution and bringing to volume with the appropriate solvent in a Class A volumetric flask, or by (2) measuring the volumes of both the standard solution and the solvent using a calibrated syringe or Class A pipette and combining them in a vial.

**7.3 High-Level Calibration Mix, Prepared from Stock Standards**

This high level standard must be replaced every 1 year or sooner if comparison with check standards prepared from independent sources indicate a problem.

A solution is prepared to contain most standard analytes at a concentration of 100 µg/mL each in acetonitrile (see details in standards database instructions). Nitroglycerin, PETN, 3,5-Dinitroaniline, 2,4-diamino-6-nitrotoluene and 2,6-diamino-4-nitrotoluene are purchased as separate stock standards, and are not included in this mixture. They are added to the intermediate level standards in Section 7.4.

**7.4 Intermediate Level Calibration Standards**

**8330IntermStk**: Prepare a 10 µg/mL solution (nitroglycerin and PETN at 100 µg/mL) from the high-level calibration mix (see Section 7.3) by diluting 1.0 mL of the High-Level Calibration mix along with 1.0 mL each of stock standards of nitroglycerin and PETN to a final volume of 10.0 mL in acetonitrile. The shelf life of this material is 6 months.

**8330_ADDs**: Prepare a 20 µg/mL solution from stock standards by diluting 1.0 mL each of stock standards of 3,5 -dinitroaniline, 2,4-diamino-6-nitrotoluene, and 2,6-diamino-4-

nitrotoluene to a final volume of 5.0 mL in acetonitrile. The shelf life of this material is 6 months.

**8330 DMT**: Prepare a 20 µg/mL solution from stock standard by diluting 1.0 mL of MNX, TNX, DNX stock to a final volume of 5 mL. The shelf life of this material is 6 months.

### 7.5 Working Level Standards for Calibration Curve

Prepare calibration standards by diluting the intermediate standard solutions as shown in the table below using the 75%:25% (v/v) acidic water:ACN solution (described in Section 7.8.7). These standards must be prepared fresh on the day of calibration and refrigerated if not used immediately. All volumes are measured using the appropriately sized Hamilton syringe.

**7.5.1** On the primary (C18) column, the mixes 8330IntermStk, 8330_ADDs and 8330 DMT must be calibrated using a separate calibration curves due to co-elution of target analytes. The intermediate standards are prepared at the same concentration; therefore, the calibrations are made with the same volumes of intermediate stock and solvent in the following table "Primary (C18) Column Calibration".

**7.5.2** On the confirmation (phenyl-hexyl) column, the intermediate full-list (8330IntermStk) must be calibrated using a separate calibration curve, however 8330_DMT and 8330 ADDs are combined into a single calibration curve. See Table below "Confirmation (Phenyl-Hexyl) Column Calibration".

**Recommended Calibration Levels**

| Calibration Level | Final Concentration (µg/mL) | | Primary (C18) Column Calibration | | Confirmation (Phenyl-Hexyl) Column Calibration | |
|---|---|---|---|---|---|---|
| | Standard Analytes | NG & PETN | Vol. Intermediate (µL) | Vol. Solvent (µL) | Vol. EACH Intermediate (µL) | Vol. Solvent (µL) |
| 8 | 2.5 | 25.0 | 250 ± 1 | 750 ± 9 | 250 ± 1 | 750 ± 9 |
| 7 | 1.0 | 10.0 | 100 ± 0.5 | 900 ± 10 | 100 ± 0.5 | 900 ± 10 |
| 6 | 0.7 | 7.0 | 70 ± 0.4 | 930 ± 10 | 70 ± 0.4 | 930 ± 10 |
| 5 | 0.4 | 4.0 | 40 ± 0.2 | 960 ± 10 | 40 ± 0.2 | 960 ± 10 |
| 4* | 0.25 | 2.5 | 25 ± 0.1 | 975 ± 10 | 25 ± 0.1 | 975 ± 10 |
| 3 | 0.1 | 1.0 | 10 ± 0.5 µL | 990 ± 10 | 10 ± 0.5 µL | 990 ± 10 |
| 2 | 0.05 | 0.5 | 5 ± 0.5 µL | 995 ± 10 | 5 ± 0.5 µL | 995 ± 10 |
| 1 | 0.02 | 0.2 | 2 ± 0.1 µL | 998 ± 10 | 2 ± 0.1 µL | 998 ± 10 |

- Level 4 concentration is used for the daily and continuing calibrations.
- Nitroglycerine and PETN are 10X higher than the other analytes in all calibration levels.

### 7.6 Extractions Standards

#### 7.6.1 LCS Spike Solution

The LCS spike solution is prepared at a working level concentration of 10 µg/mL (nitroglycerin and PETN at 100 µg/mL) in acetonitrile. This standard is stored in a freezer at –20 °C to –10 °C and given a 6-month expiration date. The standard is allowed to come to room temperature before use and returned to the freezer as soon as possible. This standard contains all explosives target compounds except 2,4-diamino-6-nitrotoluene and 2,6-diamino-4-nitrotoluene.

**7.6.2 MNX, DNX, TNX LCS solution**

The 8330 OP DMT LCS solution is prepared at a working level concentration of 10 µg/mL in acetonitrile. This standard is stored in a freezer at –20 °C to –10 °C and given a 6-month expiration date.

**7.6.3 Diamino LCS Solution**

The Diamino LCS solution is prepared at a working level concentration of 10 µg/mL in acetonitrile of 2,4-diamino-6-nitrotoluene and 2,6-diamino-4-nitrotoluene. This standard is stored in a freezer at –20 °C to –10 °C and given a 6-month expiration date. The standard is allowed to come to room temperature before use and returned to the freezer as soon as possible. This standard is only added when these compounds are specifically requested by the client. They are added to a separate LCS/MS/MSD.

**7.6.4 Working Level Surrogate (1,2-Dinitrobenzene) Solution**

The 8330 surrogate solution is prepared at a working level concentration of 10 µg/mL in acetonitrile. This standard is stored in a freezer at –20 °C to –10 °C and given a 6-month expiration date. The standard is allowed to come to room temperature before use and returned to the freezer as soon as possible.

**7.7 Second Source Initial Calibration Verification Solution**

The second source standard must be obtained from a different source than the standards used for initial calibration. This standard is used to verify the accuracy of the calibration standards.

**NOTE:** There is currently no second source available for MNX, DNX, and TNX.

**7.7.1 Working-Level Second Source Mix**

Prepare a solution containing all compounds except 2,4-diamino-6-nitrotoluene and 2,6-diamino-4-nitrotoluene at a concentration of 0.50 µg/mL (nitroglycerin and PETN at 5.0 µg/mL). A separate solution containing 2,4-diamino-6-nitrotoluene and 2,6-diamino-4-nitrotoluene is prepared at a concentration of 0.50 µg/mL when analyzing on the primary (C18) column; the standards can be combined for analysis on the confirmation (phenyl-hexyl) column. A separate solution containing MNX, DNX and TNX is prepared at a concentration of 0.50 µg/mL. These solutions are prepared using the 75%:25% (v/v) acidic water:ACN solution (described in Section 7.8.7). These standards must be prepared fresh on the day of calibration. All volumes are measured using the appropriately sized Hamilton syringe.

**7.8 Reagents**

**7.8.1 Reagent Water**

For method blanks and laboratory control samples reagent water is generated by an ELGA water purification system. The performance of the water polishing system is checked daily and recorded per SOP DV-QA-0026.

**7.8.2** HPLC Grade Water

**7.8.3** Acetonitrile, $CH_3CN$ (ACN) - HPLC grade

**7.8.4** Methanol - HPLC grade

**7.8.5** Glacial Acetic Acid – Reagent Grade

**7.8.6** 85% Phosphoric acid, $H_3PO_4$ – Reagent Grade

**7.8.7 Acidified Water (75%): Acetonitrile Solution (25%)**
TALS Reagent: 8330AcidH2O

Take 250 mL of acetonitrile (ACN), and bring to 1.0 L with Elga or HPLC-grade water. Acidify the solution to a pH of approximately 3 by adding 20 drops (1 mL) of 85% phosphoric acid ($H_3PO_4$).

**7.8.8 Acidified Calcium Chloride, $CaCl_2$ Solution, 5 g/L**
TALS Reagent: CaCL2 Sol

Place 5 ± 0.05 g of reagent grade $CaCl_2$ into a one-liter volumetric flask containing approximately 500 mL of reagent water. Swirl the solution until the $CaCl_2$ is dissolved. Add approximately 1 mL of 85% $H_3PO_4$ to acidify the solution and bring to volume with reagent water.

**7.8.9 Sodium Phosphate Buffer Stock**
TALS Reagent: 8330bufferstk

Slowly add 115.29 grams of 85% phosphoric acid (molecular weight = 97.9924 g/mol) to approximately 500 mL of water in a 1 L beaker. Place a stir bar in the beaker and the beaker in an ice bath on top of a magnetic stirrer. Slowly add 150 mL of 10 M (10 M = 10 N) sodium hydroxide, allowing time for the mixture to cool down between additions. Transfer to a 1 L volumetric flask and bring to volume with Elga or HPLC-grade water. The final pH of this solution should be 7.2.

**7.8.10 Buffer Eluents for Analysis:**
Make up the HPLC eluents for each column as described in Sections 7.8.10.1 and 7.8.10.2. The pH of the working eluents *must* be modified by the analyst by changing the volume of glacial acetic acid added to ensure compound resolution. This is particularly necessary when the column is replaced, to ensure that picric acid does not co-elute with any other target compound. Increasing the concentration (or volume added) of glacial acetic acid will result in greater retention of picric acid. The eluent can only be adjusted at the start of an initial calibration, not with the CCVs. The calculated retention time windows should account for the drift of any specific analyte.

**7.8.10.1 Working Eluent for Primary (C18) Column:**
Combine 1 L of water, 1 mL of Sodium Phosphate Buffer Stock solution (Section 7.8.9), and Glacial Acetic acid (50-150 µL) to adjust the pH < 5. Make fresh at least weekly or more often as needed.

**7.8.10.2 Working Eluent for Confirmation (Phenyl-Hexyl) Column:**
Combine 1 L of water, 2 mL of Sodium Phosphate Buffer Stock solution (Section 7.8.9), and Glacial Acetic acid (50 – 200 µL) **to adjust pH** <5 so that picric acid does not co-elute with MNX or RDX. Make fresh before each run.

## 8.0 Sample Collection, Preservation, Shipment and Storage

### 8.1 Aqueous Samples

Water samples should be collected in duplicate 500 mL amber glass bottles with Teflon-lined caps.

**8.2 Soil and Sediment Samples**

**8.2.1** For method 8330A, soil samples should be collected in eight-ounce wide mouth jars with Teflon-lined caps.

**8.2.2** For method 8330B, sample volume will range between 250-1000 g or more. Samples may be shipped in wide mouth jars or clean plastic bags.

**8.3** Samples and sample extracts must be stored in amber glass containers at ≤ 6 °C from the time of collection through analysis, except during drying.

**8.4** Soil and sediment samples should be air dried at ambient temperature until dry enough to sieve. See DV-OP-0018 *Extraction of Nitroaromatic and Nitroamine Explosive Compounds and Picric Acid from Soil Samples* for details. Once the sample is air dried, the sample can be stored at room temperature.

| Matrix | Sample Container | Min. Sample Size | Preservation | Holding Time | Reference |
|---|---|---|---|---|---|
| Water | Amber glass | 2 x 500 mL | Cool; ≤ 6 °C | 7 Days to Extraction<br>40 Days to Analysis | SW-846<br>8330A/B |
| Soil | Glass / plastic | 50 g (8330A) /<br>up to 1 kg<br>(8330B) | Cool; ≤ 6 °C | 14 Days to Extraction<br>40 Days to Analysis | SW-846<br>8330A/B |

**Note:** If DNX, MNX, or TNX are requested analytes, additional volume will be required for MS/MSD analysis (up to 10 x 500 mL).

## 9.0 Quality Control

**9.1** The minimum quality controls (QC), acceptance criteria, and corrective actions are described in this section. When processing samples in the laboratory, use the TALS Method Comments to determine specific QC requirements that apply.

**9.1.1** The laboratory's standard QC requirements, the process of establishing control limits, and the use of control charts are described more completely in Eurofins Denver Policy DV-QA-003P *Quality Control Program*.

**9.1.2** Specific QC requirements for Federal programs, e.g., Department of Defense (DoD), Department of Energy (DOE), etc., are described in Eurofins Denver policy DV-QA-024P *QA/QC Requirements for Federal Programs*. This procedure meets all criteria for the DoD/DOE QSM (5.0 or later) unless otherwise stated. Any deviation or exceptions from QSM requirements must have prior approval in the project requirements.

**9.1.3** Project-specific requirements can override the requirements presented in this section when there is a written agreement between the laboratory and the client, and the source of those requirements should be described in the project documents. Project-specific requirements are communicated to the analyst via Method Comments in TALS and the Quality Assurance Summaries (QAS) in the public folders.

**9.1.4** Any QC result that fails to meet control criteria must be documented in a Nonconformance Memo (NCM). The NCM is automatically sent to the laboratory Project Manager by e-mail so that the client can be notified as appropriate. The QA group periodically reviews NCMs for potential trends. The NCM process is described in more detail in SOP DV-QA-0031 *Non-Conformance and Corrective*

*Action System*. This is in addition to the corrective actions described in the following sections.

**9.2 Batch Definition**

Batches are defined at the sample preparation stage. The batch is a set of up to 20 samples of the same matrix, plus required QC samples, processed using the same procedures and reagents within the same time period. Batches should be kept together through the whole analytical process as far as possible, but it is not mandatory to analyze prepared extracts on the same instrument or in the same sequence. The method blank must be run on each column on which the associated samples are analyzed. See QC Policy DV-QA-003P *Quality Control Program* for further details.

**9.3 Method Blank (MB)**

A method blank (MB) must be prepared and analyzed with each batch of samples. The MB consists of reagent water for aqueous samples, and Ottawa sand for soil samples.

The MB is created **at the time of extraction** after the samples have been dried, sieved, and ground and is processed through the extraction and analysis steps.

The method blank is used to identify any system and process interferences or contamination of the analytical system that may lead to the reporting of elevated analyte concentrations or false-positive data.

See Section 9.9 for the use of the grinding blank for Method 8330B solids samples that require ISM.

***Acceptance Criteria:*** The MB must not contain any analyte of interest >1/2 LOQ or at or above 10% of the measured concentration of that analyte in the associated samples, whichever is higher.

MBs are evaluated on each column on which associated samples are analyzed, when confirmation data are required. If there is a detection on either column in the MB, then detections for that target compound are suspect in associated samples. See Attachment 4 for guidance on interpretation of confirmation data to assess acceptance of the MB.

***Corrective Action:*** If the method blank does not meet the acceptance criteria, the source of contamination must be investigated and measures taken to correct, minimize, or eliminate the problem. Reanalyze and/or reprepare all samples associated with a failed method blank.

If the MB acceptance criteria are not met and re-preparation and reanalysis are not possible, then the sample data associated with the unacceptable MB must be qualified. This nonconformance must be addressed in the project or case narrative and the client must be notified.

**9.4 Laboratory Control Sample (LCS)**

One LCS must be analyzed with each extraction batch of samples (up to 20 samples). The LCS must contain specified analytes of interest and must be carried through the entire extraction and analytical procedure.

For water samples, the LCS is prepared by spiking the analytes of interest into reagent water. For soil samples, the LCS is prepared by spiking the analytes of interest into Ottawa sand during the extraction procedure.

The LCS is created **at the time of sample extraction** after the samples have been dried, sieved and ground. The LCS is used to monitor the accuracy of the analytical process. On-going monitoring of the LCS results provides evidence that the laboratory is performing the method within acceptable accuracy and precision guidelines.

The LCS must be analyzed on the confirmation column with samples. If there is insufficient volume to prepare an MS/MSD, and LCSD must also be prepared and analyzed.

See Section 9.10 for SRM criteria.

***Acceptance Criteria:***

Commercial Projects: The LCS recovery for each spiked analyte must be within established control limits. Laboratory default control limits are calculated as ± 3 standard deviations around the mean of historical data, as described in SOP DV-QA-003P *Quality Control Program*.

DOD/DOE QSM 5.4: QSM limits are applied unless project specific limits are requested by the client. When no QSM limits are available, laboratory historical limits are applied. Control limits are maintained in TALS.

In accordance with the TNI 2009 Standard a marginal exceedance within ± 4 standard deviations are allowed for one of the analytes. This is based on the number of analytes typically spiked for this method, which is between 11 and 30. These acceptance criteria may be superseded by project-specific limits, as applicable.

DOD/DOE QSM6.0: The LCS shall contain all surrogates and reported analytes. QSM limits are applied according the prep procedure (no ISM, or aqueous) unless project specific limits are requested by the client. When no QSM limits are available, laboratory historical limits are applied. Control limits are maintained in TALS. See Section 9.10 for SRM criteria.

***Corrective Action:*** If recoveries for all spiked analytes are not within the acceptance limits, including the one allowed marginal exceedance, the analytical system is out of control and corrective action must occur. Generally, this requires re-extraction and reanalysis of all associated samples. If the LCS is biased high and all associated samples are ND (not detected), it may be possible to report results with an NCM (see requirements for individual programs and clients).

**9.5 Matrix Spike Sample (MS) and Matrix Spike Duplicate (MSD)**

A matrix spike (MS) is a field sample to which known concentrations of target analytes have been added. A matrix spike duplicate (MSD) is a second aliquot of the same sample (spiked identically as the MS) prepared and analyzed along with the sample and matrix

spike. The soil matrix spikes are created **at the time of extraction**. Spikes are added after the sample has been dried, sieved, and ground.

One MS/MSD pair must be processed for each preparation batch (up to 20 samples). The MS/MSD results are used to determine the effect of a matrix on the precision and accuracy of the analytical process. Samples identified as field blanks, equipment blanks, or rinse blanks cannot be used for MS/MSD analysis.

***Acceptance Criteria:*** The spike recoveries must fall within established control limits. The relative percent difference (RPD) between the MS and MSD must be less than or equal to the established RPD limit. LCS limits are used for MS/MSD evaluation. Control limits are maintained in the LIMS. For DoD/DOE work, QSM limits are applied if available unless project specific limits are requested by the client. The RPD limit for DoD/DOE QSM work is 30% for Method 8330A and 20% for Method 8330B.

For QSM 6.0: The MS/D shall contain all surrogates and reported analytes. RPD limit for all analytes shall be < 20% between MS and MSD samples or sample and MD. LCS limits are used for MS/MSD evaluation and are maintained in the LIMS.

**NOTE**: RPD does not apply if the results are below the LOQ.

***Corrective Action:*** The information obtained from MS data are sample/matrix specific and are not normally used to determine the validity of the entire batch. If the MS and/or MSD recovery falls outside of the established control limits, the bracketing CCV and batch LCS recoveries must be within control limits in order to accept results for the associated samples. The following corrective actions are required for MS/MSD recovery failures to rule out lab error:

- Check calculation and instrument performance
- Verify, if possible, that the MS and MSD were spiked correctly (e.g., very low or very high recoveries)
- Consider objective evidence of matrix interference (e.g., heterogeneous sample, interfering peaks seen on chromatograms, or interference demonstrated by prior analyses);
- Flag the data for any results outside of acceptance limits
- For any single RPD failure, check calculations; verify, if possible, that the MS and MSD were spiked correctly; check instrument performance; consider objective evidence of matrix interference or sample inhomogeneity; and flag the data
- If both the parent sample and associated matrix spike results are over range the parent and the spikes shall be diluted by the same amount and the results from the reanalysis reported for both. If the analyte concentration in the parent sample is greater than 4x the concentration of spike added, then spike recovery results are not compared to control limits, and the recovery is either reported as “NC” (not calculated) or with a qualifier flag to indicate that the spike

was less than four times the analyte concentration in the sample. If the dilution will cause the spike to be less than two times the reporting limit, the MS/MSD do not need to be diluted and the recovery reported as "NC" (not calculated)

- For MS/MSD that serve as batch QC, if the parent sample result is within the calibration range and the MS/MSD results are above the calibration range, the results are reported with the MS/MSD result being flagged as an over-range measurement (e.g., the E-flag qualifier)
- If the MS/MSD are client requested and the parent sample result is within calibration range but the MS/MSD results are above the calibration range, MS/MSD are reported with narration and flagging. The sample and spike must be report from the same dilution.
- If the native analyte concentration in the MS/MSD sample exceeds 4 times the spike level for that analyte, the recovery data are reported as NC (i.e., not calculated) and the appropriate qualifier flags are added

**NOTE:** Some client programs require reanalysis to confirm matrix interferences. Check special project requirements for this corrective action.

**9.6 Surrogates**

Each calibration standard, field sample, and QC sample is spiked with the surrogate compound 1,2-dinitrobenzene. The surrogate is added to field samples and QC samples before the first extraction step for all matrices.

**QSM 6.0:** For solid samples that require ISM, the surrogate shall be added to each field sample, blank, and SRM after sieving and before any processing (drying, grinding, or extraction). Reprocessing by ISM is not possible if surrogate is outside the acceptance criteria, results will be flagged and reported with narration. An additional surrogate may be added to evaluate the extraction process.

***Acceptance Criteria:*** The recovery of the surrogate must fall within established statistical limits, which are based on historical data.

***Corrective Action:*** If recoveries for surrogates in blanks or LCSs are outside of the control limits, check for calculation or instrument problems and re-prepare and reanalyze the associated samples.

For samples with failing surrogate recoveries the decision to reanalyze or flag the data should be made as required by the project.

If matrix interference is obvious from observation of chromatograms or other objective evidence, reanalysis is unlikely to produce new or more useful information. If the matrix interference is not obvious from the initial analysis, it is only necessary to reprepare and reanalyze a sample once to demonstrate that poor surrogate recovery is due to matrix effect, so long as the extraction/instrument system is proven to be working properly.

### 9.7 Sample Replicate (ISM Soil Analysis only)

**NOTE:** Method 8330B requires the preparation of both a soil duplicate and a soil triplicate.

Although not typically required for organic analyses, a duplicate or triplicate sample may be required for project-specific quality control. The lab will extract triplicate aliquots after grinding on the client designated sample. If a sample is not designated by the client, the lab will select the sample.

Field blanks cannot be used for replicate testing. The results for replicates are reported separately and cannot be averaged when reporting results. Sample replicate results are used to evaluate the precision of the method. As such, results should be $\geqslant$ RL/LOQ for a valid statistical comparison.

**For QSM 6.0:** At the analytical subsampling step, ISM laboratory replicates shall be performed on one ISM sample in each preparation batch. ISM replicates shall not be performed on any sample identified as a QC or blank (e.g., LCS, Grinding Blank or other QC). The laboratory shall prepare and analyze three or more replicates, each consisting of a minimum of 30 increments of the same mass and depth.

***Acceptance Criteria:*** The RPD between the sample and the sample duplicate results must be less than the established limit.

***For QSM 6.0 Criteria***: The RPD shall not exceed 20%. RPD does not apply if all results are < LOQ

***Corrective Action:*** Results for samples that do not meet acceptance limits, particularly if due to difficulties in subsampling, shall be discussed in the final report case narrative, after client notification and agreement.

The percent relative standard deviation (%RSD) is calculated as follows:

$$\%RSD = \frac{s}{\overline{C}} \times 100\% \qquad \textit{Equation 1}$$

Where s is the standard deviation of the average concentration ($\overline{C}$) and is calculated as follows:

$$s = \sqrt{\frac{\sum_{i=1}^{n} (C_i - \overline{C})^2}{n-1}} \qquad \textit{Equation 2}$$

### 9.8 Grinding Blank (GB)

Refer to SOP DV-OP-0018 *Extraction of Nitroaromatic and Nitroamine Explosive Compounds and Picric Acid from Soil Samples* for details on how the grinding blanks for soils by method 8330B are prepared. The DOD/DOE QSM 6.0 requires one grinding blank per ISM batch, processed after the ground SRM, or after a client identified sample with known contamination, or at the end of the batch.

***Acceptance Criteria:*** The grinding blank must not contain any analyte of interest ≤ LOQ/RL or > 10% of the measured concentration of that analyte in the associated samples, whichever is higher.

***QSM 6.0:*** In addition to the above criteria, the grinding blank must be spiked with surrogate prior to the ISM process. Reprocessing the ISM is not possible grinding blank contains an analyte of interest, results will be flagged and reported with narration. The method blank can be used to asses if contamination was introduced during the ISM or extraction process.

***Corrective Action:*** If the method blank does not meet the acceptance criteria, the source of contamination must be investigated and measures taken to correct, minimize, or eliminate the problem. If there is remaining sample volume, re-subsample, re-analyze and/or re-prepare all samples associated with a failed method blank.

If the MB acceptance criteria are not met and re-preparation and reanalysis are not possible, then the sample data associated with the unacceptable MB must be qualified. This nonconformance must be addressed in the project or case narrative and the client must be notified.

**9.9 Grinding LCS (LCSSRM)**

Refer to SOP DV-OP-0018 *Extraction of Nitroaromatic and Nitroamine Explosive Compounds and Picric Acid from Soil Samples* for details on how the grinding LCS for soils by method 8330B is prepared. The grinding LCS is spiked by an commercial vendor, and then ground with the associated samples. One grinding SRM per batch is required.

***Acceptance Criteria:*** The grinding LCS recovery for each spiked analyte must be within established control limits. Control limits are maintained in TALS.

***Corrective Action:*** If the surrogate compound recovers below control limits, or every compound recovers outside of control limits, but at approximately the same percentage, this could be an indication of a bad extraction (post-grinding). Associated samples will be sent for re-extraction and re-analysis.

According to QSM 5.4, grinding may introduce a bias and is not recommended for certain compounds. This statement has been removed in QSM 6.0, although is still relevant.

**QSM 6.0 Criteria** Where an assignable cause isolated to only the SRM is identified, the SRM may be reanalyzed. Otherwise, reprepare (re-extract) and (re) analyze the SRM and all affected QC and field samples in the associated preparatory batch for the analytes outside acceptance criteria (beginning at the subsampling step for ISM samples) if sufficient sample material is available.

If the samples cannot be reprepared (re-extracted) and analyzed, apply qualifier to affected analyte results of all samples in the associated preparatory batch and explain in the case narrative. The ISM process cannot be redone.

## 10.0 Procedure

**10.1** One-time procedural variations are allowed only if deemed necessary in the professional judgment of supervision to accommodate variation in sample matrix, radioactivity,

chemistry, sample size, or other parameters. Any variation in procedure shall be completely documented using an NCM.

**10.2** Any deviations from this procedure identified after the work has been completed must be documented in an NCM, with a cause and corrective action described.

**10.3** **Extraction of Water Samples –** *Please reference DV-OP-0017 Solid Phase Extraction of Nitroaromatic and Nitroamine Explosive Compounds and Picric Acid from Water Samples for details*

Samples are extracted using a 500 mL initial volume and are concentrated to a 5 mL final volume.

**10.4** **Extraction of Soil Samples –** *Please reference DV-OP-0018 Extraction of Nitroaromatic and Nitroamine Explosive Compounds and Picric Acid from Soil Samples for details*

**10.4.1** Samples for method 8330A are extracted using a 2 g initial weight and delivered to the analytical group with a 10 mL final volume. Samples for method 8330B are extracted using a 10 g initial weight and delivered to the analytical group with a 20 mL final volume.

**10.4.2** TALS prep batches for soils will show a final volume of 20 mL for 8330A extracts, and 40 mL for 8330B extracts. These final volumes include the 1:1 dilutions with the acidified calcium chloride done by the analyst prior to instrument analysis. (See Section 10.5.2.)

**10.5 HPLC Analysis**

**10.5.1** HPLC Startup: All electronic equipment should be allowed to warm up for 30 minutes. During this period, at least 15 void volumes of mobile phase are passed through the column. Continue until the detector's baseline has stabilized.

**10.5.2** Prior to analysis, soil extracts (or a portion of the extract) must be diluted exactly 1:1 with the acidified calcium chloride solution that is described in Section 7.8.8.

**10.5.3** Analyze the samples using the chromatographic conditions given in Attachment 5. All positive measurements above the method detection limit observed on the primary C18 column are confirmed by injection of the sample extract onto the confirmation Phenyl-Hexyl column. The MB and LCS must be analyzed on the confirmation column if samples are analyzed on that column. The MS and MSD must be analyzed on the confirmation column if the parent sample is analyzed on the confirmation column. Many EDDs require the parent and MS/MSD results be from the same analytical batch. For DoD/DOE work, calibration and QC criteria are the same as for primary column analysis. QC must pass on both columns when confirmation analysis is performed for DoD or DOE.

**10.5.4** Analytes are introduced by direct injection of the extract. Samples, standards, and QC samples must be introduced using the same procedure.

**10.5.5** It has been demonstrated that water samples with total concentrations of 16,000 µg/L can yield low recoveries due to saturation of the extraction cartridge. The client should be contacted to determine if re-extraction using a smaller sample aliquot size is required for samples with concentrations in this range. The low extraction recovery may meet the client's action limit, such that a re-extraction may not be necessary.

**10.5.6 Analytical Sequence**

**10.5.6.1** The analytical sequence starts with either an initial calibration or a Continuing Calibration Verification (CCV). If the sequence begins with a CCV, the center of the retention time window is set based on the initial CCV in the sequence. Do not reset the retention times with the bracketing CCV.

**10.5.6.2** The CCV includes analyzing standards that contain all target analytes. If 2,4-diamino-6-nitrotoluene and 2,6-diamino-4-nitrotoluene are not target compounds, it is not required to analyze a CCV for these analytes.

**10.5.6.3** If there is a break in the analytical sequence greater than 12 hours since the analysis of a CCV standard, a new CCV standard must be analyzed before proceeding with the sequence.

**10.5.7 Retention Time Windows**

**10.5.7.1** Retention time windows must be determined for all analytes at method set up and after major maintenance (e.g. column change). Make an injection of all analytes of interest each day for a 3-day period. Calculate the retention time window width by 3x the standard deviation of each analyte retention time from a 72 hour study or 0.03 min, whichever is greater.

**10.5.7.2** The chromatograms in Attachments 6 and 7 summarize the estimated retention times on both the C18 and Phenyl-Hexyl columns for many of the compounds analyzed using this method.

**10.5.7.3** If the retention time window, as calculated above, < ± 0.035 minutes for the C18 column or < ± 0.07 minutes for the phenyl hexyl column, use ± 0.035 or ± 0.07 minutes as the retention time window. This allows for slight variations in retention times caused by sample matrix.

Picric Acid is known to shift in retention time for given sample matrix.

**10.5.8 Daily Retention Time**

The RTs are updated using the mid-point of the initial calibration, or the initial CCV of the sequence (i.e., the CCV that begins the analytical sequence).

**Note:** Chromatographic conditions, including the exact makeup of the eluent are determined at the time of the initial calibration and shall not be changed until the next initial calibration.

***Corrective Action:***

If there are shifts in retention times for target compounds between CCVs that are outside the established retention time window (see Section 10.5.7), all samples analyzed after the last compliant standard must be reanalyzed unless the following conditions are met for any compound that elutes outside the retention time window:

- The retention time of that compound in the standard must be within the retention time range equal to twice the original window, as determined by the opening CCV of a bracket, and

- The retention time of the compound must be shifted in the same direction as the surrogate and by approximately the same amount.

If these two conditions are met, reset the window and reprocess the data.

**10.6 Calibration Range and Dilutions**

**10.6.1** If the concentration of any analyte exceeds the working range as defined by the calibration standards, then the sample must be diluted and reanalyzed. Dilutions should target the most concentrated analyte in the upper half (between the CCV and highest standard) of the calibration range.

**10.6.2** Samples that are analyzed immediately following a sample with an unusually high concentration of explosives must be evaluated for carryover. The potential for carryover is minimized in the analytical system by continuously flushing the HPLC needle with solvent. If contamination is suspected, the sample should be re-aliquoted and re-analyzed.

**10.6.3 Guidance for Dilutions Due to Matrix Interference:**
It may also be necessary to dilute samples because of matrix interferences. If the sample is initially run at a dilution and only minor matrix peaks are present, then the sample should be reanalyzed at a more concentrated dilution.

Analyst judgment is required to determine the most concentrated dilution that will not result in instrument contamination. Ideally, the dilution chosen will make the response of the matrix interferences equal to approximately half the response of the mid-level calibration standard.

**10.6.4 Reporting Dilutions**
Some projects require reporting of multiple dilutions (check method comments in TALS). In other cases, the lowest dilution with no target compounds above the calibration range will be reported. In general, a maximum of two dilutions will be reported; one at the lowest dilution and one in which the most concentrated target analyte is in the upper half of the calibration range.

**10.7 Instrument Maintenance and Troubleshooting**

**10.7.1** Minor instrument maintenance may include back flushing the column, changing the guard cartridge, and changing the frit on the front end of the column.

**10.7.2** The solvent channel on which the buffer is run should be rinsed weekly with pure water followed by pure methanol and finally pure water again before reloading the buffer in order to prevent the buildup of salts and prevent bacterial growth in the system.

**10.7.3** A cleanup method is provided in the instrument software to remove the buffer from the column. It should be run as the last injection of any run sequence. The buffer solution should not be left on the column for extended periods when the instrument is not in use or decreased column lifetime will be observed.

**10.7.4** Noisy baseline, particularly noticeable in RL level standards and MDLV samples, is normally due to a noisy UV Lamp. If the noise is sufficient to interfere with the quantitation of these samples, the lamp should be replaced and the instrument recalibrated. Less commonly, noisy baselines are the result of dirty flow cell windows, which should be cleaned or replaced according the manufacturer's instructions.

**10.7.5** Unstable retention times are normally due to a malfunction somewhere in the flow path of the instrument. Likely sources are the active inlet valve, outlet ball valve, multichannel gradient valve or purge valve. Dirty solvent inlet filters can starve the pump and may also result in unstable retention times.

## 11.0 Instrument Calibration

**11.1** Detailed calibration equations can be found in the corporate SOP NDSC-US-TS-QP44940 *Calibration Curves and the Selection of Calibration Points*.

### 11.2 Instrument QC

**11.2.1** External calibration is used for this analysis. Prepare standards containing each analyte of interest at a minimum of five concentration levels. The low level standard should be at or below the reporting limit. The other standards define the working range of the detector. Recommended calibration levels are given in Attachment 2.

**11.2.2** A new calibration curve must be generated after major changes to the system or when the continuing calibration criteria cannot be met. Major changes include a new column and any changes in instrument operating parameters (including solvent flows, replacement of a detector lamp, replacement of the flow cell windows, etc.).

**11.2.3** With the exception noted in Section 11.2.4 below, it is NOT acceptable to remove points from the calibration curve for the purpose of meeting criteria, unless the points are the highest or lowest on the curve AND the reporting limit and/or linear range is adjusted accordingly. At least 5 points must be included in a linear calibration curve and at least 6 points for a second order calibration curve.

**11.2.4** A mid-level point may be removed from the calibration only if the reason can be clearly documented (i.e., a broken vial or an injection error). Due to the difficulty involved in properly documenting these errors, removing mid-points should be avoided if at all possible. The curve must also still satisfy the requirements for total numbers of points, five levels must remain in the calibration for a linear model and six for a second order model. The documentation must be retained with the initial calibration.

### 11.3 Initial Calibration

Calibrations are modeled either as average response factors or as calibration curves, using a systematic approach to selecting the optimum calibration function in order as follows. When calibration acceptance criteria cannot be met for a model, appropriate corrective action must be taken. This may include processing the data using another model, instrument maintenance and or re-preparation of standards followed by recalibration.

**11.3.1** The following requirements must be met for any calibration to be used:

**11.3.1.1** Response must increase with increasing concentration.

**11.3.1.2** Calibration curves will not be forced through the origin.

**11.3.1.3** The absolute value of the intercept of the curve at zero response should ideally be less than the MDL for the analyte. At a minimum the intercept must be less than ½ the on-column equivalent of the reporting limit.

### 11.3.2 Linear Calibration Using Average Calibration Factors

**11.3.2.1** External standard calibration using average calibration factors involves the comparison of instrument response (e.g., peak area or peak height) from the target compounds in the sample to the responses of the target compounds in the calibration standards. The ratio of the detector response to the concentration of target analyte in the calibration standard is defined as the calibration factor (CF), as follows:

$$CF = \frac{R_x}{C_s} \qquad \textit{Equation 3}$$

Where: $R_x$ = Response for analyte
$C_s$ = Concentration in calibration standard, µg/mL

**11.3.2.2** For each target analyte, calculate the average calibration factor ( $\overline{CF}$ ) as follows:

$$\overline{CF} = \frac{\sum_{i=1}^{n} CF_i}{n} \qquad \textit{Equation 4}$$

Where: n = Number of calibration levels
$CF_i$ = Calibration factor for the $i^{th}$ level

**11.3.2.3** The calibration relationship can be graphically represented as a line through the origin with a slope equal to the average calibration factor.

**11.3.2.4** The relative standard deviation (RSD) is calculated as follows:

$$RSD = \frac{SD}{\overline{CF}} x100\% \qquad \textit{Equation 5}$$

Where SD is the standard deviation of the average CF, which is calculated as follows:

$$SD = \sqrt{\frac{\sum_{i=1}^{n} \left(CF_i - \overline{CF}\right)^2}{n-1}} \qquad \textit{Equation 6}$$

**11.3.2.5** To calculate the concentration in an unknown sample extract, the equation is solved for concentration, resulting in the following equation:

$$C_{ex} = \frac{R_x}{\overline{CF}} \qquad \textit{Equation 7}$$

Where: $C_{ex}$ = Extract analyte concentration, µg/mL
$R_x$ = Response for analyte
$\overline{CF}$ = Average Calibration Factor

**11.3.3 Average Calibration Factor Evaluation**

Examine the residuals, i.e., the difference between the actual calibration points and the plotted line. Particular attention should be paid to the residuals for the highest points, and if the residual values are relatively large, a linear regression should be considered.

***Acceptance Criteria: QSM 5.4:***

The RSD of the average response factor must be ≤ 20% for 8330A. (15% for Method 8330B for DOD/DOE QSM 5.4 projects).

Examine the residuals, especially for the high points versus the fitted function. If the residual values are large, a linear regression should be considered.

The Relative Standard Error (RSE) for alternative curve types, including linear, quadratic, weighted or unweighted, must be ≤ 20% (15% for Method 8330B for DOD/DOE QSM projects)

***Corrective Action:*** If the RSD is > 20% (or > 15% for Method 8330B for DOD/DOE projects), average response factor cannot be used and least-squares linear regression should be attempted.

***QSM 6.0:*** RSD must be ≤ 20% for each analyte by 8330B if using average calibration.

**11.3.4 Linear Calibration Using Least-Squares Regression**

Calibration using least-squares linear regression produces a straight line that does not pass through the origin. The calibration relationship is constructed by performing a linear regression of the instrument response (peak area or peak height) versus the concentration of the standards. The instrument response is treated as the dependent variable (y) and the concentration as the independent variable (x).

The weighting used is the reciprocal of the concentration or the reciprocal of the square of the concentration. The regression produces the slope and intercept terms for a linear equation in the following:

$$R_x = m_1(C_s) + b \qquad \textit{Equation 8}$$

Where:
- $C_s$ = Concentration in calibration standard, µg/mL
- $R_x$ = Response for analyte
- b = y - Intercept
- $m_1$ = Slope

To calculate the concentration in an unknown sample extract, the regression equation is solved for concentration, resulting in the following equations, where $C_{ex}$ is the concentration of the target analyte in the unknown sample:

$$C_{ex} = \frac{[R_x - b]}{m_1} \qquad \textit{Equation 9}$$

Where: $C_{ex}$ = Extract analyte concentration, µg/mL
$R_x$ = Response for analyte
b = y - Intercept
$m_1$ = Slope

**11.3.5 Evaluation of the Linear Least-Squares Regression Calibration Function:**
With an unweighted linear regression, points at the lower end of the calibration curve have less weight in determining the curve than points at the high concentration end of the curve. For this reason, inverse weighting of the linear function is recommended to optimize the accuracy at low concentrations.

Note that the August 7, 1998 EPA memorandum "Clarification Regarding Use of SW-846 Methods", Attachment 2, Page 9, includes the statement "The Agency further recommends the use of this for weighted regression over the use of an unweighted regression."

***Acceptance Criteria:***

**11.3.5.1** Examine the residuals, but with particular attention to the residuals at the bottom of the curve. If the intercept or the residuals are large, a second-order regression should be considered.

**11.3.5.2** The linear regression must have a correlation coefficient (r) $\geqslant$ 0.995 ($r^2 \geqslant$ 0.990).

***QSM 6.0 Criteria:***

Option 2: Linear least square regression for each analytes must be $r^2 \geq 0.99$. Relative percent error must be $\leqslant$ 20% for mid-range concentration and $\leqslant$ 40% at the low level concentration.

**11.3.6** Non-linear Calibration Using a Second-Order Equation

**QSM 6.0 table B-3 does not include criteria for non-linear calibration.**

When the instrument response does not follow a linear model over a sufficiently wide working range, or when the previously described calibration approaches fail acceptance criteria, a non-linear, second-order calibration model may be employed. The second-order calibration uses the following equation:

*Equation 10*

$$R_x = m_2(C_s)^2 + m_1(C_s) + b$$

Where: $C_s$ = Analyte concentration in calibration standard, µg/mL
$R_x$ = Response for analyte
$m_2$ = Curvature
$m_1$ = Slope
b = y - Intercept

To calculate the concentration in an unknown sample extract, the roots of the quadratic equation are solved for:

$$C_{ex} = \frac{-m_1 \pm \sqrt{(m_1)^2 - 4(m_2)(b - R_x)}}{2m_2}$$

*Equation 11*

Where: $C_{ex}$ = Extract analyte concentration, µg/mL
$R_x$ = Response for analyte
$m_2$ = Curvature
$m_1$ = Slope
b = y – Intercept

**11.3.7 Evaluation of Second-Order Regression Calibration:**

A minimum of six points must be used for a second-order regression fit.

***Acceptance Criteria (QSM 5.4 or Commercial projects)***

**11.3.7.1** Second-order regressions should be the last option, and note that some programs (e.g., South Carolina) do not allow the use of second-order regressions.

**11.3.7.2** The coefficient of determination (COD, $r^2$) must be ≥ 0.99.

**11.3.7.3** The response increases significantly with increasing standard concentration (i.e., the instrument response does not plateau at high concentrations).

**11.3.7.4** The distribution of concentrations is adequate to characterize the curvature.

**11.3.7.5 QSM 6.0 table B-3 does not include criteria for non-linear calibration.**

**11.4 Calibration Verification**

**11.4.1 Initial Calibration Verification (ICV)**
A second-source verification standard must be analyzed with each initial calibration. The calculated concentration of the analytes in this standard may not be greater than 20% different from the calibration standard (QSM 6.0 or commercial projects).

QSM 5.0 or earlier use ≤15% for Method 8330A.

**11.4.2 Continuing Calibration Verification (CCV)**
The working calibration curve or RF must be verified by the analysis of a mid-point continuing calibration standard at the beginning of the analysis sequence, after every 10 samples, and at the end of the analysis sequence.

***Acceptance Criteria:***

For projects that require QSM 5.4 or earlier:

Results are acceptable for any individual compound if the %D (percent difference between the standard and measured values of the CCV standard) is ≤ 20%. (≤ 15% for QSM 5.4 or earlier for Method 8330A). Eurofins discourages the use of grand mean for method 8000B. The use of grand mean is not acceptable for Method 8000C (required by Arizona) or 8000D (required by North Carolina, South Carolina and West Virginia).

**NOTE:** In order to comply with DoD/DOE QSM requirements, the use of the grand mean is <u>not</u> acceptable (refer to policy DV-QA-024P QA/QC *Requirements for Federal Programs*). Results are acceptable for

individual compounds if the %D is: ≤ 15 for Method 8330A and ≤ 20 for Method 8330B.

***Corrective Action:***

If the percent difference for any analyte falls outside of ± 20% (or program specific limit such as DoD or DOE), corrective action must be taken. This may include back flushing the column, changing the guard cartridge, changing the frit on the front end of the column, or other minor instrument adjustments, followed by reanalyzing the standard. If the response for any analyte still varies by more than 20% (or program specific limit such as DoD or DOE), a new calibration curve must be prepared and analyzed. The column may also need to be replaced based on the chromatography.

Reported sample results must be bracketed by successful CCVs. When a CCV fails, all samples run since the last successful calibration verification must be reanalyzed. If the CCV recovery is > 20% D (or program specific limit such as DoD or DOE) and the associated samples are ND, the samples may be reported without reanalysis. Flag the data and document the decision in an NCM. For DoD or DOE, this must be accepted by the client and documented in the project records.

**For projects that require QSM 6.0 or later:**

***Acceptance Criteria:***

CCV must be analyzed daily before samples, after every 12 hours of analysis, and at the end of the analytical batch. All target analytes and surrogates must be withing their retention time window and within ± 20% of the true value.

***Corrective Action***

If there is an assignable cause isolated to only the CCV, one additional CCV may be analyzed immediate (within 1 hour and no samples analyzed). If the CCV is acceptable, proceed with analysis.

Correct the problem, analyzed a passing CCV or recalibrate. All affected samples shall be realized. If samples cannot be reanalyzed, qualifier the affected results and narrate.

If the CCV recovery is > 20% D (or program specific limit such as DoD or DOE) and the associated samples are ND, the samples may be reported without reanalysis. Flag the data and document the decision in an NCM.

## 12.0 Calculations / Data Reduction

**12.1** Detailed calibration equations can be found in the corporate SOP NDSC-US-TS-QP44940 *Calibration Curves and the Selection of Calibration Points*.

**12.2 Qualitative Identification**

**12.2.1** Tentative identification occurs when a peak is found within the retention time window for an analyte, at a concentration above the method detection limit. The required quantitation level is defined as the TALS reporting limit for standard reports, adjusted for initial weight and volume and any dilutions. A UV detector wavelength of 254 nm is used to quantify and report all analytes except PETN and Nitroglycerin that are quantified and reported using a UV detector wavelength of 215 nm.

**12.2.2** Identification is confirmed if a peak is also detected within the retention time window on a dissimilar column (Section 12.3).

**12.2.3 Sample Evaluation:**

**12.2.3.1** Analyst judgment weighs heavily in the evaluation of retention time shifts for client samples. The evaluation may be based on RT shifts of the surrogate standard (e.g. picric acid). The chromatograms must be examined closely to ensure that false positive / negative results are not reported. In the absence of significant shifts of the surrogate, peaks within a ± 0.035 minutes (C18 column) or ± 0.07 minutes (phenyl hexyl column) window must be considered positive results.

**12.2.3.2** If the sample required significant dilution due to high levels of target peaks or interfering compounds, the surrogate peak may not be obvious. In this case, an adjustment of RTs due to matrix for target compounds cannot be done reliably, and ± 0.035 minutes (C18 column) or ± 0.07 minutes (phenyl hexyl column) (or the established RT window described in Section 10.5.7) from the most recent CCV will be used for all compounds.

**12.2.3.3** The expected retention time for target analytes is updated with the retention times of each CCV. If sample matrix is causing significant retention time shifts between CCVs, samples may require dilution and reanalysis to minimize the matrix effects.

**12.2.3.4 Method Blank Detections:**
When a detection is observed in the method blank on either column, the result must be confirmed on the other dissimilar column to be considered a true hit. See Section 9.3 and Attachment 4 for additional information for evaluation of method blanks.

**12.2.3.5 Interferences:**
2,4,6-Trinitrotoluene elutes closely with 4-amino-2,6-dinitrotoluene on the primary (C18) column. Because of this close elution, high levels of 2,4,6-trinitrotoluene can overlap the retention time window for, and thus mask the presence of, low levels of 4-amino-2,6-dinitrotoluene. Therefore, 4-amino-2,6-dinitrotoluene may be reported as a detection from the confirmation (phenyl-hexyl) column, even though no peak could be detected on the primary column. In this event, an NCM is necessary.

Other target compound interferences may be observed in samples. Analyst judgment will be necessary to evaluate sample chromatograms and potentially report additional detections without confirmation due to interferences and/or analyze samples at dilutions. In this event, an NCM is required, documenting the decision.

**12.3 Second-Column Confirmation**

Detection of compounds on the primary column is confirmed using a second, dissimilar column. This column is calibrated using the same calibration levels as the primary column. The analysis on the second column must meet all of the instrument QC

described in Section 9.0 and 11.0. Identification is confirmed if a peak is also present in the retention time window for that analyte on the confirmatory column.

The RPD between two results is calculated using the following equation:

$$\%RPD = \frac{\left|R_1 - R_2\right|}{\frac{1}{2}\left(R_1 + R_2\right)} \times 100\% \qquad \textit{Equation 12}$$

Where $R_1$ is the result for the first column and $R_2$ is the result for the second column.

***Acceptance Criteria:***
The RPD between confirmed results should agree within 40%; results will then be reported from the primary column.

**QSM 6.0:** All results > MDL shall be confirmed. Samples without detection of target analytes do not require second-column analysis. The RPD between confirmed results should agree within 40%; results will then be reported from the primary column. RPD evaluation does not apply if both results are below the LOQ.

***Corrective Action:***
If the RPD is > 40% and there is visible positive interference, e.g., co-eluting peaks, elevated baseline, etc., for one column and not the other, then report the results from the column without the interference with the appropriate data qualifier flag, footnote, and/or narrative comment in the final report.

If the RPD is > 40% and there is visible positive interference for both columns, then report the lower of the two results with the appropriate flag, footnote, and/or narrative comment in the final report.

Special project reporting requirements may supersede these reporting schemes. Verify in the method comments or project Quality Assurance Summary.

**QSM 6.0:** Apply flags to affected results and narrate. If results are reported from the secondary column due to interference or QC outside acceptance criteria, the laboratory shall flag and narrate.

**12.4 Manual Integrations**

If manual data manipulations are necessary, they must be justified and documented. See Policy DV-QA-011P *Acceptable Manual Integration Practices* for requirements for manual integration.

**12.5 % Difference Calculation for ICV / CCV Evaluation**

The percent difference for the analysis of a CCV standard is calculated as follows:

$$\%\ \text{Difference} = \left(\frac{\text{Expected Value} - \text{Measured Value}}{\text{Expected Value}}\right) \times 100\% \qquad \textit{Equation 13}$$

**12.6 Concentration in Aqueous Samples**

The concentration of analyte in the original aqueous sample is calculated as follows:

$$\text{Concentration, } \mu\text{g/L} = \frac{C_{ex}V_t}{V_o}xDF \qquad \textit{Equation 14}$$

Where: $C_{ex}$ = Extract analyte concentration, µg/mL
$V_t$ = Volume of total extract in mL (normally 5 mL)

$V_o$ = Volume of water extracted in liters (normally 0.5 L)
DF = Dilution factor, as appropriate

**12.7 Concentration in Soil Samples**

The concentration of analyte in the original non-aqueous sample is calculated as follows:

$$\text{Concentration, } \mu\text{g/kg} = \frac{C_{ex} V_t}{WD} \times DF \qquad \textit{Equation 15}$$

Where:
$C_{ex}$ = Concentration of analyte in the extract (µg/mL)
$V_t$ = Total volume of original extract in mL (normally 20 mL for 8330A or 40 mL for 8330B); this volume includes the extracted volume in ACN and the 1:1 dilution with $CaCl_2$
W = Weight (mass) of sample extracted in kg (nominal 0.002 kg for 8330A or 0.010 kg for 8330B)
D = (100-% moisture in sample)/100 for dry weight basis or 1 for wet-weight basis
DF = Dilution factor, as appropriate

**12.8 Concentration of Ammonium Picrate**

Ammonium picrate is requested by some clients as a target compound. This is the ammonium salt of picric acid. Chromatographically, there is no difference between these two compounds, therefore, upon request, the result for ammonium picrate ($C_{AP}$) is calculated based on the measured concentration of picric acid, as follows:

$$C_{AP} = Picric\ Acid\ Result \times \left( \frac{246.13\,(Molar\ Mass\ of\ \ Ammonium\ Picrate)}{229.11\,(Molar\ Mass\ of\ \ Picric\ Acid)} \right) \qquad \textit{Equation 16}$$

In TALS, this calculation is accomplished by opening the batch information in the analytical batch, and setting the calculation line to 1 (Yes).

**12.9 LCS and CCV Percent Recovery**

$$\text{ControlSpike Recovery} = \frac{S_{SR}}{S_A} \times 100\% \qquad \textit{Equation 17}$$

Where
$S_{SR}$ = Calculated analyte concentration of spiked sample
$S_A$ = Concentration of standard added

**12.10 MS / MSD Percent Recovery Calculation**

$$\text{Matrix Spike Recovery} = \frac{S_{SR} - S_R}{S_A} \times 100\% \qquad \textit{Equation 18}$$

Where
$S_{SR}$ = Calculated analyte concentration of spiked sample
$S_R$ = Calculated analyte concentration of parent sample
$S_A$ = Concentration of standard added

**12.11 Relative Percent Difference Calculation for the MS/MSD**

$$RPD = \frac{\left| MS_R - MSD_R \right|}{1/2(MS_R + MSD_R)} \times 100 \qquad \textit{Equation 19}$$

Where
RPD = Relative percent difference
$MS_R$ = Matrix spike result of analyte
$MSD_R$ = Matrix spike duplicate result of analyte

**12.12** Reporting limits may be found in TALs. If samples require dilutions or smaller volumes than normally used, the MDLs and RLs will be correct based on the actual volume used and/or the dilution factor. Reporting limits for soil samples are adjusted for the actual weight of sample extracted. As samples are dried prior to subsampling for analysis percent moisture is not determined.

**12.13** All results are subject to two levels of technical review. See SOP DV-QA-0020 *Data Review* for a more detailed description for data review and an example of this checklist.

## 13.0 Method Performance

### 13.1 Method Detection Limit Study (MDL)

The method detection limit (MDL) is the lowest concentration that can be detected for a given analytical method and sample matrix with 99% confidence that the analyte is present. The MDL is determined according to the laboratory's MDL policy in NDSC-US-TS-QP44940 *Calibration Curves and the Selection of Calibration Points*. MDLs reflect a calculated (statistical) value determined under ideal laboratory conditions in a clean matrix, and may not be achievable in all environmental matrices. The laboratory maintains MDL studies for analyses performed; these are verified at least annually unless method or program requirements require a greater frequency.

### 13.2 Demonstration of Capabilities

All personnel are required to perform an initial demonstration of proficiency (IDOC) on the instrument they will be using for analysis prior to testing samples. On-going proficiency must be demonstrated annually. IDOCs and on-going proficiency demonstrations are conducted as follows.

**13.2.1** Four aliquots of the QC check sample are analyzed using the same procedures used to analyze samples, including sample preparation. The concentration of the QC check sample should be equivalent to a mid- level calibration.

**13.2.2** Calculate the average recovery and standard deviation of the recovery for each analyte of interest.

**13.2.3** If any analyte does not meet the acceptance criteria, the test must be repeated. Only those analytes that did not meet criteria in the first test need to be evaluated. TNI 2009 requires consecutive passing results. Repeated failure for any analyte indicates the need for the laboratory to evaluate the analytical procedure and take corrective action.

**13.2.4** Until the IDOC is approved by the QA Manager (or designee); the trainer and trainee must be identified in the batch record.

**13.2.5** Further details concerning demonstrations of proficiency are described in SOP DV-QA-0024 *Training*.

### 13.3 Training Requirements

The Group Leader is responsible for ensuring that this procedure is performed by an associate who has been properly trained in its use and has the required experience. A new analyst must be working under documented supervision prior to approval of the IDOC. Documentation that a new analyst is performing under supervision must be entered into the batch record (View Batch Information) until that analyst's IDOC has been approved by the QA Manager (or designee). See requirements for demonstration of analyst proficiency in SOP DV-QA-0024 *Training*.

## 14.0 Pollution Control

Standards and reagents are prepared in volumes consistent with laboratory use to minimize the volume of expired standards and reagents requiring disposal.

## 15.0 Waste Management

**15.1** All waste will be disposed of in accordance with Federal, State, and local regulations. When reasonably feasible, technological changes have been implemented to minimize the potential for pollution of the environment. Employees will abide by this procedure, the policies in Section 13, *Waste Management and Pollution Prevention*, of the Corporate Environmental Health and Safety Manual, and DV-HS-001P *Waste Management Plan*.

**15.2** The following waste streams are produced when this method is carried out:

**15.2.1** Expired Chemicals/Reagents/Standards – Contact Waste Coordinator

**15.2.2** Flammable solvent waste – Waste Stream C

**15.2.3** Flammable vial waste – Waste Stream A

**NOTE:** Radioactive and potentially radioactive waste must be segregated from non-radioactive waste as appropriate. Contact the Radioactive Waste Coordinator for proper management of radioactive or potentially radioactive waste generated by this procedure.

## 17.0 Method Modifications:

### 17.1 Deviations from Method Source and Rationale

Method 8330 prescribes the shelf life for standards as follows:

| Standards | Concentration | Shelf Life per 8330A | Shelf Life per 8330B |
|---|---|---|---|
| Stock standards | 1,000,000 µg/L (1,000 ppm) | 6 Months | 1 year |
| Intermediate standards | 2.5 to 10,000 µg/L | 30 days | 1 year |
| Working standards | 1 to 500 µg/L | Daily | Daily |

This SOP describes the use of 100,000 µg/L high-level standards, which are assigned a 6 month shelf life based on Eurofins Denver's experience with these materials. Further, a 25 - 1,000 µg/L standard mix is characterized as an intermediate-level, and assigned a 30 day shelf life.

**17.2** Acidic water (pH < 3) is added to the concentrated extract, dilutions, and all calibration and check standards in place of reagent water. This is to preserve any Tetryl present in the extract.

**17.3** The samples are dried, sieved, subsampled, ground, and extracted per project specification. See DV-OP-0018 for more details.

## 18.0 Attachments

Attachment 1. Analyte List

Attachment 2. Suggested Calibration Levels (µg/mL)

Attachment 3. Spike Levels

Attachment 4. Assessment of Method Blank Results

Attachment 5. Suggested Instrument Conditions

Attachment 6. Example Chromatogram from Primary Column – Ultracarb ODS (20)

Attachment 7. Example Chromatogram from Confirmation Column – Luna Phenyl-Hexyl

## 19.0 Revision History

This section has been added beginning with Revision 0. Only details of the last two revisions are incorporated into this SOP. Prior revisions are documented in the QA files and available upon request.

Revision 28, dated 13 July 2023

- Annual Review
- Language and formatting corrected throughout
- Changed Appendix to Attachment throughout document
- Add QSM 6.0 criteria throughout
- Removed Section 1.3
- Removed Section 1.3.4. 3,5-dinitroaniline is offered by 8330A and B and has been added into the 8330 Intermediate spike mix. Sections 7.6.2, 7.6.4, 7.7.1, 7.5.2, 10.5.6.2, Attachment 1 and 2.
- Updated Section 2.2 to include correct Appendix reference.
- Updated Section 6.3 on computer software and hardware
- Removed measurement uncertainty from Section 7.4
- Updated concentration in Sections 7.7.1
- Updated Note in Table 8.4 to include volume for MS/MSD
- Update Section 10.5.7 and 10.5.8 for clarity
- Remove Section 17.3

Revision 27, dated 13 July 2023

- Updated copyright information
- Section 11.3.3 updated to include %RSE for linear, quadratic, weighted, or unweighted curve types.
- Section 9.9 grinding blanks criteria are updated.

**Attachment 1. Analyte List**

| Compound | Peak # | | CAS # | Symbol |
|---|---|---|---|---|

## Scope

This method is suitable for the determination of low-level semivolatile compounds in soils and waters by selected ion monitoring (SIM) Gas Chromatography/Mass Spectrometry (GC/MS). The analysis applies to a concentration range that spans from an MDL of 0.01 µg/L in water (0.33 µg/kg for soil) to an upper calibration concentration of 10 µg/L in water (330 µg/kg for soil). Specific compound lists and their associated MDLs/LOQs are found in the Laboratory Information Management System (LIMS) under the analysis numbers listed on the front page of this SOP.

## Basic Principles

Water samples are extracted according to *T-OE-SVOA-WI11432* for 8270 analysis or *T-OE-SVOA-WI10947* for 625.1 analysis. Soil samples are extracted according to either *T-OE-SVOA-WI10928* or *T-OE-SVOA-WI10916*.

An environmental sample (soil, water, sludge, etc.) is solvent extracted and then analyzed by electron impact gas chromatography/mass spectrometry (EI GC/MS). A predetermined aliquot of an extract containing organic compounds in solvent is injected onto a fused silica capillary column coated with a relatively non-polar stationary phase, which is enclosed in a temperature controlled oven. A carrier gas, which is ultra-pure helium, passes continuously through the column. The GC oven is temperature programmed and the organic mixture separates into its individual components as it moves along the length of the column. This separation is the function of the polarity and boiling point of the individual compounds. This column empties into a mass selective detector. When a compound reaches the detector, it is bombarded by high-energy electrons (70 eV). This causes the compounds to fragment, forming ions. By applying various voltages to the lens, the positive ions are thrust into a quadrupole mass analyzer, which selects for a given mass fragment at a given time. These selected fragments reach an electron multiplier that detects and generates a signal for each mass fragment. The signals are amplified and sent to a computer. By analyzing for specific masses over a narrow mass range, SIM analysis allows for longer dwell times at specific masses. This allows for significantly greater sensitivity of analysis with a small reduction in specificity of analysis.

Target compounds are identified on the basis of spectral match and relative retention times as they compare to standards that are injected every 12 hours on the same system. Quantification is achieved via use of the internal standard calibration technique. The average relative response factor of a multi-point calibration is used for quantification when the appropriate criteria are met.

## Interferences

Method interferences may be caused by impurities in solvents, reagents, glassware, or other hardware used in the processing of samples. All glassware is solvent rinsed before use and a method blank is extracted with each extraction batch to demonstrate that the extraction system is free of contamination.

Sample matrices can have an effect on the ability of the GC/MS system to resolve the individual masses used for quantification. Samples may require dilutions, a reduction in the extraction volume/weight used, a raised final extraction volume, or extract clean-up using various techniques in order to achieve proper target separation and determination.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See Chemical Hygiene Plan for general information regarding employee safety, waste management, and pollution prevention.

The toxicity or carcinogenicity of each reagent used in this method has not been precisely defined; therefore, each chemical compound should be treated as a potential health hazard. Exposure to these chemicals must be reduced to the lowest possible level by whatever means available, such as the use of fume hoods, lab coats, safety glasses, and gloves.

All solvent waste generated from this analysis must be collected for recycling (if applicable) or must be disposed of in designated containers. These will then be transferred to a lab-wide disposal facility. Any solid waste material (disposable pipettes, broken glassware, and pH paper) must be disposed of in the normal solid waste collection containers or sharps containers, as applicable.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Uncontrolled Copy

Initially, each analyst performing instrumental analysis must work with an experienced analyst for a period of time until they can independently perform daily maintenance, calibrate the instrument, change the column, clean the source, interpret chromatograms, perform calculations, review data, and enter data into the LIMS. The analyst is also trained on the preparation of dilutions and calibration standards. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an Initial Demonstration of Capability (IDOC).

For 8270D/E the IDOC consists of four laboratory control samples that are spiked at 1-4x the LOQ and are carried through all steps of the procedure. For 625.1, the IDOC is spiked near the midpoint of the calibration. The defined acceptance criteria must be met. The criteria include the calculation of mean accuracy and standard deviation. The mean accuracy for all compounds must fall within the laboratory's most recent statistically derived LCS limits ±20% and must exhibit a standard deviation ≤20% for methods 8270D/E. The mean accuracy for all compounds must fall within the limits listed in table V under 'X' and must exhibit a standard deviation less than or equal to the limits listed in Table V under 's' for method 625.1. Analytes not listed in table V in 625.1 use statistically derived limits. See statistical info/method performance for more information.

Various options are available for a DOC and can include four laboratory control samples or one blind sample. Refer to *QA-SOP11178* for more guidance on these options.

## Sample Collection, Preservation, and Handling

Water samples are collected in 250mL or 1L glass amber containers with PTFE-lined lids and may be preserved with sodium thiosulfate ($Na_2S_2O_3$). They are stored at 0°C to 6°C, not frozen, prior to extraction and must be extracted within 7 days of collection.

Solid samples are collected in glass wide-mouth jars with PTFE-lined lids and are not preserved. They are stored at 0°C to 6°C, not frozen, prior to extraction and must be extracted within 14 days of collection.

All sample extracts must be stored at ≤-10°C (freezer) and protected from light using amber glass vials. All samples, sample extracts, and standards must be stored separately and in an area free from contamination. All extracts must be analyzed within 40 days of sample extraction.

## Apparatus and Equipment

1. Hewlett-Packard Model 6890 Gas Chromatograph or equivalent

2. Hewlett-Packard Model 5973 and 5975 Mass Selective Detector or equivalent

3. Hewlett-Packard ChemStation Software or equivalent

4. Chrome Peak Review data system or equivalent

5. Column:

30 m x 0.25 mm x 0.5 µm film thickness, Restek Rxi-5Sil MS or equivalent
30 m x 0.25 mm x 0.25 µm film thickness, Agilent DB-5MS or equivalent

6. Hamilton Gastight syringe, or equivalent – various volumes

7. Amber GC vials with crimp caps

## Reagents and Standards

Refer to *T-SVOA-WI11998* for all standard preparation information.

## Calibration

Calibration is accomplished using an internal standard calibration technique. Calibration standards at five or more concentration levels are analyzed. See Procedure F for the initial calibration process and criteria and see Procedure G for the continuing calibration process and criteria. If any client, state, or agency has more stringent calibration criteria, these must be followed instead.

**NOTE**: South Carolina does not allow the use of quadratic fits.

## Procedure

A. Standard preparation

Uncontrolled copy

Solutions are used to standardize the GC/MS system every 12 hours. Refer to *T-SVOA-WI11998* for standard preparation. Calibration solutions may be used up to the labeled expiration date or until component degradation is observed. Degradation is determined by the inability to pass continuing calibration checks or by observations of unacceptable chromatography.

B. Internal standards

Internal standard mix is added to all standards and subsequent samples at a concentration of 1 µg/mL for soil and 1L analyses, and 0.25 µg/mL for 250 mL analyses. Using a 25 µL syringe, add 10 µL of internal standard to 1 mL of sample extract or standard. See Table III for the list of compounds calibrated for and the internal standard that is assigned to each.

C. Daily maintenance

Refer to *T-SVOA-WI9598* for this procedure

D. Instrument conditions

1. The GC/MS system must be capable of meeting the following specifications:

| | |
|---|---|
| Mass range: | 35 to 500 amu |
| Scan time: | 1 scan/sec |
| GC column: | 30 m x 0.25 mm x 0.5 µm film Restek Rxi – 5 or equivalent |
| Injector temperature and mode: | 250° to 300°C; splitless |
| Transfer line temperature: | 250° to 300°C |
| Detector temperature: | 300°C |
| EI condition: | 70 eV |
| Mass scan: | Capable of SIM scanning (see manufacturer's instructions) |
| Carrier gas: | Helium at approximately 30 cm/sec. |
| GC Oven temperature program: | Initial temperature – 35°C<br>Initial hold time – 1.82 minutes<br>GC Ramp #1 – 20°C/minute to 310°C<br>GC Ramp #2 – 4°C/minute to 325°C<br>Final hold time – 4.30 minutes |

**NOTE:** It is not necessary to use the exact parameters listed above. Equivalent columns and conditions may be used to improve the linearity, sensitivity, overall chromatography, and performance required by the method on each GC/MS system.

2. Prior to analysis by SIM, a check standard must be analyzed in the full scan mode to determine where the specific start and stop times are for each of the groups. Each time column maintenance is performed, the scan times are reviewed to ensure that all ions are included. The GC/MS is configured in the SIM mode with a total cycle time (including voltage reset time) of 1 second or less. Set the Low Res to “N” and the Start Time for each group. In the m/z field, enter the ions for each group from the following tables:

| **GROUP 1 (Dwell – 60 msec)** | | | |

**NOTE:** Each program must be identical for the Temperature and Pressure programs so that the peak retention times are the same.

E. Tuning

1. The DFTPP tune check standard is used to assess GC column performance and injection port inertness as well as mass spectrometer performance. The GC/MS system's tune is checked by inspecting the mass spectrum of the DFTPP peak and column performance and injection port inertness is evaluated with pentachlorophenol, benzidine, and DDT.

2. The GC/MS should be tuned using a 50 ng/µL solution (12.5 ng/µL for 250 mL analyses) of DFTPP containing decafluorotriphenylphosphine, pentachlorophenol, benzidine, and DDT. This solution is prepared as indicated in *T-SVOA-WI11998*. See the table below for acceptance criteria and corrective actions.

| **Frequency** | **Acceptance Criteria** | **Corrective Action** |
|---|---|---|
| Prior to initial calibration and every 12 hours prior to continuing calibration standard<br><br>**NOTE**: Analysis of DFTPP, the LCS, and the blank are outside of the 12-hour analysis shift for method 625.1. The total time for DFTPP, the LCS, the blank, and the 12-hour shift must not exceed 15 hours. | 1. Ion Acceptance Criteria in Table I<br><br>2. DDT breakdown ≤20%*<br><br>3. Tailing factors:<br><br>a. 8270D/E:<br>- Benzidine ≤2<br>- Pentachlorophenol ≤2**<br><br>b. 625.1:<br>- Benzidine <2<br>- Pentachlorophenol <2** | 1. Re-tune. Analysis cannot proceed until tune meets criteria.<br><br>2. More aggressive injection port maintenance.<br><br>3. Clean the source.<br><br>4. Change the column. |

*DDT breakdown greater than 20% may be acceptable if calibrating for polynuclear aromatic hydrocarbon (PAH) compounds only. Consult supervisor when this situation occurs.

**Unless project requirements dictate otherwise, the PCP tailing factor may fail acceptance criteria as only compounds with basic or neutral properties are targets of interest by SIM.

3. Use only the background-subtracted spectrum of the following when evaluating the DFTPP:

A three scan average of the apex of the scan, the apex of the scan -1, and the apex of the scan +1.

**NOTE:** All standards, samples, and associated quality control samples analyzed within a particular tune must use the identical conditions of the mass spectrometer.

F. Initial calibration (ICAL)

1. The initial calibration consists of analyzing standards at 6 concentration levels (0.05, 0.2, 0.5, 1, 5, and 10 ng/µL for solid and 1L water analyses) (0.01, 0.05, 0.1, 0.5, 1, and 2.5 ng/µL for 250-mL analyses). The initial calibration for 8270D soil and 1L water extractions includes an additional calibration point at 0.01 ng/µL. Response factors are produced for each level. An average response factor is then generated for each compound and surrogate. The relative standard deviation (%RSD) of the response factors determines the

Uncontrolled Copy

suitability of the average relative response factor for calculation of compound concentration. Use of the average relative response factor requires at least four calibration levels. If an alternate fit is required for any compound, at least five calibration levels are required for linear fits, and six calibration levels are required for quadratic fits. At the end of the calibration standard injections, inject the Method Detection Limit (MDL) standard and an initial calibration verification (ICV) standard. See the tables below for acceptance criteria and corrective actions.

| ICAL Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| 1. Initially establish with at least 6 levels of standards.<br><br>2. When % drift in the daily continuing calibration check standard fails criteria. | 1. %RSD requirements (if these criteria are met, then calculate concentrations based upon the average response factor fit):<br><br>a. 8270D/E: %RSD ≤20%<br><br>b. 625.1: %RSD ≤35%<br><br>2. The relative retention time of each target compound in each calibration standard should agree within 0.06 relative retention time units.<br><br>3. Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer-peaks is <25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs.<br><br>4. 8270D/E: See table II for minimum response factors for each compound. It is not necessary to meet these specifications. They are provided merely as guidance.<br><br>5. The %Error is measured between the calculated and expected amounts of a compound at each calibration level to determine the calibration function acceptability for linear and quadratic curve fits. The % error must be ≤50% for the low calibration point. For calibration points above the LOQ the % error must be ≤30%. **NOTE:** For 625.1 calibrations, only the low calibration point and the mid-point need to be evaluated. | 1. If the %RSD for any compound is greater than the defined acceptance criteria, use a first degree(linear) fit provided the correlation coefficient (CC; r) is ≥0.995 or the coefficient of determination (COD;r2) is ≥0.99. If the linear fit fails to meet this criteria, then a second order (quadratic) fit may be used provided the coefficient of determination is ≥0.99.* If use of both the linear fit and the quadratic fit is acceptable using these criteria for any given compound, then use the fit with the smallest negative y-intercept. When using a quadratic fit, if the y-intercept quantifies to be greater than the MDL, consult your supervisor immediately or re-calibrate.<br><br>2. Re-inject any levels that appear to be outliers due to an injection error.<br><br>3. If standard levels on the outside of the curve appear to be outliers for individual compounds and are throwing off the calibration curve, they can be dropped from the calibration keeping the following in mind:<br><br>a. If a low calibration point is dropped, the analyst must ensure that the compound is still being calibrated down to or below its RL.<br><br>b. If a high calibration point is dropped, any detections must recover below the new upper calibration limit.<br><br>4. Re-prep calibration standards.<br><br>5. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

*South Carolina does not allow the use of quadratic fits.

| MDL Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Immediately following an initial | 1. The system must be able to | 1. If any compounds are not |

Uncontrolled Copy

| | | |
|---|---|---|
| calibration and before sample analysis | detect all compounds in the MDL solution. | detected in the MDL standard, analysis can proceed if the compound is detected at or below its MDL in a higher concentration level.<br><br>2. If the system does not detect the compound(s), then the tuning and/or calibration procedure must be repeated under conditions that will yield a detection for the compound(s) or the MDL must be raised for the compound(s).<br><br>3. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

**NOTE:** 625.1 does not require the analysis of an MDL standard as part of the initial calibration.

| ICV Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Immediately following an initial calibration and before sample analysis | 1. The ICV must be prepared using a second source standard<br><br>2. %D requirements:<br><br>a. 8270D/E: ±30%D<br><br>b. 625.1: Criteria listed under Q in Table V of this SOP<br><br>3. The EICP area for each internal standard must fall within the window of -50% to +100% of the areas from the mid-level calibration standard produced during the initial calibration.<br><br>Surrogate compounds must be included in the processing list for analysis 625.1 and must meet the same criteria as target compounds. | 1. Re-prep and re-analyze the ICV.<br><br>2. If the recovery for any compound fails these criteria low, the compound cannot be analyzed for under the calibration until a new ICV has been analyzed.<br><br>3. If the recovery for any compound fails these criteria high, the compound may be analyzed for but any samples with detections should be re-analyzed under a valid ICAL or will be reported with a qualifying comment.<br><br>4. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

2. One of the calibration standards must be at a concentration at or below the limit of quantitation (LOQ). The other concentrations correspond to the expected range of concentrations found in samples or should define the working range of the GC/MS system.

3. The concentration of the MDL standard may require modification dependent upon the current MDL values.

G. Continuing calibrations

Perform the continuing calibration verification (CCV) by injecting a predetermined aliquot of a calibration standard at a concentration near the mid-point of the calibration, not to exceed ½ the highest level in the calibration. See the table below for acceptance criteria and possible corrective actions.

| CCV Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| 1. Every 12 hours.<br><br>2. The CCV is analyzed each day a curve is not analyzed. | 1. %Drift:<br><br>a. 8270D/E: ≤20%<br><br>b. 625.1: Criteria listed under Q in Table V of this SOP | 1. If the CCV fails and the cause is obvious such as in the case of a concentrated standard or a mis-injection, re-inject the CCV, making sure to select another |

Uncontrolled Copy

| | | |
|---|---|---|
| 3. The CCV is analyzed after DFTPP. | 2. The relative retention times of the internal standards must be within 10 seconds of the retention times from the mid-level calibration standard of the last initial calibration. The exception would be in the case of column maintenance.<br><br>3. The EICP area for each internal standard must fall within the window of -50% to +100% of the areas from the mid-level calibration standard produced during the last initial calibration.<br><br>4. 8270D/E: See Table II for minimum response factors for each compound. It is not necessary to meet these specifications. They are provided merely as guidance.<br><br>5. Structural isomers that produce very similar mass spectra are identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved when the height of the valley between two isomer peaks is <25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. | standard vial if a bad standard is suspected.<br><br>2. If the %Drift for any compound is >20% high and it is not detected in samples, data can be reported.<br><br>3. If the %Drift for any compound is >20% low, perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* or adjust the tune file. Document the corrective action in the form of a non-conformance memo. Re-inject DFTPP and the calibration standard. If the CCV does not pass after corrective action, a new initial calibration must be established.<br><br>**NOTE:** For method 8270D, in cases where compounds recover >20%D low, they may still be reported as non-detects if it can be demonstrated that there was adequate sensitivity to detect the compounds at the applicable quantitation limit. For situations when the failed compound is present, the concentrations must be reported as estimated values. |

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

H. Analysis of Samples

1. All sample extracts are stored at ≤-10°C and protected from light from the time of sample extraction.

2. Prior to sample analysis, add 10 µL of internal standard to each 1.0 mL of sample extract.

3. Analyze a predetermined aliquot of each sample extract under the same conditions used for the initial and continuing calibrations.

4. At the conclusion of data acquisition, use the same software to tentatively identify peaks within the retention time window of interest. Examine the ion abundances of components of the chromatogram. If the ion abundance of the target ion used for quantitation exceeds the calibration range, dilute the aliquot and reanalyze. When preparing dilutions, add sufficient internal standard to maintain the same concentration as that of the ICAL.

a. Dilution criteria

I. Initial dilutions are recommended in the following situations:

i. More than three internal standard recoveries are <50%.

ii. Either of the last two internal standard recoveries are <20%.

iii. The analyst's judgment of a sample extract's color or viscosity indicates possible matrix interference.

iv. Raised final prep volume can also be indicative of potential matrix interference

Uncontrolled Copy

I. Secondary dilutions are required to bring all target compounds into the calibration range of the GC/MS.

A. Qualitative Analysis:

A compound is identified by comparison of the following parameters with those of a standard of the suspected compound (standard reference spectra). The reference mass spectrum used for this comparison should be generated by the laboratory using the conditions of the method. In order to verify identification, the following criteria must be met:

1. The sample component relative retention time should compare within ±0.06 RRT units of the RRT of the standard component.

2. The intensities of the characteristic ions of the compound must maximize in the same scan or within one scan of each other. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 20% relative intensity if less than three such ions occur in the reference spectrum.

3. The relative intensities of the characteristic ions:

   a. 8270D/E - The relative intensities of the characteristic ions must agree within 30% of the relative intensities of these ions in the reference spectrum. (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%.)

   b. 625.1 - The relative intensities of the characteristic ions must agree within 50% to 200% (0.5 to 2 times) for the quantitation and secondary m/z's in the reference mass spectrum stored in the data system. For example, if a peak has an intensity of 20% relative to the base peak, the analyte is identified if the intensity of the peak in the sample is in the range of 10% to 40% of the base peak. Analyst discretion is used to determine compound identification.

4. The above criteria apply to detections greater than or equal to the LOQ. For detections between the MDL and the LOQ, the above criteria and analyst discretion are used to determine compound identification. If identification is ambiguous, an experienced spectrometrist must determine the presence or absence of the compound.

B. Quantitative Analysis:

When a compound has been identified, quantitation is based on the internal standard technique and the integrated abundance from the extracted ion current profile (EICP) of the primary characteristic ion.

## Calculations

Refer to *T-SVOA-FRM9602* for all departmental calculations.

## Statistical Information/Method Performance

LCS, MS, surrogate, and RPD recoveries are compared to the limits stored in the LIMS. The surrogate recoveries will be compared to statistically generated limits for acceptance criteria for 8270D/E and for the surrogate in Table IV for 625.1. The LCS and MS recoveries will be compared to statistically generated limits for 8270D/E and for all 625.1 compounds contained in Table IV. For any compounds not contained in table IV, the LCS and MS recoveries will be compared to limits contained in Table V and the surrogate recoveries will be compared to limits contained in Table VI for 625.1.

For 8270D/E LCS and surrogate limits are statistically derived every six months in accordance with *T-SVOA-WI9604*. For 625.1 limits are derived anually. All RPDs are set to a default value of 30%, and MS limits are set equal to LCS limits.

All current and historical limit data is stored in the LIMS under the methods listed in the header of this SOP. The historical data for MDLs, MS/D, LCS/D, and measurement of uncertainty is reviewed at least annually and kept on file. Refer to the QA/QC section of this SOP and the criteria listed throughout this procedure for additional information on the performance of this method.

## Quality Assurance/Quality Control

Uncontrolled Copy

A. Batch QC

1. Each extraction batch of ≤20 samples must contain a method blank, a laboratory control sample (LCS) and an unspiked background sample (US), a matrix spike (MS), and a matrix spike duplicate(MSD).

2. A laboratory control sample/laboratory control sample duplicate (LCS/LCSD) is prepared with the extraction batch if adequate sample volume is not provided to prepare a matrix spike and matrix spike duplicate.

3. Additional QC samples may be required to meet project or state certification requirements.

B. QC and sample spiking

1. The LCS/D and MS/D are spiked at a concentration of 1 ppm.

2. All samples are spiked with surrogates at a concentration of 1 ppm by the extraction group to evaluate the extraction process.

3. Prior to analysis each sample extract is spiked with an internal standard mix.

4. All spiking concentrations are 4x lower for 250-mL aqueous analyses.

C. QC items, acceptance criteria, and corrective actions.

**NOTE: If any client, state, or agency has more stringent QC, QC limits, or batch requirements, these must be followed instead.**

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Internal Standards | 1. Peak area within -50% to +100% of the area in the associated reference standard.<br>2. Retention time (RT) within 30 seconds of RT for associated reference standard. | 1. Check instrument for possible problems and then re-inject sample(s).<br>2. If re-injection meets the criteria, report this injection.<br>3. If re-injection still shows the same problem, report first injection.<br>4. If there is substantial matrix interference, the analyst may dilute the extract as outlined in Procedure H.4. |

Uncontrolled copy

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Method Blank | 1. Must meet internal standard criteria.<br>2. Must meet surrogate criteria.<br>3. All target compounds must be less than the reporting limit for the associated samples.<br>4. For 625.1 the method blank must be analyzed immediately after the LCS and before the MS/D. | 1. Inspect system for possible problems and reanalyze.<br>2. If the surrogates are out of spec high data can be used provided there aren't detections in the method blank.<br>3. If the surrogates are out of spec low and there aren't detections in the associated samples, the data can be used.*<br>4. If the method blank contains target compounds and the associated samples do not contain these compounds, no corrective action is required.<br>5. If the target compounds in the blank are also in the associated samples at a concentration <10x that in the blank, the samples are re-extracted unless the detection does not interfere with project data requirements.<br>6. If the target compounds in the blank are also in the associated samples at a concentration >10x that in the blank the data is usable.<br>7. Phthalates may be detected in the method blank and data reported as long as the phthalate detection is <LOQ. |
| Instrument Blank** | 1. Must run after the CCV if no clean method blank is analyzed at the beginning of the 12-hour analytical period.<br>2. Must meet internal standard criteria.<br>3. All target compounds must be less than the reporting limit for the associated samples. | 1. Inspect system for possible problems and reanalyze.<br>2. If the instrument blank contains target compounds and the associated samples do not contain these compounds, no corrective action is required.<br>3. If the target compounds in the blank are also in the associated samples, the samples should be re-extracted unless it does not interfere with project data requirements or if sample detections are at a level 10x higher than the detections in the blank. |

Uncontrolled Copy

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Laboratory Control Sample/Laboratory Control Sample Duplicate | 1. Must meet internal standard criteria.<br>2. Must meet surrogate criteria.<br>3. % Recoveries within QC limits. Refer to the analysis numbers in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis.<br>4. RPDs within QC limits. | 1. If non-compliant, check for calculation or preparation errors.<br>2. If no errors found, check system for problems and reanalyze.<br>3. If LCS/LCSD recoveries are still outside acceptance limits, one of the following actions must be taken:<br>a. if recoveries are outside acceptance limits low, the sample(s) must be re-extracted.<br>b. if recoveries are outside acceptance limits high, data may be usable if the compounds that recovered above QC limits are not detected in samples.<br>c. if recoveries are outside acceptance limits high and there are detections of the failing compounds, the sample(s) must be re-extracted.<br>4. If RPDs fail but recoveries are within QC limits, no further action is required.<br>5. If surrogates fail to meet criteria but all target compounds are within specification, data is usable.*<br>6. Marginal exceedance limits, as defined in the NELAC standards, may be used if the defined requirements have been met for 8270D/E.<br>7. South Carolina requires an aqueous LCS recovery criterion of 70-130% for PAH SIM analysis. |
| Matrix Spike/Matrix Spike Duplicate (MS/MSD) | 1. Must meet internal standard criteria.<br>2. Must meet surrogate criteria.<br>3. % Recoveries within LCS limits. Refer to the analysis number in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis.<br>4. RPDs within QC limits. | 1. If LCS within QC limits, proceed with sample analysis.<br>2. If most recoveries or RPDs out of spec, consult supervisor. BKG, MS, MSD may need to be re-extracted. |

Uncontrolled Copy

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Surrogates | 1. %Recoveries within QC limits. Refer to the methods in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis. | 1. If non-compliant, check for calculation or preparation errors.<br>2. If no errors found, check system for problems and reanalyze.<br>3. If no problem is found, re-extract and reanalyze.<br>4. If surrogates are out of spec high and no targets are detected in the sample no corrective action is required.<br>5. For samples analyzed only at a dilution ≥10x, no further action is required for surrogate failures. |

*Requires approval of supervisor.
**Method blank or instrument blank in each 12-hour analytical period required for 8270E. (an instrument blank is recommended for all methods to demonstrate the instrument is free of contamination)

**NOTE:** Any failures without corrective action require approval of supervisor and completion of a non-conformance memo (NCM).

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

D. Lower Limit of Quantitation (LLOQ)

1. The lower limit of quantitation (LLOQ) is verified annually through the extraction and analysis of an LCS at 0.5 to 2 times the established LLOQ.
2. The LLOQ is performed on similar analytical instruments such that all are included, at a minimum, within a 3 year time period.
3. Until the laboratory has sufficient data to determine the acceptance limits, the LLOQ criteria is ± 20% of the LCS limits.
4. Refer to *QA-SOP11892* for additional initial and ongoing LLOQ requirements.

E. Method Detection Limit (MDL)

1. Initial MDL studies must contain at least seven replicates and must be prepped across three different calendar days.
2. The MDLs must be analyzed on every instrument used for that analysis across three different calendar days.
3. Two ongoing MDLVs are analyzed and confirmed quarterly on each instrument, and MDLs are updated, if necessary, after enough points have been collected.
4. All compounds in the ongoing MDL verifications must be spiked at the same concentration level as the initial study.
5. Refer to *QA-SOP11892* for additional initial and ongoing MDL requirements.

F. Limit of Quantitation (LOQ)

1. Initial LOQ studies are spiked with compounds at the laboratory assigned LOQ and are analyzed on every instrument used for that analysis.
2. One ongoing LOQV is analyzed and confirmed quarterly on each instrument, and the LOQs are updated, if necessary.
3. Until the laboratory has sufficient data to determine the acceptance limits, the LOQ criteria is ±20% of the LCS limits.

Uncontrolled copy

4. Refer to *QA-SOP11892* for additional initial and ongoing LOQ requirements.

**Table I**

**DFTPP Key Ion Abundance Criteria (8270C/D/E/625.1)**

| Mass | Ion Abundance Criteria |
|---|---|
| 51 | 10% to 80% of mass 198 |
| 68 | less than 2% of mass 69 |
| 70 | less than 2% of mass 69 |
| 127 | 10% to 80% of mass 198 |
| 197 | less than 2% of mass 198 |
| 198 | base peak, or >50% mass 442 |
| 199 | 5% to 9% of mass 198 |
| 275 | 10% to 60% of mass 198 |
| 365 | greater than 1% of mass 198 |
| 441 | present but less than 24% of mass 442 |
| 442 | Base peak, or >50% of mass 198 |
| 443 | 15% to 24% of mass 442 |

| *T-WC-WI9901* | Equipment Muffle Furnaces and Ovens |

## Scope

This procedure is applicable to the determination of the distribution of particle sizes in soils and solids. Particle sizes in the range 75 to 0.075 mm are determined by sieving. Distribution of particle sizes smaller than 0.075 mm is determined by a sedimentation process using a hydrometer.

## Basic Principles

A portion of sample is soaked in a dispersing agent then partitioned into separate portions: material retained on a #10 sieve and material passing the #10 sieve. The material retained on the #10 sieve is dried to constant weight then passed through a large size sieve stack; the material retained on each sieve is measured and recorded. Material passing the #10 sieve is subject to hydrometer analysis then passed through a small size sieve stack; the material retained on each sieve is measured and recorded. All measurements: large and small sieves and hydrometer readings, and the hygroscopic moisture are used to establish the particle size distribution of the sample.

This SOP is based on the following reference methods: ASTM Standard D2217-8585 (Re-approved 1998), ASTM Standard D422-63 (Re-approved 2007), ASTM Standard D6913-17, and ASTM Standard D7928-17.

NOTE: ASTM D2217 was withdrawn without replacement by ASTM in 2007. A withdrawn standard is an ASTM standard that has been discontinued by the ASTM Sponsoring Committee responsible for the standard.

NOTE: ASTM D422-63 was withdrawn by ASTM in January 2016. Individual methods for gradation by sieve analysis (ASTM D6913-17) and gradation by sedimentation/hydrometer analysis (ASTM D7928-

Uncontrolled Copy

17) were promulgated as replacement approaches. At the time of this writing, ASTM has not yet developed a combined sieve/hydrometer approach. The laboratory's procedure will utilize elements of these two new methods into a combined approach.

## Interferences

Any sample that contains non-soil particle(s) will cause an interference particularly in the hydrometer phase of the test, which leads to anomalous particle size distribution. This manifests itself in the particle size distribution curve bottoming out at zero then starts to climb again. Analysts must evaluate the data and inform the client via a Non Conformance Memo (NCM) to notify them of this sample matrix issue.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each technician performing these techniques must work with an experienced technician for a period of time until they can independently perform the procedure. Analysts are considered proficient when they have successfully demonstrated competency under supervision of a supervisor or other trained analyst, with a documented OJT form.

## Sample Collection, Preservation, and Handling

Sample are collected in a glass jar or plastic bag. A minimum of 500g of sample is recommended. There is no holding time for this analysis. Samples are stored at 0 to 6 degrees C; not frozen.

The lab will reject samples that have questionable matrices for the grainsize test. If the lab determines that a matrix is inappropriate for analysis, this will be communicated to the client with a Non Conformance Memo (NCM).

## Apparatus and Equipment

1. Top-Loading Balance, capable of weight measurement to 0.01 g
2. Mechanical Stirring Device and Dispersion Cup
3. Thermometer: Accurate to 0.5°C
4. Mortar and Rubber Tipped Pestle
5. Sedimentation Cylinder(s) 1000 mL
6. Hydrometer: ASTM 151H in specification E 100.
7. Sieves, of the following size(s): Gilson Company, Inc. or equivalent
    1. 3.0" (75.00 mm)

Uncontrolled copy

2. 2.0” (50.00 mm)
3. 1.5” (37.50 mm)
4. 1.0” (25.00 mm)
5. 3/4" (19.00 mm)
6. 3/8” (9.50 mm)
7. # 4 (4.75 mm)
8. #10 (2.00 mm)
9. #20 (850.0 um)
10. #40 (425 um)
11. #60 (250.0 um)
12. #80 (180.0 um)
13. #100 (150.0 um)
14. #200 (75.0 um)

8. Drying Oven with temperature range of 60-110°C
9. Stainless Steel Spatulas & Spoons
10. Metal & Bristle Brushes
11. Sieve Shaker
12. Timer

## Reagents and Standards

Alternate weights may be used as long as the final concentrations remain the same.

1. Sodium hexametaphosphate solution

a. Using a 1000-mL volumetric flask, dissolve 40 g of sodium hexametaphosphate in reagent water.

b. Dilute to final volume once dissolved.

c. Store at room temperature in a glass or plastic container.

d. Solution expires one month from date of preparation.

## Calibration

Balance calibration must be checked each day before use.

## Procedure

Uncontrolled copy

## A. % Solids Test

Check to be sure that the balance has been calibrated each day before use.

1. Label an aluminum pan with the Lab ID for each sample.

2. Tare the balance. Weigh the aluminum pan and record in spreadsheet *T-WC-FRM46355*.

3. Mix the sample with a stainless steel spatula. Measure at least 10-15 g of each sample into the labeled aluminum pan and record the weight of sample in the spreadsheet.

4. Place the pan and sample in an oven maintained at a temperature of 110°C +/- 5°C and dry the sample for at least 16 hours. Reweigh each pan and record the weight measurement in the spreadsheet.

## B. Hydrometer Analysis

Check to be sure that the balance has been calibrated each day before use.

1. Use calculated % Solids from Procedure A. and Table 2 to determine the amount needed for analysis. Add an NCM and contact the PM if there is insufficient sample to perform the test.

2. Using the sample in the 250-mL beaker add 125 mL of sodium hexametaphosphate solution. Stir the soil-water slurry until it is thoroughly moistened. Cover and label beaker with sample number. Allow this slurry to soak for at least 16 hours.

3. At the end of the soaking period, transfer the soil-water slurry into a dispersion cup using room temperature reagent water. Be sure to rinse all residue from the beaker into the dispersion cup.

**NOTE:** Extra care needs to be taken when rinsing the sample into another container or when using any apparatus. **All particles need to be rinsed into the new container or a loss in sample weight is possible to occur.**

4. Stir for one minute using the stirring apparatus. **Rinse stirring apparatus well into dispersion cup to prevent loss of sample.**

5. Place the #10 sieve in a funnel above a 1000-mL glass sedimentation cylinder. Transfer the soil-water slurry into the cylinder, rinsing well. Add room temperature reagent water until the total volume is 1000 mL.

a. Label an aluminum pan with the sample ID. Transfer the sample retained on the #10 sieve to the aluminum pan. Place the pan in the oven set to 110°C +/- 5°C and dry the sample for at least 16 hours. Inspect materials in Procedure C.1 and perform Sieve Analysis in procedure C.2.

6. Cover the open end of the cylinder with parafilm, then placing the palm of the hand over the end, invert the cylinder and agitate for a period of one minute. Place the cylinder in a location where it will not be disturbed or moved during the sedimentation readings (for 24 hours). Start a timer.

7. Remove the parafilm and immediately begin the hydrometer readings, recording the temperature reading after each suspension. Record the readings at the following intervals (measured from the beginning of sedimentation): 2, 5,15, 30, 60, 250, and 1440 minutes. Insert the hydrometer about 20 to 25 seconds before the reading is due to the approximate depth. Read the hydrometer from the top of the meniscus to the nearest 0.0005 and enter the reading on the worksheet *T-WC-FRM46355*. Clean the hydrometer before the first reading, and between readings, by placing it into reagent water and twisting with a spinning motion.

Uncontrolled Copy

**NOTE: The hydrometer used in the process will be calibrated on an annually basis by a certified vendor.**

8. After hydrometer reading, insert a calibrated thermometer into the cylinder to the same depth as the hydrometer reading. Read the temperature to the nearest 0.5°C and enter the temperature measurement on the worksheet. Rinse the temperature probe in the hydrometer rinse bath.

9. After hydrometer analysis, proceed to Small Sieve Analysis in Procedure C.3.

## C. Sieve Procedure

1. Inspect the sample material in the aluminum pan and record a description of the non-soil material (e.g.- sticks, grass, wood, plastic), hardness of material, and shape of material in the worksheet. Hardness qualifiers include hard, soft, and brittle. Shape qualifiers include well-rounded, rounded, subrounded, subangular, and angular.

2. Sieve Analysis

a. Weigh the 3/4", 3/8", #4 and #10 sieves and enter the weight measurements in the worksheet as the tare weight.

b. Stack the sieves and then transfer the sample material from the aluminum dish to the sieve stack. If the sample material is less than 30 g, manually shake the sieve stack for 2 minutes. If the sample material is greater than 30 g, place the sieve stack into the Ro-tap machine and shake the sieve stack for 10 minutes.

c. Weigh each sieve and record these measurements in the worksheet.

3. Small Sieve Analysis

a. Quantitatively transfer the sample from the graduated cylinder to a #200 wet wash sieve. Ensure the entire sample has been transferred to the #200 wet wash sieve by rinsing the graduated cylinder several time with reagent water. Using reagent water, wash the sample through the #200 sieve until the water runs clear, then transfer the material retained on the sieve into a 250-mL glass beaker labeled with the sample ID.

b. Place the beaker in the drying oven and dry at a temperature of 110ºC for at least 16 hours. After 16 hours, remove the beaker from the oven and allow it to cool.

c. Gently mix the dried contents of the beaker with a rubber-tipped pestle to break up any soil aggregates that may have formed during the drying stage.

d. Tare the balance and weigh the sieve stack sized between #20 and #200 and record the tare weights.

e. Transfer the sample to the sieve stack and ensure complete transfer. Use hair or wire brushes to clean the beaker. Place the sieve stack on the RoTap machine and shake for ten minutes.

f. Weigh each sieve and record these measurements in the worksheet.

## Calculations

### A. Sample Used (SU): Dry Preparation

SU = (pan+ dry sample - pan) - (pan + non- soil material - pan) x HMCF

Where:
HMCF = Hygroscopic moisture correction factor.

### B. Sieve Analysis (Percent Finer = PF)

Uncontrolled Copy

Large Sieves:

3 inch: PF = 100-100* (Sieve and Sample (3 inch) - Sieve (3 inch))/SU

2 inch: PF = PF (3 inch) - 100*(Sieve and Sample (2 inch) - Sieve (2 inch))/SU

and so on through the #10 Sieve.

Small Sieves:

#20: PF = PF(#10) - 100*(mass passing #10/sample mass (Hyd))*(sieve and sample (#20) - sieve(#20))/sample used

#40: PF = PF (#20) - 100*(mass passing #10/sample mass (Hyd))*(sieve and sample (#40) - sieve (#40))/sample used and so on up through #10 sieve.

**B. Hydrometer Analysis**

Particle size, Micron

1000*sqrt [930*viscosity/980*(SG-1))*(effective depth/time)]

Viscosity at sample temperature, poises

Effective Depth, cm = 16.29-264.5*(actual Hydrometer reading - 1) above equation for effective depth based on equation found with table 2 in method, in which 16.29 = 0.5*(14.0-67.0/27.8)+10.5 and 264.5 = (10.5-2.3)/0.031

Time, minutes = Time of hydrometer reading from beginning of sedimentation

Sqrt - square root

SG - Specific Gravity of soil

Viscosity - is the resistance of a liquid to flow

**C. Percent Finer (PF):**

PF = Constant*(actual hydrometer reading - hydrometer correction factor - 1)

Where:

Constant = (100,000/W)*SG/(SG-1)

W = (Total sample used *sample used for hydrometer analysis*HMCF)/Amount of total sample passing #10 sieve

Hydrometer Correction = slope*sample temperature + Intercept

Slope = ((low temp. reading -1)-(high temp. reading -1)/(low temp. - high temp.))

Intercept = (low temp. reading -1) - (low temp. * slope)

## Statistical Information / Method Performance

Not applicable to this procedure

## Quality Assurance / Quality Control

When possible, perform duplicate analyses for particle size on a routine basis.

Uncontrolled copy

Batch size is limited to 20 samples or less.

Any sample that contains non-soil particle(s) will cause an interference particularly in the hydrometer phase of the test, which leads to anomalous particle size distribution. This manifests itself in the particle size distribution curve bottoming out at zero then starts to climb again. Analysts must evaluate the data and inform the client via a Non Conformance Memo (NCM) to notify them of this sample matrix issue.

## Purpose

The purpose of this SOP is to provide detailed instructions for the preparation of vials used for field-preservation of soil samples to be analyzed for volatiles.

## Scope

This procedure applies to analysts who prepare pre-preserved containers used in the field for soil sampling of volatile analyses, as well as pre-tared/pre-purchased vials

## Basic Principles

An aliquot of preservative is placed in a volatile-free container and weighed. The weight of the container and preservative is then captured using the Container PrePrep program in LIMS. When requested, the container is sent to the client for use in field preservation of a solid sample. When the container and the soil sample are returned to the lab, it is re-weighed and the actual sample weight is calculated. Samples are then spiked with the appropriate surrogate as determined by the analysis being performed.

## Definitions

Laboratory Control Sample/ Laboratory Control Sample Duplicate (LCS/LCSD) – A sample of known composition analyzed with each batch of samples to demonstrate laboratory accuracy. The samples either naturally contain the analytes of interest or are clean samples fortified with known concentrations used to demonstrate laboratory accuracy. A duplicate is a second aliquot of a sample that is treated identically to the original to determine precision of the test.

## Interferences

Sample contamination can occur if the vial preparation is not performed in a volatile-free environment; therefore, this process must be performed in one of the designated volatile-free laboratories. Samples also become contaminated if volatiles diffuse through the sample vial septum. A trip blank carried through sampling, storage and handling acts as a check of such contamination.

## Safety Precautions and Waste Handling

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

Methanol is flammable. Containers of this solvent must be kept away from any sources of open flames or sparks. Due to the potentially toxic nature of samples received from clients for analysis, safety precautions must be observed when handling samples. Safety glasses, lab coats, and gloves are required. Weighing out of the samples must always take place in a hood if the samples has an odor or if fine/ 'powder-like'

The solvents utilized in this procedure are disposed of in a solvent waste container which is transferred to the lab-wide disposal facility. Expired standards in methanol are disposed of as hazardous waste. Bulk sample containers and methanolic sample preparations are returned to the sample storage area for future disposal. Other wastes generated by Lancaster Labs are disposed of via incineration at EPA licensed facilities.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding and agreeing to follow the current version of this SOP.

The initial training consists of observing the procedure being carried out by an experienced analyst/technician. Next, the trainee performs the procedure while the experienced person watches, answers questions, and gives feedback. Following the initial training, experienced individuals are available as a resource until no longer required. Analysts are considered proficient when they are able to perform the procedure independently.

## Sample Collection, Preservation, and Handling

Sample containers must be refrigerated at 0° to 6°C, not frozen, after preparation. Containers containing surrogates are not kept for more than 2 weeks before being discarded or sent into the field for use in sample collection. Packaging of sample containers must follow all DOT regulations. When returned, samples must be preserved and refrigerated unfrozen at 0° to 6°C or frozen in reagent water at = -10° within 48 hours of collection. See individual technical area SOPs for method specific hold times.

## Apparatus and Equipment

1. 40-mL vials with Teflon™-lined septa and screw caps

2. 40-mL vials with stir bars, Teflon™-lined septa, and screw caps

3. 125-mL amber glass wide mouth jar with Teflon™-lined septa and screw caps

4. Pipette capable of dispensing up to 25 ± 0.25 mL.

5. 50-µL syringe

6. 1000-mL volumetric flask, class A

7. Analytical balance capable of weighing ±0.01 g.
8. Label printer/labels

9. LIMS VOA prep application and Reagent, Solution, and Balance Applications which integrates a PC with an analytical balance to collect data directly from the balance. It organizes the data, performs calculations, and stores final results in the Laboratory Information Management System (LIMS).

## Reagents and Standards

**NOTE:** A rinse using reagent water followed by methanol must be performed on the pipette dispensers before adding a new lot of solution or standards.

1. Methanol – Purge and trap grade.

   a. Store at room temperature and re-analyze yearly.

   b. Use methanol that has been previously tested and approved for use by the labs.

2. 8260A/B Surrogate Mix, Restek Catalog #30340 (2500 µg/mL) or equivalent.

   a. Store at = -10°C for up to 1 year.

   b. Use standard as is, or diluted in methanol to a final concentration of 2.5 µg/mL. Diluted standard must be stored at = -10°C for up to 6 months.

   c. This standard is used for the GC/MS analyses.

3. Custom a,a,a-trifluorotoluene (TFT), Restek Catalog #54357 (15,000 µg/mL) or equivalent.

   a. Dilute standard in methanol to a final concentration of 750 µg/L for the working solution. A prep dilution of 0.5 mL of TFT to 10 mL of methanol is used when spiking returned field preserved containers.

   b. Store at = -10°C for up to 30 days.

   c. This standard is used for the GC analyses.

4. Sodium hydrogen sulfate anhydrous powder, Fluka, Catalog #2316657 or equivalent.

   a. Store at room temperature and re-analyze yearly.

   b. If compounds are detected above the method detection limit (MDL), prepare another vial and repeat the analysis. If compounds are still detected above the MDL, a new container must be tested and used.

5. Sodium Bisulfate Solution –

   a. Prepare by diluting 200 ±0.5 g of the Sodium hydrogen sulfate anhydrous into 1000 mL of reagent water in 1000-mL volumetric flask. Cap and invert at least 10 times to mix.

   b. Store at room temperature and re-analyze every 6 months if supply remains.

c. If compounds are detected above the method detection limit (MDL), repeat the analysis. If compounds are still detected above the MDL, remake the solution and test before using.

6. Reagent water – water in which target analytes are not detected at or above the reporting limit for parameters of interest. In general, the deionized water supplied via pre-tared vials meets criteria. If the reagent water does not meet the requirements, see your supervisor for further instructions.

7. Polyethylene glycol (PEG) – Average molecular weight 400 amu, EM Science preferred.

a. Any lot/vendor must meet a cleanliness level of <50 mg/kg volatile content.

b. Store at room temperature and re-analyze each year if supply remains.

## Calibration

Not applicable to this procedure.

## Procedure

A. Prepare preservative containers

**NOTE:** Pre-purchased vials can be used for selected preps. Vials containing 5 mL of DI Water, vials containing 5 mL of Sodium Bisulfate and vials containing 5, 10 and 15 mL of methanol are available for field preserved analyses. The vials contain the initial tare weight, vial lot number, and the preservative lot number.

1. Check to make sure the pipette calibration has been performed.

2. Use the pipette to add the appropriate amount of preservative to a clean container. A 40-mL vial is used unless otherwise indicated on T-VOA-FRM10681.

a. For AK101 and 10mL DE Vials for 8260 the appropriately diluted surrogate solution must be added at this time using a pipette.

b. For NJ 25mL vials for 8260 use a pump that has the surrogate and methanol already mixed into a 40-mL vial. 1 µL of 8260A/B surrogate for every 1 mL of methanol in the vial.

3. Seal the container with a screw cap and septum seal.

4. Label the container with the tracking number.

5. Check to make sure the balance has been calibrated each day before use.

6. Place the container on a zeroed balance and capture the weight electronically to the nearest 0.01 g using Container PrePrep

7. Store the prepared containers in the designated area in the Volatile Prep room. Vials containing surrogates must be stored in the freezer, vials containing just methanol are stored at room temperature or refrigerated.

8. Pull vials as requested via e-mail from client services and place on the designated shelf in the bottles room storage area. The containers are now ready to be sent into the field for sample collection.

9. Send a reply e-mail to the client service representative to notify them that the order has been completed.

B. Re-weigh preservative containers after return from the field

1. Using Analyst Desktop application, type in the tracking number on the ID Label. This brings up the information documented from the preparation step described above.

**NOTE:** If using purchased pre-tarred vials insert the vial ID, preservative, and tare weight information on the Pre-Tarred tab within the Volatile Prep Application.

2. Check to make sure the balance has been calibrated each day before use. Place the container on a zeroed balance and capture the second weight electronically using the VOA Prep application.

3. Analyst Desktop calculates the net weight. (weight of vial, solution, and soil minus the weight of the vial and solution).

4. If there are any holding-time issues or if weights are outside of the Action Requirement, an NCM should be created and the PM contacted.

5. Record any unusual observations about the sample in the comment section.

C. Sample spiking

**NOTE:** Wipe samples do not require a surrogate to be spiked into the methanol.

A 1:1 ratio of µL to mL is required when spiking surrogate into methanol, except for analysis 0388 MA-VPH samples which require 30 µL to the 15 mL of methanol.

1. Determine the amount of methanol in the sample. This is determined by the analysis number and the mL of methanol printed on the vial label

2. Fill the syringe with the appropriate surrogate slightly past the amount of µL needed.

a. Add the appropriate surrogate based on the department receiving the sample.

b. GC requires a TFT surrogate mix to be used.

c. GC/MS requires an 8260A/B surrogate mix to be used.

3. Dispense the surrogate from the syringe until the required level of µL is reached. This assures no air bubbles are present and the syringe contains surrogate.

a. Tilt the vial so the methanol comes toward the top of the vial, take off the cap(s), submerging the tip of the syringe into the methanol.

b. Shake the vial to disperse the surrogate throughout the sample.

c. Put an “S” on the vial label to indicate surrogate has been added and the amount of surrogate, such as "5-5, 5-10" (specify if the surrogate was TFT, VPH, etc, ex: "VPH 5-30").

d. Clean the syringe before proceeding to the next sample.

D. Deliver samples to the labs

Once the sample containers have been re-weighed, they must be transported to the laboratory for analysis. Each department has a designated refrigerated drop-off spot. All trip blanks and field blanks submitted must follow the sample containing the same preservative. Blanks submitted as waters are to be stored in the designated volatile refrigerator.

**NOTE:** Any sample designated for prescreen must be taken to the appropriate refrigerator and placed in a box sorted in numerical order. If a methanol sample is designated for prescreen and a corresponding methanol trip blank or field blank is submitted the blanks must follow the associated samples through the entire process including sample prescreen.

## Calculations

Calculation of sample weight : Wn = Ws - Wf

**Where:**

Wf = weight of container + solution (first weight)

Ws = weight of container + solution + soil (second weight)

Wn = net weight of soil sample

## Statistical Information/Method Performance

Not applicable to this procedure.

## Quality Assurance/Quality Control

The number of containers requested from Client Services includes the appropriate amount of extra bottles to serve as matrix quality control (QC) for volatile analyses requested. The matrix QC spiking for this process is noted in Procedure C. All other QC samples such as the LCS, LCSD, and method blanks are prepared as outlined in the individual technical area's SOPs.

## Scope

This method is for preparation of solid samples (received in bulk containers) for analysis using GC/MS purge and trap techniques.

## Basic Principles

The low-level sample preparation consists of weighing an aliquot of the soil sample into a vial with a stir bar, adding reagent water, and freezing. The vial is thawed prior to the purge and trap analysis.

The high-level preparation consists of weighing an aliquot of the soil sample into a vial, adding methanol (including surrogates), and shaking to dissolve the volatile organic compounds into the solvent layer. A portion of this solvent layer is diluted in reagent water by the GC/MS Volatiles department for analysis on the purge and trap system according to the determinative method.

## Definitions

1. Preparation – Refers to the preservation steps that are performed at the lab, not an extraction step.

2. Reagent water – Water in which target analytes are not detected at or above the reporting limit for parameters of interest. In general, the deionized water supplied at the taps in the laboratory meets criteria. If the reagent water does not meet the requirements, see your supervisor for further instructions.

3. Analyst Desktop – Reports that reside on the LIMS database. Using the Analyst Desktop application and moisture results pulled from LIMS, the report is populated and calculations are performed to achieve a Final Extraction Volume to be used when necessary by the GC and GC/MS groups.

## Interferences

Care must be exercised to prevent sample cross-contamination of glassware, utensils, solvents, and other equipment. A clean spatula must be used for each new sample. To avoid sample contamination, perform this procedure in one of the designated volatile free laboratories.

## Preparation of Glassware/Utensils

All glassware and utensils are washed in accordance with *S-SS-WI10683*.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Methanol is flammable. Containers of this solvent must be kept away from any sources of open flames or sparks. Vials containing methanol must be stored in explosion-proof refrigerators.

Due to the potentially toxic nature of samples received from clients for analysis, safety precautions must be observed when handling samples. Safety glasses, lab coats, and gloves are required as personal protective wear. Only when instructed to do so in the Lab Notes, weighing out of the samples must always take place in a hood.

The solvents utilized in this procedure are disposed of in a solvent waste container. Expired standards in methanol are disposed of as hazardous waste. Bulk sample containers and sample preparations are returned to the sample storage area for future disposal. Other wastes generated by Lancaster Labs are disposed of via incineration at EPA licensed facilities.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability.

The initial training consists of observing the procedure being carried out by an experienced analyst/technician. Next, the trainee performs the procedure while the experienced person watches, answers questions, and gives feedback. Following the initial training, experienced individuals are available as a resource until no longer required. Analysts are considered proficient when the procedure can be carried out independently.

## Sample Collection, Preservation, and Handling

Samples are collected in a 2-oz. glass jar with a Teflon™-lined cap. Samples must be refrigerated at 0 - 6°C, not frozen, and prepared within 48 hours of receipt.

## Apparatus and Equipment

1. 40-mL pre-cleaned Teflon™ lined, screw-cap vials

2. Utensils

3. Magnetic stir bars, Teflon™ coated, 12-mm

4. Top-loading balance capable of weighing ±0.01 g

5. Pipette capable of dispensing up to 25 ±0.25 mL, or equivalent

6. Glassware – funnels and volumetric flasks, Class A

7. Analyst Desktop Application – integrates a PC with a balance to collect data directly from the balance. It organizes the data, performs calculations (when required), and stores final results in the Laboratory Information Management System. This procedure is used whenever possible to facilitate data transfers and other tracking. If necessary, data is recorded traditionally in a logbook. Refer to *QA-SOP11913*.

## Reagents and Standards

**NOTE:** A rinse using reagent water followed by methanol must be performed on the pipette dispensers before adding a new lot of solution or standards. A clean funnel is used to transfer the new solution into the pipette dispenser.

A. Reagents

1. Reagent water – see definition section

2. Methanol – purge and trap grade or equivalent

The methanol used must have been previously tested and approved for use by the labs. See 1-P-QM-QMA-9015516 for further information.

B. Standard

8260 surrogate standard (SS) spiking solution – Prepare a solution in methanol containing dibromofluoromethane, toluene-d8, 4-bromofluorobenzene, and 1,2-dichloroethane–d4 at a concentration of 25 µg/mL.

Personnel in the GC/MS Volatiles lab prepare the SS spike by volumetric dilution in methanol using an ampulated stock standard mix purchased from a supplier. All standards are stored at -10° to -15°C. The ampulated standards are stored until the expiration date indicated by the vendor or for 2 years if no expiration date is provided. The SS spike is stored for 6 months.

## Calibration

Not applicable to this procedure

## Procedure

A. Ensure that the balance is calibrated according to *QA-SOP11880* and that the pipette dispenser is calibrated according to *T-VOA-WI11168* before proceeding.

B. Each unhomogenized sample is received in a "zero-headspace" container to preserve any aromatics and to ensure accuracy of the method.

**NOTE:** Headspace is defined as a significant amount of space between the sample level and the top of the jar. Some sample settling is acceptable. However, a significant amount of headspace exists when more than a 1/4 of the volume in the container is missing.

C. If headspace is present, a comment is added to the Notes Section on the batch's Worksheet tab in the LIMs

D. Low level prep method 5030C Solid NAC/8260 – This prep is performed on samples expected to contain less than 1000 to 1500 µg/kg of VOCs.

1. In Analyst Desktop, create a new batch using the 5030C_Solid_NAC method code

2. Create a method blank in Login, using the earliest collection date and time from the samples to be prepped.

3. Enter the method blank into the first line in the batch. Scan the sample ID's using the Run Log tab

4. Print the batch labels and label the vials with the appropriate container number.

5. Weigh 5+/- 0.50g into a tared 40mL screw-capped vial with a stir bar.

   a. Add the purged DI lot number and amount to the reagent tab.

   b. All dates, times, and analyst information is pulled in when assigning the final weight taken.

6. Add 5 mL of reagent water to the vial containing the weighed sample along with a stir bar. Seal the screw cap on the vial to prevent leakage. Please perform this step quickly to minimize the loss of VOC from the sample and minimize the possibility of airborne contamination of the sample

   a. If the sample absorbs the full 5 mL, a smaller sample weight is used. On the worksheet tab, a note must be added to explain the reason for the change.

   b. When it is not possible to use 5 g of sample due to the nature of the sample matrix or limited sample volume, smaller sample weights are acceptable. On the worksheet tab, a note must be added to explain the reason for the change.

7. Once the samples are prepared, they are transported to the appropriate laboratory for analysis.

   a. The low level soil preparations are stored in the designated freezer location.

   b. The original sample containers are returned to ASRS for storage.

8. See specific analytical method for dilution information and QC standard spiking procedures.

E. High level prep method 5030C H/8260 – This prep is performed in conjunction with the low level prep to provide a high level option for the volatile group in case the VOCs are greater than 1000 to 1500 µg/kg.

1. In Analyst Desktop, create a new batch using 5030C H method. Scan the sample ID using the Run Log tab, and record the weight using the Worksheet tab. Weigh 5 ± 0.50 g into a tared, 40-mL screw-capped vial.

   a. Be sure to label the vial with the appropriate sample number provided from Sample Administration

   b. Weight 5 +/- 0.50g into a tared 40mL screw-capped vial.

   c. Other information provided includes: assigning a container number along with the Methanol/8260 surrogate solution lot number under the reagent tab, assigning the sample weight, headspace observed, any additional comments, and assigning the ELLE sample number, method and A-method.

d. All dates, times, and analyst information are pulled in when assigning the final weight taken.

e. When it is not possible to use 5 g of sample due to the nature of the sample's matrix or limited sample volume, smaller sample weights are acceptable.

2. Add 5 mL of 8260/MeOH solution to the vial containing the weighed sample. Seal the screw cap on the vial to prevent leakage.

a. If the sample absorbs the full 5 mL, add 5mL more.

b. Perform these steps quickly to minimize the loss of VOC from the sample and to minimize the possibility of airborne contamination of the sample.

3. Once the methanol has been added, cap and shake the sample for approximately 2 minutes.

4. Centrifuge the vial until the soil is separated from the MeOH layer.

5. Once the samples are prepared, they are transported to the appropriate laboratory for analysis. Each department has a designated refrigerated location. The original sample containers are returned to ASRS for storage.

6. See specific analytical method for dilution information and QC standard spiking procedures.

## Calculations

See analytical methods.

## Statistical Information/Method Performance

See analytical methods.

## Quality Assurance/Quality Control

1. Preservation blanks are created each day samples are prepared. The preparation of a low level blank consists of dispensing 5 mLs of reagent water into a 40-mL screw-capped vial with a stir bar. These blanks are then stored in a designated spot in the freezer and are analyzed by a GC/MS low level analysis.

2. Laboratory Control Sample (LCS), Laboratory Control Sample Duplicate (LCSD), and method blank are prepared as outlined in the individual technical areas SOPs.

5. *Total Petroleum Hydrocarbons Analysis - Gasoline Method*, California Department of Health Services, LUFT Task Force.

6. *Chemical Hygiene Plan*, current version.

## Purpose

The purpose of this SOP is to describe the proper procedure to prepare high level solid sample received in bulk containers for GC and VPH analyses.

## Scope

This method is used to prepare high level solid samples (received in bulk containers) for the determination of aromatic analytes and/or gasoline range organics using GC purge and trap techniques. Care must be exercised to prevent sample cross-contamination of glassware, utensils, solvents, and other equipment.

## Basic Principles

An aliquot of the soil sample is weighed into a vial, methanol (including the surrogate) is added, and after capping, the vial is shaken to dissolve the volatile organic compounds into the solvent layer. A portion of this solvent layer will be diluted in reagent water by the Volatiles GC department for analysis on the purge and trap system according to the determinative method.

## Reference Modifications

A 10-g sample to 10-mL methanol preparation is used in place of the 20-g sample to 20-mL methanol preparation discussed in Reference 1. The requirements of the method are met since the 1:1 ratio is maintained.

## Definitions

1. Preparation – Refers to the preservation steps that are performed at the lab, not an extraction step.

2. Reagent water – Water in which target analytes are not detected at or above the reporting limit for parameters of interest. In general, the deionized water supplied at the taps in the laboratory meets criteria. If the reagent water does not meet the requirements, see your supervisor for further instructions.

3. Analyst Desktop – Reports that reside on the LIMS database. Using the Analyst Desktop application and moisture results pulled from LIMS, the report is populated and calculations are performed to achieve a Final Extraction Volume to be used when necessary by the GC and GC/MS groups.

## Interferences

A clean spatula must be used for each new sample to prevent contamination during the preparation process. Preparations must be performed in one of the designated volatile free laboratories to prevent contamination.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Methanol is flammable. Containers of this solvent must be kept away from any sources of open flames or sparks.

Due to the potentially toxic nature of samples received from clients for analysis, safety precautions must be observed when handling samples. Safety glasses, lab coats, and gloves are required as personal protective wear. Weighing out of the samples may need to take place in a hood, if samples are highly contaminated.

The solvents utilized in this procedure are disposed of in a solvent waste container which is transferred to a lab-wide disposal facility. Expired standards in methanol are disposed of as hazardous waste. Bulk sample containers and methanolic sample preparations are returned to the sample storage area for future disposal. Other wastes generated by Lancaster Labs are disposed of via incineration at EPA licensed facilities.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability.

The initial training consists of observing the procedure being carried out by an experienced analyst/technician. Next, the trainee performs the procedure while the experienced person watches, answers questions, and gives feedback. Following the initial training, experienced individuals are available as a resource until no longer required. Analysts are considered proficient when they are able to perform the procedure independently.

## Sample Collection, Preservation, and Handling

Samples are collected in a glass jar with a Teflon™-lined cap, stored at 0 to 6°C, not frozen, and preserved within 48 hours of receipt.

## Apparatus and Equipment

1. 40-mL pre-cleaned Teflon™-lined, screw-capped vials
2. Pipette or pipette dispenser capable of dispensing up to 25 ±0.25 mL, or equivalent
3. Top-loading balance capable of weighing ±0.01 g with 100-g capacity
4. Utensils/glassware are washed in accordance with S-SS-WI10683.

5. Analyst Desktop Application – Integrates a PC with a balance to collect data directly from the balance. It organizes the data, performs calculations (when required), and stores final results in the Laboratory Information Management System. This procedure is used whenever possible to facilitate data transfers and other tracking; however, it is allowable to record data traditionally in a logbook if necessary.

6. Gas-tight syringes – Various sizes (used to prepare the surrogate solution)

7. Volumetric flasks – Class A, various sizes (used to prepare the surrogate solution)

## Reagents and Standards

The methanol used in this procedure must be tested and approved by the labs prior to use.

A. Reagents

1. Reagent water – See Definitions section

2. Methanol (MeOH) – Purge and trap grade or equivalent stored at room temperature.

B. Standard

1. Personnel in the Volatiles by GC lab prepare the surrogate standard by dilutions in methanol using an ampulated stock standard purchased from a supplier.
2. All ampulated standards are stored at =-10°C until the expiration date indicated by the vendor or for 1 year if no expiration date is provided.

3. Secondary dilution and working standards in methanol are stored in vials at =-10°C until they expire (30 days from the date of preparation).

**NOTE:** All standard aliquots are measured in a syringe capable of holding the appropriate volume of standard.

C. Purgeable Aromatics in High-Level Soils

1. Trifluorotoluene (TFT) surrogate stock solution – A standard that is purchased from an analytical supplier at a concentration of 15,000 ppm.

2. TFT working standard – Prepared by adding 0.5 mL of the TFT surrogate stock solution to 10 mL of MeOH.

3. TFT/MeOH Solution – Prepared by adding 2 mL of the TFT working standard to 2000 mL of MeOH.

## Calibration

Not applicable to this procedure.

## Procedure

1. Ensure that the balance is calibrated.

2. Ensure that the pipette dispenser is calibrated

3. Each sample to be analyzed must be unhomogenized and received in a "zero-headspace" container to preserve any aromatics and to ensure accuracy of the method.

a. When one or both of the previous criteria have not been met, a comment is added to the prep batch to outline any inadequacies.

**NOTE:** Headspace is defined as a significant amount of space between the sample level and the top of the jar. Some sample settling is acceptable. However, a significant amount of headspace exists when more than a 1/4 of the volume in the container missing.

4. For GC Prep Methods 5030C H/8015, weigh 10 ±1.0 g into a tared, 40-mL screw-capped vial.

a. In Analyst Desktop, create a new batch using 5030C H method. Scan the sample ID using the run log tab and record the weight using the bulk tab in the worksheet tab.

When it is not possible to use 10 g of sample due to the nature of the sample's matrix or limited sample volume, smaller sample weights are allowed. However, a minimum of 2 g must be utilized.

b. Be sure to print the batch labels and label the vial with the appropriate container number found using the run log tab.

c. Other information provided includes assigning a container number along with the MeOH/Surrogate solution lot number under the reagent tab, assigning the sample weight, headspace observed, any additional comments, and assigning the LLI sample number, method and A-method.

d. All dates, times, and analyst information is pulled in when assigning the final weight taken.

5. Add 10 mL of TFT/MeOH solution to the vial containing the weighed sample. Seal the screw cap on the vial to prevent leakage.

a. Perform these steps quickly to minimize the loss of VOC from the sample and to minimize the possibility of airborne contamination of the sample.

b. If the sample is not dense enough to be covered by the 10 mL of the solution or if the sample absorbs the full 10 mL, a smaller sample weight must be used.

c. If <10 g of sample is available, maintain a 1:1 sample to methanol ratio, if possible.

6. Once the methanol has been added, cap and shake the sample for 2 minutes.

7. Centrifuge the vial until the soil is separated from the MeOH layer.

8. Once the samples are prepared, the TFT vial is prescreened prior to being transported to its designated refrigerator location.

a. Each department has a designated refrigerated location.

b. The original sample containers are returned to sample support for storage.

9. See specific analytical method for dilution information and QC standard spiking procedures.

10. For VPH Prep Methods 5030A_M_7d/MTVPH, weigh 15 ±3.75 g into a tared, 40-mL screw-capped vial.

a. Record the sample number and the weight using the bulk tab in the VOA Prep application.

When it is not possible to use 15 g of sample due to the nature of the sample's matrix or limited sample volume, smaller sample weights are allowed. However, a minimum of 5 g must be utilized.

b. Be sure to print the batch labels and label the vial with the appropriate container number found using the run log tab.

c. Other information provided includes: assigning a container number along with the MeOH/Surrogate solution lot number under the reagent tab, assigning the sample weight, headspace observed, any additional comments, and assigning the LLI sample number, method and A-method.

d. All dates, times, and analyst information is pulled in when assigning the final weight taken.

11. Add 15 mL of MeOH to the vial containing the weighed sample and spiked with 30 uL of TFT Working standard. Seal the screw cap on the vial to prevent leakage.

a. Perform these steps quickly to minimize the loss of VOC from the sample and to minimize the possibility of airborne contamination of the sample.

b. If the sample is not dense enough to be covered by the 15 mL of the solution or if the sample absorbs the full 15 mL, a smaller sample weight must be used.

c. If <15 g of sample is available, maintain a 1:1 sample to methanol ratio, if possible.

12. Once the methanol has been added, cap and shake the sample for 2 minutes.

13. Centrifuge the vial until the soil is separated from the MeOH layer.

14. Once the samples are prepared, the sample is prescreened prior to being transported to the laboratory that will be analyzing them.

a. The original sample containers are returned to sample support for storage.

15. See specific analytical method for dilution information and QC standard spiking procedures.

## Calculations
See analytical methods.

## Statistical Information/Method Performance
See analytical methods.

## Quality Assurance/Quality Control

1. Preservation blanks are created each day samples are prepared. The preparation of a low level blank consists of dispensing 5 mLs of Reagent Water into a 40-mL screw-capped vial. These blanks are then stored in a designated spot in methanol sample storage.

2. Laboratory Control Sample (LCS), Laboratory Control Sample Duplicate (LCSD), and method blank are prepared as outlined in the individual technical areas SOPs.

## Scope

This procedure addresses the following calibration, verification, and routine maintenance procedures for laboratory support equipment.

- Balances (analytical and top-loading) - Procedure B
- ASTM Class 1 Weights - Procedure C
- Mechanical pipettes - Procedure D, including
- Volumetric Syringe Verification (≤10-µL in size) - Procedure E, including:
  - Eppendorf-style
  - Repeators
- Temperature Measuring Devices - Procedure F, excluding
  - The calibration of ETM probes, which is discussed in *QA-SOP11191*
  - NIST-traceable thermometers
- Volumetric Labware - Procedure G
- Other Laboratory Equipment Requiring Verification - Procedure H

Instruments (equipment that give analytical results) are addressed in *QA-SOP11901*. Bottle-top dispensers are verified by this procedure only if used for critical volumes. The requirement for verification applies to equipment where quantitative results are dependent on their accuracy.

Some regulatory programs or special-use equipment have additional requirements for calibration checks and/or maintenance. Because of the wide variety of these devices used by the laboratory, it is recommended that analysts also refer to the manufacturer’s instruction manual for additional information.

Manufacturing procedures identified in the Equipment Operating Manuals are referenced for safe handling, transport storage, and use and planned maintenance of measuring equipment to ensure proper functioning and in order to prevent contamination or deterioration.

**NOTE:** This procedure does not apply to instrument autosampler syringes.

## Definitions

1. NIST – National Institute of Standards and Technology

2. ASTM – American Society for Testing and Materials

3. Class 1 Weights (ASTM) – These weights are designated as high-precision standards for calibration. They are used for the monthly (or daily, if desired) calibration check of balances as reference standards for calibrating other weights. These weights are recommended for calibration of balances using optical or electrical methods for accurately weighing quantities below 20 mg.

4. DOD QSM – Department of Defense Quality Systems Manual

5. Sensitivity – The smallest amount that the equipment can measure.

6. Accuracy - The degree of agreement between an observed value and an accepted reference value.

7. Precision - The degree to which a set of observations or measurements of the same property, obtained under similar conditions, conform to themselves; a data quality indicator. Precision is usually expressed as standard deviation, variance or range, in either absolute or relative terms.

8. Support Equipment - machines that are required to complete the steps of the analysis - i.e. autoclaves, hot water baths, digestors, sonicators, microwaves, etc. Equipment does not generate analytical data.

9. Instrument - Instruments provide a measurable result of an analyte. Instruments have specific calibration criteria. See *QA-SOP11901*.

## Personnel Training and Qualifications

Personnel performing this procedure must have documentation of reading, understanding and agreeing to follow this version of the SOP.

Analysts must be trained to use the equipment and work with an experienced analyst prior to performing the verification procedure independently.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

## Procedure

## A. Verification and Calibration Requirements

1. All verifications, calibrations, repairs or maintenance must be documented in a maintenance and calibration logbook and/or a verification logbook or acceptable alternative (database, excel spreadsheet, etc.). See *QA-SOP11913* for further documentation requirements.

2. The acceptance criteria must be noted in the log.  Corrective action must be documented for any checks that are out of specification.The results of any calibration or verification must be within specified acceptance limits in order to proceed. The acceptance limits are defined by the regulations and the intended use of the equipment.

3. If the equipment fails to meet the specified limits, it must be taken out of service using Form *QA-FRM6871* until repaired. In the case of temperature measuring devices, a correction factor may be applied.

4. Records of all maintenance, including service calls and external calibrations, must be maintained.

5. The unique identification of the equipment (balance, pipette, weight set, etc.) used to perform the various calibrations must also be documented.

## B. Balances

### Calibration - Annual

An annual check of the balance must be made by a qualified (ISO 17025 accredited) professional service firm. This check includes a calibration verification and appropriate preventative maintenance (e.g., cleaning). The balances must be calibrated at a full range of use. The Environmental Quality Assurance Department is responsible for scheduling this annual check. Calibration records are maintained on the D4052 shared network. The date of the calibration must be noted on the balance. A confirmation of the calibration range defined on the label by the balance is performed following the annual calibration of the balance. *Q-EQA-FRM52624* may be used to track this process.

### Verifications - Daily

Check each balance for proper calibration **prior to use** on each day that it is used. Verify using at least three Class 1 weights that bracket the range of use. Document the results of the verification either in a physical logbook or in the Balance module within the LIMS.

1. Confirm and document that the balance is level.

2. Tare the balance with a container representative of the weighing vessel normally used.

3. Ensure the balance pan is free of debris before placing a weight on the pan. Record the readback of the balance as the verification. **Note:** In order to preserve the highly accurate nature of the weights, they must be handled with great care. Never touch weights with anything other than forceps, and transfer the weights directly from the case to the pan of the balance.

4. The verification is acceptable if this criteria is met:

    - For **top-loading balances**, the reading must be ±0.2% or ±0.02g of the true value of the weight, whichever is greater.

    - For **analytical balances**, the reading must be ±0.1% or ±0.5mg, whichever is greater.

5. If a balance must be physically moved during the day, perform an additional check of the level and calibration.

6. Corrective actions

    a. For a balance that is not operating within the stated acceptance criteria, first verify the cleanliness of the weighing pan. Clean weights and perform the check again. Some balances are equipped with built-in calibration weights permitting automatic calibration. Consult the manufacturer's manual to see if any adjustments are recommended to correct the problem.

    b. If the problem cannot be resolved, immediately take the balance out of service using Form *QA-FRM6871* and place a call to the manufacturer or the professional balance service firm to address the situation. See *QA-SOP11901* in the event of a calibration check failure or the need to take the balance out of service.

    c. Data generated since the last acceptable daily/monthly calibration must be evaluated by management on a case-by-case basis.

7. The manager or designee must review these verification records a minimum of once per month.

### Daily Use

1. The range, accuracy, and sensitivity of a balance must be appropriate for its use. Balances used in drinking water analyses should be able to weigh to 0.0001 g.

2. Analytical balances must be in an area that is vibration-free in order for the balance to remain level and supply accurate readings. A stabilizing slab can be used on a counter top or in a hood in order to minimize vibrations.

3. Balances must be located away from laboratory traffic and protected from drafts and sudden temperature and humidity changes whenever possible.

4. Special precautions must be taken to avoid spillage of chemicals on the pan or inside the balance case. The interior of the balance housing must be kept scrupulously clean.

5. Before using any balance, check to assure that it is level and free of dust. In order to obtain accurate readings, a balance must be level. It is the responsibility of each user to ensure that the bubble within the level is fully within the indicator circle each time that they approach the balance for use. If any portion of the bubble is outside of the circle, the balance must be brought back to level and the calibration re-verified prior to use.

6. Do not overload the balance and avoid jarring. Gently place all objects to be weighed on the pan.

7. Each balance is marked with its range and it must not be used for weights outside that range. The total weight placed on the balance is equal to the weight of the tared vessel plus the vessel contents and this total must be within the weight range capacity of the balance. Balance calibration checks must span the range of use.

8. A balance could be marked as limited use. The firm that performs the annual check may add a limited use sticker to the balance that will state the limitation such as “corners”. This indicates that the balance does not weigh properly when the load is not placed in the center of the pan. Therefore caution should be used to properly center all loads when weighing.

## C. Weights

### 1. Reference Weight Set Calibration/Recertification - 3-5 Years

a. Quality Assurance (QA) maintains a Class 1 reference weight set for departments to use for annual verification of working weight sets.

b. The weights must be signed out and returned upon completion of the check. It is the responsibility of QA to have the weights reclassified every 3 years by a qualified (ISO 17025 accredited) calibration firm. A 3-year cycle is required under PALA (Quebec) accreditation. This weight set is used for checking balances in the labs that come under the PALA scope.

c. If a technical department not under PALA accreditation chooses to purchase their own Class 1 weights, it is their responsibility to ensure they are reclassified every 5 years by a qualified (ISO 17025 accredited) calibration firm.

d. A certificate of reclassification is maintained on file to document traceability to NIST materials used in the recalibration operation. This certification statement, provided with mass standards, certifies that the nominal values of the weights are correct within the prescribed limits. The reclassification certificates for the weights are filed in QA.

e. Any weight that is qualified on the reclassification certificate as failing the ‘As Found tolerance test’('F' qualified) must be evaluated by a member of the QA department prior to returning the weight to use.

1. Use Form *QA-FRM50673* (F Qualified Weight Impact Assessment Spreadsheet) to determine if there is an impact to balance calibration checks that were performed using the 'F' qualified weights.

2. Maximum Low or Maximum High values that fall outside the low or high balance acceptance limits in Table II of *QA-FRM50673* require further investigation for potential impact on the ELLE balance calibration checks and subsequent measurements obtained from that balance. An Investigation and Corrective Action must be initiated. QA will also enter the occurrence in the Risk Assessment Registry.

**2. Working Weight Set Verification - Annually**

a. Annually, departments must sign out the reference weight set from QA in order to perform a weight set verification.

b. Use *QA-FRM70571* to document the verification of the weight set. Print this form as a PDF and submit the form to QA.

c. The working weights are compared to the QA reference weights, using a analytical balance that has been verified that day. The working weights must be ±0.1% or ±0.0002 g, whichever is greater.

d. QA files the form and provides a verification label using *QA-FRM72988*.

**3. Working Weight Set Daily Use**

a. If weights are dropped or potentially damaged they need to be checked against alternate weights either from Quality Assurance(QA) or another weight set.

b. Document the comparison in the logbook. Be sure to include the serial number of the alternate weights.

c. All weights must meet the defined acceptance criteria.

**4. Transportation**

a. All weight sets are received "as is" from the manufacturer, in its original case with bubble wrap and packing paper to fill in all the gaps and prevent movement of the weights during shipping. Upon receipt, they are delivered directly to the department

b. Weights that are shipped out are packaged in their original case with packing materials in a box and delivered to the Shipping department for shipping.

## D. Pipettes and Dispensers

**1. Verification - Daily**

a. When the pipette or dispenser is used for critical volumes, verification must be performed each day of use, prior to use. Bottle-top dispensers used for non-critical volumes may have quarterly verification. Daily verification must be used in applications where quantitative results are dependent on their accuracy.

b. Perform a minimum of three trials at each nominal volume (volume of use). For variable volume pipettes, two volumes bracketing the range of use can also be used for the verification.

c. Change the pipette tip between each trial.

d. This calibration check is documented either in a locked Excel file on the department's network drive or in the Pipette Module within the LIMS.

e. Weigh an aliquot of room-temperature solvent into a tared container. The measured weight to set volume comparison is made based on the density of of the solvent at ambient temperature. Record the readback on the balance.

f. The verification is acceptable if this criteria is met:

- The mean must be within ±2% of the nominal volume (bias).
- RSD must be ≤ 1% of the nominal volume (precision).

g. If the check fails, the test can be repeated but there must be two passing checks. Otherwise, perform cleaning and maintenance followed by verification.

### 2. Daily Use

a. Refer to manufacturer's instructions for specific information regarding operation of the pipette.

b. Any pipette found to be contaminated by aspirated liquid or contain a plunger that is excessively "sticky" must be cleaned and verified prior to use.

c. The range, accuracy, and sensitivity of a pipette must be appropriate for its use. For adjustable pipettes, never use a setting below the lowest volume or above the highest volume of the pipette.

d. Pipettes held at an angle will take up more liquid than pipettes held vertically. Pipettes should be held in an upright, vertical position.

e. The density of liquid is dependent on the temperature of the water. Hot and cold liquids can lead to errors in the amount of liquid aspirated. To avoid temperature interferences, pipette liquids that have reached ambient temperature.

## E. Syringes

### 1. Verification - Semi-Annually

a. Verification is not required for syringes used for handling gas standards.

b. When performing this verification, gloves must be worn to eliminate the possibility of oils from your hands adding weight to the weighing vessel.

c. Pull a volume of reagent water into the syringe that represents half the total volume of the syringe (e.g. 25 µL for a 50-µL syringe, 100 µL for a 200-µL syringe).

d. Ensure that there are no air bubbles and accurately set the syringe to the volume to be measured.

e. Dispense the reagent water into a tared medicine cup or small vial on an analytical balance. Use QA-FRM45536 to record these verifications and save the files in department records as a PDF.

f. The weight must fall within the tolerance limits listed in Table 1 below.

Table 1 - Syringe Tolerance Limits

| Syringe Size (µL) | Volume of Water (µL) | Target Weight (g) | Tolerance Limit (g) |
|---|---|---|---|
| 10 | 5 | 0.005 | (±4%) 0.0048 - 0.0052 |
| 20 | 10 | 0.010 | (±2%) 0.0098 - 0.0102 |
| 50 | 25 | 0.025 | (±2%) 0.0245 - 0.0255 |
| 100 | 50 | 0.050 | (±2%) 0.049 - 0.051 |
| 200 | 100 | 0.100 | (±2%) 0.098 - 0.102 |
| 500 | 250 | 0.25 | (±2%) 0.245 - 0.255 |
| 1000 | 500 | 0.5 | (±2%) 0.49 – 0.51 |

g. Verification Frequency

a. Initial verification upon receipt:

- Perform ten (10) trials as described in Syringe Verification procedure above.
- If there are several syringes from one lot, test one representative syringe from that lot.
- Do not place a syringe (or lot) that is outside the acceptable tolerance into general use.
- Notify the department supervisor when new syringes fail and ensure that the vendor is contacted.
- If the syringe is within the acceptable tolerance apply the appropriate tape label, using designated color scheme from Table 2 below, and place it in the laboratory for general use.

| Table 2 - Syringe Tape Color Code | |
|---|---|
| Month/Year of calibration | Tape Color |
| January – even year | Red |
| July – even year | Blue |
| January – odd year | Yellow |
| July – odd year | Green |

b. Continuing verification is performed every six months in January and July.

- Perform three (3) trials as described in the Syringe Verification procedure above.
- If the syringe is within the acceptable tolerance apply the appropriate tape label and place it in the laboratory for general use.
- **Discard any syringe that is outside the tolerance during this verification.**

c. If evidence of wear or deterioration is observed during normal lab operations, recheck the syringe to ensure proper operation and accuracy or discard.

## F. Temperature Measuring Devices

**Transportation -** All thermometers and temperature measuring devices are received in their original packaging and delivered directly to the department. If being shipped out, all thermometers and temperature measuring devices are wrapped by the department in either a case or box with packing materials and delivered to the Shipping Department to be mailed out.

**Calibration**

1. All thermometers must be calibrated before first use against a NIST-traceable thermometer. After the first calibration, the calibration period is defined as follows:
    - Mercury thermometers - Annually
    - Alcohol thermometers - Annually
    - Dial thermometers - Quarterly
    - ETM probes - Annually
    - Chart recorders - Quarterly
    - Infrared thermometer – Quarterly
    - Digital thermometers – Quarterly
2. For thermometer calibrations sent to the offsite vendor, the environmental technical departments have the following responsibilities:

    a. Contact vendor when the calibration is due to make arrangements for the calibration. **NOTE:** The laboratory must request that correction factors be reported on the calibration report and label affixed

to the thermometer after calibration by the vendor.

b. Label all expired thermometers as Do Not Use using *QA-FRM6871*. Multiple thermometers may be stored in one box with the Do Not Use label attached.

c. Use a back-up thermometer with a current calibration in the interim.

d. When the thermometer is returned to the laboratory, update the correction factor on the thermometer ID tag and/or on any printed material in the department. If the calibration procedure has determined that no correction factor is needed, a CF of 0°C must still be documented.

e. Maintain the calibration certificates and/or records on the department's local shared drive. The records must include the date of calibration, NIST reference thermometer identification, working thermometer identification, reference thermometer temperature reading, working thermometer temperature reading, correction factor, and the initials of the individual conducting the calibration.

1. All new thermometers must be calibrated before use or purchased as calibrated thermometers.

2. All thermometers must be calibrated at the temperature of use or at two temperatures that bracket the range of use. If two temperatures are used, assume linearity between the two.

   - If the device is used at one temperature or a range 10°C or less, a single temperature point can be used for verification.

   - If the device is used at a temperature range of over 10°C, at least two temperature points must be used.

   - Do not use a temperature measuring device to cover a range of more than 30°C.

**Applying Correction Factors**

1. Correction factors are documented on the calibration paperwork for each thermometer. Correction factors must be immediately accessible to employees using the thermometer. Technical department management must ensure that the actual correction factor for each thermometer in use is clearly displayed on the thermometer itself or posted in the area that the thermometer is used.

2. The correction factor must be applied to the temperature reading. The corrected value must be recorded in the data records and used to evaluate compliance of the temperature, as applicable.

3. When reporting a temperature, record the "corrected temperature" as the sum of the measured temperature and the correction factor of the temperature range, if any.

   Example:
   Lab Measured temperature = 25.3°C
   Calibration Determined Correction factor = -0.4°C
   Corrected temperature = 25.3°C + (-)0.4°C = 24.9°C

4. In most areas of the laboratory, temperatures are only required to be evaluated to a whole degree. (For example, a required temperature of 90 ± 5 degrees.) In this case correction factors that are <1 degree do not need to be applied. The displayed/posted correction factor would be 0. However, a required temperature of <6.0 degrees requires application correction factors to one-tenth of a degree. Any thermometer with a correction factor greater than 2°C must be discontinued.

5. If the temperature measuring device has been calibrated at various points over a range and each point has a corresponding correction factor, use the correction factor for the calibration point that is closest to your measured temperature.

   Example:
   Lab Measured Temperature = 6.3°C
   Calibration determined correction factor at 4°C = 0.1°C
   Calibration determined correction factor at 10°C = 0.0°C

Corrected Temperature = 6.3°C+0.1°C = 6.4°C

6. Corrective actions for temperatures outside of designated ranges are performed in accordance with the individual technical methods. However, all evaluations of compliance are made using the corrected temperature reading.

**Daily Use**

1. All thermometers in use must be uniquely identified and labeled with the calibration date and correction factors. If the calibration procedure has determined that no correction factor is needed, a CF of 0°C must still be documented.

2. Each thermometer selected for use must be graduated to the level required for the temperature measurements of the method, at least in 0.5°C. Estimated readings between the gradations are not permitted.

3. If there is separation in the liquid column of a glass thermometers, it must not be used.

4. In order to ensure the traceability of the temperature measurements to calibration and correction factor information, the thermometer ID used to obtain the temperature reading must be recorded in the data records.

5. It is required that thermometer probes must be immersed in sand (if used for ovens) or liquid (water/ethylene/glycol)

**Temperature Monitoring**

1. The temperatures of all refrigerators and freezers are checked and documented on a daily basis. There must be at least one thermometer per unit. These thermometers must be graduated in increments no larger than 1°C. Ovens, incubators, water baths are checked and documented every day of use.

2. Monitoring is performed via the ETM. See *QA-SOP11191* for more information. Any freezer, refrigerator, oven, incubator or water bath **not** being monitored by the ETM must use *S-SS-FRM10674* to record the temperature once per day. Record the date, time, the equipment ID, the corrected temperature (with CF applied), and employee initials.

   a. Refrigerators must be between 0-6°C

   b. Freezers must be less than or equal to -10°C.

   c. Ovens, incubators, water baths must meet the requirements of analytical testing for which they are being used.

3. When any freezer, refrigerator, oven, incubator, or water bath is outside the acceptance window, corrective action must be taken and documented.

## G. Incubators, Ovens, Water Baths

### 1. Temperature Monitoring - Daily

1. The temperatures of all refrigerators and freezers are checked and documented on a daily basis. There must be at least one thermometer per unit. These thermometers must be graduated in increments no larger than 1°C. Ovens, incubators, water baths are checked and documented every day of use.

2. Monitoring is performed via the ETM. See *QA-SOP11191* for more information. Any freezer, refrigerator, oven, incubator or water bath **not** being monitored by the ETM must use *S-SS-FRM10674* to record the temperature once per day. Record the date, time, the equipment ID, the corrected temperature (with CF applied), and employee initials.

a. Refrigerators must be between 0-6°C

b. Freezers must be less than or equal to -10°C.

c. Ovens, incubators, water baths must meet the requirements of analytical testing for which they are being used.

3. When any freezer, refrigerator, oven, incubator, or water bath is outside the acceptance window, corrective action must be taken and documented.

## H. Volumetric Labware

Class A glassware (volumetrics, burets, graduated cylinders, glass pipettes, etc.) are exempt from calibration.

**Verification of Class B Volumetric Labware** - e.g. Teflon and HDPE flasks and graduated cylinders that are not used for critical volumes. Note: Plastic labware is to be considered Class B and not considered to be "Class A" even if it is labelled such by the manufacturer and should not be used in instances that require volumetric measurements.

1. If the labware is to be used for critical volume preparations (i.e. standard preparation), the labware must be verified to Class A specifications.

2. Must be performed by lot, or prior to first use and annually thereafter.

3. Perform and record 10 trials at each nominal volume (volume of use).

   a. The mean must be within ±2% of the nominal volume (bias).

   b. Based on the replicate measurements, RSD must be ≤ 1% of the nominal volume (precision).

   c. If the check fails, the test can be repeated but there must be two passing checks. Otherwise, perform cleaning and maintenance followed by verification.

**Verification of labware to Class A glassware specifications**

1. Tare the clean and dry volumetric on a top-loading balance with at least 0.001 g specificity.

2. Fill volumetric to the mark with reagent water, taking care not to splash water on the walls of the volumetric.

3. Measure and record the weight of the reagent water in the volumetric.

4. Determine the temperature by placing a thermometer in the volumetric after weighing.

5. Calculate the volume (see Calculation section).

6. Verify that the weight meets the tolerances listed in Table 3 below.

7. Engrave an “A” next to the engraved serial number as verification that the volumetric has been checked and meets Class A acceptance criteria.

| Table 3 - Required tolerances | | |
|---|---|---|
| **Capacity (mL)** | **Class A flasks (+/- mL)** | **Class A graduated cylinders (+/- mL)** |
| | | |
| **5** | 0.02 | 0.05 |
| **10** | 0.02 | 0.10 |
| **25** | 0.03 | 0.10 |
| **50** | 0.05 | 0.25 |
| **100** | 0.08 | 0.50 |
| **200** | 0.10 | 0.50 |
| **250** | 0.12 | 1.00 |
| **500** | 0.20 | 2.00 |
| **1000** | 0.30 | 3.00 |
| **2500** | 0.50 | 6.00 |

## I. Timer Verifications

### 1. Verification - Annually

a. Annually, departments must verify all timers used in the laboratory.

b. Use *QA-FRM72827* to document verification of all timers. Print this form as a PDF and submit the form to QA.

c. The timer is tested using the NIST reference time phone number (303) 499-7111. Set the timer to two minutes, and start/stop the timer at the time the minute tone is played on the line. The elapsed time recorded from the timer must be less than one second (00:01.00).

d. QA files the form and provides a verification label using *QA-FRM72988*.

## J. Other Laboratory Equipment Requiring Verification

All equipment that has an effect on the accuracy, precision, or validity of an analysis or preparation must be calibrated and/or verified at least annually. The procedures must be listed in the department's Work Instructions. Use form *QA-FRM41248* to track scheduled maintenance for equipment.

This section lists some common laboratory equipment and the criteria for annual verifications. However, some methods, regulatory programs, special-use equipment, or manufacturer's instructions may require other verifications or more frequent verifications.
Any equipment verification requirements must be detailed in the department's work instructions or SOPs.

Verification can be performed internally with measuring equipment with a current NIST-traceable certificate of analysis, or externally by an ISO 17025 certified vendor.

Microwaves - verify the temperature at least annually.

Autoclaves - verify the temperature and pressure at least annually.

Barometers - verify the pressure reading at least annually.

Tumblers, Shakers, Rotators with specific RPM specifications - verify the RPMs at least annually.

## K. Calculations

A. Percent Difference (%D):

$$\%D = \frac{Measured\ Weight - Targeted\ Weight}{Targeted\ Weight} \times 100$$

B. Relative Standard Deviation (RSD):

$$RSD = \frac{Standard\ Deviation\ of\ the\ data\ set}{Mean\ of\ the\ data\ set} \times 100$$

**NOTE:** The measured weight to set volume (targeted weight) comparison is made based on the density of reagent water being equivalent to 1 g/mL.

C. Volume Calculation for Class A glassware specifications:

$$V_{flask} = \frac{W_{flask+water} - W_{flask}}{\rho_{water}}$$

where:

$V_{flask}$ = volume of the flask or graduated cylinder

$W_{flask + water}$ = weight of the water and flask or graduated cylinder

$W_{flask}$ = weight of the flask or graduated cylinder

$\rho_{water}$ = density of water based off the measured temperature

| Density of reagent water | |
|---|---|
| Temperature °C | Density (g/mL) |
| 16.0 | 0.99897 |
| 16.5 | 0.99889 |
| 17.0 | 0.99880 |
| 17.5 | 0.99871 |
| 18.0 | 0.99862 |

| Density of reagent water | |
|---|---|
| Temperature °C | Density (g/mL) |
| 18.5 | 0.99853 |
| 19.0 | 0.99843 |
| 19.5 | 0.99833 |
| 20.0 | 0.99823 |
| 20.5 | 0.99812 |
| 21.0 | 0.99802 |
| 21.5 | 0.99791 |
| 22.0 | 0.99780 |
| 22.5 | 0.99768 |
| 23.0 | 0.99757 |

**Purpose**
This document serves as a guideline for both general and comprehensive maintenance procedures to be used in the GC/MS and GC Volatiles Department at Eurofins Lancaster Laboratories Environmental (ELLE).

**Scope**
The guidelines outlined in this standard operating procedure are used when performing preventive or corrective maintenance on the following GC/MS and GC systems:

Hewlett-Packard/Agilent Technologies (6890GC/5973MSD)

Agilent Technologies (7890GC/5975MSD/5977MSD)

Agilent Technologies (8890GC/5977MSD/5978MSD)

Hewlett-Packard (5890GC)

Hewlett-Packard (6890GC)

OI Analytical (4560, 4660, 4760)

OI Analytical (4551)

OI Analytical (4430, 5230, 4410)

OI Analytical (4430, 5230, 4410)

Archon (5100)

EST Centurion (W/S)

**Basic Principles**
Maintenance is to be done in order to ensure maximum system performance.

**Safety Precautions and Waste Handling**
All laboratory waste is accumulated, managed and disposed of in accordance with Federal and State laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management and pollution prevention. Certain instrument preparations need to be made to ensure the personal safety of all laboratory employees or service personnel. For example, the mass spectrometer needs to be properly cooled and/or vented before the ion source is removed for cleaning. The necessary preparation is indicated in the specific instrument's manual for the desired maintenance procedure.

**Personnel Training and Qualifications**
All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP.

The analyst must mentor with a trained analyst. Mentoring includes observation of maintenance and hands-on practice. This continues until the trainee performs the maintenance independently.

**Procedure**
1. General maintenance – This is done on an as needed basis. The analyst informs the supervisor of the need for maintenance due to the instrument performance. Along with input from the supervisor or experienced analyst, it is determined what maintenance is needed. A rigid schedule is not followed for the frequency of mechanical pump or turbo pump oil changes. General maintenance involves the following:

a. Purge and Trap maintenance (GC and GC/MS)

b. Septum replacement (GCMS)

c. Mechanical or turbo pump oil changes (GC/MS)

2. Comprehensive maintenance – This is also done on an as needed basis. The analyst must inform the supervisor of the need for maintenance due to the instrument performance. Along with input from the supervisor, it is determined what maintenance is needed and whether the analyst, or the appropriate service personnel performs the maintenance. In the event that a supervisor is unavailable, an

experienced analyst performs the maintenance deemed necessary. Comprehensive maintenance involves, but is not limited to the following:

a. Ion source cleaning (GC/MS)

b. Filament replacement (GC/MS)

c. Electron multiplier replacement (GC/MS)

d. Column replacement (GC and GC/MS)

e. Injection port cleaning or replacement (GC and GC/MS)

f. PID lamp replacement (GC)

The manuals for each instrument contain guidelines on the appropriate procedure for comprehensive maintenance.

3. Troubleshooting – Some common GC/MS problems are indicated by the following:

| Symptom | Possible Cause | Solution |
|---|---|---|
| Inability to tune BFB | Dirty Source | Clean |
| High baseline | Clogged column/injection port | Clean/replace |
| Small or no peaks and high column pressure | Clogged injection port | Clean/replace |
| Poor peak shapes | Bad column/improper He flow | Replace/adjust flow |

Note- See Appendix I for GC Troubleshooting

All service calls, maintenance and repairs must be recorded in the appropriate instrument's maintenance logbook. The logbook entry must include why maintenance was needed, a detailed description of the maintenance performed, and resolution (as left). Each entry must be signed (initials and employee number) and dated by the ELLE personnel who performed the maintenance or observed maintenance handled by an outside contractor. Maintenance logs are reviewed on a monthly basis for accuracy.

## Appendix I

### GC Troubleshooting Guide

| Symptom | Instrument | Possible Cause | Remedy |
|---|---|---|---|
| **Low purge flow** | Purge & Trap | Purge flow regulator not set correctly | While in Purge-Ready, pressure gauge should be set to 20 PSI |
| | | Leak in gas line upstream of sparge vessel | Check gas lines leading to purge flow regulator |
| | | Clogged or dirty sparge filter | Inspect or replace sparge filter |
| | | Clog in line downstream of sparge vessel | Inspect or replace lines to 6-port and trap |
| **Low response** | Purge & Trap | Transfer line not turned on | Turn on transfer line to correct temp. |
| | | Trap not heating | Make sure trap is heating during desorb. Turn trap power on. |
| | | Desorb time set to zero | Set desorb time to correct setting |
| | | Low purge flow | |

| | | | |
|---|---|---|---|
| | | | See symptoms of low purge flow |
| | | Leak in sparge vessel | Leak check sparge vessel and fix any leaks |
| | | Purge pressure out of range | In purge, pressure gauge should read between 6-10 PSI |
| | | Leak in gas line downstream of sparge vessel | Inspect or replace lines to 6-port and trap |
| | | Clogged or dirty sparge filter | Inspect or replace sparge filter |
| | Detector | Detectors not turned on | Turn detectors on to correct temp. |
| | | Detector gas flows not within specs | Adjust gas flows to proper settings |
| | | PID electrometer not set correctly | Adjust setting of PID electrometer to correct setting |
| | | Leak around PID lamp | Replace o-ring at base of PID lamp |
| | GC | Injector not turned on | Turn on injector to correct temp. |
| | | Dirty septa in injection port | Replace septa in injection port |

| Symptom | Instrument | Possible Cause | Remedy |
|---|---|---|---|
| **No response (FID)** | Detector | Flame not lit | Ignite flame |
| | | Detectors not turned on | Turn on detectors to correct temp |
| | | Trap not turned on | Turn trap temp to on |
| | | Desorb time set to zero | Set desorb time to correct setting |
| | | Computer not acquiring data | Turn computer off and on |
| | | Detector gas flows not within specs | Adjust gas flows to proper settings |

| | | | |
|---|---|---|---|
| **No response (PID)** | Detector | PID lamp not lit | Check lamp to see if it's lit; replace lamp if defective |
| | | Detectors not turned on | Turn on detectors to correct temp |
| | | Trap not turned on | Turn trap temp to on |
| | | Desorb time set to zero | Set desorb time to correct setting |
| | | Computer not acquiring data | Turn computer off and on |
| | | Detector gas flows not within specs | Adjust gas flows to proper settings |
| | | Leak around PID lamp | Replace o-ring at base of PID lamp |

| | | | |
|---|---|---|---|
| **Noisy baseline (FID)** | Detector | Detector gas flows not within specs | Adjust gas flows to proper settings |
| | | Data integration set to low in Chromperfect method | Adjust area reject, threshold, and peak width in method |
| | | Bad wire connection | Check wiring for loose connections or weak spots |

| | | | |
|---|---|---|---|
| **Noisy baseline (PID)** | Detector | Old PID lamp | |

| | | | |
|---|---|---|---|
| | | | Inspect or replace PID lamp |
| | | Voltage of PID lamp set too low | Increase PID voltage on PID power supply |
| | | Fault in Chromperfect data board | Reboot computer |
| | | Detector gas flows not within specs | Adjust gas flows to proper settings |
| | | Data integration set to low in Chromperfect | Adjust area reject, threshold, and peak width in method |
| | | Bad wire connection | Check wiring for loose connections or weak spots |

| Symptom | Instrument | Possible Cause | Remedy |
|---|---|---|---|
| **Shifting retention times** | GC | Leak in gas line downstream of sparge vessel | Inspect or replace lines to 6-port and trap |
| | | Leak at injection port | Inspect around injection port for leaks |
| | | Column flow too low for mass flow controller | Increase column flow |
| | | GC oven exhaust doors not closing during heat ramp | Motor for exhaust doors will need replaced |
| | | Faulty mass flow controller | Inspect and replace mass flow controller |

| | | | |
|---|---|---|---|
| **No surrogates or internal standards** | SIM/SAM | SIM not turned on | Turn SIM on in 4560 configuration |
| | | No response (see symptom for No response) | See causes for no response |
| | | SIM board fault | Inspect SIM LEDs while sampling to ensure power to SIM |
| | | Bubble in standard syringe | Inspect syringe for leaks |
| | | SIM spiker valve not turning correctly | Inspect and replace SIM spiker valve |

| | | | |
|---|---|---|---|
| **Surrogate Standard inconsistent** | SIM/SAM | Standard in wrong SIM syringe | Refill SIM syringe with correct standard |
| | | SIM spiker valve not turning correctly | Inspect and replace SIM spiker valve |
| | | Dirty sparge filter or sparge vessel | Change sparge filter, clean sparge vessel |
| | | Dirty lines from 6-port valve | Inspect or replace lines to 6-port and trap |
| | | Dirty water management | Inspect or replace Water management |
| | | Standard syringe not seated properly in SIM valve | Tighten standard syringe |
| | | Bubble in standard syringe | Inspect syringe for leaks |
| | | SAM gas pressure not turned on or set too low | Inspect that head pressure is set above 30 PSI and toggle is turned on |
| | | SAM spiker inlet tube clogged | Remove and inspect the inlet tube to make sure it is free flowing |

| Symptom | Instrument | Possible Cause | Remedy |
|---|---|---|---|
| | Autosampler | Autosampler fault | |

| | | | |
|---|---|---|---|
| **Needle tower not ready error** | | | Turn autosampler off/on to reset |
| | | Autosampler needle bent | Replace needle and sleeve, turn autosampler off/on to reset |
| | | Slider on needle tower not sliding or spring is missing | Inspect needle tower slider to make sure it is sliding up and returning |
| | | Needle tower switch broken | Inspect and replace needle tower switch |
| | | CPU board on 4560 has faulty memory | Remove jumpers (JP1 & JP2) on 4560 CPU board to clear memory |
| | | CPU board on 4551 has faulty memory | Remove jumper (JP1) on 4551 CPU board to clear memory |

| | | | |
|---|---|---|---|
| **Sparge vessel not being rinsed with water** | Autosampler | No water in wash vial | See symptoms of no water in wash vial |
| | | Wash cycle out of calibration | Perform wash station calibration according to O.I. manual |
| | | Peristaltic pump tubing worn | Replace peristaltic pump tubing |
| | | Pinch valve tubing worn | Replace pinch valve tubing |

| | | | |
|---|---|---|---|
| **No water in wash vial** | Autosampler | Wash cycle out of calibration | Perform wash station calibration according to O.I. manual |
| | | No water in water reservoir bottle | Fill water bottle with water |
| | | Peristaltic pump tubing worn | Replace peristaltic pump tubing |
| | | Pinch valve tubing worn | Replace pinch valve tubing |
| | | Wash pump not operating correctly | Inspect and replace wash pump |
| | | Siphon tube filter in wash bottle is clogged | Replace siphon tube filter |

| Symptom | Instrument | Possible Cause | Remedy |
|---|---|---|---|
| **Wash vial overflowing** | Autosampler | Wash cycle out of calibration | Perform wash station calibration according to O.I. manual |
| | | Peristaltic pump tubing worn | Replace peristaltic pump tubing |
| | | Pinch valve tubing worn | Replace pinch valve tubing |

| | | | |
|---|---|---|---|
| **Water being left on top of vial in autosampler** | Autosampler | Pinch valve tubing worn | Replace pinch valve tubing |

| | | | |
|---|---|---|---|
| **Water leak in autosampler** | Autosampler | Lines to autosampler six port loose | Inspect and tighten fittings around six port |
| | | Lines to autosampler needle loose | Inspect and tighten fittings around needle |
| | | Lines to SIM spiker loose | Inspect and tighten fittings around SIM |

## Scope

This method is suitable for the determination of the concentration of certain semivolatile organic compounds (priority pollutant list, target compound list, Appendix IX list, TCLP list, and CCW list) found in soils, tissues, waters, and leachates. Typical limits of quantitation (LOQ) achieved are 33 µg/kg for soils, 132 µg/kg for tissues, 1 µg/L for waters, and 0.002 mg/L for leachates. Specific compound lists and associated method detection limits (MDLs) and LOQs can be found in the Laboratory Information Management System (LIMS) under the analysis numbers listed in the header of this SOP.

## Basic Principles

Water samples are extracted according to *T-OE-SVOA-WI11432*. Soil samples are extracted according to T-OE-SVOA-WI10925 or *T-OE-SVOA-WI10928*. Leachates are extracted according to *T-OE-SVOA-WI10935*. Non-water soluble matrices are extracted according to *T-OE-SVOA-WI10917*.

An environmental sample (soil, water, sludge, etc.) is solvent extracted and then analyzed by electron impact gas chromatography/mass spectrometry (EI GC/MS). A predetermined aliquot of an extract containing organic compounds in solvent is injected onto a fused silica capillary column coated with a relatively non-polar stationary phase, which is enclosed in a temperature controlled oven. A carrier gas, which is ultra-pure helium, passes continuously through the column. The GC oven is temperature programmed and the organic mixture separates into its individual components as it moves along the length of the column. This separation is the function of the polarity and boiling point of the individual compounds. This column empties into a mass selective detector. When a compound reaches the detector, it is bombarded by high-energy electrons (70eV). This causes the compounds to fragment, forming ions. By applying various voltages to the lens, the positive ions are thrust into a quadrupole mass analyzer, which selects for a given mass fragment at a given time. These selected fragments reach an electron multiplier that detects and generates a signal for each mass fragment. The signals are amplified and sent to a computer. Target compounds are identified on the basis of relative retention times and spectral match to standards that are injected every 12 hours on the same system.

Quantification is achieved via use of the internal standard calibration technique. The average relative response factor of a multi-point calibration is used for quantification when the appropriate criteria are met.

## Interferences

Method interferences may be caused by impurities in solvents, reagents, glassware, or other hardware used in the processing of samples. All glassware is solvent rinsed before use and a method blank is performed with each extraction batch to demonstrate that the extraction system is free of contamination.

Sample matrices can have an effect on the ability of the GC/MS system to resolve the individual masses used for quantification. Samples may require dilutions, a reduction in the extraction volume/weight used, a raised final extraction volume, or extract clean-up using various techniques in order to achieve proper target separation and determination.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

The toxicity or carcinogenicity of each reagent used in this method has not been precisely defined; however, each chemical compound and reagent should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means are available such as fume hoods, safety glasses, lab coats, and gloves.

All solvent waste generated from this analysis must be collected for recycling (if applicable) or must be disposed of in designated containers. These are then transferred to a lab-wide disposal facility. Any solid waste material (disposable pipettes, broken glassware, pH paper) must be disposed of in the normal solid waste collection containers or sharps containers, as applicable.

### Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each analyst performing instrumental analysis must work with an experienced analyst for a period of time until they can independently perform daily maintenance, calibrate the instrument, change the column, clean the source, interpret chromatograms, perform calculations, review data, and enter data into the LIMS. The analyst is also trained on the preparation of dilutions and calibration standards. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an Initial Demonstration of Capability (IDOC).

The IDOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation (per EPA 8000D, the statistical LCS window and RSD </= 20%)).

Various options are available for a DOC and can include four laboratory control samples or one blind sample. The RSD criteria is 20%.

Refer to *QA-SOP11178* for more guidance on these options.

### Sample Collection, Preservation, and Handling

Water samples are collected in 250mL or 1L glass amber glass containers with PTFE-lined lids and may be preserved with sodium thiosulfate ($Na_2S_2O_3$). They are stored at 0ºC to 6ºC, not frozen, prior to extraction and must be extracted within 7 days of collection.

Solid samples are collected in glass wide-mouth jars with PTFE-lined lids and are not preserved. They are stored at 0ºC to 6ºC, not frozen, prior to extraction and must be extracted within 14 days of collection.

All sample extracts must be stored at ≤-10ºC (freezer) and protected from light using amber glass vials. All samples, sample extracts, and standards must be stored separately and in an area free from contamination. All extracts must be analyzed within 40 days of extraction.

### Apparatus and Equipment

1. Hewlett-Packard Model 5890 (Series I and II) or Hewlett-Packard/Agilent 6890 or 7890 Gas Chromatograph or equivalent
2. Hewlett-Packard Models 5971, 5972, and Hewlett-Packard/Agilent 5973, 5975 Mass Selective Detector or equivalent
3. Hewlett-Packard ChemStation Software
4. Thru-Put Systems Target Acquisition Software/Oracle Database or equivalent
5. Column – 20 M × 0.18 mm ID × 0.18 µm, Agilent DB-5MS or equivalent
6. Column - 30M × 0.25 mm ID x 0.25 µm df, J&W Scientific DB-5MS or equivalent
7. Hamilton Gastight syringe, or equivalent – various volumes
8. Amber GC vials with crimp caps

### Reagents and Standards

A. Reagents - All reagents are stored per manufacturer guidelines unless otherwise noted. Reagent vendors are subject to change without notification.

1. Helium carrier gas, UPC grade
2. Methylene chloride ($MeCl_2$ or $CH_2Cl_2$) – Baker Ultra Resi-Analyzed

B. Standards

1. Supelco Equity Semivolatile Internal Standard Mix, Part #46955-U or equivalent, 1000 µg/mL in methylene chloride. Ampulated solutions are maintained under refrigeration (0° to 6°C, not frozen) until consumed or manufacturer determined expiration date. Working solution is maintained at room temperature and is replenished daily from ampulated solutions. For 250 mL aqueous analyses Supelco Equity Semivolatile Internal Stanadard Mix is diluted 4x to make a 250 µg/mL in methylene chloride solution. This solution is maintained under refrigeration (0° to 6°C, not frozen) for up to 6 months.

2. Refer to *T-SVOA-WI11998* for the preparation and storage of tuning, calibration, and spiking solutions.

### Calibration

See Procedure F for initial calibration processing and Procedure G for continuing calibration check processing.

### Procedure

A. Standard preparation – Solutions are used to standardize the GC/MS system every 12 hours and are prepared approximately every 20-30 days or more frequently if needed based on consumption. See *T-SVOA-WI11998* for standard preparation. Calibration standard solutions may be used up to the labeled expiration date or until component degradation is observed. Degradation is determined by the inability to pass continuing calibration checks or by observations of unacceptable chromatography.

B. Internal standard mix is added to all standards and subsequent samples at a concentration of 20 µg/mL (5 µg/mL for 250 mL aqueous analyses). Using a 25-µL syringe, 20 µL of Supelco Equity Semivolatile Internal Standard Mix or equivalent, 1000 µg/mL (250 µg/mL for 250 mL aqueous analyses) in

methylene chloride are added to 1 mL of standard or sample extract. If only 0.5 mL of sample is in the vial, 10 µL of internal spiking solution is added to the sample. See Table II for the list of compounds calibrated for and the internal standard that is assigned to each.

C. Daily maintenance – Refer to *T-SVOA-WI9598* for this procedure.

D. Instrument conditions

Equip a GC/MS (such as referenced under Apparatus and Equipment) in one of the two following manners:

1. For a 5890/5971 or 5972 and 6890/5973 or 5975

   a. Column – 30M × 0.25 mm ID x 0.25 µm df, J&W Scientific DB-5MS or equivalent

   b. Injector – Split/splitless operated in splitless mode

   c. Injector Temp – 275°C

   d. Detector Temp – 300°C

   e. Gas – Helium at approximately 1.5 mL/min, constant flow mode

   f. Oven Temp – 45°C for 3 minutes, ramp at 8°C/minute to 225°C, then ramp at 12°C/minute to 300°C and hold for 7.5 minutes.

2. For a 6890/5973 or 5975

   a. Column – 20M × 0.18 mm ID x 0.18 µm df, J&W Scientific DB-5MS or equivalent

   b. Injector – Split/splitless operated in split mode, 20:1 split

   c. Injector Temp – 275°C

   d. Detector Temp – 280°C

   e. Gas – Helium at approximately 1.0 mL/min, constant flow mode

   f. Oven Temp – 40°C for 1 minute, ramp at 25°C/minute to 100°C, then ramp at 30°C/minute to 280°C, followed by another ramp at 25°C/minute to 320°C, hold for 2 minutes.

**NOTE:** It is not necessary to use the exact parameters listed above. Equivalent columns and conditions may be used to improve the linearity, sensitivity, overall chromatography, and performance required by the method on each GC/MS system.

E. Tuning

1. The DFTPP tune check standard is used to assess GC column performance and injection port inertness as well as mass spectrometer performance. The GC/MS system's tune is checked by inspecting the mass spectrum of the DFTPP peak and column performance and injection port inertness is evaluated with pentachlorophenol, benzidine, and DDT.

2. The GC/MS should be tuned using a predetermined aliquot of a 50 ng/µL or 12.5 ng/µL solution of DFTPP containing decafluorotriphenylphosphine, pentachlorophenol, benzidine, and DDT. This solution is prepared as indicated in *T-SVOA-WI11998*. See the tables below for acceptance criteria and corrective actions.

| DFTPP Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Prior to initial calibration and every 12 hours prior to continuing calibration standard | 1. Criteria in Table I<br><br>2. DDT breakdown ≤20%*<br><br>3. Tailing factors:<br>- Benzidine ≤ 2<br>- Pentachlorophenol ≤ 2 | 1. Re-tune. Analysis cannot proceed until tune meets criteria.<br><br>2. More aggressive injection port maintenance.<br><br>3. Clean the source.<br><br>4. Change the column. |

*__NOTE:__ DDT breakdown greater than 20% may be acceptable if you are calibrating for polynuclear aromatic hydrocarbon compounds only. Consult your supervisor when this situation occurs.

3. Use only the background-subtracted spectrum of the following when evaluating the DFTPP:

A three scan average of the apex of the scan, the apex of the scan −1 and the apex of the scan +1.

**NOTE**: All standards, samples, and associated quality control samples with a particular tune must use the identical conditions of the mass spectrometer.

F. Initial calibration (ICAL)

1. Perform standardization by analyzing at least five levels of calibration standards ranging from 0.5 µg/mL to 120 µg/mL or from 0.125 µg/mL to 30 µg/mL for mini-sep waters analysis. (Refer to *T-SVOA-WI11998* for the preparation of calibration standards.) Use the internal standard calibration technique to generate an average relative response factor for each target compound and surrogate. The relative standard deviation (%RSD) of the response factors determines the suitability of the average relative response factor for calculation of compound concentration. At the end of the calibration standard injections, inject a Method Detection Limit (MDL) standard and an initial calibration verification (ICV) standard. See the tables below for acceptance criteria and corrective actions.

| ICAL Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Initially and when the daily calibration standard fails criteria. | 1. Minimum response factors must be met in all levels of the calibration – especially in the | 1. Any target compound with a %RSD <20% will use the average RRF. For any compound in which the %RSD |

| | | |
|---|---|---|
| | lowest level of the calibration (see table IV).**<br><br>2. %RSD for each compound must be ≤20%. If more than 10% of the compounds in the ICAL exceed 20% RSD and/or also do not meet the minimum correlation coefficient for alternate fits (ie, the correlation coefficient is <0.990) then the analysis cannot proceed.<br><br>3. For any compound on a linear or quadratic fit the % error is measured between the calculated and expected amounts of the compound(s) at each calibration level to determine the calibration function acceptability for linear and non-linear curves. The % error must be ≤50% for the low calibration point. For calibration points above the LOQ the % error must be ≤30%.<br><br>4. The relative retention times of the target compounds must agree within 0.06 relative retention time units.<br><br>5. Structural isomers that produce very similar mass spectra are identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is <25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. | >20%, use a first degree (linear) fit provided the correlation coefficient (CC; r) is ≥0.995 or the coefficient of determination (COD;$r^2$) is ≥0.99. If the linear fit fails to meet this criteria, then a second order (quadratic) fit may be used*** provided the coefficient of determination is ≥0.99. If use of both the linear fit and the quadratic fit is acceptable using this criteria for any given compound, then use the fit with the smallest negative y-intercept. When using a quadratic fit, if the y-intercept quantifies to be greater than the MDL, consult your supervisor immediately or re-calibrate. See below for corrective action if the coefficient of determination for a quadratic fit is <0.99.*<br><br>2. Re-inject any levels that appear to be outliers due to an injection error.<br><br>3. If standard levels on the outside of the curve appear to be outliers for individual compounds and are throwing off the calibration curve, they can be dropped from the calibration keeping the following in mind:<br><br>a. If a low calibration point is dropped, the analyst must ensure that the compound is still being calibrated to or below its LOQ.<br><br>b. If a high calibration point is dropped, any detections must recover below the new upper calibration limit.<br><br>4. Re-prep calibration standards.<br><br>5. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

*See USEPA Method 8000D for the calculations associated with non-linear fit types.
**Minimum response factors are not required to be met for method 8270E. They are provided for guidance.
***Quadratic fits are not permitted when analyzing samples from South Carolina.

| MDL Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Immediately following an initial calibration and before sample analysis | 1. The system must be able to detect all compounds in the MDL standard. | 1. If any compounds are not detected in the MDL standard, analysis can proceed if the compound is detected at or below its MDL in a higher concentration level.<br><br>2. If the system does not detect the compound(s), then the tuning and/or calibration procedure must be repeated under conditions that will yield a detection for the compound(s) or the MDL must be raised for the compound(s).<br><br>3. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

| ICV Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| Immediately following an initial calibration and before | 1. The ICV must be prepared using a second source standard. | 1. Re-prep and re-analyze the ICV. |

| ICV Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| sample analysis | 2. %Drift for each compound must be ≤30%<br><br>3. The EICP area for each internal standard must fall within the window of -50% to +100% of the areas from the mid-level calibration standard produced during the initial calibration. | 2. If the recovery for any compound fails these criteria low, the compound cannot be analyzed for under the calibration until a new calibration has been established or a passing ICV has been analyzed.<br><br>3. If the recovery for any compound fails these criteria high, the compound may be analyzed for but any samples with detections should be re-analyzed under a valid ICAL or will be reported with a qualifying comment.<br><br>4. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

With supervisory approval, the following problematic compounds can be allowed to fail the 0.99 coefficient of determination criteria for a quadratic fit. If the COD is less than 0.99 for any other compound, the system should be inspected for problems and re-calibrated. Supervisory approval is required for exceptions to these guidelines.

| |
|---|
| 1,4-Phenylenediamine |
| 4-Aminobiphenyl |
| 3,3’-Dimethylbenzidine |
| 4,4’-Methylenebis(2-chloroaniline) |
| 4-Nitroquinoline-1-oxide |
| 1,4-Naphthoquinone |
| methapyrilene |

**Note that this allowance is not to be used for compliance samples, and any data reported under the calibration must be qualified.**

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

3. Six levels of calibration standards must be used if a quadratic (second-order) type calibration fit is used.

4. One of the calibration standards must be at a concentration at or below the limit of quantitation (LOQ). The other concentrations correspond to the expected range of concentrations found in samples or should define the working range of the GC/MS system.

5. The concentration of the MDL standard may require modification dependent upon the current MDL values.

G. Continuing Calibration Verification (CCV)

1. Perform a continuing calibration verification (CCV) by injecting a predetermined aliquot of a calibration standard at a concentration near the mid-point of the calibration, not to exceed ½ the highest level in the calibration.

| CCV Frequency | Acceptance Criteria | Corrective Action |
|---|---|---|
| 1. Every 12 hours.<br><br>2. The CCV is analyzed each day a curve is not analyzed.<br><br>3. The CCV is analyzed after the DFTPP. | Target compounds must meet the minimum response factor criteria (see Table IV).*<br><br>1. The maximum % drift for all target compounds is 20%. No more than 20% of the target compounds can be greater than 20% drift. All target compounds that exceed 20% drift must be less than or equal to 50% drift.<br><br>2. The relative retention times of the internal standards must be within 10 seconds of the retention times from the mid-level calibration standard of the last initial calibration. The exception would be in the case of column maintenance.<br><br>3. The EICP area for each internal standard must fall within the window of -50% to +100% from the areas of the mid-level standard produced during the last initial calibration.<br><br>4. Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is <25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. The resolution should be verified on the mid-point concentration of the ICAL as well as the check standard. | 1. In cases where compound(s) recover >20%D low, they may still be reported as non-detects if it can be demonstrated that there was adequate sensitivity to detect the compound(s) at the applicable quantitation limit. For situations when the failed compound is present, the concentrations must be reported as estimated values.<br><br>2. In cases where compound(s) recover >20%D high, analysis may continue, but any samples with detections should be re-analyzed under a valid CCV or the results will be qualified.<br><br>3. Perform more aggressive system maintenance as outlined in *T-SVOA-WI9598* and re-calibrate. |

*Minimum response factors are not required to be met for method 8270E. They are provided for guidance.

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

2. In the event that a CCV fails and the cause is not obvious such as in the case of a concentrated standard or a mis-injection, corrective action must be taken. The corrective action must be documented in the form of a non-conformance memo. If the CCV does not pass after corrective action, a new initial calibration must be established.

H. Analysis of Samples:

1. All sample extracts are stored at ≤-10°C and protected from light from the time of sample extraction.

2. Prior to sample analysis, add 20 µL of internal standard to each 1.0 mL of sample extract. Concentration of internal standards in extract is 20 ng/µL (5 ng/µL for 250 mL aqueous analyses).

3. Analyze a predetermined aliquot of each sample extract under the same conditions used for the initial and continuing calibrations.

4. At the conclusion of data acquisition, use the same software to tentatively identify peaks within the retention time window of interest. Examine the ion abundances of components in the chromatogram. If the ion abundance of the target ion used for quantitation exceeds the calibration range, dilute the aliquot and reanalyze. When preparing dilutions, add sufficient internal standard to maintain the same concentration as that of the ICAL.

Dilution criteria:

1) Initial dilutions are recommended in the following situations:

i. More than three internal standard recoveries are <-50%

ii. Either of the last two internal standard recoveries are <-80%.

iii. The analyst’s judgment of a sample extract’s color or viscosity indicates possible matrix interference.

2) Secondary dilutions are required to bring all target compounds into the calibration range of the GC/MS.

I. Qualitative analysis

A compound is identified by comparison of the following parameters with those of a standard of the suspected compound (standard reference spectra). The reference mass spectrum used for this comparison should be generated by the laboratory using the conditions of the method, but the laboratory may also use a certified reference library. In order to verify identification, the following criteria must be met:

1. The intensities of the characteristic ions of the compound must maximize in the same scan or within one scan of each other. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 30% relative intensity if less than three such ions occur in the reference spectrum.

2. The RT should be within ±10 seconds of the RT for this analyte in the CCV run at the beginning of the 12-hour period (delta RT 0.17 minute) or within ±10 seconds relative to the shift of the associated IS (delta RT of the IS ± 10 seconds). If the RT for the IS has shifted, the sample should be inspected for similar shifts for the associated target analytes. If RT drift is significant, relative retention time (RRT) may be used as an alternative to delta RTs.

3. The relative intensities of the qualifier ion(s) should agree within 30% of the relative intensities of these ions in the reference spectrum.

**NOTE:** N-Nitrosodiphenylamine decomposes in the gas chromatographic inlet and cannot be separated from diphenylamine. For this reason, it is acceptable to report the combined result for both n-nitrosodiphenylamine and diphenylamine for either of these compounds as a combined concentration.

**NOTE:** 1,2-Diphenylhydrazine is unstable even at room temperature and readily converts to azobenzene. Given the stability problems, it would be acceptable to calibrate for 1,2-diphenylhydrazine using azobenzene. Under these poor compound separation circumstances the results for either of these compounds should be reported as a combined concentration.

J. Quantitative analysis

Once a compound has been identified, quantitation is based on the internal standard technique and the integrated abundance from the extracted ion current profile (EICP) of the primary characteristic ion. The list of primary characteristic ions and secondary ions can be found in Table III.

### Calculations

Refer to *T-SVOA-FRM9602* for all calculations.

### Statistical Information/Method Performance

LCS, MS, surrogate, and RPD recoveries are compared to the limits stored in the LIMS. LCS and surrogate limits are statistically derived every six months in accordance with *T-SVOA-WI9604*. All RPDs are set to a default value of 30%. MS limits are set equal to LCS limits.

Historical data for MS/Ds, LCS/Ds, surrogates, and measurement of uncertainty is reviewed at least annually.

Refer to the QA/QC section of this SOP and the criteria listed throughout this procedure for additional information on the performance of this method.

### Quality Assurance/Quality Control

A. Batch QC

1. Each extraction batch of ≤20 samples must contain a method blank, a laboratory control sample (LCS) and an unspiked background sample (US), a matrix spike (MS), and a matrix spike duplicate (MSD).

2. A laboratory control sample/laboratory control sample duplicate (LCS/LCSD) is prepared with the extraction batch if adequate sample volume is not provided to prepare a matrix spike and matrix spike duplicate.

3. Additional QC samples may be required to meet project or state certification requirements.

B. QC and sample spiking

1. The LCS/D and MS/D are spiked at a concentration of 50 µg/L with the exception of the following (in µg/L):

| | | | |
|---|---|---|---|
| Hexachlorocyclopentadiene | 100 | Benzoic acid | 100 |
| 2,4-Dinitrophenol | 100 | 1-Naphthylamine | 100 |
| 2-Naphthylamine | 100 | 3,3’-Dimethylbenzidine | 100 |
| Benzidine | 250 | 3-Methylphenol | 25 |
| 4-Methylphenol | 25 | | |

2. All samples are spiked with surrogates by the organic extraction group to evaluate the extraction process. Acid extractable surrogates are spiked at a concentration of 200 ng/µL and base/neutral extractable surrogates are spiked at a concentration of 100 ng/µL.

3. Prior to analysis each extract is spiked with an internal standard mix at a concentration of 20 ng/µL.

4. All spiking concentrations are 4x lower for 250 mL aqueous analyses.

C. QC items, acceptance criteria, and corrective actions.

**NOTE: If any client, state, or agency has more stringent QC, QC limits, or batch requirements, these must be followed instead.**

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| Internal Standards | 1. Peak area within -50% to +100% of the area in the associated reference standard.<br><br>2. Retention time (RT) within 30 seconds of RT for associated | 1. Check instrument for possible problems and then re-inject sample(s).<br><br>2. If re-injection meets the criteria, report this injection. |

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| | reference standard. | 3. If re-injection still shows the same problem, report first injection.<br><br>4. If there is substantial matrix interference, the analyst may dilute the extract as outlined in Procedure H.4. |
| Method Blank | 1. Must meet internal standard criteria.<br><br>2. Must meet surrogate criteria.<br><br>3. All target compounds must be less than the reporting limit for the associated samples. | 1. Inspect system for possible problems and reanalyze.<br><br>2. If the surrogates are out of spec high data can be used provided there aren't detections in the method blank.<br><br>3. If the surrogates are out of spec low and there aren't detections in the associated samples, the data can be used.*<br><br>4. If the method blank contains target compounds and the associated samples do not contain these compounds, no corrective action is required.<br><br>5. If the target compounds in the blank are also in the associated samples at a concentration <10x that in the blank, the samples are re-extracted unless the detection does not interfere with project data requirements.<br><br>6. If the target compounds in the blank are also in the associated samples at a concentration >10x than in the blank the data is usable. |
| Instrument Blank** | 1. Must run after the CCV if no clean method blank is analyzed at the beginning of a 12-hour analytical period.<br><br>2. Must meet internal standard criteria.<br><br>3. All target compounds must be less than the reporting limit for the associated samples. | 1. Inspect system for possible problems and reanalyze.<br><br>2. If the instrument blank contains target compounds and the associated samples do not contain these compounds, no corrective action is required. If the target compounds in the blank are also in the associated samples, the samples should be re-extracted unless it does not interfere with project data requirements or if sample detections are at a level 10x higher than the detections in the blank. |
| Laboratory Control Sample/Laboratory Control Sample Duplicate | 1. Must meet internal standard criteria.<br><br>2. Must meet surrogate criteria.<br><br>3. % Recoveries within QC limits. Refer to the analysis numbers in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis.<br><br>4. RPDs within QC limits. | 1. If non-compliant, check for calculation or preparation errors.<br><br>2. If no errors found, check system for problems and reanalyze.<br><br>3. If LCS/LCSD recoveries are still outside acceptance limits, one of the following actions must be taken:<br><br>a. if recoveries are outside acceptance limits low, the sample(s) must be re-extracted.<br><br>b. if recoveries are outside acceptance limits high, data may be usable if the compounds that recovered above QC limits are not detected in samples.<br><br>c. if recoveries are outside acceptance limits high and |

| Quality Control Item | Acceptance Criteria | Corrective Action |
|---|---|---|
| | | there are detections for the failing compounds, the sample(s) must be re-extracted.<br><br>4. If RPDs fail but recoveries are within QC limits, no further action is required.<br><br>5. If surrogates fail to meet criteria but all target compounds are within specification, data is usable.*<br><br>6. Marginal exceedance limits, as defined in the NELAC standards, may be used if the defined requirements have been met. |
| Matrix Spike/Matrix Spike Duplicate(MS/MSD) | 1. Must meet internal standard criteria.<br><br>2. Must meet surrogate criteria.<br><br>3. % Recoveries within LCS limits. Refer to the analysis number in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis.<br><br>4. RPDs within QC limits. | 1. If LCS within QC limits, proceed with sample analysis.<br><br>2. If most recoveries or RPDs out of spec, consult supervisor. BKG, MS, MSD may need to be re-extracted. |
| Surrogates | % Recoveries within QC limits. Refer to the analysis numbers in the header of this document in LIMS for acceptance limits. These are reviewed and updated on a semiannual basis. | 1. If non-compliant, check for calculation or preparation errors.<br><br>2. If no errors found, check system for problems and reanalyze.<br><br>3. If no problem is found, re-extract and reanalyze.<br><br>4. If surrogates are out of spec high and no targets are detected in the sample no corrective action is required.<br><br>5. For samples analyzed only at a dilution ≥10x, no further action is required for surrogate failures. |

*Requires approval of supervisor
**Method blank or instrument blank in each 12-hour analytical period required for 8270E.

**NOTE:** Any failures without corrective action require approval of supervisor and completion of a non-conformance memo (NCM).

**NOTE:** All data associated with failed quality control will be qualified on the final report. QC outlier qualifiers are added to the associated sample results on the report by the LIMS.

D. Lower Limit of Quantitation (LLOQ)

1. Refer to *QA-SOP11892* for initial and ongoing LLOQ requirements.

E. Method Detection Limit (MDL)

1. Refer to *QA-SOP11892* for initial and ongoing MDL requirements.

F. Limit of Quantitation (LOQ)

1. Refer to *QA-SOP11892* for initial and ongoing LOQ requirements.
2. Until the laboratory has sufficient data to determine the acceptance limits, the LLOQ criteria is ± 20% of the statistically determined LCS limits.

**Table I**

**DFTPP Key Ions and Ion Abundance Criteria**

| Mass | Ion Abundance Criteria |
|---|---|
| 51 | 10% to 80% of mass 198 |
| 68 | <2% of mass 69 |
| 70 | <2% of mass 69 |
| 127 | 10% to 80% of mass 198 |

| | |
|---|---|
| 197 | <2% of mass 198 |
| 198 | Base peak, or >50% of mass 442 |
| 199 | 5% to 9% of mass 198 |
| 275 | 10% to 60% of mass 198 |
| 365 | >1% of mass 198 |
| 441 | Present but less than 24% of mass 442 |
| 442 | Base peak, or >50% of mass 198 |
| 443 | 15% to 24% of mass 442 |

### Scope

This method is for the extraction of semivolatile organic compounds at low ppb to low ppm levels in aqueous samples that are not prone to emulsions. High levels of organic compounds and/or extreme alkalinity or acidity in the sample often interfere with normal detection limits.

### Basic Principles

A sample is placed into a separatory funnel. Surrogate standards are added to each sample to monitor recovery. The pH of the sample is adjusted to >11 and the sample is serially extracted with methylene chloride. The pH is then adjusted to <2 and the sample is again serially extracted with methylene chloride. The solvent fractions are combined, and the extract is concentrated to 1.0 mL.

Procedural changes to use a reduced sample aliquot while maintaining the default reporting limits are permitted as long as the reagent aliquots are reduced proportionally and a demonstration of capability study is performed and on file.

### Reference Modifications

Surrogate and matrix spiking solutions are not added before the transfer to the separatory funnel for several reasons:

1. Samples must be poured from the amber bottles to determine the matrix and volume of sample to use for each extraction.
2. Many sample bottles have no headspace and there is no room to add surrogate to the sample in the bottle.
3. Due to the volume of samples extracted, a separate graduated cylinder for each sample is unrealistic.
4. To maintain consistency with all extractions, no samples are spiked in the bottle or graduated cylinders.

### Interferences

High levels of organic compounds in the sample lead to interferences with normal detection limits.

Impurities in solvents, reagents, glassware, or other hardware used in sample processing lead to interferences with the method. All glassware must be rinsed with solvent before use. A method blank is performed with each batch of samples to demonstrate that the extraction system is free of contaminants. See *T-OE-GEN-WI10864* for glassware cleaning instructions.

### Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

The toxicity or carcinogenicity of each reagent used in this method has not been precisely defined. Each chemical compound must be treated as a potential health hazard. Exposure to these chemicals must be reduced to the lowest possible level by whatever means available, such as fume hoods, lab coats, safety glasses, and gloves.

Extracts are concentrated on a steam bath, rapid vap, or Buchi; caution must be exercised while working around these apparatuses.

All solvent waste generated from this preparation must be collected for recycling (if applicable) or disposed of in the designated containers. These are transferred to the lab-wide disposal facility. Any solid waste material (disposable pipettes, broken glassware, pH paper) is disposed of in the normal solid waste collection containers.

### Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the employees training records.

Initially, each technician performing the extraction must work with an experienced employee for a period of time until they can independently perform the extraction. Proficiency is measured through a documented Initial Demonstration of Capability (IDOC).

The IDOC consists of four laboratory control samples that are carried through all steps of the extraction and analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation. Various options are available for a DOC and can include four laboratory control samples, or one blind sample.

### Sample Collection, Preservation, and Handling

Samples must be collected in amber glass bottles with PTFE-lined lids and stored under refrigeration at 0º to 6ºC, not frozen, prior to extraction. Samples must be extracted within 7 days of collection. The extract is stored in an amber autosampler vial in the freezer at ≤-10 °C for up to 40 days prior to analysis.

### Apparatus and Equipment

1. Separatory funnel for extracting organic components from an aqueous matrix
2. Kuderna-Danish (K-D) assembly with appropriate ampule for concentrating the solvent used during the extraction
3. Water bath – VWR/LLI Model #1127 or equivalent
4. Graduated cylinders – Class A, assorted sizes
5. Pipettes – Class A, assorted sizes
6. Pipettes – Disposable
7. Solvent pumps – Beckman, adjustable
8. Balance – Capable of weighing to 0.01 g
9. Automatic shaker – Capable of holding 2L separatory funnels
10. Centrifuge – Beckman GS-6 or equivalent
11. Sodium sulfate columns with extra course frits
12. Micro-snyder columns
13. Wash bottles – Teflon™
14. Amber autosampler vials with crimp caps
15. Teflon™ boiling chips
16. Teflon™ separatory funnel
17. pH paper - wide range or Hydrion (or equivalent) 10 to 12 range and 1 to 2.5 range.
18. Automated Water Extraction Bench – capable of holding separatory funnels for 250-mL extractions.
19. Rapid-Vap Evaporators – for concentration of 250-mL extractions
20. Rapid-Vap Evaporator Tubes – Class A
21. N-evap nitrogen evaporator with nitrogen supply
22. Erlenmeyer flasks - 250mL
23. Buchi Concentrator
24. Buchi Concentrator Tubes

### Reagents and Standards

Unless otherwise noted, use ACS grade reagents or equivalent. See *T-OE-GEN-WI10876* for storage and handling of spikes.

1. Methylene chloride ($MeCl_2$ or $CH_2Cl_2$) – Pesticide grade or equivalent. Store at room temperature for up to one year.
2. Methanol (MeOH) - pesticide grade or equivalent. Store at room temperature for up to 1 year.
3. Hexane - Pesticide grade or equivalent. Store at room temperature for up to 1 year.
4. Acetone - Pesticide grade or equivalent. Store at room temperature for up to 1 year.
5. 10N Sodium hydroxide (NaOH) – Lab chem or equivalent. Store at room temperature for up to one year.

6. Sulfuric acid($H_2SO_4$) – ACS grade or equivalent, concentrated. Store at room temperature for up to one year.
7. Sodium sulfate – Anhydrous reagent grade or equivalent. Bake at approximately 400°C for a minimum of 4hours in a shallow pan prior to use to remove organic contaminants. After baking, store in a glass jar at room temperature for up to 1year.
8. Tap water - In general the laboratory tap water has been shown not to contribute interferences at or above the reporting limits for parameters of interest.
9. Reagent water – Deionized water ($DIH_2O$) in which interferences are not observed at or above the reporting limit for parameters of interest. In general, the reagent water supplied at the $DIH_2O$ taps in the laboratory meets this criterion. If the reagent water does not meet the requirements, see your supervisor for further instructions.
10. Trimethylsilyldiazomethane (TMSD) - Follow manufacturer's storage and expiration information
11. Silicic Acid - Follow manufacturer's storage and expiration information
12. Diazald (N-methyl-N-nitroso-*p*-toluenesulfonamide) - Follow manufacturer's storage and expiration information
13. Potassium Hydroxide (KOH) – ACS Certified, Fisher Chemical or equivalent. Store at room temperature for up to 5 years
14. Reagent Alcohol GR. Store at room temperature for up to 1 year

All QC standards added during extraction process are prepared by the organic extraction department using the Reagent module in LIMS as a guide. Detailed instructions can be found in *T-SVOA-WI11998*.

### Calibration

Not applicable to this procedure

### Procedure

1. Prepare the glassware to be used as outlined in *T-OE-GEN-WI10864*. If the sample is entered for analytical method Dinoseb_ATP, perform a thorough acid rinse of the separatory funnel through the stopcock, followed by a thorough water rinse and finally, a thorough solvent rinse using 1:1 Acetone/Hexane prior to extraction.
2. Determine the volume of sample to be used for each extraction. Ideally, one full bottle is used. (Typically, this is 250 mL for 3510C_LVI extractions or 1 L for 3510C extractions).
   a. Samples being extracted using 1 L are entered for 3510C.
   b. Samples being extracted using 250 mL are entered for 3510C_LVI.
3. If using one full bottle:
   a. Place the full sample bottle with the cap on the scale. Record this weight in the LIMS as the gross weight.
   b. Shake the bottle vigorously.
   c. Pour the sample into a separatory funnel.
   d. Record any comments about the sample in the LIMS.

   **NOTE:** Reduced volumes of sample are only used with prior approval by the client or if the matrix of the sample does not allow the extraction to proceed using the full volume. The sample must then be diluted with reagent water to 1 L or 250 mL depending on the extraction.
4. The method blank, laboratory control sample (LCS), and laboratory control sample duplicate (LCSD) (if applicable) are prepared using 1 L (or 250 mL for mini-extractions) of tap water (except for isotope dilution (ID) analytical methods 8270D_SIM_ID_D5, 8270D_SIM_ID_DK, 8270D_SIM_MS_ID which are prepared with reagent water) measured into the separatory funnel.
5. The background, MS, and MSD are prepared on three separate aliquots of a field sample.
6. Surrogates

   Unless noted otherwise, surrogate spike is added to all samples, blanks, LCS, LCSD (if applicable), MS, and MSD (if applicable). See *T-SVOA-WI11998* for preparation of spikes. See *T-OE-GEN-WI10876* for storage and handling of spikes.
   a. For samples entered for any of the 8270 methods referenced in the cross reference section of this SOP paired with extraction method 3510C (1 L) - Add 1.0 mL BNA surrogate (OP_BNA_SS). Exception: Any samples entered for analytical method Dinoseb_ATP - Add 0.2 mL Mini BNA surrogate.
   b. For samples entered for any of the 8270 methods referenced in the cross reference section of this SOP paired with extraction method 3510C_LVI (250 mL) – Add 1.0 mL of Mini BNA surrogate (OP_MINIBNA_SS). Exception: for isotope dilution methods listed in step 4 - Add 0.25 mL of Mini 1,4- Dioxane-d8 Surrogate (OP_14DX-d8_SS).

   **NOTE:** The standard must drip directly into the aqueous sample without touching the glass side of the separatory funnel to avoid poor recoveries.
7. Spiking solutions

   Unless noted otherwise, spiking solutions are added to the LCS, LCSD (if applicable), MS, and MSD (if applicable).

a. For methods 8270D, 8270D_DKQP, 8270D_DOD5, 8270DEL, 8270E, 8270MCP, 8270RCP paired with extraction method 3510C, add 1.0 mL of LCS Spike Mix #1 (OP_LCS1_MS). The analytes contained in this mix can be found in Table I. The following additional spikes may also be added as indicated below dependent upon the requested analyte list.

   i. Add 1.0 mL of LCS Spike Mix #2 (OP_LCS 2_MS) if benzaldehyde, atrazine, or caprolactam are requested analytes.

   ii. Add 1.0 mL of Benzenethiol Spike (OP_BENTHIO_MS) if phenylmercaptan is requested. This will be spiked into a separate LCS/D.

   iii. Add 1.0 mL of APPIX Mix #1 (OP_APPIX1_MS) if any analytes contained in Table II are requested. This will be spiked into a separate LCS/D.

   iv. Add 1.0 mL of APPIX Mix #2 (OP_APPIX2_MS) if p-Phenylenediamine is requested. This will be spiked into the same LCS/D as APPIX Mix #1. Note: APPIX Mix #2 will not be requested without APPIX Mix #1.

b. For methods 8270D, 8270D_DKQP, 8270D_DOD5, 8270D_MPhenols, 8270DEL, 8270E, 8270MCP, 8270RCP paired with extraction method 3510C_LVI, add 1.0 mL of Mini LCS Spike Mix #1 (OP_MINLCS1_MS). The analytes contained in this mix can be found in Table I. The following additional spikes may also be added as indicated below dependent upon the requested analyte list.

   i. Add 1.0 mL of Mini LCS Spike Mix #2 (OP_MINLCS2_MS) if benzaldehyde, atrazine, or caprolactam are requested analytes.

   ii. Add 0.25 mL of Benzenethiol Spike (OP_BENTHIO_MS) if phenylmercaptan is requested. This will be spiked into a separate LCS/D. Note: A spiking solution is not prepared at a lower concentration for reduced volume analysis.

   iii. Add 1.0 mL of Mini APPIX Mix #1 (OP_MINAPP1_MS) if any analytes contained in Table II are requested. This will be spiked into a separate LCS/D.

   iv. Add 0.25 mL of APPIX Mix #2 (OP_APPIX2_MS) if p-Phenylene diamine is requested. This will be spiked into the same LCS/D as APPIX Mix #1. Notes: APPIX Mix #2 will not be requested without APPIX Mix #1. A spiking solution is not prepared at a lower concentration for reduced volume analysis.

c. For the isotope dilution methods listed in Step 4, add 0.25 mL of 1,4-Dioxane LCS Spike (OP_1,4-D_MS).

d. For Dinoseb_ATP add 0.08 mL Mini APPIX #1 Spike (OP_MINAPP1_MS).

e. For methods 8270_SIMMCP, 8270_SIMRCP, 8270D_SIM, 8270D_SIM_DKQP, 8270D_SIM_DOD5, 8270E_SIM paired with extraction method 3510C, add 1.0 mL of SIM spiking solution (OP_SIMLCS_MS).

f. For methods 8270_SIMMCP, 8270_SIMRCP, 8270D_SIM, 8270D_SIM_DKQP, 8270D_SIM_DOD5, 8270E_SIM paired with extraction method 3510C_LVI, add 0.25 mL of SIM spiking solution (OP_SIMLCS_MS).

g. For methods 8270D_SIM_Alkyl and 8270D_SM_Alk_D5 paired with extraction method 3510C, add 1.0 mL of Alkyl PAH spike (OP_ALK_PAH_MS).

h. If the sample requires analytes in addition to those found in the above mixes and in Tables I and II, add 1.0 mL (or 0.25 mL for 250-mL extractions) of the appropriate spiking solution.

**NOTE:** The standard must drip directly into the aqueous sample without touching the glass side of the separatory funnel to avoid poor recoveries.

8. Adjusting the pH of samples

   a. See *T-OE-GEN-FRM23822* for instructions on checking the pH of samples.

   b. For samples entered for analytical method Dinoseb_ATP, only the acid fraction is extracted. If samples are entered with a LabNote requesting 'reverse pH prep', or if the sample is acid-preserved, the acid fraction is extracted first, followed by the base-neutral fraction.

   c. For all other analytical methods, the base-neutral fraction is extracted first.

9. Adjusting the pH of samples to >11 for 1 L extractions:

   a. Add approximately 12 drops of 10 N sodium hydroxide to all batch QC and samples using a disposable Pasteur pipette. Swirl to mix.

   b. Check the pH of samples using Hydrion 10 to 12 range pH paper or equivalent to check if pH of >11 has been attained.

   c. If a pH of >11 is not observed, add approximately 6 to 7 drops of 10 N sodium hydroxide using a disposable Pasteur pipette. Swirl and re-check the pH with Hydrion 10 to 12 range pH paper or equivalent. See a supervisor if a pH of >11 is not achieved after repeating the 10 N sodium hydroxide addition five times. Note any issues in the LIMS batch for any samples that are difficult to pH adjust.

10. Adjusting the pH of samples to >11 for 250 mL extractions:

    a. Add approximately 4 drops of 10 N sodium hydroxide to all batch QC and samples using a disposable Pasteur pipette. Swirl to mix.

    b. Check the pH of samples using Hydrion 10 to 12 range pH paper or equivalent to check if pH of >11 has been attained.

    c. If a pH of >11 is not observed, add approximately 2 to 3 drops of 10N sodium hydroxide using a disposable Pasteur pipette. Swirl and re-check the pH with Hydrion 10 to 12 range pH paper or equivalent. See a supervisor if a pH of >11 is not achieved after repeating the 10 N sodium hydroxide addition five times. Note any issues in the LIMS batch for samples that are difficult to pH adjust.

11. If the original sample bottle is empty:

    a. Use a solvent pump to measure 60 mL of methylene chloride for 1 L extractions (15 mL for 250-mL extractions).

b. Rinse the sample bottle by adding the methylene chloride to the bottle. Swirl the bottle to rinse the interior of the bottle with methylene chloride.

c. Transfer the solvent to the separatory funnel.

d. Place the empty sample bottle, with the cap, on the scale.

e. Record this weight in the LIMS as the tare weight. The initial weight is automatically calculated.

f. If the sample container is not empty, use a solvent pump to measure 60 mL of methylene chloride (15 mL for 250 mL extractions) and add the solvent to the graduated cylinder or directly to the separatory funnel.

12. Cap the funnel, invert it, and vent immediately.

13. Handshake and vent frequently until the pressure is stable.

14. For 1 L extractions - Place the funnel on the automatic shaker and shake at the designated speed for 2 minutes with the stopcocks closed.
For 250 mL extractions – Separatory funnels remain on the Automated Water Extraction bench. Press the green "start" button to lower the hood and activate the Automated Water Extraction Bench. The bench will tumble for 2 minutes. The sash will rise after the samples have tumbled.
**NOTE:** Shaker speeds vary greatly between instruments; the proper setting is marked on each.

15. For 1 L extractions - Place the separatory funnel on the rack and allow it to sit undisturbed until the methylene chloride layer (bottom layer) has separated from the water.
For 250 mL extractions - the separatory funnel will sit undisturbed on the Automated Water Extraction Bench.
The time required for extracts to sit undisturbed is based upon visual confirmation that the layers are adequately separated. Additional time may be necessary for samples with unusually high density (i.e. high salt content).
If an emulsion forms and is >1/3 of the volume of the solvent layer, mechanical techniques such as stirring and centrifugation must be employed to complete the separation.

16. For 1L extractions, drain the solvent layer into a metal beaker and pour it through approximately 10 cm (~4 inches) of sodium sulfate into a K-D apparatus containing Teflon™-boiling chips.
For 250 mL extractions, drain the solvent layer directly into the sodium sulfate column containing approximately 5 cm of sodium sulfate (~2 inches). This drains into a concentrator tube.

17. Use a solvent pump to add 60 mL of methylene chloride (15 mL for 250 mL extractions) to the separatory funnel and repeat Procedure 14 through 16, venting only as necessary.

18. Use a solvent pump to add another 60 mL of methylene chloride (15 mL for 250 mL extractions) to the separatory funnel and repeat Procedure 14 through 16, venting only as necessary, a second time for the third of three methylene chloride extractions.

**NOTE:** The acid extract is also added to this K-D (or evaporator tube for 250 mL extractions).

19. Adjusting the pH of samples to <2 for 1 L extractions:

a. Add approximately 1 mL (1/2 full disposable Pasteur pipette) of concentrated sulfuric acid to all batch QC and samples using a disposable glass pipette. Swirl to mix.

b. Check the pH of samples using Hydrion 1 to 2.5 range pH paper or equivalent to check if pH of <2 has been attained.

c. If a pH of <2 is not observed, add approximately 10 to 11 drops of concentrated sulfuric acid using a disposable Pasteur pipette. Swirl and re-check the pH with Hydrion 1 to 2.5 range pH paper or equivalent. See a supervisor if a pH of <2 is not achieved after repeating the concentrated sulfuric acid addition six times. Note any issues in the LIMS for samples that are difficult to pH adjust.

20. Adjusting the pH of samples to <2 for 250 mL extractions:

a. Add approximately 12 drops of concentrated sulfuric acid to all batch QC and samples using a disposable glass pipette. Swirl to mix.

b. Check the pH of samples using Hydrion 1 to 2.5 range pH paper or equivalent to check if pH of <2 has been attained.

c. If a pH of <2 is not observed add approximately 3 to 4 drops of concentrated sulfuric acid using a disposable Pasteur pipette. Swirl and re-check the pH with Hydrion 1 to 2.5 range pH paper or equivalent. See a supervisor if a pH of <2 is not achieved after repeating the concentrated sulfuric addition six times. Note any issues in the LIMS for samples that are difficult to pH adjust.

21. After a pH of <2 has been attained: Using three 60-mL aliquots of methylene chloride (15 mL for 250 mL extractions), serially extract the sample as described in Procedure 14 through 16, venting only as necessary.

22. Collect the solvent in a K-D setup (or evaporator tube for the 250 mL extractions). For 1 L extractions, rinse the metal beaker with approximately 20 mL of methylene chloride and pour into the sodium sulfate column.

23. Use a wash bottle to rinse the sodium sulfate column with approximately 20 mL of methylene chloride (approximately 5 mL for 250 mL extractions).

24. For 1 L extractions:

a. Attach a 3-ball Snyder column to the K-D, wet with solvent, and concentrate the extract to approximately 2-mL on a steam bath at 80° to 90°C. At the proper rate of distillation, the balls of the column will actively chatter, but the chambers will not flood. Adjust the vertical position of the apparatus and the water temperature as needed to complete the concentration in 10 - 20 min. Allow the extracts to cool for approximately 10 minutes.

**NOTE:** This steam bath temperature ensures concentration in a reasonable length of time. Do not allow the ampule to go dry.

b. If extracting samples entered for client-requested analytical method Dinoseb_ATP, the extracts are methylated at this time. For all other extractions, proceed to step 24d. The methylation steps outlined below must be followed utilizing a hood containing no electrical appliances or

steam baths. Additional heat and electrical hazards must be avoided. **Note:** In the case of limited availability of TMSD, the use of Diazomethane for esterification can be used. If using Diazomethane, skip step 24b and go to step 24c.

i. After allowing the 2-3 mL of extract to cool for 10 minutes, add 1 mL TMSD.

ii. Add 0.5 mL MeOH, mix with a Pasteur pipette, and let sit for 10 minutes.

iii. Quench with approximately 10 mg of silicic acid.

iv. Quantitatively transfer to a new ampule to remove the extract from the silicic acid.

v. Concentrate on N-evap nitrogen evaporator to bring the extract below 1 mL.

vi. The extract is quantitatively transferred from the ampule using a Pasteur pipette to a 2 mL amber autosampler vial using hexane. The final volume of 1 mL is quantified by comparing the extract auto sampler vial to a reference auto sampler vial containing exactly 1 mL of hexane.

vii. If too much solvent is added to the sample vial, the extract from the vial should be transferred back into the ampule. Concentrate on N-evap nitrogen evaporator to bring the extract below 1 mL. The previous step is then repeated to bring the extract to 1 mL.

viii. Cap the vial securely and store in the freezer at ≤-10°C.

ix. Record the final volume in the LIMS.

**NOTE: TMSD is flammable and acutely toxic. Only open the container in a drawn hood. If the solution is spilled, leave the area immediately and contact safety. Wear gloves at all times during this procedure. Additional protection such as a safety shield is also recommended. All glassware used in this procedure must be taken directly to wash room personnel. Do not place it on a cart with other dirty glassware.**

c. Set up diazomethane generator and esterify the extract as described below:

Safety precautions

i. Diazald is a carcinogen. **Wear gloves at all times during this procedure**.
ii. Perform esterification in a hood with the sash down. Additional protection, such as a safety shield, is recommended. **Avoid inhalation of diazomethane.**
iii. Avoid using etched or scratched glassware, ground glass joints, and glass stirrers - **EXPLOSION may result**.
iv. **To avoid explosion do not heat over 90°C.**
v. All glassware used in this procedure must be taken directly to wash room personnel, not placed on cart of dirty glassware.
vi. The generator must be set up in a hood containing no electrical appliances or steam baths. Additional heat and electrical hazard must be avoided.

Diazomethane Generator Procedure

i. Prepare the KOH solution.

Reagents must be mixed in the following order:

(a) Place 5 g of KOH in a 125-mL Erlenmeyer flask.
(b) Use a graduated cylinder to add 8 mL of reagent water and swirl to dissolve the KOH.
(c) **Allow the solution to cool.**
(d) Use a graduated cylinder to add 25 mL of reagent alcohol.
(e) Use a graduated cylinder to add 25 mL of ethyl ether.
(f) The amount of KOH solution needed depends on the number of samples extracted. One solution can be used for eight to ten samples. If more than ten samples are to be extracted, prepare a second solution for use during esterification.

ii. Fill 40-mL vials with ethyl ether for rinsing the generator between samples. Use 1 vial per 3 samples.

iii. Prepare the diazomethane solution under a hood and just prior to starting the procedure:

(a) Add approximately 3 g of diazald powder to each KOH solution.
NOTE: Add the diazald powder immediately before use.
(b) Clamp the Erlenmeyer in place.

iv. Fill a plastic beaker with warm water from the steam bath (not to exceed 80º to 85ºC for safety concerns using diazomethane) and hold under the Erlenmeyer containing the diazomethane solution. At the same time, hold a rinse vial of ethyl ether at the end of the generator.

v. When the rinse vial begins to turn yellow, remove the vial and begin placing samples at the end of the generator.

(a) Use a rinse vial to rinse the generator between samples.
(b) Be sure each sample turns bright yellow before going on to the next sample. This ensures that esterification is complete.
(c) If the yellow color does not persist in all of the samples after methylation is complete, remethylate the samples that are no longer yellow.

vi. After esterification, N-Evap the samples below 1 mL.

vii. The extract is quantitatively transferred from the ampule using a Pasteur pipette to a 1 mL amber autosampler vial using hexane. The final volume of 1 mL is quantified by comparing the extract auto sampler vial to a reference auto sampler vial containing exactly 1 mL of hexane.

viii. Cap the vial securely and store in the freezer at≤-10ºC.

ix. Record the final volume in the LIMS.

d. Attach a microsnyder to the ampule and concentrate on a steam bath to slightly below 1 mL.

e. The extract is quantitatively transferred from the ampule using a Pasteur pipette to a 2 mL amber autosampler vial using methylene chloride. The final volume of 1 mL is quantified by comparing the extract auto sampler vial to a reference auto sampler vial containing exactly 1 mL of methylene chloride.

f. If too much solvent is added to the sample vial, the extract from the vial should be transferred back into the ampule. A microsnyder is then attached to the ampule and the extract is concentrated on a steam bath to around 0.5 mL. The previous step is then repeated to bring the extract to 1 mL.

g. Cap the vial securely and store in the freezer at ≤-10°C.

h. Record the final volume in the LIMS.

25. For 250-mL extractions:

Buchi Vacuum Concentrator - refer to *T-OE-GEN-WI10861* for parameter settings.

a. Turn on the SyncorePlus, Chiller, and Vacuum Pump by using the green switch located on the front of the devices.

b. Turn on the heat of the SyncorePlus by pressing the green knob on the control panel.

1. To adjust the temperature of the heating bath and the heated cover, press the set button on the control panel and rotate the knob to the correct
temperature needed.

2. The heating bath needs to be slightly filled with DI H2O. (Approximately 25mL per reservoir)

3. **Note** - The heated cover is set differently based on the solvent used. Consult a supervisor about the appropriate temperatures for the solvent being concentrated.

c. Turn on the cool flow of the Chiller by pressing the green control knob on the front of the device.

1. To adjust the temperature of the chiller, rotate the knob to the correct temperature needed.

d. From the interface attached to the vacuum pump, go to the operating modes menu tab (pen & paper button). The methods used for concentration are
listed in the methods sub-item. For all 8270 methods use the 90mL Methylene Chloride concentration method.

e. In the event that further concentration is needed, the Timer sub-item in the operating modes menu tab can be used with a selected method.

1. Once in the timer sub-item the timer can adjusted to the desired time. Consult a supervisor about appropriate times for remaining solvent.

7. After each concentration the solvent must be emptied from the collection flask into a carboy.

8. The extract is quantitatively transferred from the evaporator tube using a Pasteur pipette to a 2 mL amber autosampler vial using methylene chloride. The final volume of 1 mL is quantified by comparing the extract auto sampler vial to a reference auto sampler vial containing exactly 1 mL of methylene chloride.

9. If too much solvent is added to the sample vial, the extract from the vial should be transferred back into the evaporator tube and concentrated on the rapid vap down to around 0.5 mL. The previous step should then be repeated to bring the extract to 1 mL.

10. Cap the vial securely and store in the freezer at ≤-10°C.

11. Record the final volume in the LIMS.

Rapid-Vap Concentrator

a. Place the evaporator tube containing the solvent extract into the pre-heated (approximately 80°C) Rapid-Vap Evaporator. Set the timer for 10 minutes and speed at 75% (the speed is the rotation within the unit while the sample is evaporating). After 10 minutes, rinse the tube with approximately 5-7 mL methylene chloride and set the timer for 10 more minutes. Confirm that the nitrogen is set at approximately 15 PSI (this is adjusted on the regulator attached to the nitrogen line). Allow samples to concentrate to around 0.5 mL.

**NOTE:** The temperature, timer, and speed settings can be adjusted as necessary to accommodate difficult sample matrices, etc.

b. The extract is quantitatively transferred from the evaporator tube using a Pasteur pipette to a 2 mL amber autosampler vial using methylene chloride. The final volume of 1 mL is quantified by comparing the extract auto sampler vial to a reference auto sampler vial containing exactly 1 mL of methylene chloride.

c. If too much solvent is added to the sample vial, the extract from the vial should be transferred back into the evaporator tube and concentrated on the rapid vap down to around 0.5 mL. The previous step should then be repeated to bring the extract to 1 mL.

d. Cap the vial securely and store in the freezer at ≤-10°C.

e. Record the final volume in the LIMS.

### Calculations

See analysis method.

### Statistical Information/Method Performance

See analysis method.

### Quality Assurance/Quality Control

A batch is defined as the samples to be extracted on any given day but not to exceed 20 field samples. If more than 20 samples are prepared in a day, an additional batch must be prepared. If any client, state, or agency has more stringent QC or batch requirements, these must be followed instead.

Each extraction batch (up to 20 samples) must contain a method blank, a LCS, and an unspiked background sample, MS, and MSD. An LCSD is required if insufficient sample volume is submitted for a background/MS/MSD. If the batch contains only field or equipment blank samples, the LCS/LCSD QC pairing should be used.

QC limits for surrogates, LCS/LCSD, and MS/MSD are established through statistical analysis of historical data. The limits are evaluated as frequently as defined in the analytical method and updated as needed. The limits are maintained in the LIMS for the relevant analysis numbers.

### Table I

**LCS Mix #1 Reagent Analyte List**

1,1'-Biphenyl
1,2,4,5-Tetrachlorobenzene
1,2,4-Trichlorobenzene
1,2-Dichlorobenzene
1,2-Diphenylhydrazine
1,3-Dichlorobenzene
1,3-Dinitrobenzene
1,4-Dichlorobenzene
1,4-Dioxane
1-Methylnaphthalene
1-Methylphenanthrene
2,3,4,6-Tetrachlorophenol
2,2'-oxybis[1-chloropropane]
2,3-Dichlorobenzeneamine
2,4,5-Trichlorophenol
2,4,6-Trichlorophenol
2,4-Dichlorophenol
2,4-Dimethylphenol
2,4-Dinitrophenol

## Reference

1. Hardware Manual: HP 5973 Mass Selective Detector, Hewlett Packard, Hewlett-Packard Company, 1996.

2. 5975 Series MSD Troubleshooting and Maintenance Manual, Agilent, 2010.

3. HP 6890 Series Gas Chromatograph Maintenance and Troubleshooting Manual, Hewlett-Packard Company, 1989-1994.

4. *Chemical Hygiene Plan*, current version.

## Purpose
Preventative and corrective maintenance are crucial in maintaining the overall performance of the GC/MS system. This SOP explains the basic principles of managing the integrity of the GC/MS system.

## Scope
This document serves as a guideline for the performance of preventative and corrective maintenance on HP6890 and HP7890 GC and HP5973, HP5975, and HP5977 MSD GC/MS systems.

## Safety Precautions and Waste Handling
All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

Safety glasses must be worn and all necessary safety precautions taken when performing any type of preventative or corrective maintenance. See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

## Personnel Training and Qualifications
All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP.

Each new chemist will train with an experienced chemist for the first 8 weeks depending on the individual and their previous experience. The first 8 weeks is spent working one-on-one with the trainer. This time may be less if the new chemist has prior experience in the GC/MS Semivolatiles area.

During the training period, the new chemist will learn daily preventative maintenance and corrective maintenance procedures, column and source changing procedures, calibration techniques, data and library search review, and form generation. They are also required to read all relevant SOPs and EPA methods. They can also participate in on-line GC/MS tutorials.

## Procedure
Routine preventative maintenance is required to maintain a GC/MS system that will perform to method specifications. The performance of preventative maintenance is at the discretion and determination of the chemist, based on experience and what may be required to meet method performance specifications.

Corrective maintenance may be performed by the chemist based on the observed non-conformance. If, however, it is determined that an outside contractor must be contacted to perform certain types of preventative or corrective maintenance on a system, the chemist should consult with their group leader. The group leader will then help determine if contact must be made with the outside contractor and will determine who will make that contact.

The various types of maintenance are as follows:

A. Routine preventative maintenance:

Routine preventative maintenance may be performed daily on the gas chromatograph injector and gas chromatograph column to ensure maximum system performance. Specific maintenance techniques may vary

from instrument to instrument depending on analyst experience, instrument setup, method requirements, and types of samples run.

Routine preventative maintenance may include the following:

1. Injector maintenance

a. Lower the GC oven temperature to 30ºC and the injection port temperature to 70°C. Turn off the pressure/flow.

b. To replace the septum, remove the automatic injection tower and set aside. Lift the GC cover; loosen, remove, and set aside the septum retainer nut. Remove and discard the old septum. Place a new septum on top of the inlet base. (Be sure the inlet is free of particulate matter.) Replace the septum retainer nut, tightening to finger tightness. Avoid overtightening; the retainer nut is spring-loaded to provide sufficient pressure for sealing. Turn the pressure on and check to be sure head pressure has returned to the level it was prior to performing this task.

c. To replace the inlet liner, remove the insert retainer nut. Remove the insert liner already in place. (Optional: Swab the port with methylene chloride or other suitable solvent.) Inspect the new liner; if chipped or cracked, **DO NOT USE – DISCARD**. Place a silicone O-ring on the insert liner, about 2 to 3 mm from the top end.

Install the insert liner by pressing it straight down, as far as possible, into the inlet. Replace the insert retainer nut. Turn the pressure on and check to be sure head pressure has returned to the level it was prior to performing this task.

d. To clean or replace the injector seal, turn off the GC oven and open the oven door. With a small wrench, loosen, remove, and set aside the column nut. Remove and set aside the bottom insulation cover. (You may need to loosen one or two screws to do this.) With a large wrench, remove the reducing nut. The washer and seal are inside the reducing nut. Swab the seal with methylene chloride or an appropriate solvent. Check for graphite in the ferrule end of the seal. If graphite is clogging the opening, remove it. If the flat side of the seal is visibly dirty and cannot be cleaned properly, replace it with a new seal. Place the washer back in the bottom of the reducing nut; place the seal, flat side up, on top of the washer. Screw the reducing nut in place. Secure the bottom insulation cover. Move to column maintenance.

2. Column maintenance

a. While the column is still disconnected from the injection port, slide the desired amount of column to be removed through the column nut and clip the head of the column with a column-cleaving tool. Check for a clean break. (The amount of column removed is at the chemist's discretion based on the type of samples run. 1-3" is typical for systems designated for water samples; 6" to 1' is typical for systems desigated for soil samples. More length may be taken if extremely dirty samples were analyzed. The reason for sliding the column through the column nut and ferrule BEFORE clipping is to avoid blockage by graphite particles at the head of the column.) Slide the column nut 6 to 12 mm from the end of the column and insert the column nut and column into the injector port.

Tighten the column nut. Turn the pressure on and check to be sure head pressure has returned to the level it was prior to performing this task. Close the oven door and set the temperature zones to 300ºC.

b. Fill out the routine maintenance page of the maintenance logbook found next to the instrument. Record all maintenance performed in a clear, concise manner.

B. Vacuum System Preventative Maintenance:

Vacuum system preventative maintenance may be performed every six to nine months to ensure maximum vacuum system performance. Specific maintenance techniques may vary from instrument to instrument depending on analyst and instrument setup. For specific maintenance techniques, chemists should refer to the proper hardware manual. This maintenance may be performed by an outside contractor.

Vacuum system preventative maintenance includes the following:

1. Check and, if necessary, replace foreline pump fluid
2. Check and, if necessary, replace diffusion pump fluid
3. Check and, if necessary, refill calibration vial
4. Replace carrier gas trap

Vacuum system preventative maintenance must be documented on the non-routine maintenance page of the maintenance logbook in a clear, concise manner.

C. Corrective Maintenance

Corrective maintenance is performed on the gas chromatograph and mass spectrometer only when symptoms indicate they are necessary to ensure maximum system performance, or to correct poor system performance. The specific maintenance required will vary depending on the observed problem(s), instrument setup, types of samples run, and method requirements. Following is a list of possible corrective maintenance and related symptoms; to properly troubleshoot the instrument symptoms, chemists should refer to the proper hardware manual. This maintenance may be performed by an outside contractor.

Corrective maintenance may, depending on symptoms, include the following:

1. Remove and clean the ion source
2. Replace the column
3. Replace ion source parts
4. Replace filaments
5. Replace electron multiplier (detector)
6. Replace entire analyzer
7. Replace purge lines and insert assembly
8. Replace heater/sensor assembly
9. Replace electronics (fuses, printed circuit boards)

Related symptoms may be grouped in the following categories:

1. General symptoms
    a. GC or MSD does not turn on
    b. Foreline and/or diffusion pump is not operating
2. Chromatographic symptoms
    a. No peaks
    b. Does not pass tune
    c. Peaks are tailing or fronting
    d. Peaks have flat or split tops
    e. Baseline is high
    f. Baseline is rising or falling

g. Baseline wanders

h. Retention times for all peaks drift

i. Poor sensitivity

j. Poor repeatability

3. Mass spectral symptoms

Missing isotopes or incorrect isotope ratios

a. High background

b. High abundances at m/z 18, 28, 32, 44

c. Mass assignments incorrect

d. Peaks have precursors

e. Peak widths inconsistent

f. Poor high mass sensitivity

g. Pressure symptoms

h. Foreline pressure is too high or too low

i. Vacuum manifold pressure is too high or too low

j. Temperature symptoms

k. Ion source will not heat up

l. Mass filter (quad) heater will not heat up

m. GC/MSD interface will not heat up

4. Error messages

Numerous possibilities, refer to proper system hardware manual

5. Contamination

Excessive background in mass spectra

6. Air leaks

a. Higher than normal vacuum pressure

b. Higher than normal background

c. Peaks characteristic of air (m/z 18, 28, 32, 44)

d. Poor sensitivity

All corrective maintenance procedures, whether performed internally or by outside contractor, must be fully documented in the instrument maintenance logbook in a clear, concise manner.

**Scope**
This procedure is used to clearly outline the steps taken for the extraction of semivolatile compounds from soils or solid wastes using microwave technology.

**Basic Principles**
A portion of sample is placed in an extraction vessel. Surrogate standards are added to each sample to monitor recovery. The vessel is then loaded into the instrument and extracted. The organic compounds present in the sample dissolve in the solvent, which is then removed. The extract is concentrated to about 1 mL. At this time, it is determined if the sample requires gel-permeation cleanup (GPC). If needed, the extract is diluted to 10 mL then cleaned using GPC. The extract is stored in an amber-autosampler vial in the freezer until analysis.

**Reference Modifications**
Base/Neutral and Acid compounds are added at a concentration of 50 ppm in the matrix spiking and LCS solutions so that the concentrations in the extract are within calibration range.

**Interferences**
Impurities in solvents, reagents, glassware, or other hardware used in sample processing can interfere with the method. All glassware must be rinsed with solvent before use. A method blank is performed with each batch of samples to demonstrate that the extraction system is free of contaminants.

**Safety Precautions and Waste Handling**
All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

The toxicity or carcinogenicity of each reagent used in this method has not been precisely defined. Each chemical compound must be treated as a potential health hazard. Exposure to these chemicals must be reduced to the lowest possible level by whatever means available, such as fume hoods, lab coats, safety glasses, and gloves.

Extracts are concentrated on a steam bath; caution must be exercised while working around this apparatus.

All solvent waste generated from this preparation must be collected for recycling (if applicable) or disposed of in the designated containers. These are then transferred to the lab-wide disposal facility. Any solid waste material (disposable pipettes, broken glassware, pH paper) is disposed of in the normal solid waste collection containers.

**Personnel Training and Qualifications**
All personnel performing this procedure must have documentation of reading, understanding and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each technician performing the extraction must work with an experienced employee for a period of time until they can independently perform the extraction. Proficiency is measured through a documented Initial Demonstration of Capability (IDOC).

The IDOC and the DOC consists of four laboratory control samples (or alternatively, one blind sample for the DOC) that is carried through all steps of the extraction and meet the defined acceptance criteria. The criteria for the LCSs include the calculation of mean accuracy and standard deviation.

**Sample Collection, Preservation and Handling**
Samples are collected in glass wide-mouth jars with PTFE-lined lids and stored under refrigeration at 0° to 6°C, not frozen, prior to extraction. Samples must be extracted within 14 days of sample collection. Extracts are stored in the freezer at ≤-10° C and must be analyzed within 40 days of the date extracted.

**Apparatus and Equipment**
1. MARS Xpress – CEM Corp. or equivalent
2. Balance – Capable of weighing to 0.01 g
3. Beakers – Stainless steel – Assorted sizes
4. Scoop
5. Pipettes – Class A, assorted sizes
6. Wash bottles – Teflon®
7. Disposable pipettes
8. Autosampler vials – Amber, crimp top

9. Funnels – Stainless steel or Teflon®

10. Extraction vessels

11. Sodium sulfate columns

12. Buchi Concentrator

13. Buchi Concentrator Tubes

**Reagents and Standards**

1. Methylene chloride ($CH_2Cl_2$) – Pesticide grade or equivalent. Store at room temperature for up to one year.

2. Acetone – Pesticide grade or equivalent. Store at room temperature for up to one year.

3. Sodium Sulfate ($Na_2SO_4$) – Reagent grade or equivalent. Bake at 400°C for a minimum of 4 hours in a shallow pan to remove contaminants. Store in a glass jar for up to 1 year after baking.

**NOTE:** All QC standards added during extraction process are prepared by Organic Extractions using instructions generated by the standards database. Detailed instructions can be found in the corresponding analytical analyses for scans *T-SVOA-WI9587*, *T-SVOA-WI9995*, *T-SVOA-WI9252*, *T-SVOA-WI9617*

**Calibration**

Not applicable to this procedure.

**Preparation of Glassware**

See *T-OE-GEN-WI10864*.

**Procedure**

1. Sample aliquot

   a. If Sample Registration has pre-weighed the sample into a glass jar, proceed to procedure step 2.

   b. If the sample is not pre-weighed, weigh 30.0 - 30.5 g of sample into a labeled stainless steel beaker. If sample matrix is tissue, use 15.0 - 15.5 g.

      (1) Record the initial weight and any comments about the sample in the LIMS.

      (2) Alternative sample weights may be used to meet certain reporting limits. However, if sample weight greater than 30.5 g is used the sample must be divided among multiple vessels and the extracts combined.

   c. Process all tissues by Analysis *T-OE-GEN-WI7154* prior to extraction.

2. Add approximately 5 g of sodium sulfate to each sample and mix.

   a. If the sample has high water content or is a clay-like soil, add an additional 10 g (approximate) of sodium sulfate.

   b. Mix the sodium sulfate and sample until a free-flowing consistency is reached.

3. Perform the background, matrix spike (MS), and matrix spike duplicate (MSD) on three separate aliquots of a field sample.

4. Prepare the Blank, laboratory control sample (LCS), and laboratory control sample duplicate (LCSD) (if applicable) by filling a Teflon® extraction vessel with 35 g of sodium sulfate. Use 15.0 g tilapia if matrix is tissue. Record 30.0 g in the LIMS (or 15.0 for tissue samples). (The sodium sulfate used for the QC samples is measured out as 35.0 g to account for the 30 g "sample" plus the 5g of sodium sulfate.)

5. Place each sample into its clearly marked corresponding extraction vessel. Use a funnel to prevent spillage and loss of sample.

6. Add surrogate standards and spiking solutions using pipettes. Add surrogates to all samples, blanks and spiked samples. Add spikes to the LCS, LCSD (if applicable), MS, and MSD samples. Typically they are as follows:

   a. Analysis *T-SVOA-WI9623* – Surrogate: 1.0mL of BNA surrogate. Spike: 1.0mL of LCS spike. If required, spike 1.0 mL of Benzenthiol spike in a separate LCS/LCSD. If required, Spike 1.0 mL of AppIX Mix #1 in a separate LCS/LCSD. If required, Spike 1.0 mL of AppIX Mix #2 in a separate LCS/LCSD.

   b. Analysis *T-SVOA-WI9995* – Surrogate: 1.0mL of BNA surrogate. Spike: 1.0mL of SIM LCS spike.

   c. Analysis *T-SVOA-WI9587* – Surrogate: 1.0mL of BNA Surrogate. Spike: 1.0mL of TEL/TML spike.

      **NOTE:** If the sample is being analyzed for Benzoic Acid, a separate LCS/LCSD must be created with 1.0 mL of Appendix IX Mix#1 spike.

   See *T-OE-GEN-WI10876* for storage and handling of spikes and *T-SVOA-WI11998* for SVOA spiking and calibration standards.

      **NOTE:** If the sample is being divided among multiple vessels, the spike must be divided among the vessels as well.

7. Add 30 mL of 50% acetone in methylene chloride to each vessel.

8. Cap each vessel according to manufacturer's guidelines.

9. Invert each vessel to ensure mixing of sample and solvent.

10. Place the vessels into the carousel. When all samples are loaded, place the carousel into the microwave.

11. Run Program "LL Soils". See Table I for Instrument conditions. Verify that the run reaches the 100 °C temperature requirement and document in the LIMS.

12. Uncap the cooled vessel.

13. Pour the extract and sample from the vessel into a salt column filled with approximately 10 cm of sodium sulfate on top of an evaporator tube.

14. Rinse the microwave vessel with 10 to 20 mL of methylene chloride from a wash bottle and pour it into the salt column.

15. Allow the salt column to drip dry into the concentrator tube.

**Note:** If using the Buchi concentrator refer to *T-OE-GEN-WI10861* for parameter settings.

16. Buchi Vacuum Concentrator

a. Turn on the SyncorePlus, Chiller, and Vacuum Pump by using the green switch located on the front of the devices.

b. Turn on the heat of the SyncorePlus by pressing the green knob on the control panel.

1. To adjust the temperature of the heating bath and the heated cover, press the set button on the control panel and rotate the knob to the correct temperature needed.

2. The heating bath needs to be slightly filled with DI H2O. (Approximately 25mL per reservoir)

3. **Note** - The heated cover is set differently based on the solvent used. Consult a supervisor about the appropriate temperatures for the solvent being concentrated.

c. Turn on the cool flow of the Chiller by pressing the green control knob on the front of the device.

1. To adjust the temperature of the chiller, rotate the knob to the correct temperature needed.

d. From the interface attached to the vacuum pump, go to the operating modes menu tab (pen & paper button). The methods used for concentration are listed in the methods sub-item. For all 8270 extractions use the 90mL Methylene Chloride concentration method for soils.

e. In the event that further concentration is needed, the Timer sub-item in the operating modes menu tab can be used with a selected method.

1. Once in the timer sub-item the timer can adjusted to the desired time. Consult a supervisor about appropriate times for remaining solvent.

7. After each concentration the solvent must be emptied from the collection flask into a carboy.

17. If GPC is not needed, go to Procedure Step 18.

a. For samples that require GPC bring the final volume to 10.0 mL with methylene chloride in a class A volumetric. Filter extracts into a 100 mm. screw cap tubes using a 10mL Luer-Lok glass syringe and a disposable 0.45-micron filter (Whatman catalog number 6874-2504 or equivalent).

b. Place the extract into the appropriate GPC queuing area for storage until the cleanup is performed. See *T-OE-SVOA-WI10554*.

18. Bring to a final volume of 1.0 mL with methylene chloride in a labeled amber GC vial.

a. The final volume is determined by placing the extract into an amber-autosampler vial and comparing the level in the vial to a reference vial containing the exact targeted final volume.

b. The vials used for bottling must be the same lot number as the reference vial.

c. Methylene chloride is added to the extract using a disposable pipette until exactly the same level is in both vials.

d. If too much solvent is added to the sample vial, remove the extract from the vial and concentrate it by adding it to a concentrator tube to be re-concentrated to slightly less than the targeted final volume and rebottle.

e. Cap the vial and store in the freezer until analysis.

f. Record the final volume in the LIMS.

## Calculations
See analysis method.

## Statistical Information/Method Performance
See analysis method.

## Quality Assurance/Quality Control
For each batch of samples extracted, a method blank, an LCS, an unspiked background sample, an MS, and an MSD must be extracted. If insufficient volume of sample is available for MS/MSD, then an LCSD must be prepared instead.

A batch is defined as the samples to be extracted on any given day but not to exceed 20 field samples. If more than 20 samples are prepared in a day, an additional batch must be prepared. If any client, state, or agency has more stringent QC or batching requirements, these must be followed.

| *T-PEST-WI9981* | Nitroaromatics and Nitroamines by Method 8330B in Water and Solids using HPLC with UV Detection |
| *T-OE-GEN-WI10864* | Glassware Cleaning for Organic Extractions |
| *T-OE-GEN-WI10876* | Organic Extraction Standards Storage and Handling |

### Scope

The method is for the extraction of trace levels of nitroaromatics and nitroamines from explosives in water samples.

### Basic Principles

A portion of the sample is passed through a Porapak RDX cartridge. The cartridge is then eluted with acetonitrile and the extract is brought to exactly 5 mL. The extract is diluted to 10 mL using a calcium chloride solution.

### Interferences

Impurities in solvents, reagents, glassware, or other hardware used in sample processing interfere with the method. All glassware must be is rinsed with solvent before use. A method blank is performed with each batch of samples to demonstrate that the extraction system is free of contaminants.

### Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

The toxicity or carcinogenicity of each reagent used in this method has not been precisely defined. Each chemical compound must be treated as a potential health hazard. Exposure to these chemicals must be reduced to the lowest possible level by whatever means available, such as fume hoods, lab coats, safety glasses, and gloves.

All solvent waste generated from this preparation must be collected for recycling (if applicable) or disposed of in the designated containers. These are then transferred to the lab-wide disposable facility. Any solid waste material (disposable pipettes, broken glassware, pH paper) is disposed of in the normal solid waste collection containers.

**Samples suspected of being high in explosives must be handled with extreme care.**

### Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the technicians training records.

Initially, each technician performing the extraction must work with an experienced employee for a period of time until they can independently perform the extraction. Proficiency is measured through a documented Initial Demonstration of Capability (IDOC).

The IDOC and the DOC consists of four laboratory control samples (or alternatively, one blind sample for the DOC) that is carried through all steps of the extraction and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation.

### Sample Collection, Preservation, and Handling

Samples are collected in 500 mL or 1-L, unpreserved, amber glass bottles with PTFE-lined lids and stored refrigerated at 0° to 6°C, not frozen, prior to extraction. Samples must be extracted with 7 days of collection. The extract is stored in a clear autosampler vial in a refrigerator at 0° to 6°C, not frozen, for up to 40 days after extraction.

### Preparation of Glassware

See *T-OE-GEN-WI10864*.

### Apparatus and Equipment

1. Porapak RDX Sep-pak extraction cartridges – Waters
2. SPE vacuum manifold system – Baker or equivalent
3. Disposable pipettes – glass
4. Volumetric pipettes – Class A, assorted sizes
5. Graduated cylinders – Class A, assorted sizes
6. Disposable cartridge membrane filters – 0.2-µm Teflon
7. Clear crimp cap autosampler vials
8. 12-mL screw cap vials
9. Volumetric flask – Class A, assorted sizes
10. Filter paper – Fisher glass fiber or equivalent
11. Buchner funnel
12. Balance - Capable of weighing to 0.1 g

### Reagents and Standards

1. Acetonitrile (ACN) – HPLC grade. Store at room temperature for up to 1 year.
2. Calcium Chloride ($CaCl_2$) – Reagent grade.
   a. To prepare solution:
      (1) Add 5.0 g $CaCl_2$ to approximately 800 mL of reagent water.
      (2) Shake until the $CaCl_2$ goes into solution.
      (3) Dilute to 1000 mL with reagent water.
   b. Store at room temperature in a glass bottle. Reagent is stable 1 year.
   c. Preparation of larger volumes is acceptable if equivalent volumes are used.
   d. Document all reagent preps in the appropriate logbooks.

4. All QC standards added during extraction process are prepared by Organic Extractions using instructions generated by the reagent module of the LIMS. Detailed instructions can be found in the corresponding analytical SOP *T-PEST-WI9981*.

### Calibration

Not applicable to this procedure.

### Procedure

1. Rinse all glassware with acetone using a wash bottle.
2. Place the full sample bottle, with cap, on the balance. Record this weight in the LIMS as the gross weight.

3. If necessary, filter the samples through a Buchner funnel and filter paper.

If any samples are filtered, the blank, LCS, and LCSD must also be filtered.

4. Use pipettes to add surrogate standards and spiking solutions directly to the sample bottle. Volumetric flasks are used for the Blanks, LCS, and LCSD (if applicable).

a. Surrogates are added to all samples (including all QC).

b. Spikes are added to the LCS, LCSD (if applicable), Matrix Spike (MS), and Matrix Spike Duplicate (MSD) samples.

c. The surrogates and spikes are as follows:

(1) Surrogate: 0.5 mL Explosives Water Surrogate (OP_EXPW_SS)

(2) Spike: 0.5 mL 8330B Explosives Spike (OP_8330B_MS)

(3) If 2,4-diamino-6-nitrotoluene or 2,6-diamino-4-nitrotoluene are requested, create an additional LCS/LCSD. Add 0.1 mL of OP_246DIA_STK and OP_264DIA_STK to both.

d. See *T-PEST-WI9981* for spike details.

e. See *T-OE-GEN-WI10876* for storage and handling of spikes.

5. Assemble the SPE vacuum manifold with the Porapak RDX cartridges.

6. With the valves closed, use a graduated cylinder to add 15 mL of ACN to each reservoir.

a. Elute the solvent through the cartridge at 10 mL/min.

b. Empty the waste in the chamber into the appropriate solvent waste container.

7. Again, with the valves closed, use a graduated cylinder to add 30 mL of reagent water to each reservoir.

Elute the water through the cartridge at 10 mL/min.

8. Pull all samples through the cartridge at 10 mL/min. Once sample bottle is empty, rinse the bottle with DI water, and pass this rinse through the cartridge. Empty the chamber as needed so it does not overflow.

9. Place the rinsed, empty sample bottle, with cap, on the balance. Record this weight in the LIMS as the tare weight. The initial volume is calculated in the LIMS by subtracting the tare weight from the gross weight.

10. Place labeled 5-mL volumetric flasks, numbered to match the cartridges, into the tube holder.

a. Place the tube holder into the vacuum chamber.

b. Place the top onto the vacuum chamber; the drip tips must go into the top of the volumetric flasks.

11. Use a graduated cylinder to elute the cartridge with 5 mL of ACN.

a. Disassemble the vacuum chamber.

b. Bring each sample to exactly 5.0 mL with ACN.

12. Use a disposable pipette to transfer the extract to a 10-mL volumetric flask.

13. Use $CaCl_2$ solution to rinse the 5-mL volumetric flask and add the rinseate to the 10-mL flask.

a. Add enough $CaCl_2$ solution to the flask to bring the extract to exactly 10.0 mL.

b. Mix thoroughly.

14. Filter the extract through a 0.2-µm filter into two clear crimp cap auto sampler vials. Verify that both vials are labeled with the appropriate sample number.

## Calculations

See analysis method.

### Statistical Information/Method Performance

See analysis method.

### Quality Assurance/Quality Control

A batch is defined as the samples to be extracted on any given day, but not to exceed 20 field samples. If more than 20 samples are prepared in any day an additional batch must be prepared.

For each batch of samples extracted a blank, an LCS, an MS and an MSD must be extracted. If there is limited sample preventing the preparation of the MS/MSD, then an LCSD must be prepared instead. If the batch contains only field or equipment blank samples, the LCS/LCSD QC pairing must be used.

If any client, agency, or state has more stringent QC or batch requirements, these must be followed instead.

**Purpose**
The purpose of this SOP is to provide clear instructions for performing the separatory funnel extraction procedure on samples that are to be analyzed for pesticides and PCBs.

**Scope**
This procedure is for the extraction of organochlorine and organophosphorous pesticides and PCBs from wastewaters.

**Basic Principles**
An aliquot of the sample is placed into a separatory funnel. The volume of sample extracted is adjusted (if appropriate) depending on the physical appearance of the sample and the volume sent for analysis. A surrogate standard is added to the sample to monitor recovery. The sample is then extracted with methylene chloride. The extract is dried, concentrated, and exchanged to hexane. Several cleanup procedures are available to eliminate matrix interferences before the sample is analyzed. They include sulfuric acid treatment, copper treatment, florisil, and Gel-Permeation Cleanup (GPC).

**Reference Modifications**
1. Surrogate and matrix spiking solutions are not added before the transfer to the extractor. For several reasons:

   a. Samples must be poured from the amber bottles to determine the matrix and volume of sample to use for each extraction.

   b. Many sample bottles have no headspace and there is no room to add surrogate to the sample in the bottle.

   c. Due to the volume of samples extracted, a separate graduated cylinder for each sample is unrealistic.

   d. To maintain consistency with all extractions, no samples are spiked in the bottle or graduated cylinders.

2. In Procedure Step 19 the joint of the KD is not rinsed with fresh solvent when the ampule is removed. Quad and MDL studies have shown that this step is unnecessary.

**Interferences**
Impurities in solvents, reagents, glassware, or other hardware used in sample processing interfere with the method. All glassware must be rinsed with solvent before use. A method blank is performed with each batch of samples to demonstrate that the extraction system is free of contaminants.

**Safety Precautions and Waste Handling**
See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

The toxicity or carcinogenicity of each reagent used in this method has not been precisely defined. Each chemical compound must be treated as a potential health hazard. Exposure to these chemicals must be reduced to the lowest possible level by whatever means available, such as fume hoods, lab coats, safety glasses, and gloves.

Extracts are concentrated on a steam bath; caution must be exercised while working around this apparatus.

All solvent waste generated from this preparation must be collected for recycling (if applicable) or disposed of in the designated containers. These are transferred to the lab wide disposal facility. Any solid waste material (disposable pipettes, broken glassware, pH paper) is disposed of in the normal solid waste collection containers.

**Personnel Training and Qualifications**
All personnel performing this procedure must have documentation of reading, understanding and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the employees training records.

Initially, each technician performing the extraction must work with an experienced employee for a period of time until they can independently perform the extraction. Proficiency is measured through a documented Initial Demonstration of Capability (IDOC).

The IDOC consists of four laboratory control samples that are carried through all steps of the extraction and analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation. Various options are available for a DOC and can include four laboratory control samples, or one blind sample.

**Sample Collection, Preservation, and Handling**
Samples are collected in amber glass bottles with PTFE-lined lids, preserved with sodium thiosulfate, and stored refrigerated at 0 - 6°C, not frozen. The sample hold times are 365 days unless collected from New Jersey or requested as shorter by the client for PCB samples. The sample hold times are 7 days starting from day of collection for Pesticide samples. Extracts are stored in a freezer, in the dark, at less than or equal to -10°C.

**Apparatus and Equipment**
1. Separatory funnel for extracting organic components from an aqueous matrix
2. Kuderna-Danish (K-D) assembly with appropriate ampule for concentrating the solvent used during the extraction
3. Water bath – VWR/LLI Model #1127 or equivalent
4. Sodium sulfate column with extra course frit
5. Nitrogen evaporation (N-Evap) with nitrogen supply – Organomation Associates or equivalent
6. pH paper – Wide range
7. Automatic shaker – Glass Col or equivalent, capable of holding 2-L separatory funnels

8. Pipettes – Class A, assorted sizes
9. Graduated cylinders – Class A, assorted sizes
10. Pipettes – Disposable
11. Solvent dispenser – Brinkmann, adjustable or equivalent
12. Balance – Capable of weighing to 0.01 g
13. Centrifuge – Beckman GS-6 or equivalent
14. Micro-Snyder columns
15. Wash bottles – Teflon
16. Vials – Assorted sizes
17. Teflon boiling chips
18. Syringes - Assorted sizes
19. Micro-pipetter
20. Automated Water Extraction Bench – capable of holding separatory funnels for 250 mL extractions.
21. Buchi Concentrator
22. Buchi Concentrator Tubes

**Reagents and Standards**

1. Methylene chloride (CH2Cl2) – Pesticide grade or equivalent. Store at room temperature for up to 1 year.
2. Acetone – Pesticide grade or equivalent. Store at room temperature for up to 1 year.
3. Hexane – Pesticide grade or equivalent. Store at room temperature for up to 1 year.
4. 10N Sodium hydroxide (NaOH) – Lab Chem or equivalent. Store at room temperature. Follow manufacturer's expiration date.
5. Sulfuric acid (H2SO4) – ACS grade or equivalent. Store at room temperature. Follow manufacturer's expiration date.
6. Sodium Sulfate (Na2SO4) – Reagent grade or equivalent. Bake at approximately 400°C for a minimum of 4 hours in a shallow pan to remove organic contaminants. Store in a glass jar at room temperature for up to 1 year after baking.
7. Reagent water – water in which an interferent is not observed at or above the reporting limit for parameters of interest. In general, the reagent water supplied at the taps in the laboratory meets this criterion. If the reagent water does not meet the requirements, see your supervisor for further instructions.
8. Extraction fluid – Prepared and delivered by the leachate department. Store refrigerated at 0-6°C, not frozen, in a glass container with a PTFE-lined lid.
9. Sodium chloride (NaCl) – Bake at approximately 400°C for a minimum of 4 hours in a shallow pan prior to use to remove organic contaminants. After baking, store in a glass jar at room temperature for up to 1 year.
10. All QC standards added during extraction process are prepared by Organic Extractions using instructions generated by the standards database. Detailed instructions can be found in *T-PEST-WI9998*, *T-PEST-WI9843*, *T-PEST-WI11971, T-PEST-WI9997, T-PEST-WI9238*, *T-PEST-WI9961*.

**Calibration**

Not applicable to this procedure.

**Preparation of Glassware**

See SOP *T-OE-GEN-WI10864*.

**Procedure**

1. Determine the volume of sample to be used for each extraction. Typically, this is 1L or 250 mL. For 1311/8081: 50 mL of sample is measured from the sample bottle and diluted to 250 mL in a sep funnel.

1 Liter Analyses: *T-PEST-WI9961*

250 mL Analyses: *T-PEST-WI9998*, *T-PEST-WI9843, T-PEST-WI11971, T-PEST-WI9997, T-PEST-WI9238*

a. If uncertain of the volume to extract for any sample, ask your supervisor.

b. Use one full bottle for all analysis scans (with the exception of 1311/8081) unless the matrix is poor (thick, lots of sediment, extremely foul odor).

(1) If using reduced volume due to matrix, take as much as possible while trying to minimize matrix problems, document why the reduced volume was used.

(2) Reduced volume aliquots due to matrix are typically are 500, 200, or 100 mL (100, 50, or 25 mL for 250 mL extractions).

c. For 1311/8081:

(1) If the sample bottle contains at least 100 mL of sample, measure 50 mL.

(2) If the sample bottle contains <100 mL of sample, use 1/2 of the available volume or 10 mL, whichever is greater.

(3) If a matrix spike (MS) or MS/matrix spike duplicate (MSD) is required for the sample, use 50 mL each.

(4) After adding the 50 ml of sample add approximately 200 mL of Di water to bring the volume in the sep funnel to 250 mL.

d. The background, MS, and MSD are performed on three separate aliquots of a field sample.

2. Prepare the blank, laboratory control sample (LCS), laboratory control sample duplicate (LCSD) (if applicable) with 1 L of reagent water (or 250mL for 250 mL extractions) measured into the separatory funnel.

Exception: For 1311/8081 - The blank, LCS, and LCSD (if applicable) are prepared using 50 mL of extraction fluid measured into the separatory funnel. Add approximately 200 mL of DI water to bring the volume to 250 mL.

3. For samples using 1 entire bottle:

a. Weigh the entire bottle including the cap on a balance and record in gross weight column in the LIMS.

b. Shake the bottle vigorously and then pour the contents into a separatory funnel.

4. For all samples requiring a specified volume:

a. Shake each bottle vigorously.

b. Use a clean graduated cylinder to measure the desired volume.

c. Pour the sample from the graduated cylinder into the separatory funnel.

d. Record any comments about the sample appearance or odor. Also record comments if a reduced volume was taken due to sample matrix or insufficient available sample.

e. If <1000 mL (or <250mL for 250mL extractions) of sample is used, use a graduated cylinder to add enough reagent water to bring the volume in the separatory funnel to 1-L (or 250mL for 250mL extractions).

5. For 8082 PCB preps: add 25g of NaCl for 250mL and 50g for 1L extractions to the sample in the separtory funnel. Add stopper and shake by hand to dissolve the N

6. Use pipettes to add surrogate standards and spiking solutions to the aqueous sample in the separatory funnel.

a. Be certain the standard drips directly into the aqueous sample without touching the glass side of the separatory funnel to avoid poor recoveries.

b. Surrogates – Surrogates are added to all samples, blanks, and spikes.

The type of surrogate is determined by the analysis scan number. Typically they are as follows:

(1) For *T-PEST-WI9961* – 0.1 mL of SW-846 Surrogate.

(2) For *T-PEST-WI18000*, *T-PEST-WI9843*, *T-PEST-WI9997*, *T-PEST-WI9238*, *T-PEST-WI9998* – 0.25 mL of SW-846 Surrogate.

(3) For *T-PEST-WI9998* by 1311/8081- Use 1.0 mL of Mini Sep. SW846 Surrogate

c. Spiking Solutions – Spiking solutions are added to the LCS, LCSD (if applicable), MS, and MSD.

(1) The type of spike is determined by an analysis number. Typically they are as follows:

(a) For *T-PEST-WI18000*, *T-PEST-WI9238* – 0.25 mL PCB Spike.

(b) For *T-PEST-WI9998*, *T-PEST-WI9997* – 0.25 mL SW-846 Spike.

(c) For *T-PEST-WI9998* by 1311/8081 – 1.0 mL of Mini TCLP Pesticides Spike regardless of initial volume

(d) For *T-PEST-WI9998* – 0.25 mL Chlordane Spike

(e) For *T-PEST-WI9961* – 0.1 mL of PCB Spike

(2) Spike details can be found in the corresponding analytical SOP(s)

(3) This is changed to accommodate specific-client requirements, if appropriate.

(4) If a sample requires any special compounds in addition to the standard list, an appropriate spike containing those compounds is added at this time.

(5) See SOP *T-OE-GEN-WI10876* for storage and handling of spikes.

7. Measure the pH of the sample using wide-range pH paper. Record the pH of the sample in the initial pH column of the LIMS. See *T-OE-GEN-FRM23822* for instructions to check and adjust pH.

a. If necessary, adjust the pH to between 5 and 9 using 10N NaOH (to bring up the pH) or concentrated H2SO4 (to lower the pH).

b. To adjust the pH, add a few drops of the appropriate solution with a disposable pipette, swirl the separatory funnel and re-check the pH.

c. If the pH now falls between 5 and 9, record the adjusted pH in the 1st pH column of the LIMS.

d. If the pH is still out of range, continue adding small aliquots of base or acid, swirling and checking the pH until it is within the specified range.

e. Record the adjusted pH in the 1st pH column of the LIMS.

**NOTE:** Any samples from North Carolina require that the volume of acid or base added to the sample to adjust the pH to be recorded in the LIMS.

8. If the original sample bottle is empty:

a. Use a solvent pump to measure 60 mL (15 mL for 250 mL extractions) of methylene chloride. Add the methylene chloride to the sample bottle and swirl the bottle to rinse the interior of the bottle with methylene chloride. Add the solvent to the separatory funnel.

b. Weigh the entire bottle including the cap on a balance and record in the tare weight column in the LIMS.

c. The initial volume automatically calculates in the initial volume of the LIMS.

9. If the sample container is not empty, measure 60 mL (15 mL for 250mL extractions) of methylene chloride to the graduated cylinder used to measure out the sample volume and add it to the separatory funnel.

10. Cap the funnel, invert it, and vent immediately. With the cap on shake the separatory funnel and vent. Continue shaking and venting until the pressure in the funnel has equalized.

11. For 1 Liter Analyses: Place the sample on the automatic shaker and shake at the designated speed for 2 minutes with the stopcocks closed.

For 250 mL Analyses: Separatory funnels remain on the Automated Water Extraction Bench. Press the green "start" button to lower the hood and activate the Automated Water Extraction Bench. The bench will tumble for 2 minutes. The sash will rise after the samples have tumbled.

**NOTE:** Shaker speeds vary greatly between instruments so the proper setting is marked on each.

12. For 1 Liter Analyses: Place the separatory funnel on the rack and allow it to sit undisturbed until the solvent layer (bottom layer) has separated from the water layer (top layer). For 250 mL Analyses: the separatory funnel will sit undisturbed on the Automated Water Extraction Bench.

a. The time required for extracts to set undisturbed is based upon visual confirmation that the layers are adequately separated.

b. If an emulsion forms and is greater than 1/3 of the volume of the solvent layer, mechanical techniques such as stirring and centrifugation must be employed to complete the separation.

13. Removing the Solvent Layer.

a. For 1 Liter analyses: Remove the solvent layer by opening the stopcock and collect the solvent in a metal beaker then pour through approximately 10cm of sodium sulfate into a K-D apparatus containing Teflon boiling chips.

b. For 250 mL analyses: drain the solvent layer directly into the sodium sulfate column containing approximately 5cm of sodium sulfate. This drains into a concentrator tube.

**NOTE:** Do not use more than the recommended quantity of sodium sulfate and take care not to transfer water into the column. Excessive sodium sulfate and/or water in the column results in low aldrin recovery.

14. Use a solvent pump to add 60 mL (15mL for 250mL extractions) of methylene chloride to the separatory funnel and repeat Procedure Steps 10 through 13, venting only as necessary.

15. Again, use a solvent pump to add 60 mL (15 mL for 250mL extractions) of methylene chloride to the separatory funnel and repeat Procedure Steps 10 through 13, venting only as necessary.

16. For 1L extractions only, rinse the metal beaker that was used for solvent collection with approximately 20 mL of methylene chloride. Pour into salt column.

17. Rinse salt column with approximately 20 mL (5mL for 250mL extractions) of methylene chloride.

18. Concentrating extracts for 1 Liter analyses

a. Attach a 3-ball Snyder column to the K-D, wet with solvent, and concentrate the extract to approximately 3 to 5 mL on a steam bath at 85° to 99°C. Adjust the vertical position of the apparatus and the water temperature, as required, to complete the concentration in 10-20 minutes. At the proper rate of distillation the balls of the column will actively chatter, but the chambers will not flood. This steam bath temperature ensures concentration in a reasonable length of time.

**Note:** Do not allow the extracts to reach a point of dryness. Loss of analytes may occur.

b. Add 50 mL of hexane directly through the Snyder column after the apparent volume in the ampule reaches 3-5 mL. Continue concentrating on the steam bath until an apparent volume of 3-5 ml is reached. Allow the extracts to cool for 10 minutes prior to removing the ampule from the KD.

**Note:** Do not allow the extracts to reach a point of dryness. Loss of analytes may occur.

c. Bring the extracts to a final volume of 5 mL in the ampule with hexane.

d. Go to Procedure 21 for details on cleanup procedures.

19. Concentrating extracts for 250 mL analyses for samples that do not require GPC.

**Note:** For samples that require GPC go to Procedure 20

**Note:** If using the Buchi concentrator refer to *T-OE-GEN-WI10861* for parameter settings.

**Buchi Vacuum Concentrator**

a. Turn on the SyncorePlus, Chiller, and Vacuum Pump by using the green switch located on the front of the devices.

b. Turn on the heat of the SyncorePlus by pressing the green knob on the control panel.

1. To adjust the temperature of the heating bath and the heated cover, press the set button on the control panel and rotate the knob to the correct temperature needed.

2. The heating bath needs to be slightly filled with DI $H_2O$. (Approximately 25mL per reservoir)

3. **Note** - The heated cover is set differently based on the solvent used. Consult a supervisor about the appropriate temperatures for the solvent being concentrated.

c. Turn on the cool flow of the Chiller by pressing the green control knob on the front of the device.

1. To adjust the temperature of the chiller, rotate the knob to the correct temperature needed.

d. From the interface attached to the vacuum pump, go to the operating modes menu tab (pen & paper button). The methods used for concentration are listed in the methods sub-item. For all 8081, 8082, and 608 extractions use the 45mL Methylene Chloride for the first concentration and use the Hexane method for t

e. In the event that further concentration is needed, the Timer sub-item in the operating modes menu tab can be used with a selected method.

1. Once in the timer sub-item the timer can adjusted to the desired time. Consult a supervisor about appropriate times for remaining solvent.

7. After each concentration the solvent must be emptied from the collection flask into a carboy.

20. Concentrating samples that require GPC for 250ml analysis

**Buchi Vacuum Concentrator**

a. Turn on the SyncorePlus, Chiller, and Vacuum Pump by using the green switch located on the front of the devices.

b. Turn on the heat of the SyncorePlus by pressing the green knob on the control panel.

1. To adjust the temperature of the heating bath and the heated cover, press the set button on the control panel and rotate the knob to the correct temperature needed.

2. The heating bath needs to be slightly filled with DI H2O. (Approximately 25mL per reservoir)

3. **Note** - The heated cover is set differently based on the solvent used. Consult a supervisor about the appropriate temperatures for the solvent being concentrated.

c. Turn on the cool flow of the Chiller by pressing the green control knob on the front of the device.

1. To adjust the temperature of the chiller, rotate the knob to the correct temperature needed.

d. From the interface attached to the vacuum pump, go to the operating modes menu tab (pen & paper button). The methods used for concentration are listed in the methods sub-item. For all 8081, 8082, and 608 extractions use the 45mL Methylene Chloride.

e. In the event that further concentration is needed, the Timer sub-item in the operating modes menu tab can be used with a selected method.

1. Once in the timer sub-item the timer can adjusted to the desired time. Consult a supervisor about appropriate times for remaining solvent.

f. After each concentration the solvent must be emptied from the collection flask into a carboy.

g. Allow samples to concentrate to approximately 7 mL and then bring to final volume of 10.0 mL in a class A volumetric using Methylene Chloride. Make sure to mix the extract thoroughly to ensure the extract is homogenous.

h. Filter the extracts using a Whatman 0.45 µm filter (part number 6875-2504 or equivalent) and 10 mL Fisher disposable syringe (part number 14955459 or equivalent) into 12 mL glass screw top vials. Place the extract into the appropriate GPC queuing area for storage until the cleanup is performed. Perform GPC cleanup following SOP *T-OE-PEST-WI11410*.

21. If the extract is scheduled for PCB analysis (8082), treat the extract with sulfuric acid as described in *T-OE-PEST-WI10281*.

22. If the extract is scheduled for Pesticide analysis (8081), florisil the sample 2 mL to 2 mL as described in the Pesticide Florisil section of SOP *T-OE-PEST-WI10281*.

a. Pesticide florisil is also performed for *T-PEST-WI9843* if required due to matrix or client request.

23. If the extract is scheduled for PCB analysis, florisil the extract following the PCB Florisil section of *T-OE-PEST-WI10281*.

24. If the extract has a sulfur odor, perform copper cleanup of the extract as described in *T-OE-PEST-WI10281* for Pest and PCB (8081, 8082, or 608) samples only. Other samples are cleaned up with GPC.

## Calculations
See analysis method as listed in the Cross Reference section.

## Statistical Information/Method Performance
See analysis method as listed in the Cross Reference section.

## Quality Assurance/Quality Control
A batch is defined as the samples to be extracted on any given day, but not to exceed 20 field samples. If more than 20 samples are prepared in a day, an additional batch must be prepared.

For each batch of samples extracted a blank, an LCS, an MS and an MSD must be extracted. For method 608, the laboratory must, on an ongoing basis, spike at least 10% of the samples, if enough sample volume is received, to assess accuracy. If there is limited sample preventing the preparation of the MS/MSD, an LCSD must be prepared instead. If the batch contains only field or equipment blank samples, the LCS/LCSD QC pairing must be used.

If any client, agency, or state has more stringent QC or batch requirements, these must be followed instead.

## Purpose

The purpose of this SOP is to provide guidelines by which chromatographic problems causing nonconformance to the methods performed in the Pesticides Residue Analysis Department may be recognized and corrected. In addition, guidelines for the performance of preventative maintenance are presented to standardize the frequency and procedures of such maintenance throughout the department.

## Scope

The guidelines outlined in this SOP are for use when performing preventative or corrective maintenance on any gas chromatographs capillary columns in the Pesticides Residue Analysis Department.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP.

The analyst being trained will work with an experienced analyst performing the instrument maintenance until such time as they can independently perform the routine tasks with minimal downtime and acceptable chromatography afterwards. For troubleshooting or repairing non-routine problems, the analyst may need to consult the instrument manuals associated with the GC or detector, and/or work with a more experienced analyst periodically as they encounter unusual situations. Proficiency is measured by auditing the person performing the routine maintenance and checking the resulting chromatography.

## Procedure

### I Procedure for Troubleshooting Chromatographic Problems:

A. Nonreproducible responses

When the response of continuing calibration standards run shortly after the initial calibration do not match the initial calibration within the criteria defined by the method being run, or when certain compounds repeatedly fall outside acceptable limits, column maintenance may be required. The autosampler should first be checked when all the compound responses are consistently high or low to verify that it is injecting a constant volume of sample. If the autosampler is functioning correctly, then column maintenance must be performed. An indication of the need for column maintenance is when the responses of only a few compounds, usually the ones which suffer breakdown or are breakdown components, fall off or increase sharply during the course of a run.

B. Poor linearity

Poor linearity in the initial calibration standards of a run is another indication that column maintenance may need to be performed. Once again, check the autosampler first to determine that it is operating correctly.

C. High analyte breakdown

High breakdown of endrin to endrin ketone and endrin aldehyde, and of 4,4' DDT to 4,4' DDD and 4,4' DDE, in evaluation mixes run on the instrument are a definite sign that column maintenance needs to be performed. On capillary systems, high breakdown is an indication that injection port maintenance must also be performed (see Injection Port Maintenance).

D. Extraneous peaks

1. Extraneous peaks in chromatograms of standards are an indication of contamination somewhere in the system.

a. If extraneous peaks are present, first rebottle and reinject the standard to ensure that the extraneous peaks are not carryover from a previous injection or that the standard was not contaminated during bottling.

b. If the peaks are still present in the reinjection, clean the autosampler thoroughly and inject hexane to see if the peaks are still present.

c. If the peaks remain, make a hand injection of hexane.

d. If the peaks are not present, then the autosampler is contaminated and needs further cleaning. If the peaks are still present, then either the column, injection port, or detector is contaminated.

2. Steps to determine detector contamination on capillary systems.

a. Remove the column from the makeup gas adapter and plug the base of the adapter with a blank column nut.

b. Run the instrument through a program blank while collecting the signal.

c. If the contamination peaks appear, then the detector is contaminated and needs to be cleaned (see Detector Maintenance).

d. If the peaks do not appear, then the column or injection port is contaminated, requiring column and injection port maintenance.

E. Noisy baseline

1. A noisy baseline is another indication that column maintenance may have to be performed.

2. Baseline noise that has irregular frequency and magnitude is an indication of a leak in the system, and column maintenance must be performed to eliminate the leak.

3. Baseline noise of regular frequency and varying magnitude has been demonstrated to be the result of a capillary column connector leaking when the pressure had built up to a sufficient level to open the gap between the column and connector.

4. If a pattern of baseline noise of equivalent frequency and magnitude is seen in chromatograms, it is probably electronic noise.

5. When electronic noise is suspected:

a. First check all the connections between the instrument and the data collection system.

b. If all the connections are found to be tight, inspect all the internal connections to and from the electrometer and the motherboard of the instrument.

c. If the noise is still present, check the connection between the detector and the electrometer.

d. If all the connections have been checked and found to be tight, and the electronic noise remains, clean all the connections with a swab soaked in alcohol.

e. If electronic noise is still present, put in a work order to the equipment repair department and have them look at the instrument for problems with the boards.

F. Poor peak shape

1. Maintenance is required when analytes fail to have a sharp Gaussian peak shape, with little or no fronting or tailing.

2. Poor peak shape can be a result of injection port contamination, column leaks, or column phase degradation.

3. Peak shape directly affects the analyte peak heights and therefore, the analyte’s response.

## II Procedure for Maintenance:

A. Injection port septum or Merlin Microseal

1. Frequency of injection port septum changes:

a. The injection port septum should be changed regularly as preventative maintenance to avoid problems arising from retention time or response drift.

b. The septum life will vary from instrument to instrument.

c. A gradual retention time shift on consecutive chromatograms is an indication of a worn septum. The septum should be replaced whenever this occurs.

d. While regular septum changing is a necessary practice on capillary columns, the oxygen introduced to the column with each septum change degrades the column phase, shortens the life, and detracts from the column's performance. Therefore, only change the septum before a new initial calibration or when retention time shifts have occurred.

2. Changing:

a. On capillary column instruments, take the oven temperature down to 40°C.

b. Do not shut off the carrier and makeup gas flows.

(1) Keeping the gas flows on will minimize the time required for detectors to settle.

(2) The carrier gas flow also serves to cool the column to prevent it from overheating and purges any oxygen contamination that occurs during the septum change.

c. For EPC systems, the pressure must be turned to 0.

d. Change the septum as quickly as possible to minimize the amount of oxygen the column is exposed to.

e. To change the septum:

(1) Remove the septum retainer nut and remove the old septum with a septum puller.

(2) Place a new septum of the correct diameter in the injection port and retighten the septum nut.

f. After the septum has been changed:

(1) Set the EPC systems to the proper pressure.

(2) The oven temperature should remain at 40°C for at least 10 to 15 minutes, to purge the column of all the oxygen that was introduced during the septum change.

(3) After the 10 to 15 minutes have passed, raise the oven temperature back to the initial temperature program.

g. To change merlin microseal

(1) Remove retaining nut and old microseal.

(2) Place new microseal in injection port and tighten until pressure meets setpoint

(3) Tighten retaining nut an additional 30 degrees.

B. Column maintenance

1. Column maintenance should be performed as a preventative measure to ensure valid injections meet all the criteria necessary for the method being performed on the instrument.

2. The frequency of the maintenance will be dependent upon the type of samples being processed, the sensitivity of the analysis and detector to systemic contamination, sample matrix, and the volume of samples being processed.

3. To perform column maintenance:

a. On capillary column instruments, the oven and injection port temperature should be lowered to room temperature before any maintenance is performed on the column.

b. If ferrule is damaged, remove the column from the injection port by first loosening the column nut.

c. Slide the nut off the column, then remove and discard the ferrule in the nut.

d. Slide the nut with a new ferrule onto the column, pushing it back far enough so that it will not fall off during the following steps.

The nut and ferrule must be on the column before the final cut is made, since small amounts of graphite are shaved off and lodge in the column whenever the ferrule is slid over the column's end. This graphite may cause poor column performance and breakdown.

e. Using the capillary column cutter, remove the first 3" to 6" of the column.

(1) With a magnifying glass, inspect the cut to ensure that it is acceptable.

(2) An acceptable cut will appear smooth for the entire circumference of the column and will have no jagged edges.

(3) After the initial 3" to 6" have been removed, cut small increments of the column off until an acceptable cut is made.

f. After the liner has been inspected and, as is generally necessary, replaced (see Injection Port Maintenance), reinstall the column.

Once the column is held in place by the nut, verified by the column not sliding during gentle tugging, tighten the nut with a wrench another ¾ turn. Do not overtighten the ferrule. Overtightening will split it, cause leaking, and make it hard to remove from the nut the next time maintenance is performed.

g. The detector end of the column will rarely need maintenance. High bleed or column contamination unresolved by maintenance on the front of the column, are reason to perform detector end maintenance.

(1) First remove the column from the detector.

(2) Slide the column nut down the column, after removing and replacing the old ferrule, so that it will not fall off during the following steps.

(3) Now follow the same procedure for the cutting of the column as outlined for the front end.

(4) Reinstall the column into the detector, checking to make sure that the appropriate length of column is inserted into the detector.

C. Injection port maintenance

1. Since the injection port greatly affects the performance of the column in a capillary system, whenever column maintenance is performed, the condition of the liner should be checked to determine whether or not it needs to be replaced.

Replacing the liner is highly recommended to limit active sites caused by previous sample contamination.

2. Maintenance of split/splitless injection port

a. Split/splitless injection ports consist of a glass liner which is held in place with an O-ring, and a gold-seal at the base which maintains inertness for EPC systems.

b. Turn the pressure to 0.

c. Use a ¼" wrench to remove the column nut from the injection port fitting in the oven.

d. Use a Torx™-driver to remove the insulated cover from over the port inside the oven.

e. Use a specialized wrench to loosen the fitting below the septum nut fitting to reveal the glass sleeve. Remove the sleeve and O-ring.

f. Use the ½" wrench to remove the injection port fitting which contains the gold seal. Using cotton swab wetted with solvent, clean the inside of the port and weldment.

g. Inspect the gold seal, and the washer which will be under it.

If tarnishing is evident, replace the seal, or clean it with a mild abrasive until no tarnish is evident.

h. Generally, replacement of the washer is required. Rinse the fitting, seals, and washer with methanol or hexane before re-installation.

(1) Insert the new washer into the fitting, followed by the gold seal.

(2) Attach the fitting, and tighten with a ½" wrench until it is just snug. Do not over-tighten.

(3) Attach an O-ring to a new glass sleeve, and install from the top of the port.

(4) Press the sleeve down until it hits the base. Re-attach the cover and tighten until snug.

(5) Take care not to cross-thread the nut.

i. Re-install the insulated cover inside the oven prior to installing the column.

j. Cut 3" to 6" off of the guard column after installing the column nut and ferrule.

Make sure that the cut is clean and straight using a magnifier.

k. Insert the column into the port, making sure the column does not fall below the ferrule.

l. Tighten fingertight plus one additonal ¼ turn with a ¼" wrench to set the ferrule.

m. Re-loosen the nut, and slide the column to a distance of 2 - 4 mm above the ferrule. This distance is critical for the performance of the system.

n. Make sure the column does not slide, and re-install the nut. Re-tighten to fingertight plus ¼ turn.

o. For EPC systems, turn the pressure back to operating pressure, and check for leaks.

p. Let the system equilibrate for 15 minutes at 40°C prior to elevating temperatures to allow any oxygen to evacuate.

D. Maintenance of electron capture detector

1. Detector maintenance should be performed only when column and injection port maintenance have not corrected the problems of poor reproducibility of response, poor linearity, or contamination.

When any of these problems are present after injection port and column maintenance have been performed, then the status of the detector should be investigated.

2. A good indication of detector problems is if the baseline of the detector is elevated to a high mV reading when the instrument is sitting at either its isothermal operating temperature or the lower temperature of its temperature program.

The detector should be thermally cleaned following the guidelines provided in the appropriate manufacturer's service manual.

3. If the problems are still present once the thermal cleaning is performed, then all of the steps taken to alleviate the problem should be closely examined and repeated to ensure that the detector is the cause of the problem.

4. Rarely will persistent contamination be caused by the detector.

5. Poor linearity and drifting response are problems frequently attributable to the detector.

a. All the steps of instrument maintenance should be performed, including thermal cleaning, before the detector is replaced in an attempt to rectify these problems.

b. In these situations, the detector may be replaced with greater certainty as the solution to the problem.

6. If a detector replacement is determined as being necessary, consult the appropriate manufacturer's service manual for the procedure.

## Scope

This acid digestion procedure is used to prepare wastewater, surface water, and groundwater samples for measurement of total recoverable metals by inductively coupled plasma optical emission spectroscopy (ICP-OES) and inductively coupled plasma mass spectrometry following SW-846 protocol.

## Basic Principles

Samples are heated with nitric and hydrochloric acids with a substantial reduction in volume during digestion to dissolve metals.

## Reference Modifications

1. A 50-mL sample aliquot and final volume is used instead of 100-mL to improve digestion throughout, conserve sample usage, and limit waste generation. Because all reagents are also adjusted so that concentrations are equivalent to a 100-mL aliquot, there is no impact on the data.

2. Ribbed watch glasses or reflux caps are not used during evaporation; samples are heated without watch glasses in non-metallic hoods to speed evaporation. No contamination trends have been observed in prep blanks evaporated without using watch glasses.

3. Samples are heated at 90° to 95°C on hot plates or HotBlocks.

## Interferences

Not applicable to this procedure.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Preparing samples for inorganic analysis involves working with concentrated acids and other chemicals which are dangerous if not handled carefully:

**Nitric acid ($HNO_3$)** – This acid can cause skin burns. Add nitric acid to samples in a hood to avoid exposure to toxic fumes or use the designated dispensing equipment.

**Hydrochloric acid (HCl)** – This acid can cause skin burns. Never mix HCl with concentrated $H_2SO_4$ to avoid a violent reaction. Always use in a fume hood or use the designated dispensing equipment.

When diluting strong acids, never add water to acid; always add acid to water.

Store concentrated acids in the prep room acid lockers. Only acids are to be stored in these lockers. (Store solvents in the flammable liquid storage cabinet.) Some concentrated acids are kept in the acid reagent bottles on prep room counters. Fill reagent bottles in an operating fume hood using caution to avoid spills.

Perform acid digestions in hoods that are turned on and have active alarms. Notify a supervisor immediately if the hood is malfunctioning or the alarm sounds.

Samples that contain dust may be hazardous. Open in a fume hood.

When a hazardous flag is added indicating possible cyanide, special precautions are required to avoid exposure to hydrogen cyanide gas. Contact your supervisor prior to adding acid. Always open these samples and add the acid in a hood.

Use spill pillows to absorb large acid spills (small spills are cleaned with wet paper towels.) Use SPILL-X-A powder or equivalent to neutralize any remaining acid and then rinse the area thoroughly with water. Spill pillows and SPILL-X-A are stored on the prep room shelf.

Dispose of acid waste properly. Collect all acid digestions, waste solutions, and expired reagent solutions in waste containers. When the acid waste containers are full, a designated acid waste handler transfers the waste to the acid neutralization tank.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability for this or an equivalent procedure.

Initially, each employee performing this digestion procedure must work with an experienced employee for a period of time until they can independently set up batches and perform the necessary steps outlined in this procedure. Proficiency is measured through documentation of the critical steps in this procedure, over checking of data as well as an IDOC.

The IDOC consists of aliquots spiked at 1-4X the RL that are carried through all steps of the prep and analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy of 50 - 150% and standard deviation of </= 20%". Ongoing DOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation.

## Sample Collection, Preservation, and Handling

Samples are collected in plastic containers and preserved to a pH of <2 with $HNO_3$. (Samples to be analyzed for soluble metals requiring filtration at the lab must be submitted unpreserved. The sample is run through a 0.45 micron filter within 5 days of receipt and then preserved.) The pH is checked upon receipt and adjusted as necessary by Sample Support; samples that are pH adjusted at the lab must not be digested for a minimum of 24 hours. If samples fail to maintain a pH of <2 the Client Service Representative is notified for further direction. Samples are stored at 0° to 6°C, but not frozen, prior to digestion. Samples must be digested within 6 months of collection. Digested samples are stored in plastic at room temperature and have a 6 month holding time.

## Apparatus and Equipment

1. Polypropylene containers (digestion vessels) – certified clean and Class A equivalent
2. 250-mL beakers, 400-mL beakers (or other volumes as appropriate)
3. 100-mL graduated cylinders (or other volumes as appropriate)
4. 100-mL Class A volumetric flasks (or other volumes as appropriate)
5. 125-mL Nalgene bottles (or other volumes as appropriate)
6. Hot plates or HotBlocks adjustable and capable of maintaining a temperature of 90° to 95°C

## Reagents and Standards

For reagent preparation, shelf life, and storage conditions, see *T-MET-WI9082*.

1. Nitric acid, $HNO_3$ - Fisher, Trace Metal Grade, or equivalent. Store at room temperature and re-evaluate annually.

2. Hydrochloric acid, HCl - Fisher, Trace Metals Grade, or equivalent. Store at room temperature and reevaluate annually.

3. Nitric acid (1:1) – Add 500 mL of $HNO_3$ to 500mL of reagent water. Store at room temperature. Expires in 6 months.

4. Hydrochloric acid (1:1) – Add 500 mL of HCl to 500 mL of reagent water. Store at room temperature. Expires in 6 months.

**NOTE:** It is acceptable to prepare solutions using multiples of indicated volumes if exact ratios are maintained.

## Calibration

Not applicable to this method.

## Procedure

**This SOP has been set up to outline the procedures for HotBlock and hot plate digestion (see below). Choose the procedure that corresponds to the sample heating technique being used for sample digestion.**

A. HotBlocks

**NOTE:** It is acceptable to reduce the volume of sample being analyzed as long as the sample reagent ratios are maintained.

**NOTE:** If the sample contains high solids, use a smaller aliquot of the sample and bring sample to final volume as stated in this procedure. Make appropriate acid, reagent, and spike volume adjustments based on sample

final volume.

See HotBlock Control Point Temperature Logbook to obtain control point temperature setting for the HotBlock being used for digestion. If necessary, adjust control point temperature to the proper setting as instructed below.

1. Shake sample well. For non-leachate samples, transfer 50 mL of well-mixed sample into a 68-mL digestion vessel. For leachate samples, transfer 5-mL of well-mixed sample into a 68-mL digestion vessel and bring to 50-mL using DI water. After the sample has been poured, add the spiking solution. For sample batch spiking procedures, see *T-MET-WI9082*. For sample batch quality control requirements see *T-MET-WI11931*. LCS/LCSD and MS/MSD samples for leachate batches use 5 mL of SPLP or TCLP fluid brought to 50-mL with DI water.

2. Add 2 mL of (1:1) $HNO_3$ and 5 mL of (1:1) HCl.

3. Heat the solution in a HotBlock at about 90° to 95°C until sample volume is reduced to between 15 and 20 mL, making certain the sample does not boil.

4. Allow to cool.

5. Adjust volume to the 50-mL mark on the digestion vessel with reagent water, cap, and mix.

6. The sample is now ready for analysis.

B. Hot Plates:

**NOTE:** If boron (B) is requested on a sample, use Teflon vessels.

**NOTE:** It is acceptable to reduce the volume of sample being analyzed as long as the sample reagent ratios are maintained.

**NOTE:** If the sample contains high solids, use a smaller aliquot of the sample and bring sample to final volume as stated in this procedure. Make appropriate acid, reagent, and spike volume adjustments based on sample final volume.

1. Shake sample well. Transfer 50-mL of well-mixed sample into a glass vessel. After the sample has been poured, add the spiking solution. For sample batch spiking procedures see *T-MET-WI9082*. For sample batch quality control requirements see *T-MET-WI11931*.

2. Add 2 mL of (1:1) $HNO_3$ and 5 mL of (1:1) HCl.

3. Heat the solution on a hot plate at 90° to 95°C until sample volume is reduced to between 15 and 20 mL, making certain the sample does not boil.

4. Allow to cool.

5. Transfer the solution to a 50-mL volumetric flask. Adjust volume to the 50-mL mark with reagent water and mix.

6. Transfer the solution to a 68-mL digestion container and cap.

7. The sample is now ready for analysis.

## Block Digestor Instructions

1. Turn block digestor on by pressing rocker switch located on the cord.

2. Wait about 8 seconds until controller display indicates current block temperature.

3. Press and hold Star (*) key.

4. The display shows the Set Point Temperature.

5. The digits can be changed to the desired value by pressing the up and down arrows keys while holding the (*) key.

6. Confirm Control Point temperature is set to the block temperature that provides 90° to 95°C.

**NOTE:** See HotBlock Control Point Temperature Logbook to obtain control point temperature setting for the HotBlock being used for digestion. If necessary, adjust Control Point temperature to the proper setting.

**NOTE:** Polypropylene containers must not be heated above 130°C.

## Calculations

Not applicable to this procedure.

## Statistical Information/Method Performance

Not applicable to this procedure.

## Quality Assurance/Quality Control

A method blank, sample duplicate, sample matrix spike, sample matrix spike duplicate, and laboratory control sample must be performed for every SW-846 digestion batch. A batch is 20 samples or less.

Each piece of batch QC is digested following the procedures in this SOP.

For sample batch quality control requirements see *T-MET-WI11931* for ICP and *T-MET-WI11933* for ICP-MS

## Purpose

This SOP outlines the proper instrument maintenance of the ICP-MS 7900 instrumentation.

## Scope

This procedure applies specifically to the Agilent 7900 series instrument used at Eurofins Lancaster Laboratories Environmental (ELLE).

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP.
Initially, each analyst performing routine instrument maintenance must work with an experienced analyst for a period of time until they can independently perform routine required maintenance successfully.

## Procedure

A. Maintenance for the Agilent 7900 ICP-MS and ESI SC-8/ SC-14 FAST Autosampler

1. Documentation

Any adjustment to an instrument, replacement of parts, etc., must be documented in the appropriate instrument logbook.

**NOTE:** For more details on procedures in this document please refer to the Agilent 7900 Series ICP-MS Hardware Maintenance Manual.

**NOTE:** The 7900 system uses the ESI SC-8/SC-14 FAST autosampler, a water cooled Scott double pass spray chamber, and a teflon miramist nebulizer. Some components of the sample introduction system are different from those described in the Agilent 7900 Series Maintenance Manual.

2. Routine maintenance

a. Remove and clean the sample introduction system when instrument performance declines.

(1) Clean nebulizer and spray chamber.

(a) Put the instrument into standby mode.

(b) Once the instrument is in standby open the small cover.

(c) Remove torch box cover by undoing the latch.

(d) Remove the two metal clip holding the transfer tube in place and remove the transfer tube.

(e) Unthread and remove the nebulizer from the spray chamber. Place the protective cover over the nebulizer tip to protect it.

(f) Remove spray chamber cooling block top cover by loosening the two screws. Disconnect the make-up gas line from the spray chamber. Disconnect the dilution nozzle from the spray chamber. Disconnect the dilution nozzle from the gas line and set aside, being careful not to deform the tip.

(g) Lift spray chamber and carefully remove drain line. Disconnect the end cap from the spray chamber body.

(h) Soak the spray chamber, end cap and glass transfer tube in 10% nitric for at least 24 hours. Rinse with reagent water.

(i) Dry the outside of the spray chamber and transfer tube with a paper towel. Remove any excess water from the spray chamber using compressed air. It is not necessary to completely dry the inside of the spray chamber.

(j) The transfer tube must be completely dry before reinstallation. Accelerate drying, if necessary, placing the transfer tube in a drying oven set to 100 degrees Celsius for approximately 10 minutes.

(2) Removing and cleaning the torch

(a) Follow steps (1)a through (1)d in nebulizer removal section above.

(b) Remove gas connections from torch. Inspect the gas lines: notify a supervisor immediately if any cracks or signs of weakness are observed.

(c) Open quick release clamp. Remove the torch, platinum shield and bonnet from coil.

(d) Remove bonnet and platinum shield from the torch.

(e) Check bonnet and platinum shield for cracks or deformation.

(f) Soak torch and bonnet in 10% nitric for at least 24 hours. Rinse with reagent water.

(g) Replace torch if it shows excessive wear, devitrification or build-up that cannot be removed.

(h) The torch and bonnet must be completely dry before reinstallation. Drying may be accelerated by placing these parts in a drying oven set to 100 degrees Celsius for approximately 10 minutes.

(3) Reassembling sample introduction system

(a) Put platinum shield and bonnet on torch.

(b) Slide torch into coil. Align the small glass bump with the corresponding notch on the torch stand to ensure proper torch alignment.

(c) Close quick release clamp.

(d) Connect gas lines. Gas lines are different sizes to avoid accidental incorrect connection.

(e) Assemble spray chamber. Attach drain line and put spray chamber back in the cooling block. Connect the dilution nozzle to the gas line and attach to the spray chamber. Replace top cover and tighten plastic screws. Connect the make-up gas line to the spray chamber.

(f) Remove the cover from the tip of the nebulizer and slide the nebulizer into the end cap of the spray chamber.

(g) Install the transfer tube. Attach with metal clips.

(h) Replace torch box cover and close the clamp. Close the small cover.

(4) Cleaning the FAST valve assembly

**NOTE:** Detailed descriptions and diagrams of the FAST valve assembly are located in the pdf document "ESI SC Manual.pdf" located in the dept. 22 folder at Z:\DEPT22\ICP Training and Reference Materials\ICPMS Training and Reference Materials.

(a) Periodically clean the FAST valve assembly when instrument performance declines and instrument maintenance does not correct the problem.

(b) In the Mass Hunter software open stop the nebulizer pump.

(c) Unthread and set aside all seven connections going into the FAST valve head.

(d) Use a 9/64” Allen wrench to remove the valve head from the FAST hub.

(e) Use a 7/64” Allen wrench to remove the three screws from the valve assembly.

(f) Disassemble the valve assembly and place components on a clean dry surface.

(g) Rinse the rotor with reagent water and use compressed air to remove any deposits. Remove stubborn deposits by sonicating the rotor in a solution of up to 10% nitric acid for approximately 10 minutes, followed by rinsing with reagent water. Replace the rotor if it shows signs of excessive wear. Dry rotor with compressed air prior to reinstallation.

(h) Use compressed air on each of the seven ports on the stator. Visually inspect the openings and confirm that nothing obstructs any of the seven ports.

(i) Reassemble the valve assembly. When reinserting the 3 screws, alternate between the 3 screws to keep them evenly threaded.

(j) It is very important to avoid over tightening the 3 screws. Once you reach the point where the stator, body ring, and valve body are flush with one another tighten each screw gently until it feels snug (using forefinger and thumb only). DO NOT tighten with full force to avoid damage to the valve assembly.

(k) Reattach the valve assembly to the FAST hub. While keeping the valve assembly firmly seated against the hub, use the 9/64” Allen wrench to firmly tighten the screw. It is necessary to apply enough force to make sure the valve head does not rotate when the hub switches between LOAD and INJECT.

(l) Carefully thread each of the seven connections to the valve head. You MUST avoid cross threading and over tightening to avoid damaging the threaded connections. Threading must be smooth. If you encounter resistance STOP, reverse and restart the threading. Gently finger-tighten each connection.

b. Removing and cleaning the cones.

(1) Removing cones

(a) Open the small cover and remove the torch box cover by undoing the latch.

(b) Press the button inside the small cover to move the torch box to the maintenance position. You may need to disconnect the drain line from the spray chamber to prevent excessive tension on it while the torch box is in the

maintenance position. Alternatively, on the Mass Hunter instrument control panel click on hardware and then right click on sample introduction. Select maintenance from the pop up. This allows you to move the torch box between initialize and maintenance.

(c) Unscrew the sampling cone retaining ring, use of the sampling cone tool might be necessary. Place the tool into the respective holes on the retaining ring and use a screwdriver for added leverage.

(d) Slide skimmer cone wrench into hole where skimmer cone is and turn until magnets lock pins into place. If necessary, use a screwdriver for leverage in loosening the skimmer cone.

(2) Cleaning cones

(a) Rinse cones in reagent water. Use a wet paper towel to help remove deposits.

(b) If deposits are still observed after completing step (a), additional cleaning must be performed following steps (c). and (d). below. Otherwise skip to step (e) below.

(c) Sonicate cones in 2% Citranox for 5-10 minutes. Rinse with reagent water.

(d) If necessary, use a 5% $HNO_3$ solution with q-tips to gently polish the cones until the q-tips stay clean. Sonicate in reagent water for 5 minutes.

(e) Rinse each cone thoroughly with reagent water to remove all traces of loose deposits and.

(f) Sonicate cones in a beaker containing only reagent water for 5 minutes.

(g) Remove form Beaker. Rinse with reagent water and dry. Accelerate drying, if necessary, by placing the cones in an oven set to 100°C for approximately 10 minutes. Cones must be completely dry before reinstallation.

(h) Visually check the tip of the cone and the back of the cone for abnormalities. Replace any cone that appears to have an oversized or non-round tip, or has surface deformities on the back of the cone.

(i) Visually inspect the graphite gasket for cracks or tears. Replace if necessary.

(3) Reinstalling cones

(a) Put skimmer cone in the skimmer cone wrench and turn until magnets lock pins into place. Slide wrench with cone attached into the interface and carefully thread the cone onto the lens stack. Be sure to not cross thread.

(b) Seat the sampling cone onto the interface and secure with the retaining ring. Be careful not to cross thread it.

(c) Press the button inside the small cover to move the torch box to the initialize position. Reattach the drain line to the spray chamber if removed while the torch box was in the maintenance position. Alternatively, on the Mass Hunter instrument control panel click on hardware and then right click on sample introduction. Select maintenance from the pop up. This allows you to move the torch box between initialize and maintenance.

(d) Replace the torch box cover and secure the latch.

(e) Close small cover.

c. Removing and cleaning the lenses

(1) Removing Lenses (There are multiple lenses to clean: the lens stack assembly, the Reaction cell which contains the Cell Focus and Cell Entrance Lens, Plate Bias Lens.)

(a) Follow steps a. through c. in the Cleaning Nebulizer section.

(b) Press the button inside the small cover to move the torch box to the maintenance position. You may need to disconnect the drain line from the spray chamber to prevent excessive tension on it while the torch box is in the maintenance position. Alternatively, on the Mass Hunter instrument control panel click on hardware and then right click on sample introduction. Select maintenance from the pop up. This allows you to move the torch box between initialize and maintenance.

**NOTE:** If you are not cleaning the Reaction Cell it is not necessary to put the instrument in shutdown mode or to vent the vacuum chamber. Once the instrument is in standby mode skip to step g. below. DO NOT put the instrument in shutdown mode or vent the vacuum chamber if you are only cleaning the Extraction Lens-Omega-Lens assembly.

(c) Put the instrument in shutdown mode (turn off vacuum). Turn computer off and then turn off instrument using the button on the front of the instrument.

(d) Open the large cover. Turn the vent valve (located on the front left of the vacuum chamber) one turn. A slight hissing sound is heard.

(e) While the chamber is hissing remove screws on the vacuum chamber lid.

(f) Once the vacuum chamber has equalized, remove the lid. Remember to retighten the vent valve. Rest the lid on top when not working in the vacuum chamber to avoid entrance of dust and particles.

(g) Remove the sampling cone and skimmer cone by following steps c. and d. in Removing cones section.

(h) Loosen three screws on skimmer base. Remove the lens stack assembly. Disassemble the lens stack according to the 7700 maintenance manual. Slide off each lens and keep spacers in order. There are four lenses.

**NOTE:** If you are not cleaning the Reaction Cell skip to Cleaning lenses section (2) below. Follow steps i. through l. only if you are cleaning the Reaction Cell.

(i) Open vacuum lid and loosen reaction cell screw. Loosen but do not completely remove plate bias wire terminal screw. Remove wire. Unplug plastic wire connector. Carefully remove reaction cell by lifting out at an angle.

(j) Loosen but do not completely remove plate bias wire screws. Remove wire ends. Remove the four cell assembly screws. Separate housing and carefully remove octopole unit. Be sure not to touch the octopole to avoid misaligning the poles.

(k) Remove the two screws from the entrance side of the octopole. Slide off the cell focus, spacer and cell entrance lens. Secure octopole plate with same screws. Remove the other two screws from the exit side. Remove cell exit lens, spacer and QP focus. Secure octopole plate with same screws. Place octopole unit aside to avoid damage. There are four lenses.

l) Open the vacuum chamber lid and loosen the plate bias lens screws. Remove cell exit guide and plate bias lens.

(2) Cleaning lenses

(a) Polish each lens with #400 polishing paper. Then use #1200 paper. Clean the orifice of each lens using an alumina powder slurry.

(b) Rinse with water.

(c) Sonicate in water for 5 minutes after polishing.

(d) Rinse with water.

(e) Sonicate in water for additional five minutes.

(f) Allow lenses to dry. Do not wipe. Accelerate drying, if necessary, by placing the lenses in an oven set to 100 degrees Celsius for approximately 10 minutes. Lenses must be completely dry before reinstallation.

(3) Reinstalling lenses

**NOTE:** If you are not cleaning the Reaction Cell skip to step f. below. Follow steps a. through e. only if you are cleaning the Reaction Cell.

(a) Remove vacuum chamber cover. Put plate bias lens and cell exit guide in place. Secure with screws.

(b) Remove each octopole plate and reattach the lenses on either side of the octopole. Be aware that there are two different sized holes so that the lenses go back on in the correct orientation. Place reassembled octopole unit into the reaction cell and put the four screws back in.

(c) Reattach the wires to the back of the reaction cell. The top screw holds down the wire that is attached to the reaction cell. The bottom screw holds the currently loose wire.

(d) Carefully put the reaction cell back into the vacuum chamber. Tighten the reaction cell screw. Replace wire in the plate bias lens screw and tighten screw. Plug the wire connector back in.

(e) Put the vacuum chamber lid back on. Secure it with the four screws tightly. Make sure the vent valve is tight as well. Close top cover.

(f) Reassemble the lens stack assembly. Slide into the interface. Tighten the screws.

(g) Put cones back in. Use steps a. and b. in reinstalling cones section.

(h) Turn instrument and computer on. Turn on vacuum in Mass Hunter. Wait 15 to 60 minutes for the vacuum to pump down. Once instrument is pumped down, press the button inside the small cover to move the torch box to the initialize position. Reattach the drain line to the spray chamber if removed while the torch box was in the maintenance position. Alternatively, on the Mass Hunter instrument control panel click on hardware and then right click on sample introduction. Select maintenance from the pop up. This allows you to move the torch box between initialize and maintenance.

(i) Turn Plasma on. Give the instrument time to equilibrate with the vacuum and the plasma both on. Check instrument performance.

d. Replace pump tubing when it shows stretching, flat spots, or increased relative standard deviations. Inspect all tubing to ensure that it is secure and in good condition. Periodically perform visual check on the oil level of the vacuum pump and the water level in the recirculating chiller.

B. Preventative Maintenance (performed as needed).

1. Vacuum instrument air filters

2. Vacuum chiller air filters; chiller air filters may also be removed and run under tap water to remove dust build up.

3. Change vacuum pump oil

C. Taking an instrument/analysis out of service/returning an instrument/analysis to service

**NOTE:** The following information is taken from 1*QA-SOP11901*. In the event of an equipment failure, perform the following:

1. Document the nature of the failure in the maintenance logbook.

2. Document how and when the defect was discovered.

3. Notify a supervisor or responsible person to decide on appropriate action to take.

4. The instrument must be clearly tagged as *Out of Service*. The tag must contain the following information:

   a. Date taken out of service

   b. Employee who took the instrument out of service

   c. Reason for tagout

5. The date taken out of service and the date returned to service must be documented in the logbook.

6. Document any corrective action that was taken to bring the equipment back into service.

7. Document results of the corrective action (e.g., system calibration within specifications, etc.)

8. Supervisory personnel must perform a documented evaluation and review of instrumentation/equipment where a major or uncommon failure has occurred to assess the potential impact of the failure on the calibration and/or qualification of the instrument.

9. After repair, document whether the function has been fixed. Calibration or verification activities are performed before the instrumentation is put back into service.

## Reference

1. Test Methods for Evaluating Solid Wastes, SW-846 Method 7470A, September 1994

2. *Chemical Hygiene Plan*, current version.

### Cross Reference

| Document | Document Title |
|---|---|
| *T-MET-WI9082* | Working Instructions for Prep Solutions and Standards |
| *T-MET-WI7965* | Mercury in Aqueous, Solid and Tissue Samples by EPA 7471A, 7471B, 7470A, and 245.1 rev 3 by Cold Vapor AA |

### Scope

This procedure is used for automated and manual digestion of samples and standards for Mercury analysis in aqueous samples by SW-846 Method 7470A.

### Basic Principles

The samples are digested with nitric acid, sulfuric acid, potassium permanganate, and potassium persulfate to oxidize mercury compounds to mercuric ions. Mercuric ions are reduced to mercury metal using stannous chloride. Mercury measurement is performed using the mercury cold vapor technique.

### Interferences

Not applicable to this procedure.

### Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Preparing samples for inorganic analysis involves working with concentrated acids and other chemicals which are dangerous if not handled carefully:

**Nitric acid (HNO3)** – This acid can cause skin burns. Add nitric acid to samples in a hood to avoid exposure to toxic fumes, or use the designated dispensing equipment.

**Sulfuric acid (H2SO4)** – This acid is a strong oxidizing agent and can cause severe burns. Sulfuric acid spills are extremely slippery, adding to the danger. Always use in a fume hood, or use the desinated dispensing equipment. Never mix with concentrated HCl or concentrated KMNO4 to avoid a violent reaction (explosive splattering and extreme heat).

**Hydrochloric acid (HCl)** – This acid can cause skin burns. Never mix HCI with concentrated H2SO4 to avoid a violent reaction. Always use in a fume hood, or use the designated dispensing equipment.

When diluting strong acids, never add water to acid; always add acid to water.

Store concentrated acids in the prep room acid lockers. Only acids are to be stored in these lockers. (Store solvents in the flammable liquid storage cabinet.) Some concentrated acids are kept in the acid reagent bottles on prep room counters. Fill reagent bottles in an operating fume hood using caution to avoid spills.

Perform acid digestions in hoods that are turned on and have active alarms. Notify a supervisor immediately if the hood is malfunctioning or the alarm sounds.

When a hazardous flag is added indicating possible cyanide, special precautions are required to avoid exposure to hydrogen cyanide gas. Contact your supervisor prior to adding acid. Always open these samples and add the acid in a hood.

Use spill pillows to absorb large acid spills (small spills are cleaned with wet paper towels.) Use SPILL-X-A powder or equivalent to neutralize any remaining acid and then rinse the area thoroughly with water.

Dispose of acid waste properly. Collect all acid digestions, waste solutions, and expired reagent solutions in waste containers. When the acid waste containers are full, a designated acid waste handler transfers the waste to the acid neutralization tank.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each employee performing the digestion must work with an experienced employee for a period of time until they can independently perform digestions. The IDOC must be spiked at 1 to 4x the RL. Proficiency is measured through documented audits of the tasks listed as well as an Initial Demonstration of Capability (IDOC).

The DOC consists of four laboratory control samples (LCS's) that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation.

## Sample Collection, Preservation, and Handling

Aqueous samples are collected in plastic or glass containers (drinking water sample volume is 1-L). Samples are preserved to a pH of <2 with nitric acid at collection and the pH is checked upon receipt and adjusted as necessary by Sample Support; samples that are pH adjusted at the laboratory must not be digested for a minimum of 24 hours. If samples fail to maintain a pH of <2 the Client Representative is notified for further direction. Samples are stored at 0 to 6°C, not frozen, prior to digestion. Samples must be analyzed within 28 days of collection.

Dissolved Mercury: Samples are to be filtered within 15 minutes of collection by the client. Clients may submit unpreserved bottles to the lab for dissolved mercury analysis. The sample is run through a 0.45 micron filter within 5 days of receipt and then preserved to a pH of <2 with HNO3.

Digested samples are stored in plastic bottles at room temperature. Store samples, standards, and digested samples separately.

## Apparatus and Equipment

1. 50-mL polypropylene containers and covers (digestion vessels for block digestion) – certified clean and Class A equivalent

2. Environmental Express HotBlock (block digester) – adjustable and capable of maintaining a sample temperature of 95°C.

## Reagents and Standards

1. For standards preparation, shelf life, and storage conditions, see *T-MET-WI9082*. This form also has instructions for the initial preparation of Method Blanks, LCSs, Matrix Spikes and General Solutions.
2. Store all standards and reagents at room temperature. Label the container with the solution name, lot number, date prepared, the expiration date, the initials of the person preparing the solution, and the storage conditions.
3. Standard/spiking concentration and reagent vendors are subject to change without notification.
4. Nitric acid, 70.0% to 71.0% $HNO_3$, J.T Baker ACS Grade, or equivalent. Follow manufacturer's expiration date.
5. Sulfuric acid, 95.0% to 98.0%, $H_2SO_4$, 36 N, J.T Baker, ACS Grade, or equivalent. Follow manufacturer's expiration date.
6. Potassium permanganate, $KMnO_4$, Baker Analyzed reagent, ACS, or equivalent. Follow manufacturer's expiration date.
7. Potassium persulfate, $K_2S_2O_8$ Baker Analyzed reagent, ACS, or equivalent. Follow manufacturer's expiration date.
8. Sodium chloride, NaCl, J.T. Baker, Certified ACS, or equivalent. Follow manufacturer's expiration date.
9. Hydroxylamine hydrochloride, $NH_2OH{\cdot}HCl$, J.T. Baker, Certified ACS, or equivalent. Follow manufacturer's expiration date.
10. Stannous chloride, $SnCl_2$, Baker Analyzed reagent, ACS, or equivalent. Follow manufacturer's expiration date.
11. Hydrochloric acid, HCl, 36.5% to 38.0%, J.T Baker ACS Grade, or equivalent. Follow manufacturer's expiration date.

## Calibration

Not applicable to this procedure.

### Calculations

Not applicable

### Statistical Information/Method Performance

Not applicable

### Quality Assurance/Quality Control

1. Each digestion batch is up to 20 samples.

2. Each digestion batch must contain a MB, LCS, BKG, DUP, MS and/or MSD when applicable. If insufficient sample for a duplicate or per client requirement, an LCSD/MSD is added to the batch.

   a. MB – Method Blank also equivalent to a Preparation Blank.

   b. LCS/LCSD – Laboratory Control Sample/Laboratory Control Sample Duplicate

   c. BKG – unspiked background sample

   d. DUP – duplicate

   e. MS – Matrix Spike

   f. MSD – Matrix spike duplicate

### 11924) Procedure

A. Manual hot block digestion

1. Turn block digester on and allow block to reach the Control Point setting that provides 95° ± 1°C sample temperature.
2. Before digestion, check the temperature with a calibrated thermometer and record in the logbook.
3. If the sample to be digested is not in split bin location:
   a. Scan parent bottle into LIMS prep batch.
   b. Shake sample well.
   c. Transfer 20 mL of well-mixed sample (or an aliquot diluted to 20 mL) into the polypropylene container. If a different final volume is necessary, adjust reagent volumes accordingly.
4. Scan split samples from bin into the LIMS prep batch.
5. Prepare batch QC and calibration standards. Prepare a Method Blank using 20 mL of Reagent Water. Matrix Spike and Matrix Spike Duplicate are spiked in the same manner as the LCS/LCSD. See *T-MET-WI9082* for preparation instructions and concentrations. See the Quality Assurance/Quality Control section for the required batch QC.

**NOTE**: Exception - For leachate batches containing leachate spiked QA samples, use one of the leachate spiked QA samples as the batch QC matrix spike and matrix spike duplicate, and proceed with the spiking procedures for the LCS according to *T-MET-WI9082*.

1. Add 1 mL of $H_2SO_4$ and mix.
2. Add 0.5 mL of $HNO_3$ and mix.
3. Add 3 mL of 5% $KMnO_4$ solution and mix.
4. Allow the sample to stand for 15 minutes and then check sample for purple color.
   a. purple color does not persist for at least 15 minutes, perform a dilution on the sample beginning with a DF5.

b. Continue diluting in increments of 5 or 10 until the purple color persists for at least 15 minutes.

5. Add 1.6 mL of 5% $K_2S_2O_8$ solution and mix.
6. Place containers in block digester.
7. Place a calibrated thermometer in a container with reagent water.
8. Put a polypropylene cover on each container. Remove after the samples reach 95° ± 1°C.
9. Heat for 2 hours in the block digester at 95° ± 1°C. The temperature is checked with a calibrated thermometer and recorded in the logbook.
10. Remove samples from block digester and cool.
11. Add 1.2 mL of 12% sodium chloride/hydroxylamine hydrochloride solution to reduce excess permanganate (color change is from purple to colorless). If the solution is not colorless, add reductant in 1-mL increments until $KMnO_4$ is completely reduced.
12. Screw on cap and shake sample
13. Adjust the volume to 20 mL with reagent water and mix. Reserve for analysis.

**NOTE:** The block temperature is different than the temperature of the liquid being digested.

B. Block Digester Instructions:

1. Turn block digester on by pressing rocker switch located on the cord.
2. Wait about 8 seconds until controller display indicates current block temperature.
3. Press and hold STAR (*) key.
4. The display shows the Set Point Temperature.
5. The digits can be changed to the desired value by pressing the up and down arrow keys while holding the (*) key.
6. Confirm Control Point temperature is set to the block temperature that provides 95°C.

**NOTE:** See HotBlock Control Point Temperature Logbook to obtain control point temperature setting for the HotBlock being used for digestion. If necessary, adjust Control Point temperature to the proper setting.

**NOTE:** Polypropylene containers must not be heated above 130°C.

## Cross Reference

| Document | Document Title |
|---|---|
| *T-MET-WI7965* | Mercury in Aqueous, Solid and Tissue Samples by EPA 7471A, 7471B, 7470A and 245.1 rev 3 by Cold Vapor AA |
| *T-MET-WI9084* | Preparation of Mercury Solutions and Standards |

## Scope

This procedure is used to prepare soil, sediment, sludge, oil, tissue and wipe samples for the measurement of mercury by atomic absorption cold vapor technique following SW-846 7471A or 7471B protocol. If this dissolution procedure is not sufficient to dissolve a specific matrix type or sample, then this method is not applicable for that matrix. Samples that require additional homogenization are addressed on a case-by-case basis and homogenized by the Sample Support Group (Department 6055).

## Basic Principles

Soil and solid samples are mixed and aliquoted during soil sample splitting by Sample Administration staff or by metals staff. Full homogenization must be requested additionally by clients.

Samples are digested with aqua regia and potassium permanganate to oxidize mercury compounds to mercuric ions and eliminate possible interference from sulfide. Samples high in chlorides require additional permanganate. At the time of analysis, excess permanganate is reduced with sodium chloride/hydroxylamine hydrochloride. Mercuric ions are reduced to mercury metal using stannous chloride. Mercury measurement is performed using mercury cold vapor technique.

## Reference Modifications

To increase efficiency, polypropylene containers are used in place of BOD bottles. Prior to analysis (after excess potassium permanganate is reduced with sodium chloride/hydroxylamine hydrochloride solution) samples are adjusted to 100 mL in volumetric flasks. This allows aliquots to be taken as required for analysis; aliquots cannot be taken when BOD bottles are used. No impact on the quality of the data generated using this modification has been observed.

## Interferences

Not applicable to this procedure.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Preparing samples for inorganic analysis involves working with concentrated acids and other chemicals which are dangerous if not handled carefully:

**Nitric acid ($HNO_3$)** – This acid can cause skin burns. Add nitric acid to samples in a hood or use the designated dispensing equipment to avoid exposure to toxic fumes.

**Hydrochloric acid (HCl)** – This acid can cause skin burns. Never mix HCl with concentrated $H_2SO_4$ to avoid a violent reaction. Always use in a fume hood or use the designated dispensing equipment.

When diluting strong acids, never add water to acid; always add acid to water.

Store concentrated acids in the prep room acid lockers. Only acids are to be stored in these lockers. (Store solvents in the flammable liquid storage cabinet.) Some concentrated acids are kept in the acid reagent bottles on prep room counters. Fill reagent bottles in an operating fume hood using caution to avoid spills.

Perform acid digestions in hoods that are turned on and have active alarms. Notify a supervisor immediately if the hood is malfunctioning or the alarm sounds.

Samples that contain dust may be hazardous. Open in a fume hood.

When a hazardous flag is added indicating possible cyanide, special precautions are required to avoid exposure to hydrogen cyanide gas. Contact your supervisor prior to adding acid. Always open these samples and add the acid in a hood.

Use spill pillows to absorb large acid spills. (Small spills are cleaned with wet paper towels.) Use SPILL-X-A powder or equivalent to neutralize any remaining acid and then rinse the area thoroughly with water. Spill pillows and SPILL-X-A are stored on the prep room shelf.

Dispose of acid waste properly. Collect all acid digestions, waste solutions, and expired reagent solutions in waste containers. When the acid waste containers are full, a designated acid waste handler transfers the waste to the acid neutralization tank.

### Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each employee performing this digestion procedure must work with an experienced employee for a period of time until they can independently set up batches and perform the necessary steps outlined in this procedure.

The IDOC consists of aliquots spiked at 1-4X the RL that are carried through all steps of the prep and analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy of 50 - 150% and standard deviation of </= 20%.

Various options are available for a DOC and can include four laboratory control samples (LCS) or one blind sample. The mean recovery of four LCSs must meet the accuracy criteria of an LCS, and the standard deviation must be </= 20% .

### Sample Collection, Preservation, and Handling

Samples are collected in either glass or plastic containers with no preservatives. They must be stored at 0° to 6°C, not frozen and digested and analyzed within 28 days of collection.

Digested samples are stored in plastic containers at room temperature. Store samples, standards, and digested samples separately.

### Apparatus and Equipment

1. Polypropylene containers (digestion vessels) - Certified clean and Class A equivalent
2. Balance, capable of reading 0.1 mg
3. Polypropylene covers, (digestion vessel covers)
4. Chemware Ultra-Pure PTFE boiling stones, or equivalent
5. Environmental Express HotBlock (block digestor), adjustable and capable of maintaining a temperature of 95° ± 1°C

### Reagents and Standards

A. Store all prepared standards and reagents in glass or polyethylene bottles at room temperature. Label the bottle with the solution name, lot number, date prepared, the expiration date, the initials of the person preparing the solution, and the storage conditions.

B. Standard/ spiking concentration and reagent vendors are subject to change without notification.

C. Reagents - Follow manufacturer's storage conditions and expiration date. If no expiration date is provided, re-evaluate annually or set a one year expiration date. Use the following or equivalent:

1. Hydrochloric acid, 36.5% to 38.0% HCl, JT Baker Trace Metal Grade reagent
2. Nitric acid, 70.0% to 71.0% $HNO_3$, JT Baker. Trace Metal Grade reagent

3. Potassium permanganate, $KMNO_4$, Fisher or equivalent. Certified ACS.

4. Sodium chloride, NaCl, J.T. Baker or equivalent. Certified ACS.

5. Hydroxylamine hydrochloride, $NH_2OH{\cdot}HCl$, J.T. Baker or equivalent. Certified ACS.

6. 1000 mg/L Hg standard solution, Inorganic Ventures or equivalent.

D. Working instructions for the preparation of mercury solutions and standards are contained within *T-MET-WI9084*. This form includes shelf life and storage conditions.

1. Hg intermediate standard (10 mg/L).

2. Hg intermediate standard (1.0 mg/L).

3. 40 ppb Hg Water Standard.

4. 100 ppb Hg Soil Standard.

5. Potassium permanganate solution (5%).

6. Aqua regia.

7. Sodium chloride/hydroxylamine hydrochloride solution.

E. Adjust all additions according to final solution volume if larger or smaller volumes are needed. Thoroughly mix the solution after diluting to volume.

### Calibration
Not applicable to this procedure.

### Block Digestor Instructions
1. Turn block digestor on by pressing rocker switch located on the cord.

2. Wait about 8 seconds until controller display indicates current block temperature.

3. Press and hold STAR (*) key.

4. The display shows the Set Point Temperature.

5. The digits can be changed to the desired value by pressing the up and down arrow keys while holding the (*) key.

6. Confirm Control Point temperature is set to the block temperature that provides 95° ± 1°C sample temperature.

**NOTE:** See HotBlock Control Point Temperature Logbook to obtain control point temperature setting for the HotBlock being used for digestion. If necessary, adjust Control Point temperature to the proper setting.

### Procedure

1. Turn block digestor on and allow block to reach the Control Point setting that provides 95° ± 1°C sample temperature.

   Note: Soil samples for metals typically go through soil splitting. Mixing and aliquoting is performed in soil splitting, and splits are delivered to the metals preparation laboratory in the digestate tube. Solids are mixed. Full homogenization must be requested additionally by the client.

   Note: For 7471A/B_Prep weigh 0.6-0.65 g
   For 7471B_Prep_2X weigh 1.2 - 1.3

1. Collect samples and batch from the split bins. If a sample is not located in a split bin, weigh three aliquots, taken from three different areas of a well-mixed, as-received sample into a polypropylene digestion vessel according to the prep method.

2. Add an amount of Chemware Ultra-Pure PTFE boiling stones to the vessel for the MB and LCS according to the prep method.

3. Enter the MB weight as 0.6 or 1.2 depending on the prep with final volume of 100 mL and the LCS weight as 0.6 or 1.2 depending on the prep with final volume 100 mL in the LIMS. In the notes section, record the actual weight in grams of boiling stones used.

4. Matrix exceptions:

    a. Samples with a liquid consistency: increase weight to 1 g (1.00 to 1.05 g).

    b. Oil samples: weigh 0.2000 g to 0.2500 g (to the nearest 0.0001 g) of sample and add 0.2000 g to 0.2499 g of Teflon Chips to the MB and LCS container. Enter the blank weight as 0.2000 to 100.0000 final volume, and the LCS weight as 0.2000 to 100.0000 final volume in LIMS.

    c. Wipes: one blank media each must be used for the batch MB, the LCS, and the LCSD. Use reagent water to rinse any particulate matter from the wipe container into the vessel containing the wipe before digesting. Digest wipes in their own batch. Enter as "1 wipe" into prep batch.

    d. Tissue samples: spike the LCS, LCSD in the same manner as the matrix spike and matrix spike duplicate (Refer to *T-MET-WI9084*). Digest tissue samples in their own batch.

5. For sample batch quality control preparation, spiking procedures and concentration levels see *T-MET-WI9084*.

6. All spiking must be performed prior to starting the digestion procedure.

7. Add about 5 mL reagent water and about 5 mL of aqua regia solution.

8. Place sample containers in block digestor, bring to 95°C ± 1°C and heat approximately 2 minutes. (Place a calibrated thermometer in batch blank container.)

9. Remove sample containers from block and allow to cool.

10. Add 50 mL of reagent water and 15 mL of 5% $KMnO_4$ solution and mix by carefully swirling the container.

    a. Add additional portions of 5% $KMnO_4$ solution (in 5-mL increments, up to as much as 25 mL), if necessary, until the purple color persists for at least 15 minutes.

    b. Add the same amount of $KMnO_4$ solution to entire digestion batch.

    c. If the maximum amount of 25 mL of 5% $KMnO_4$ solution was added and the purple color did not persist for at least 15 minutes, then contact group leader, further dilutions are required. A comment must be placed on the batch sheet documenting the reason for the dilution.

11. Transfer sample containers to block digestor.

12. Place a calibrated thermometer in batch blank container.

13. Put a polypropylene cover on each container.

14. When the thermometer indicates 95° ± 1°C, continue heating for 30 minutes.

15. Remove sample containers from digestion block and allow to cool.

16. Add 6 mL of sodium chloride/hydroxylamine hydrochloride solution to reduce excess permanganate. Adjust volume to the 100 mL mark with reagent water, seal container with screw cap and mix.

17. The sample is now ready for analysis.

## Calculations
Not applicable to this procedure.

## Statistical Information/Method Performance
Not applicable to this procedure.

## Quality Assurance/Quality Control

Each digestion batch (up to 20 samples) must contain a method blank (MB), LCS, and either an unspiked background sample, duplicate (DU), matrix spike (MS), matrix spike duplicate (MSD) or an LCS/LCSD.

Refer to *T-MET-WI7965* for sample batch quality control requirements, acceptance criteria, and corrective action.

4. Astroia 2 Analyzer Operation Manual, Astoria-Pacific, Revised 5/16

5. *Chemical Hygiene Plan*, Lancaster Laboratories, current version.

## Purpose

The purpose of this SOP is to provide a guideline for the proper maintenance of the continuous flow analyzers. Proper maintenance and calibration are essential for extending the life of the instrument as well as keeping the instrument running appropriately.

## Scope

This maintenance procedure covers the upkeep of all components of the autoanalyzer system.

## Personnel Training and Qualifications

Analysts are considered proficient when they documentation of reading, understanding and agreeing to follow the most current version of this SOP.

## safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.

Dispose of acids in appropriate acid waste container.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

## Procedure

As needed maintenance:

1. Clean the sample probe (by flushing a syringe full of deionized water through it).

2. Replace pump tubes approximately every 160 to 200 hours or 20 to 30 runs. Replace all pump tubes associated with the analysis simultaneously.

3. Rinse flowcell and debubbler with methanol.

4. If buildup is noticed in the block or if the flow becomes erratic flush the system with 20% ChemSolv for 10-15 minutes, followed by 20 minutes of DI water.
5. Clean systems by pumping with 5N $H_2SO_4$, 1N NaOH, and/or 30% $H_2O_2$, followed by deionized water.

6. Periodically flush the sampler wash reservoir with 1N HCl to prevent the growth of algae or bacteria. A solution of 1 part sodium hypochlorite (household bleach) mixed with 19 parts of water can also be used. Flush thoroughly with deionized water.

7. Wipe platens and pump rollers with methanol. If pump seems to be rolling unevenly, or is making noise when rolling, send to instrument maintenance technician for a thorough cleaning.

8. Wipe down all exterior parts of instrument after each run. Immediately clean up any spills.

9. Refer to the detector instruction manual for the proper procedure to replace/clean any parts excluding the pump tubing.

**NOTE:** Document performance of maintenance in the appropriate logbook.

| *QA-SOP11188* | Reagents and Standards |
| *T-WC-WI11519* | pH Probes and Meters |

**Scope**

This Process is suitable for preparation of the cation exchange capacity of soils.

The procedure is a preparation for determination of displaced sodium concentration by method SW-846 6010

**Basic Principles**

A soil sample is mixed with an excess of sodium acetate solution, resulting in the exchange of the added sodium cations for the matrix cations. Subsequently, the sample is washed with isopropyl alcohol. An ammonium acetate solutions then added, which replaces the adsorbed sodium. The concentration of the displaced sodium is then determined by method SW-846 6010.

**Interferences**

Impurities in solvents, reagents, glassware, or other hardware used in sample processing lead to interferences. A method blank is performed with each batch of samples to demonstrate that the extraction system is free of contaminants

**Safety Precautions and Waste Handling**

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

**Personnel Training and Qualifications**

All Personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP.

Initially, each employee performing this digestion procedure must work with an experienced employee for a period of time until they can independently set up batches and perform the necessary steps outlined in this procedure

**Sample Collection, Preservation, and Handling**

Samples are collected in either plastic or glass and must be stored at 4 ± 2°C prior to extraction. Sample extraction must be started within 14 days of collection.

**Apparatus and Equipment**

1. 50mL centrifuge tubes
2. Analytical Balance
3. pH Meter
4. Orbital Shaker
5. Vortex
6. Centrifuge
7. Glassware - General Laboratory Glassware

**Reagents and Standards**

**NOTE:** All chemicals used be ACS reagent grade unless otherwise noted

Different volumes or weights may be used provided the ratios remain equivalent.
See *QA-SOP11188* for the appropriate labeling and documentation of reagent and standard preparation.

1. Glacial Acetic acid –Fisher chemical or equivalent. Store at room temperature in a glass bottle. Follow manufacture guide for expiration time.

2. 10N sodium Hydroxide - Fisher chemical or equivalent. Store at room temperature in a plastic bottle. Follow manufacture guide for expiration time.

3. 1.0N Sodium Acetate –
   a. Weigh out 136g of sodium acetate into a 1-L Class-A volumetric flask containing 500mL of reagent water.
   b. Mix thoroughly and bring to volume with reagent water.
   c. Measure the pH of the solution, the pH must be 8.2 (±0.05). The solution can be adjusted using the acetic acid and/or sodium hydroxide from above.

4. 1.0N ammonium Acetate -
   a. Weigh out 154 g of ammonium acetate into a 2-L Class-A volumetric flask containing 100mL of reagent water.
   b. Mix thoroughly and bring to volume with reagent water.
   c. Solution is stable for 6 months at room temperature.

5. 99% Isopropyl Alcohol, ACE grade VWR part# BDH1133 or equivalent

**Calibration**
Not applicable to this procedure

**Procedure**

A. Weigh a 5 g aliquot of the soil sample into a tared 50-mL centrifuge tube.

B. Using a Class-A graduated cylinder add 30mL of 1.N sodium Acetate solution. Cap the tube, and shake on an orbital shaker for 5 minutes. Centrifuge the sample at 2000 PRM for 15 minutes or until the supernatant is clear. Decant and discard the liquid using care to not lose any of the soil sample. Repeat this step 3 more times.

C. Using a Class-A graduated cylinder add 30mL of 99% isopropyl alcohol. Cap the tube, and shake on an orbital shaker for 5 minutes. Centrifuge the sample at 2000 PRM for 15 minutes or until the supernatant is clear. Decant and discard the liquid using care to not lose any of the soil sample. Repeat this step 2 more times.

D. Using a Class-A graduated cylinder add 30mL of 1.0 N ammonia Acetate. Cap the tube, and shake on an orbital shaker for 5 minutes. Centrifuge the sample at 2000 PRM for 15 minutes or until the supernatant is clear. Decant the liquid into a 100mL volumetric flask labeled with the sample number, using care to not lose any of the soil sample. Repeat this step 2 more times, combining all three aliquots of each sample supernatant.

E. Dilute the combined ammonium acetate washings to 100mL using excess ammonium acetate solution.

F. Analyze the solution for sodium using method SW-846 6010.

**Calculations**
Calculation of Cation Exchange Capacity (CEC) in Meg/100qm

$$\frac{raw\ result\ (mg/L) \times volume\ used\ (L) \times .0437\ mequiv/mg}{g\ of\ wt.\ used} = final\ result\left(\frac{mequiv}{g}\right)$$

$$final\ result\left(\frac{mequiv}{g}\right) \times \frac{100}{100} = \frac{mequiv}{100\ g}$$

**Statistical Information/Method Performance**

Not applicable to this procedure. See analysis procedure *T-MET-WI11931* or *T-MET-WI11933*.

**Quality Assurance/Quality Control**

A method blank, sample duplicate is required per every batch of 20 samples. The Method Blank (MB) is prepared by weighing out approximately 5.0 g of glass beads that are processed in the same manner as the analytical samples.

**Figure 1**

## Scope

This procedure applies to analyses performed in the Metals department using Inductively Coupled Plasma (ICP) Atomic Emissions Spectroscopy for identification and quantitation of metallic constituents by Methods 6010B/C/D (aqueous, solid, tissue) and EPA 200.7 (aqueous).

The Reporting Limits (RLs) are based on annual statistical evaluation of laboratory data and are subject to change without notification. The current method detection limits (MDLs) and RLs are maintained in the laboratory information management system (LIMS).

This SOP also outlines the proper operation and maintenance of the ICP instrumentation and provides consistent guidelines for the evaluation of ICP data.

## Routine Methods

Elements routinely analyzed on the Thermo Scientific iCAP 6000 and 7000 Series Analyzers:

| Element | Wavelength (nm) |
|---|---|
| Ag | 328.06 |
| Al | 308.21 |
| As | 189.04 |
| B | 249.67 |
| Ba | 455.4 |
| Be | 313.04 |
| Ca | 317.93 |
| Cd | 226.5 |
| Co | 228.62 |
| Cr | 267.72 |
| Cu | 327.4 |
| Fe | 261.19 |
| K | 766.49 |
| Li | 670.78 |
| Mg | 285.21 |
| Mn | 257.61 |
| Mo | 202.03 |
| Na | 589.59 |
| Ni | 231.6 |
| P | 177.49 |
| Pb | 220.35 |
| S | 182.03 |
| Sb | 206.83 |
| Se | 196.09 |

| | |
|---|---|
| Si | 251.6 |
| Sn | 189.99 |
| Sr | 421.55 |
| Th | 401.913 |
| Ti | 334.94 |
| Tl | 190.86 |
| V | 292.4 |
| W | 207.911 |
| Zn | 213.86 |
| Zr | 339.19 |

## Basic Principles

If required, samples are digested with acids and heated to solubilize metals. Samples are received from the prep area in digestion vials.
After the analytical batch is prepared it is loaded onto the autosampler for trace metals analysis.

Samples are transported to a nebulizer via an autosampler and peristaltic pump. The nebulizer introduces an aerosol into a spray chamber; the resulting mist is then transported to an argon plasma torch where excitation of atoms occurs. Characteristic atomic-line emission spectra are produced by a radio-frequency (R.F.) inductively coupled plasma. The spectra are dispersed by a diffraction grating and the intensities of the light at each wavelength are monitored by a photosensitive device. The signals from the photosensitive device are processed by a computer. A background correction technique is required to compensate for variable background contribution to the spectra of trace elements.

## Interferences

Spectral interferences are caused by background emission, stray light from high concentration elements or overlap from a spectral line from another element. Spectral interferences are compensated for by the use of background points, alternate wavelengths and interelement corrections.

Physical and chemical interferences caused by the change in sample matrix affecting sample transport and/or nebulization must be compensated for by using internal standardization. Yttrium is used as the internal standard. Sample results are adjusted by the software using the intensity of Yttrium in the calibration blank and comparing it to the intensity of Yttrium in each sample and standard. Cesium is used as an ionization buffer that allows the ICP plasma to compensate for changes to the plasma excitation conditions.

Memory interference, or carryover, is the contribution of analyte signal from a previous sample onto the next sample analysis. Adequate rinse time of the autosampler tubing overcomes any memory interference.

## Safety Precautions and Waste Handling

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Preparing samples for inorganic analysis involves working with concentrated acids and other chemicals which are dangerous if not handled carefully:

**Nitric acid (HNO3)** – This acid can cause skin burns. Add nitric acid to samples in a hood to avoid exposure to toxic fumes.

**Hydrochloric acid (HCl)** – This acid can cause skin burns. Never mix HCI with concentrated H2SO4 to avoid a violent reaction. Always use in a fume hood.

When diluting strong acids, never add water to acid; always add acid to water.

Store concentrated acids in the prep room acid lockers. Only acids are to be stored in these lockers. (Store solvents in the flammable liquid storage cabinet.) Fill reagent bottles in an operating fume hood using caution to avoid spills.

Dispose of acid waste properly. Collect all acid digestions, waste solutions, and expired reagent solutions in waste containers. When the acid waste containers are full, a designated acid waste handler transfers the waste to the acid neutralization tank.

In case of spills contact the Emergency Response Team.

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each analyst performing the instrumental analysis must work with an experienced analyst for a period of time until they can independently calibrate the instrument, use the sequence editor to set up the run, perform calculations, interpret raw data, and enter data into the LIMS. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an IDOC (Initial Demonstration of Capability).

The IDOC consists of aliquots spiked at 1-4X the RL that are carried through all steps of the prep and analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy of 50 - 150% and standard deviation of </= 20%.

Arizona Drinking Water requires that each analyst perform an MDL study that consist of 7 spikes over 3 days.

Various options are available for a DOC and can include four laboratory control samples (LCS) or one blind sample. The mean recovery of four LCSs must meet the accuracy criteria of an LCS, and the standard deviation must be </= 20%.

## Sample Collection, Preservation, and Handling

A. Preservation and Holding time

1. All samples are typically shipped and stored at 0°to 6°C, not frozen, but room temperature is acceptable. Samples are analyzed within 6 months of collection.

2. Aqueous samples are collected in plastic or glass containers and are preserved to pH <2 with nitric acid. If samples are received > pH 2, they are preserved at the lab and held at least 24 hours until digestion. See *S-SS-WI10695*.

3. Drinking water samples are digested if the turbidity is > 1 NTU. See *S-SS-WI10695*.

4. Dissolved metals must be filtered within 15 minutes of sampling. If this is not done, the lab filters the samples of unpreserved bottles within 5 days of submission to the laboratory. Lab-filtered samples are preserved to pH <2 with nitric acid after filtration.

5. Solid samples are collected in glass containers with no chemical preservation.

6. Sample digestates are stored in plastic bottles at room temperature.

B. Sample Discard - The general practice in the metals group is to discard the digestions after all the required metals from a batch of samples have been analyzed and verified in the LIMS. Samples which require the digestate to be held for long term storage are periodically evaluated for discard.

## Apparatus and Equipment

The following is a list of the hardware and apparatus necessary for ICP analysis. More detailed hardware information is located in the *Operator's Manuals*.

1. 15-mL graduated polypropylene test tubes with caps (certified ±1%)

2. 10-mL sterile disposable syringes

3. syringe filters, PTFE, 0.45-µm

4. 30-mL polypropylene medicine cups

5. Calibrated hand-held pipettes and tips (10 – 5000 µL) - FisherBrand or equivalent.

6. Spectrometer - The Thermo Scientific iCAP™ 6000, 6500, and 7000 series Trace Analyzer utilizes a high performance solid state Charge Injection Device (CID) camera system to deliver high contrast/low noise imaging and quantification of all wavelengths in the analytical range. With the entire spectrometer and foreoptics purged with either Argon or Nitrogen, it features a 52.91 grooves/mm grating and dual-view detector.

7. Auto-sampler – The ESI SC-14 auto-sampler and integrated "FAST" system offer increased capacity and reduce sample introduction times. The parameters for each automated run are entered into the auto-sampler table in the iTEVA™ software as described in Instrument Operation, Section A of this SOP.

8. Coolflow –The ThermoFlex™ 900 cooling device for the iCAP™ 6000 series Trace Analyzer operates at 17°C.

9. Personal computer – The iCAP™ 6000 series Trace Analyzer is controlled by PCs.

## Reagents and Standards

Reagent and standard information and the preparation of the following standard and solutions are located in *T-MET-WI12063*:

Initial Calibration (ICAL)
Blank (ICIS) and Calibration Standard (STD1)
Initial Calibration Verification (ICV) standard
Continuing Calibration Verification (CCV) standard
Rinse/Carrier and Profile Solutions
Interference Check Solutions (ICSA and ICSAB)
Low Level Check (CRI) standards
Post Digestion Spike (PDS)
Serial Dilution (SD)
Linear Range Standards (LRC)
Initial Calibration Blank (ICB)
Continuing Calibration Blank (CCB)
Internal Standard Solution
Instrument Detection Limit (IDL) and MDL Solutions
Method Reporting Limit (MRL)

## Calibration

See T-MET-WI35797 for the frequency, acceptance criteria and corrective action of the ICAL, ICV, ICB, CRI, ICSA/ICSAB.

## Procedure

A. Setting up an ICP run sequence file

1. Determine the batches to be analyzed and determine any special requirements by viewing Batch notes and/or Comments that are with the batch paperwork delivered from the metals prep area.

2. Complete necessary pouring for the prep batch following Section B

   a. Batches with only field blanks or equipment blanks do not need a post-digest spike or a serial dilution.

   b. "As Received" samples must be run with a blank and LCS, LCSD (prepared and documented in the LIMs system by the analyst).

   NOTE: Arizona Drinking Water samples require the preparation and analysis of an MRL

3. Open run template following Instrument Operations Section 2.

4. Scan samples by digestate bottle into program.

5. When setting up a run, Batch QC must be placed in the same block of ten or fewer samples. If there are two LCSs, they must be placed one after the other. [The order of the batch QC is typically MB, LCS, (LCSD), BKG, PDS, DUP, MS, (MSD) and SD.]

NOTE: Arizona Drinking Water samples require the preparation and analysis of an MRL. MRL can be placed after the MB.

   a. ICV/ICB must be analyzed immediately after the calibration curve. (NOTE: 200.7 requires the analysis of 2 ICVs. The RSD of both ICVs must be <3%)

   b. CRI, ICSA, ICSAB, CCV, CCB must immediately follow the ICV/ICB.

   c. 6010D requires analysis of LRCs prior to beginning the analytical run

   c. CCV/CCB must be analyzed after every ten analytical samples.

   d. Additional QC are added per client requirements at the end of the run: CRI, ICSA, ICSAB.

   e. Any deviations from protocol must be noted in the LIMs system

6. Edit dilution factors (DF) and auto-sampler locations as needed.

7. Remove all unnecessary QC standards by selecting individual lines and clicking on the remove samples icon at the top of the screen.

8. Save the sequence file

B. Pouring ICP samples and QC samples

It is important to minimize any chance of contamination, both of yourself and the samples. Keep your hands and the work area clean at all times. Do not re-use any pipette tips.

Run QC standards are prepared separately, and kept in separate auto-sampler racks to be obtained at the time of analysis.

1. Use the prep paperwork to document the following information when pouring samples: initials, employee number, PDS lot number, test tube lot number, filter lot number(if applicable) and the date.

2. Carefully examine the batch to ensure there are no discrepancies between the Batch Preparation Sheet and the physical placement of samples in the batch.

3. Obtain and label all required test tubes, and place them in test tube racks.

4. Prepare and label the PDS required for each new batch (sample volume permitting).

    a. A PDS is prepared using 0.2 mL of a custom-ordered PDS solution into 9.8 mL of background sample.

        i. If sample volume is limited, reduce volumes but keep ratios equivalent (i.e. 0.1 mL PDS solution into 4.9 mL background sample.)

        ii. If the background sample must be diluted, add a reduced volume of background sample and bring to volume with the appropriate matrix.

5. Prepare a DF5 serial dilution(SD) of the background sample by pipetting 2 mL of background sample into 8 mL of the matrix solution.

    a. If the background sample chosen for serial dilution has been diluted due to matrix interference or to bring the concentration into the linear range of the instrument, the serial dilution must also be diluted by 5 times the dilution factor of the background (i.e., if Bkg = DF5, S.D. must = DF25).

6. If samples need to be filtered due to cloudiness or contain particulate, then the corresponding method blank (MB) and laboratory control sample (LCS) must be filtered.

    a. Filter using a 10-mL sterile disposable syringe fitted with a 0.45 µm PTFE syringe filter.

    b. Document lot of filters on the preparation batch sheet and mark each sample lid with an “F” to indicate that it was filtered.

7. Perform any additional spiking or dilutions and document on the preparation batch sheet

8. Cover the samples with lids or with plastic wrap to prevent contamination.

9. Place the poured batch on the bench top to await analysis, or return samples to their ICP sample storage location.

10. Take **NOTE** of the following:

    a. A PDS and a serial dilution (SD) must be performed on one sample in each digestion batch unless the batch contains only field blanks or equipment blanks.

b. Analysis information, including standard lot numbers, run number, method, analyst and date of analysis, are captured in the LIMs system

c. Documentation is of utmost importance. Double check all entries.

d. Dilute samples when necessary to yield a response that falls within the calibration range. When there are multiple analytes over range, only run a maximum of three tubes, the DF 1 if needed, the highest dilution required for the highest analyte, and a dilution in between.
Exception: If analytes are over range at a DF1, and the next dilution they are ND, take the data

e. If a batch requires re-analysis, it is acceptable to re-use dilutions and/or spiked samples that were prepared for the previous analysis. A "P" on the preparation batch sheet is used to indicate that a previously poured test tube is being re-used.

## Instrument Operations

A. iTEVA™ software: The Thermo Scientific iCAP instrument is operated through iTEVA™ software. From the Start menu, select "iTEVA™ Control Center" to start the software.

1. Plasma ignition

a. Open the plasma status window by clicking on the icon at the bottom of the screen.

b. Verify that all parameters are within acceptable range for ignition as indicated by a green light.

c. Ensure that the drain tubing for the spray chamber is properly connected to the peristaltic pump and positioned to drain into a waste carboy.

d. Select "Ignite plasma". After the plasma has ignited, the instrument automatically performs optimization of the nebulizer gas pressure, and then starts the on-board peristaltic pump.

e. If the plasma does not light, repeat steps b-d.

f. Once the plasma operating parameters have engaged, exit the Plasma status window by clicking on Close.

g. If the plasma has been off for more than 15 minutes let the instrument warm up for 30 minutes. If the plasma has been off less than 15 minutes, let the instrument warm up 5 to 10 minutes.2. Automated analysis using the iTEVA™ software

a. Open the Analyst window from the Control Center by clicking on the Analyst icon. When prompted, select the appropriate method.

b. In the Analyst window, click on the Sequence tab at the bottom of the screen.

c. From the Auto-session menu, select New Autosampler.

d. The "New automation-session" window opens.

e. Click on "New" to add a sequence and the "New sequence" window appears.

f. Click on the "Import from delimited text file" option and choose an appropriate template or previously prepared run sequence from the drop-down menu for the run to be entered.

g. Change the sequence name to reflect the run number, but do not change the method revision number in the parentheses.

h.Click OK at the bottom of the New Automation session window to continue.

i. The sequence template is loaded. When prompted in the import warning window, click OK to choose the populate the auto-sampler.

j. Right-click on the most recent auto-sampler session and select "Auto-locate All" to have autosampler positions automatically assigned.

k. Click on the "list view" icon and scan calibration information into the table using barcodes provided.

l. Scan client samples into table from digestate bottle to include sample number and hand enter the dilution factor if greater than a DF1.

m. Additional samples and QC are added using the "Add sample" and "Add QC" icons, respectively, at the top of the screen. Unused rows are removed by selecting the entire row(s) and using the "remove sample" icon at the top of the screen.

n. Verify that the sample list you entered into the autosampler sequence matches the samples loaded.

o. Carefully examine the batch to ensure there are no discrepancies between the preparation batch sheet, auto-sampler sequence table and the physical placement of samples in the batch.

p. Click on the "Run auto-session" icon to start the run sequence. If a run sequence is to be started at a sample or standard other than the initial calibration, open auto session run using the plus sign. Open the run and use the plus sign to open the required sample or standards. Right-click on the appropriate sample or standard and choose "Start Auto-Session Run at this Sample". Deselect the reslope (or Calibration option if running Multi Point Method) and QC, then click OK.

3. Running an AutoPeak in iTEVA™

a. In an open autosampler session (autosampler must be initialized), right-click on the location of the AutoPeak solution, and choose "Go to..."

b. Click on the Analysis tab to open the Analysis window.

c. From the Instrument menu, select Perform AutoPeak.

d. Click on All elements, then OK.

e. When prompted to aspirate the high standard ( STD1,ICV or CCV), click OK. The AutoPeak is now performed.

f. When the AutoPeak has finished, click on Done.

4. Manual analysis in iTEVA™

a. In an open autosampler session (autosampler must be initialized), add sample(s) to be analyzed to a new or existing sequence as detailed in section A.2 of this section.

b. To start analysis, right-click on the appropriate sample and choose "Start Auto-Session Run at this Sample" and elect not to run the "start actions."

c. When analysis is complete, results can be printed from the Analysis tab by right-clicking on the sample name and selecting "Print Sample…"

5. Performing an interelement correction (IEC) in iTEVA™

a. Prepare a solution of the interfering element at the linear range of the instrument. Perform manual analysis according to section A.4 of this section.

b. Note results of elements with a known interference that are greater than the limit of quantitation.

c. Divide the result of each interfered element by that of the interfering element. These values represent the amount the current IECs need to be adjusted.

d. In the Method window, click on Elements to expand the list of elements in the method.

e. Click on the targeted element to view the settings for that element.

f. Click on the IECs tab to view the current IECs for that element.

g. Add each calculated result to the correction factors currently in the first column corresponding to each pair of elements.

h. Enter the new correction factors in the table.

i. Repeat steps d-f as needed.

j. Click on the Save method icon to save the method.

k. For routine IECs that are completed every six months, an experienced analyst updates the LIMs database with the information provided by a calculated analytical run. For non-routine IECs the analyst must document changes in the instrument log book with updated information.

B. Import Analytical and Raw data into LIMs System

1. Within the "Analyst" tab of ITeva, right click on the calibration bracket and select export all samples.

2. Enter the most recent run number that was documented in the instrument laboratory data logbook.

3. Highlight the run number and type Control C on the keyboard.

4. Individually select all of the brackets that acquired after the cal, and export the file as listed above. The Control V function will paste the run number originally typed.

5. Make sure all brackets have been exported and in the proper order.

6. Once again right click on the calibration bracket and select "Print Selected Samples".

7. When the printer box opens, select "pdf Factory Pro" from the drop down list, then hit "OK".

8. Print all of the brackets that acquired after the calibration using the same steps listed above in steps 6 and 7.

9. Open the pdf Pro document that was created at the bottom of the screen. Click on the save tab then hit Control V again to populate the run number. Hit "Save".

10. Within the "Sequence" tab of ITeva, select the upper left hand box of the spreadsheet to highlight the entire sequence.

11. Press the Print Samples List Icon at the top of the screen, and select 'pdf Factory Pro" from the drop down list. Hit "OK".

12. Open the pdf Pro document, and select the save tab. Type Control V to enter the run number. Append "Runlog" to the end of the file name and hit "Save".

**NOTE: For DOD samples these steps must be taken**

a. Right click on run number and select edit report option

b. Select output mode to intensity ratio for unknowns as well as QC standards.

c. Right click on run number after and post process samples.

d. Export with same name used in step 2 with "RAW" at the end of the file

e. Do this for both the Calibration file and the Sample file.

13. Insert a Thumb Drive into the Instrument PC tower.

14. Locate the files you just created within the favorites tab, and copy all associated files onto the Thumb Drive.

15. Right Click on the external Thumb Drive and select "Eject".

16. Remove the Thumb Drive.

17. Insert the Thumb Drive into a PC with a network connection.

18. Locate the (\\corptalsapp19\410-ELLE-RawData\Metals) folder. Copy the export "txt" file from the Thumb Drive and paste it to the correct instrument folder.

19. Copy the samples pdf, runlog pdf, and DOD raw data pdf files from the Thumb Drive and paste them into the correct instrument raw data folder on the public drive.

20. Once the pdfs have been copied to the public drive, copy the sample pdfs to your mapped personal folder. If the run included DOD samples, copy the "Raw" sample pdfs to this folder as well.

21. Open the LIMS and select Analyst - Analyst Desktop II.

22. Expand the Equipment Tab in the upper left of the screen, and scroll down to find the correct instrument folder.

23. Expand the Instrument folder and select the top folder from the list. This will open the file in analyst desktop.

24. Hit the edit button at the top of the screen. When asked if you want to process the samples , select "No".

25. Hit the Reagent Tab at the bottom of the screen.

26.Rename the "S0" that acquired at the beginning of the run as "ICIS".

27. Rename the "S1" as "STD1".

28. Locate the tab called MT_IJ_RINSE at the top of the screen. Enter "#" for the matrix rinses that acquired before the calibration and for the "ICIS".

29. Locate the Enter/Scan New Reagent box at the bottom of the screen. Type the correct LIMS Lot # for the "S1" standard used.

30. Once added, the "S1" standard will appear as one of the reagent tabs across the top of the screen.

31. Locate the "S1" tab and enter a "#" into the associated box.

32. Type the current "PDS" or Post Digestion Spike reagent into the New Reagent box at the bottom of the screen.

33. Locate the "PDS" tab that was created, and enter 0.2 into the amount column for all associated post digestion spikes.

34. Select the Worksheet tab at the bottom of the screen. Enter 10 ml as the final amount for all associated post digestion spikes.

35. Go to the "Docs" tab at the top of the screen. Right click within the box and select "Add New Document". Navigate to your personal folder and locate the raw data file from the run. Select them and hit "OK" to add them to the analyst desktop batch.

36. Right click anywhere within Analyst Desktop and select " View Batch Information". Populate this box with the correct Lot numbers used to prep/run the samples. Add your name to the Analyst Tab in the top right of the date box and hit "OK".

37. Press "F6" on the keyboard to process all of the samples in the run.

38. Save the Analyst Desktop Batch.

## Routine Maintenance for the ICAP™ 6000 Duo Analyzer

A. Sample introduction system removal and cleaning: Remove and clean the sample introduction system when instrument performance declines (See **Figure 1**). Any adjustment to an instrument (replacement of parts, etc.) must be documented in the appropriate instrument logbook.

1. Turn plasma off and let instrument cool for approximately 5 to 10 minutes.

2. Remove spray chamber and nebulizer.

    a. Unclamp spray chamber from spray chamber adapter by gently squeezing clamp with one hand while supporting the spray chamber with the other hand.

    b. Gently remove the nebulizer from the spray chamber by pulling it out.

    c. Disconnect the argon and sample tubing from the nebulizer by pinching the Luer lock and pulling the tubing off the nebulizer.

    d. Remove the drain tubing from the spray chamber.

3. Prepare ultrasonic bath. Make sure the bath is at least ½ full with clean reagent water.

4. Clean radial cup
    a. remove gently from box by wiggling back and forth

    b. place radial cup in medicine cup and fill inside radial cup and medicine cup with matrix rinse or 1:1 HCL

    c. allow it to soak for approximately 10 minutes and then rinse off with reagent water

    d. dry radial cup and place back in torch box prior to reconnecting the torch

5. Clean torch, injector tip, and nebulizer.

    a. Invert the torch with tip assembly in a 250-mL vacuum flask of 50% HCl and place in the sonicator for approximatley 10 minutes. After sonication, rinse the torch with reagent water. (Be careful not to get a lot of water down into the base of the torch.) Carefully dry the torch with a paper towel.

    b. For a plastic nebulizer, use a syringe to force the 50% HCl solution through the nebulizer to clean and/or remove any clogs.

    c. Clean the spray chamber by filling with 50% HCL letting sit for approximately 5 minutes and then rinsing with reagent water.

6. Removal and disassemble the torch and tip if dirty or damaged ( cracked,melted,ect)

    a. Gently pull the spray chamber adapter out of the torch assembly.

    b. Unlock the torch assembly by turning it clockwise and remove it from the instrument.

    c. Turn the injector tip assembly counter clockwise to separate it from the torch housing.

    d. Gently pull the center tube out of housing to clean.

    **Note: If the torch and tip is disassembled a torch alignment must be performed before an ICAL is ran**

B. Reassemble the sample introduction system: (See **Figure 1**)

1. Torch.

    a. Inspect The o-rings on the metal torch mount and replaced if any wear or damage is visible.

    b. Push on the quartz torch to ensure that it is firmly seated in the housing assembly

    c. The circular "target" design on the torch **MUST** align with the circular notch on the torch mount.

    d. Make sure the tip is fully inserted into the center tube holder.

    e. Mount the torch assembly back into the instrument by inserting it straight through the torch hole and coil, being careful not to disturb the quartz bonnet above the radial view lens.

    f. Turn the assembly counter-clockwise to lock it into position.

    g. Gently push the spray chamber adapter into the back of the center tube assembly.

2. Reassemble the spray chamber and nebulizer.

a. Reattach the drain tube to the spray chamber.

b. With a twisting motion, insert the nebulizer into the spray chamber so that the collar is a tight fit.

c. Attach the sample and nebulizer gas tubing to the nebulizer.

d. Clamp the spray chamber to the spray chamber adapter.

3. Ignite the plasma.

C. Changing the pump tubing: Change pump tubing on the peristaltic pump when routine maintenance is performed or when the tubing shows wear. Inspect all tubing to insure that it is secure and in good condition.

D. Documentation for instrument/analysis tag out and return to service.

**NOTE:** The following information is taken from QA-SOP11901: In the event of an equipment failure, the following must be performed:

1. Document the nature of the failure in the maintenance logbook

2. Document how and when the defect was discovered

3. Notification of supervisor or responsible person who can decide on appropriate action to take

4. The instrument must be clearly tagged as *Out of Service*. The tag must contain the following information:

a. Date taken out of service

b. Employee who took the instrument out of service

c. Reason for tagout

Form Q-EQA-FRM6871is used for "tagging out".

5. The date taken out of service and the date returned to service must be documented in the maintenance logbook.

6. Document any corrective action that was taken to bring the equipment back into service.

7. Results of the corrective action (i.e., system calibration within specifications, etc.)

8. Supervisory personnel must perform a documented evaluation and review of instrumentation/equipment where a major or uncommon failure has occurred to assess the potential impact the failure could have on the calibration and/or qualification of the instrument. This is done on a case-by-case basis.

9. After repair, document whether the function has been fixed. Then determine if calibration or verification activities need to be performed before the instrumentation is put back into service.

## Calculations

1. Final Result

a. Water sample (mg/L)

$$\text{Instrument Reading} \times \frac{\text{Dilution Volume}}{\text{Aliquot Volume}} \times \frac{\text{Final Volume}}{\text{Sample Volume}}$$

b. Solid sample (mg/kg)

$$\text{Instrument Reading} \times \frac{\text{Dilution Volume}}{\text{Aliquot Volume}} \times \frac{\text{Final Volume}}{\text{Sample Weight (grams)}}$$

2. Relative percent different (RPD)

$$RPD = \frac{S - D}{(S + D)/2} \times 100$$

**Where:**

S = first sample value

D = duplicate sample value

3. Spike recovery

$$\%\ Recovery = \frac{SSR - SR}{SA} \times 100$$

**Where:**

SSR = spiked sample result

SR = sample result

SA = spike added

4. Correlation Coefficient

$$r = \frac{\sum XY - \frac{\sum X \sum Y}{N}}{\sqrt{\left(\sum X^2 - \frac{(\sum X)^2}{N}\right)\left(\sum Y^2 - \frac{(\sum Y)^2}{N}\right)}}$$

**Where :**

X = the known concentration

Y = the instrument response

N = the total number of data points

5. Serial Dilution

$$\%\ Difference = \frac{(5 \times SDR) - SR}{SR} \times 100$$

**Where:**

SDR = serial dilution result

SR = sample result

6. Total Hardness Calculation (SM2340B), Standard Methods 2340B-2011. The calcium result (mg/l) is multiplied by a factor of 2.497, the magnesium result is multiplied by a factor of 4.118, and the two values are added together for the hardness result.

7. Trivalent Chromium (7199_CR3) water and soils. Calculation is performed by subtracting hexavalent chromium from total chromium.

8. Ferric Iron (3500_F+3_B_Calc) is calculated by subtracting ferrous iron from the total iron.

## Statistical Information/Method Performance

Generate MDLs and RLs according to *QA-SOP11892*. Perform an MDL study on each instrument used for the analysis. Determine the MDL by taking seven spiked replicates through the entire digestion and analysis procedure. Compare and pool results to determine the final reporting MDL. The department supervisor maintains annual study data. The department supervisor requests that a Quality Assurance Specialist update to the LIMS as needed. Update the department database via a download from the LIMS.

QC acceptance limits (MS, MSD, LCS and LCSD) are established as statistical limits (see *QA-SOP11896* for guidance). Limits are evaluated every 6 months by the department and updated in LIMS by QA as directed by the department supervisor.

## Quality Assurance/Quality Control

A. For 6010B, 6010C, and 6010D each digestion batch (up to 20 samples) must contain a method blank (MB), LCS, unspiked sample (BKG), Duplicate (DUP), MS, and MSD. If there is not sufficient sample or per client requirement and LCSD is included.

B. For 200.7, each digestion batch (up to 10 samples) must contain a MB, LCS, BKG, DUP, and MS. If there is not sufficient sample or per client requirement and LCSD is included.

NOTE: Arizona Drinking Water samples require the preparation and analysis of an MRL.

C. Batch Quality Control - For the preparation and concentrations see *T-MET-WI12063* and for the frequency, acceptance criteria and corrective action see SOP T-MET-WI35797.

D. Data Quality Checks

1) For SPLP and TCLP samples, an MSA (method of standard additions, EPA 1311 section 8.4.2, EPA 1312 section 8.4.2) is required if:

a. The sample concentration falls between 80% to 100% of the regulatory limits, AND

b. The SPLP or TCLP Matrix Spike (QA) recovers < 50%.

2) For all EW samples (samples from public drinking water sources); check the results against the MCL (maximum contaminant level). If an analyte **exceeds** the MCL, notify a verifier at once. An automated email is sent to the Client Service Representative and the state for the analytes listed in QA-SOP11886. Suppliers must be notified within 24 hours.

F. When raw data checks are complete, check the following:

1. All samples requiring reread/redigestion are listed on the reread/redigestion schedule forms. Any dilutions required have been calculated correctly and added to the reread/redigestion form. Specific instrument has been noted for client requirements if necessary.

2. Data for samples following Good Laboratory Practices (GLP) must be retained as permanent storage.

G. Instrument detection limits are performed when an instruments detector is changed or a new instrument is added to the lab. Method detection limits (MDLs) follow guidelines in SOP ***QA-SOP11892***. Inter-Element Correction factors (IECs) are checked routinely every 6 months for each analytical instrument. Linear ranges are verified semi-annually.

H. For data review reference SOP T-MET-WI35797

## Appendix I

Definitions and explanations of the codes and symbols used on the raw data

A. Sample table information

1. The run number.

2. The page number.

3. The tube number.

4. The sample number.

5. The first and second of four asterisks denote whether the sample is a background (U*), duplicate (D*), spike (R*), MSD (M*), post-digestion spike (UP), serial dilution (UL), or not a QC sample (**).

6. The weight to volume or volume to volume digestion ratio, consisting of the initial quantity of sample used and the final digest volume.

7. The dilution factor – Indicating if the digest solution was diluted prior to analysis. An undiluted sample is labeled DF1.

8. Digestion batch number – Assigned when designated samples are scheduled for preparation, this number is used to track samples and QC prepared together.

9. The protocol by which the data is reviewed (SW-846, EPA-600).

10. Date and time of the sample injection into the instrument.

11. The ICAP identification number.

B. The ICP scans all of the method elements simultaneously during the analysis. The QC review lists all the samples on the run. The QC review lists elements verified, good phantom, and elements/phantom that are bad (need to be reread for run or batch QC). The reviewer or verifier documents on the QC review if any element(s)/sample(s) were selected/deselected.

C. The following are error codes in the iTEVA™ software.

1. S = Saturation – The concentration of the element is more than the detector can quantify.

2. K = The Elements Affected by a Saturated Element – The concentration listed is not accurate, and a more accurate result can be obtained by running the sample at a dilution.

D. Along with the average concentration (in ppm), the average intensity, %RSD and all three replicates are shown for each analyte. Internal standard values are intensities (cts/s).

Not applicable

**Purpose**

The purpose of this SOP is to describe the proper technique to perform the preparation of soil samples for low and high concentration volatile analysis when submitted in a coring device.

**Scope**

This SOP covers the preparation of vials used when preparing soil samples for low and high concentration volatile analysis. It also covers preparing soil samples that have been collected in a coring device for analysis, such as the Encore™ sampler.

**Basic Principles**

The sample is collected in a coring device (Encore™) and extruded into a pre-weighed volatile-free container and preserved within 48 hours of collection. The weight of the container, preservative, and soil is captured and the net weight of the sample is calculated and captured in the Volatile Preparation program in LIMS.

**Definitions**

Analyst Desktop - Reports that reside on the LIMS database. Using the Analyst Desktop application and moisture results pulled from LIMS, the report is populated and the calculations are performed to achieve a Final Extraction Volume to be used when necessary by the GC and GC/MS groups.

**Interferences**

Sample preparation must be performed in a volatile free environment to avoid contamination. Therefore, this process must be performed in one of the designated volatile free laboratories. It is possible for samples to become contaminated by diffusion of volatiles through the sample vial septum; a trip blank carried through sampling, storage and handling acts as a check for such contamination.

**Safety Precautions and Waste Handling**

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Methanol is flammable. Containers of this solvent must be kept away from any sources of open flames or sparks. Due to the potentially toxic nature of samples received from clients for analysis, safety precautions must be observed when handling samples. Safety glasses, lab coats, and gloves are required. Weighing of hazardous samples must always take place in a hood; see lab notes for further direction.

The solvents utilized in this procedure are disposed of in a solvent waste container which is transferred to a lab-wide disposal facility. Expired standards in methanol are disposed of as hazardous waste. Bulk sample containers and methanolic sample preparations are returned to the sample storage area for future disposal. Other wastes generated by Lancaster Labs are disposed of via incineration at EPA licensed facilities.

**Personnel Training and Qualifications**

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP which is maintained in the employee's training record.

The initial training consists of observing the procedure being carried out by an experienced analyst/technician. Next, the trainee performs the procedure while the experienced person watches, answers questions, and gives feedback. Following the initial training, experienced individuals are available as a resource until no longer required. Analysts are considered proficient when able to perform the procedure independently.

**Sample Collection, Preservation, and Handling**

Samples in either Encore™ sampling devices or jars used for the effervescence check must be refrigerated at 0° to 6°C, not frozen. (Jars used for collection must be glass with a PTFE-lined lid.) Samples must be preserved or frozen in reagent water at ≤-10°C within 48 hours of collection. See individual technical area SOPs for method specific hold times.

**Apparatus and Equipment**

It is acceptable to use alternate weights and volumes as long as the final concentrations remain the same.

1. 40-mL vials with stir bars, Teflon™-lined low-bleed septa, and screw caps. SciSpec Catalog #376740-MB or equivalent.

2. Encore™ sampler, or equivalent.

3. Pipette capable of dispensing up to 25 mL.

4. Analytical balance capable of weighing 0.01 g

5. Extruder tool for EnCore™ sampler.

6. Analyst Desktop Application - integrates a PC with a balance to collect data directly from the balance. It organizes the data, performs calculations (when required), and stores final results in the Laboratory Information Management System. This procedure must be used whenever possible to facilitate data transfers and other tracking; however, it is allowable to record data traditionally in a logbook if necessary.

**Reagents and Standards**
The methanol used must have been previously tested and approved for use by the labs.

1. Methanol – Purge and trap grade, store at room temperature and re-analyze yearly. The methanol used must have been previously tested and approved for use by the labs.

2. 8260A/B Surrogate Mix, Restek Catalog #30340 (2500 µg/mL) or equivalent. Store at ≤ -10° C for up to 1 year. This standard is used as is or diluted in methanol to a final concentration of 2.5 µg/mL. Diluted standard must be stored at ≤ -10°C for up to 6 months. This standard is used for the GC/MS analyses.

3. Custom a,a,a-trifluorotoluene (TFT), Restek Catalog #54357 (15,000 µg/mL) or equivalent. This standard is used as is or diluted in methanol to a final concentration of 750 µg/L. Store at ≤ -10°C for up to 30 days. This standard is used for the GC analyses.

4. Reagent water – water in which target analytes are not detected at or above the reporting limit for parameters of interest. In general, the deionized water supplied at the taps in the laboratory meets criteria. If the reagent water does not meet the requirements, see your supervisor for further instructions.

**Calibration**
Not applicable to this procedure

**Procedure**
A. Preparing vials

NOTE: Pre-purchased vials can be used for selected preps. Vials containing 5 mL of DI Water, and vials containing 5 mL of methanol are available for Encore preparations. The vials contain the initial tare

weight, vial lot number, and the preservative lot number. When using the pre-purchased vials the vial information must be added to the volatile prep application before performing any preparations.

1. Reagent water vials used in preparation for low concentration GC/MS prep method 5035LP Calc/8260.

a. Add 5 mL of reagent water to a clean 40-mL vial with a magnetic stir bar.

b. Seal the vial with a screw cap and septum seal. (Septum seal must be able to withstand an acidic solution—low bleed septum recommended).

2. Methanol vials used in preparation for high concentration GC/MS analysis prep method 5035A M Calc/8260.

a. Add required amount of methanol with 8260 surrogate (pre-made solution) to a clean 40-mL vial.

b. Seal the vial with a screw cap and septum seal.

c. Store at ≤ -10°C

3. Methanol vials used in preparation for high concentration GC prep method 5035A M Calc/8015.

a. Add required amount of methanol with TFT surrogate (pre-made solution) to a clean 40-mL vial.

b. Seal the vial with a screw cap and septum seal.

c. Store at 0° to 6°C, not frozen.

B. Preparing the sample

1. Samples are stored at 0° to 6°C, not frozen, prior to preparation.

2. Samples are removed from the refrigerator/cooler for preparation in small numbers to ensure that they remain cold.

3. Samples for low concentration analysis require three replicate collections.

a. Two replicates are prepared into reagent water.

b. One replicate is prepared into methanol as a back up in case we need to change to high level.

4. Samples for high concentration analysis only require one collection prepared into methanol.

5. The methanol vial must be prepared first to ensure at least one vial is available for each required solution.

6. Reagent vials

a. Weigh a prepared vial to the nearest 0.01 g. Capture the weight.

b. Extrude the sample from the sampling device into the vial and immediately recap the vial.

c. Weigh the vial which now contains the soil to the nearest 0.01 g and capture the weight.

d. The weight of the soil is determined by a calculation performed by the Analyst Desktop program based on subtracting the weight of the prepped vial from the weight of the vial with soil. Note in the comment section if the Encore™ sampling device is not properly sealed or if the device is not full causing a low weight. If the sample is prepped outside of the 48 hour hold time, create an NCM.

e. Record any unusual observations about the sample.

7. Methanol vials

a. Weigh a prepared vial to the nearest 0.01 g. Capture this weight.

b. Extrude the sample from the sampling device into the vial and immediately recap the vial.

c. Weigh the vial, which now contains the soil to the nearest 0.01 g, and capture this weight.

d. The weight of the soil is determined by a calculation performed by the Analyst Desktop program based on subtracting the weight of the prepped vial from the weight of the vial with soil. Note in the comment section if the Encore™ sampling device is not properly sealed or if the device is not full causing a low weight. If the sample is prepped outside of the 48 hour hold time, create and NCM.

e. Record any unusual observations about the sample.

C. Deliver sample to the labs

Once the samples are prepared into either methanol or frozen in reagent water, they must be transported to the laboratory that performs the analysis. Prescreen analysis is performed on the methanol vials before they are transported to the laboratory. Each department has a designated drop-off spot. Analysis is then performed per the methods of that department.

**Calculations**

Calculation of sample weight : Wn = Ws - Wf

**Where:**

Wf = weight of container + solution (first weight)

Ws = weight of container + solution + soil (second weight)

Wn = net weight of soil sample

**To Determine Final Extract Volume**

When there is no moisture value to consider, the Final Extract Volume = the preservation volume (mL) + MeOH added (mL).

When the moisture volume is to be considered, the Final Extract Volume = the preservative volume (mL) + MeOH added (mL) + the moisture volume (mL).

The moisture volume (mL) = weight (g) x (% moisture/100)

**Statistical Information/Method Performance**

Not applicable to this procedure.

**Quality Assurance/Quality Control**

The number of sampling devices requested from client services must include enough extra to serve as matrix QC for the volatile analyses requested. Generally, the low-level analysis requires a total of seven Encore™ sampling devices. Four are prepared: two for the unspiked sample, one for the matrix spike sample (MS), and one for the matrix spike duplicate sample (MSD). Three are prepared in methanol: one for the unspiked sample, one for the MS, and one for the MSD. Other numbers of sampling devices for matrix QC purposes are sent at the client's request.

All other QC samples such as the Laboratory Control Samples (LCS), Laboratory Control Sample Duplicates (LCSD), and method blanks are prepared and outlined in the individual technical areas SOPs.

The only surrogate addition performed under this procedure is for the high level containers as noted in Procedure A.3.a and A.4.a, are prepared and outlined in the individual technical areas SOPs.

Volatile Blanks (VB) are created for every 20 samples per reagent used. The preparation of HL lab blank consists of dispensing 5 mL of MeOH with surrogate spike (or equivilent volume used for samples) into a 40-mL screw-capped vial. These blanks are then stored with the associated samples and are analyzed by an analyst.

## Purpose

The purpose of this SOP is to outline how chromatographic data is interpreted in the pesticide residue group so that consistency between all analysts is ensured.

## Scope

This SOP applies to all pesticide, herbicide, PCB, and other analyses performed by GC and HPLC in Department 4024 with the exception of explosives. The explosives (Method 8330) are detailed in the individual methods. This SOP assumes that 1) the samples were run according to the appropriate method, 2) the data was checked for conformance to method criteria, and 3) the samples were analyzed on a calibrated run.

## Definitions

1. GC – Gas chromatography or gas chromatograph
2. HPLC – High performance liquid chromatography or chromatograph
3. LOQ – Limit of quantitation
4. MDL – Method detection limit
5. LIMS – Laboratory Information Management System
6. RPD – Relative percent difference (percent difference divided by the true value)
7. RSD – Relative standard deviation (standard deviation divided by the mean)
8. RT – Retention time
9. CCV- Continuing Calibration Verification
10. OOS- Out of specification
11. NCF - Nonconformance Form
12. NCM - Nonconformance Memo

## Personnel Training and Qualifications

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP.

Each analyst interpreting chromatography data must have documentation that they have read, understood and agree to follow this version of the SOP *T-PEST-WI9980* and the instrumental analysis and extraction methods associated with the data. They must go through several sets of data with an experienced analyst until they can independently determine surrogate and spike concentrations, perform all related calculations, understand and apply the appropriate LOQs and MDLs. They must learn to interpret data for single-component analyses over the course of several weeks, followed by interpretation of multi-component data such as PCBs. Proficiency is measured through verification of data, along with an Initial Demonstration of Capability study. Calculations must be done manually by the trainee and submitted for overchecking at least once for each type of equation used by the software programs. A Demonstration of Capability is also done annually for an ongoing evaluation of proficiency.

## Procedure

A. The samples must be run under the following conditions before accurate data interpretation can be performed:

   1. The GC or HPLC must be set up according to the method specifications.
   2. The retention times on the GC or HPLC must be stable.

3. The data system must be calibrated for each target compound and the correct RT and RT search window must be established and entered into the calibration file for accurate and consistent compound identification.

B. Quality control samples

All blanks, LCS/LCSD, and MS/MSD must conform to the QC acceptance criteria.

C. Interpretation of chromatograms

1. The following items are recorded by Chrom peak review:

    a. Laboratory sample number, with any cleanup steps, reinjection, or re-extraction noted where applicable

    b. Sample code

    c. Date and time of injection

    d. Raw data file number

    e. Extraction information – Weights, volumes

    These items are automatically recorded if proper entry of this information into the sequence file was performed following *T-PEST-WI10020* prior to data acquisition.

2. Check the surrogate standard recovery, which is recorded in the LIMS. Any problems with the surrogate standard must be noted, such as diluted out or matrix related. If the surrogate is outside the acceptance limits, the corrective action must be followed.

3. The automated LIMS forms used during data interpretation are dependent on accurate entries in the sequence file, accurate calibration files, stable retention times, and correctly labeled quantitation reports. Therefore, they must be double-checked for accuracy against the raw data (chromatograms and quantitation reports).

    The automated forms do not replace the review of raw data by the analyst but are used to provide additional information to the analyst, to perform calculations, neatly summarize results and increase the speed and accuracy of data interpretation.

4. Procedure C.5. through C.10. outline the basic raw data review process.

5. Review the chromatograms for all columns and detectors used. The following items must be checked:

    a. The integration of each peak to ensure it is correct.

        (1) Use PeakReview in TALs to correct baseline problems.

        (2) The experience of the analyst is an important factor in determining when a baseline is drawn incorrectly.

6. With the help of the LIMS, review the chromatograms and determine if any presumptive peaks are present by checking the list of analytes reported in the quantitation report for each chromatogram.

    a. A presumptive peak is one that lies within the RT window of a compound or is close enough to the RT to interfere with the detection of that compound.

    b. The experience of the analyst weighs heavily in determining if a compound separates from an interfering peak. This decision depends on the size of the interference as well as the RT of the interference in relation to the expected RT of the compound of interest. Check peak widths to assist in determining overlapping peaks.

7. A compound is reported in a sample if a presumptive peak in the chromatogram lies inside the retention time window for that compound. For dual-column or dual-detector analyses, a peak must be present within the retention time window on both columns/detectors.

8. For single column analyses, if no presumptive peak is present, the normal LOQ can be reported.

    a. If the concentration is below the LOQ but above the MDL, flag the value with a J for estimated.

    b. If the concentration is below the MDL, flag the value as <MDL. This value is not reported to the client as a detected hit.

9. For dual-column (or dual detector) analyses, the following guidelines apply:

**SW-846 Methods 8151A (CCV ±15%)**

    a. No presumptive peaks are present which confirm on the second column, the normal LOQ can be reported.

        (1) Data reporting defaults to D1 unless there is a CCV OOS on D1, then would default to D2 assuming CCV is in spec and there are no coelutions on the in-spec column.

        (2) If compound not detected on one column, and the CCVs are in spec on that column, then would report as ND from that column.

        (3) If CCV oos high and no detections, would need to comment but no reinjection necessary.

    b. If a presumptive peak is present on both columns, evaluate the agreement between the concentrations. This is done by calculating the %RPD between the values as follows:

**% RPD = difference over the average of the two results x 100**

        (1) Data is reported from the high side (surrogates all data is reported) if %D is <40% D between the 2 columns when all CCV data is within the limits (15% no grand mean follow update V(8000D)).

        (2) If > 40%, the low side is reported when all CCV data is within the limits (15% no grand mean follow update V(8000D)). P flag is on at compound level

        (3) If %D is >100% a worst-case determination is made to raise limit above the low side.

        (4) If CCV fails high on one column, then the sample would need to be reinjected for detections. If reinjection cannot be done, then sample data requires an internal NCM and a comment on the report.

        (5) If CCV fails low on one column, then the sample would need to be reinjected for detections. If reinjection cannot be done, then sample data requires an internal NCM and a comment on the report.

        (6) If a surrogate is OOS for recovery a comment is always required on the report.

        (7) Project specific requirements would supersede the above listing.

**SW-846 Methods 8081B, 8082A, (CCVs ±20%)**

    c. No presumptive peaks are present which confirm on the second column, the normal LOQ can be reported.

        (1) Data reporting defaults to D1 unless there is a CCV OOS on D1, then would default to D2 assuming CCV is in spec and there are no coelutions on the in-spec column.

(2) If compound not detected on one column, and the CCVs are inspec on that column, then would report as ND from that column.

(3) If %D is >100% a worst-case determination is made to raise limit above the low side.

(4) If ccv oos high and no detections, would need to comment but no reinjection necessary.

d. If a presumptive peak is present on both columns, evaluate the agreement between the concentrations (%RPD).

(1) Data is reported from the high side (surrogates all data is reported) if %D is <40% RPD between the 2 columns when all CCV data is within the limits (20% no grand mean follow update V(8000D)).

(2) If >40%, the low side is reported when all CCV data is within the limits (20% no grand mean follow update V(8000D)). P flag is on at compound level.

(3) If CCV fails high on one column, then the sample would need to be reinjected for detections. If reinjection cannot be done, then sample data requires an internal NCM and a comment on the report.

(4) If CCV fails low on one column, then the sample would need to be reinjected for detections. If reinjection cannot be done, then sample data requires an internal NCM and a comment on the report.

(5) If a surrogate is OOS for recovery a comment is always required on the report.

(6) Project specific requirements would supersede the above listing

e. Review for the following co-elutions to ensure the correct analyte is reported.

(1) 2,4'-DDE and gamma-chlordane.

(2) 4,4'-DDD and Kepone.

(3) 2,4'-DDT and Endrin.

**Method 608.3 (both oc pest and pcbs)**

f. No presumptive peaks are present which confirm on the second column, the normal LOQ can be reported.

(1) Data reporting defaults to D1 unless there is a CCV OOS on D1, then would default to D2 assuming CCV is in spec and there are no coelutions on the inspec column.

(2) If compound not detected on one column, and the CCVs are inspec on that column, then would report as ND from that column.

(3) If ccv oos high and no detections, would need to comment but no reinjection necessary.

g. If a presumptive peak is present on both columns, evaluate the agreement between the concentrations (%RPD).

(1) data is reported from low side if %D is <50%. All surrogate data is reported.

(2) (we would rarely use this option) If %D is >50%, if the amounts do not agree, and the RT data indicate the presence of the analyte (per Section 14), it is likely that a positive interference is present on the column that yielded the higher result. That interference may be represented by a separate peak on the other column that does not coincide with the

retention time of any of the target analytes. If the interfering peak is evident on the other column, report the result from that column and advise the data user that the interference resulted in a %D value greater than 50%.

(3) (this is the preferred option) If an interference is not identifiable on the second column, then the results must be reported as "not detected" at the lower concentration (AKA worst-case). In this event, the pesticide is not confirmed and the reporting limit is elevated.

(4) If CCV is outside the criteria, reinjection must occur unless ND and OOS high, then can report with comment. All SS CCV must pass to report the data.

(5) If CCV fails high on one column, then the sample would need to be reinjected for detections. If reinjection cannot be done, then sample data requires an NCM and a comment on the report.

(6) If CCV fails low on one column, then the sample would need to be reinjected for detections. If reinjection cannot be done, then sample data requires an NCM and a comment on the report.

(7) Any OOS SS would require commenting on the report.

h. Review for the following co-elutions to ensure the correct analyte is reported for 608.3 Pest

(1) 2,4'-DDE and gamma-chlordane.

(2) 4,4'-DDD and Kepone.

(3) 2,4'-DDT and Endrin.

**Method 531.1**

i. If CCV out on primary(D1) must reinject.

j. If reporting from confirmation must do NCM and comment.

k. If EW or PW designation no QC may fail.

l. If WW designation (531.1) may do NCM and comment for failures if reinjection is not possible.

**Method 8011**

m. Data reports from the primary column(D1)

n. If CCV out on primary must reinject (unless OOS high no hits)

o. If CCV is outside the criteria, reinjection must occur unless ND and OOS high, then can report with comment. All SS CCV must pass to report the data.

p. Confirmation column must be in spec. If the primary column CCV's pass and no detection on the primary you could report as nd without reinjection for confirmation.

q. If reporting from confirmation must do NCM and comment.

**Method 8330B 8318A**

r. Report from primary

s. If CCV out on primary must reinject

t. If reporting from confirmation, must write NCM and comment

u. Co-Elution Exceptions:

(1) Explosive 8330A

Nitrobenzene/Tetryl coelutes on D1

(2) Explosive 8330B

4-Am2,6-DNT/Nitrobenzene coelutes on D2
HMX/2,6Diamino-4-Nitrotoluene coelutes on D2

10. The following situations must be evaluated by the analyst for all analyses:

a. A presumptive peak is present with a retention time just outside the RT window on the one column and just inside the window on the second column and the amounts are both above the LOQ.

(1) If the retention times during the run are stable, the compound should not be reported.

(2) The normal LOQ can be reported if the analyst feels there would be separation of the target compound from the interference. If separation is uncertain, a worst-case determination is made.

(3) However, the compound might be reported after the following parameters have been considered: the RT of the standards bracketing the sample injection, the history of the sample and site, the peak shape, the baseline where the peak eluted, and the possible coelution of matrix interferences. The experience of the analyst weighs heavily in deciding if the compound must be reported.

b. A presumptive peak is present on both columns but the retention time is outside the windows on both columns. Only in rare cases is a compound to be reported. The parameters listed above in Procedure C.10.a. must be evaluated. The normal LOQ can be reported if the analyst feels there would be separation of the target compound from the interference. If separation is uncertain, a worst-case determination is made.

11. The LIMS lists all the target analytes found on both columns, then summarize the results into a summary report as follows. However, how the data is evaluated may change based on client or project specific requirements.

a. If a target analyte is not detected or not detected on both columns, ND is placed on the summary section, but the MDL and LOQ must have a "<" symbol in front of their respective numbers.

b. If a target analyte is detected on both columns for SW-846, the LIMS configuration is set so that it places the highest value in the summary section, unless the RPD is >40%, then the lower value is listed.

c. If a target analyte is detected on both columns for 500 series, the LIMS configuration is set so that it places the value from the primary column in the summary section.

d. If a target analytes is detected on both columns for method 608/622, the LIMS configuration is set so that it places the lowest value in the summary section, unless the RPD between columns is greater than 100%. In this case the detection limit is raised to report a less than value (to a value above the lowest concentration detected) since there is significant uncertainty to the presence of the compound.

12. The LIMS also summarizes the result for each multicomponent compound in the calibration. Each peak used for quantitation is shown as well as averages, %RSD between peaks, and the RPD between the two columns on the final data.

D. Worst-case calculation

1. A worst-case calculation is performed using the peak height (area) of the interference in a sample (see Procedure C.7.), using the lower value for dual column data (provided the associated check standards meet specifications).

2. The value obtained is rounded off to the proper number of figures as if the number were to be reported based on the LOQ. An elevated LOQ and/or MDL are established at one figure higher than this value.

3. If the worst-case value is above the LOQ, then both the LOQ and MDL must be adjusted.

For example, if the worst-case value is 0.39 µg/L for the analyte and the LOQ is 0.1, the value is rounded to 0.4 µg/L and the LOQ and MDL are set at <0.5 µg/L.

4. By raising the LOQ and/or MDL, we tell the client that the most accurate determination we can make with the data for the sample is that the analyte is not present at 0.5 µg/L or above. Due to the interference present, we cannot be sure of concentrations below this amount.

5. These values are edited into the upload file prior to uploading to the LIMS. Care should be taken to edit only the MDL and/or LOQ fields as appropriate to the situation as outlined above.

6. An NCM must be added to the report stating that reporting limits were raised due to interference from the sample matrix.

## Table I

**Qualifiers:**

J = The compound was detected at an amount below the quantitation limit and is therefore an estimated value.

E = Peak response exceeds the calibration range – a dilution must be performed.

**Abbreviations:**

R = Designates that the data is from a repeated extraction.
DF = Dilution Factor – This is the amount that the extract was diluted by (i.e., a DF10 is a 10-fold dilution).
DO = Diluted Out
WC = Worst-Case – Denotes the actual value from the worst-case calculation.

ENVIRONMENTAL

Valid To: November 30, 2026 Certificate Number: 0001.01

In recognition of the successful completion of the A2LA evaluation process, (including an assessment of the laboratory's compliance with the 2016 TNI Environmental Testing Laboratory Standard, the requirements of the DoD Environmental Laboratory Accreditation Program (DoD ELAP) as detailed in version 6.0 of the DoD/DOE Quality Systems Manual for Environmental Laboratories, and the fifth edition of the Environmental Protection Agency's Manual for the Certification of Laboratories Analyzing Drinking Water), accreditation is granted to this laboratory to perform recognized EPA methods using the following testing technologies in the analyte categories identified below, and on the following matrices as applicable: Drinking Water, Bottled Water, Water as a Component of Food and Beverage, Non-Potable Water, Food and Feed, Aqueous and Solid Hazardous Waste, and Tissue.

Testing Technologies

Atomic Absorption/ICP-AES Spectrometry, ICP-MS Spectrometry, Gas Chromatography, Gas Chromatography/Mass Spectrometry (including Single Ion Monitoring (SIM), Isotope Dilution, and Triple-Quad), Gravimetry, High Performance Liquid Chromatography, Ion Chromatography, Misc.-Electronic Probes (pH, $F^-$, $O_2$), Oxygen Demand, Spectrophotometry (Visible), Spectrophotometry (Automated), Titrimetry, TCLP, Total Organic Carbon, Turbidity, Liquid Chromatography/Mass Spectrometry/Mass Spectrometry, High Resolution Gas Chromatography/Mass Spectrometry

# Accredited Laboratory

A2LA has accredited

## EUROFINS LANCASTER LABORATORIES ENVIRONMENT TESTING, LLC

*Lancaster, PA*

for technical competence in the field of

## Environmental Testing

In recognition of the successful completion of the A2LA evaluation process that includes an assessment of the laboratory's compliance with ISO/IEC 17025:2017, the 2016 TNI Environmental Testing Laboratory Standard, the requirements of the Department of Defense Environmental Laboratory Accreditation Program (DoD ELAP) as detailed in version 6.0 of the DoD/DOE Quality System Manual for Environmental Laboratories (QSM), the A2LA *R220 – Specific Requirements – A2LA DoD Environmental Laboratory Accreditation Program*, the A2LA *R206 – Specific Requirements – Environmental Testing Laboratory Accreditation Program*, the A2LA *R210 - Specific Requirements – Kentucky Underground Storage Tank Testing Laboratory Accreditation Program,* and the A2LA *R211 – Specific Requirements – Wyoming Storage Tank Remediation Testing Laboratory Accreditation Program,* accreditation is granted to this laboratory to perform recognized EPA methods as defined on the associated A2LA Environmental Scope of Accreditation. This accreditation demonstrates technical competence for this defined scope and the operation of a laboratory quality management system (refer to joint ISO-ILAC-IAF Communiqué dated *April 2017*).

Presented this 24th of October 2024.

Mr. Trace McInturff, Vice President, Accreditation Services
For the Accreditation Council
Certificate Number 0001.01
Valid to November 30, 2026

*For the tests to which this accreditation applies, please refer to the laboratory's Environmental Scope of Accreditation.*

SCOPE OF ACCREDITATION TO ISO/IEC 17025:2017

EUROFINS DENVER
4955 Yarrow Street
Arvada, CO 80002

ENVIRONMENTAL

Valid To: October 31, 2026 Certificate Number: 2907.01

In recognition of the successful completion of the A2LA evaluation process, (including an assessment of the laboratory's compliance with the 2016 TNI Environmental Testing Laboratory Standard, the requirements of the DoD Environmental Laboratory Accreditation Program (DoD ELAP), and the requirements of the Department of Energy Consolidated Audit Program (DOECAP) as detailed in version 6.0 of the DoD/DOE Quality Systems Manual for Environmental Laboratories), and for the test methods applicable to the Wyoming Storage Tank Remediation Laboratory Accreditation Program, accreditation is granted to this laboratory to perform recognized EPA methods using the following testing technologies and in the analyte categories identified below:

Testing Technologies

Atomic Absorption/ICP-AES Spectrometry, ICP/MS, Gas Chromatography, Gas Chromatography/Mass Spectrometry, Gravimetry, High Performance Liquid Chromatography, Liquid Chromatography/Mass Spectrometry, Ion Chromatography, Misc.- Electronic Probes (pH, $O_2$), Oxygen Demand, Hazardous Waste Characteristics Tests, Spectrophotometry (Visible), Spectrophotometry (Automated), Titrimetry, Total Organic Carbon, Total Organic Halide

# Accredited Laboratory

A2LA has accredited

## EUROFINS TESTAMERICA DENVER

*Arvada, CO*

for technical competence in the field of

### Environmental Testing

In recognition of the successful completion of the A2LA evaluation process that includes an assessment of the laboratory's compliance with ISO/IEC 17025:2017, the 2016 TNI Environmental Testing Laboratory Standard, the requirements of the Department of Defense Environmental Laboratory Accreditation Program (DoD ELAP), and the requirements of the Department of Energy Consolidated Audit Program (DOECAP) as detailed in version 6.0 of the DoD/DOE Quality System Manual for Environmental Laboratories (QSM), accreditation is granted to this laboratory to perform recognized EPA methods as defined on the associated A2LA Environmental Scope of Accreditation. This accreditation demonstrates technical competence for this defined scope and the operation of a laboratory quality management system (refer to joint ISO-ILAC-IAF Communiqué dated April 2017).

Presented this 15th day of November 2024.

Mr. Trace McInturff, Vice President, Accreditation Services
For the Accreditation Council
Certificate Number 2907.01
Valid to October 31, 2026

*For the tests to which this accreditation applies, please refer to the laboratory's Environmental Scope of Accreditation.*

**NEW YORK STATE DEPARTMENT OF HEALTH**
**WADSWORTH CENTER**

Expires 12:01 AM April 01, 2026
Issued April 01, 2025

## CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

*Issued in accordance with and pursuant to section 502 Public Health Law of New York State*

*MR. ANTHONY GRIMALDI*
*EUROFINS DENVER*
*4955 YARROW STREET*
*ARVADA, CO 80002*

*NY Lab Id No: 11964*

*is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES NON POTABLE WATER*
*All approved analytes are listed below:*

**Chlorophenoxy Acid Pesticides**

| | |
|---|---|
| Dichloroprop | EPA 8321B |
| Dinoseb | EPA 8270D |
| | EPA 8270E |
| | EPA 8321B |

**Demand**

| | |
|---|---|
| Biochemical Oxygen Demand | SM 5210B-2016 |
| Chemical Oxygen Demand | EPA 410.4, Rev. 2.0 (1993) |

**Dissolved Gases**

| | |
|---|---|
| Acetylene | RSK-175 |
| Ethane | RSK-175 |
| Ethene (Ethylene) | RSK-175 |
| Methane | RSK-175 |
| Propane | RSK-175 |

**Fuel Oxygenates**

| | |
|---|---|
| Di-isopropyl ether | EPA 8260D |
| | EPA 8260C |
| Ethanol | EPA 8260D |
| | EPA 8260C |
| Methyl tert-butyl ether | EPA 8260D |
| | EPA 8260C |
| | EPA 624.1 |
| tert-amyl methyl ether (TAME) | EPA 8260D |
| | EPA 8260C |
| tert-butyl alcohol | EPA 8260D |
| | EPA 8260C |
| tert-butyl ethyl ether (ETBE) | EPA 8260D |

Serial No.: 71135

## CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

*Issued in accordance with and pursuant to section 502 Public Health Law of New York State*

*MR. ANTHONY GRIMALDI*
*EUROFINS DENVER*
*4955 YARROW STREET*
*ARVADA, CO 80002*

*NY Lab Id No: 11964*

*is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES NON POTABLE WATER*
*All approved analytes are listed below:*

**Miscellaneous**

| | |
|---|---|
| Specific Conductance | SM 2510B-2011 |
| | EPA 9050A |
| Sulfide (as S) | SM 4500-S2- F-2011 |
| | EPA 9034 |
| | SM 4500-S2- D-2011 |
| Total Organic Halides | EPA 9020B |
| Turbidity | EPA 180.1, Rev. 2.0 (1993) |

**Nitroaromatics and Isophorone**

| | |
|---|---|
| 1,3,5-Trinitrobenzene | EPA 8270D |
| | EPA 8270E |
| | EPA 8330B |
| 1,3-Dinitrobenzene | EPA 8270D |
| | EPA 8270E |
| | EPA 8330B |
| 1,4-Naphthoquinone | EPA 8270D |
| | EPA 8270E |
| 2,4,6-Trinitrotoluene | EPA 8330B |
| 2,4-Dinitrotoluene | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| | EPA 8330B |
| 2,6-Dinitrotoluene | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| | EPA 8330B |
| 2-Amino-4,6-dinitrotoluene | EPA 8330B |
| 2-Nitrotoluene | EPA 8330B |

Serial No.: 71135

## CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

*Issued in accordance with and pursuant to section 502 Public Health Law of New York State*

*MR. ANTHONY GRIMALDI*
*EUROFINS DENVER*
*4955 YARROW STREET*
*ARVADA, CO 80002*

*NY Lab Id No: 11964*

*is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES NON POTABLE WATER*
*All approved analytes are listed below:*

**Priority Pollutant Phenols**

| | |
|---|---|
| 2,4,5-Trichlorophenol | EPA 8270D |
| | EPA 8270E |
| 2,4,6-Trichlorophenol | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| 2,4-Dichlorophenol | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| 2,4-Dimethylphenol | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| 2,4-Dinitrophenol | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| 2,6-Dichlorophenol | EPA 8270D |
| | EPA 8270E |
| 2-Chlorophenol | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| 2-Methyl-4,6-dinitrophenol | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| 2-Methylphenol | EPA 625.1 |
| | EPA 8270D |
| | EPA 8270E |
| 2-Nitrophenol | EPA 625.1 |
| | EPA 8270D |

Serial No.: 71135

Property of the New York State Department of Health. Certificates are valid only at the address shown and must be conspicuously posted by the laboratory. Continued accreditation depends on the laboratory's successful ongoing participation in the Program. Consumers may verify a laboratory's accreditation status online at https://apps.health.ny.gov/pubdoh/applinks/wc/elappublicweb/, by phone (518) 485-5570 or by email to elap@health.ny.gov.

## CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

*Issued in accordance with and pursuant to section 502 Public Health Law of New York State*

*MR. ANTHONY GRIMALDI*
*EUROFINS DENVER*
*4955 YARROW STREET*
*ARVADA, CO 80002*

*NY Lab Id No: 11964*

*is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES SOLID AND HAZARDOUS WASTE*
*All approved analytes are listed below:*

**Metals III**

| | |
|---|---|
| Silica, Dissolved | EPA 6010D |
| Thallium, Total | EPA 6010C |
| | EPA 6010D |
| | EPA 6020B |
| Tin, Total | EPA 6010C |
| | EPA 6010D |
| Titanium, Total | EPA 6010C |
| | EPA 6010D |

**Minerals**

| | |
|---|---|
| Bromide | EPA 9056A |
| Chloride | EPA 9056A |
| Fluoride, Total | EPA 9056A |
| Sulfate (as SO4) | EPA 9056A |

**Miscellaneous**

| | |
|---|---|
| Boron, Total | EPA 6010C |
| | EPA 6010D |
| Cyanide, Total | EPA 9012B |
| Organic Carbon, Total | EPA 9060A |
| Perchlorate | EPA 6850 |
| Specific Conductance | EPA 9050A |
| Sulfide (as S) | EPA 9034 |

**Nitroaromatics and Isophorone**

| | |
|---|---|
| 1,3,5-Trinitrobenzene | EPA 8270D |
| | EPA 8270E |
| | EPA 8330B |
| 1,3-Dinitrobenzene | EPA 8270D |

Serial No.: 71136

## CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

*Issued in accordance with and pursuant to section 502 Public Health Law of New York State*

*MR. ANTHONY GRIMALDI*
*EUROFINS DENVER*
*4955 YARROW STREET*
*ARVADA, CO 80002*

*NY Lab Id No: 11964*

*is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES SOLID AND HAZARDOUS WASTE*
*All approved analytes are listed below:*

**Priority Pollutant Phenols**

| | |
|---|---|
| 4-Nitrophenol | EPA 8270D |
| | EPA 8270E |
| Pentachlorophenol | EPA 8270D |
| | EPA 8270E |
| Phenol | EPA 8270D |
| | EPA 8270E |

**Semi-Volatile Organics**

| | |
|---|---|
| 1,1'-Biphenyl | EPA 8270D |
| | EPA 8270E |
| 1,2-Dichlorobenzene, Semi-volatile | EPA 8270D |
| | EPA 8270E |
| 1,3-Dichlorobenzene, Semi-volatile | EPA 8270D |
| | EPA 8270E |
| 1,4-Dichlorobenzene, Semi-volatile | EPA 8270D |
| | EPA 8270E |
| 2-Methylnaphthalene | EPA 8270D |
| | EPA 8270E |
| 2-Picoline | EPA 8270D |
| | EPA 8270E |
| 4-Amino biphenyl | EPA 8270D |
| | EPA 8270E |
| Acetophenone | EPA 8270D |
| | EPA 8270E |
| Aramite | EPA 8270D |
| | EPA 8270E |
| Benzaldehyde | EPA 8270D |
| | EPA 8270E |

Serial No.: 71136

# PERRY JOHNSON LABORATORY ACCREDITATION, INC.

# *Certificate of Accreditation*

*Perry Johnson Laboratory Accreditation, Inc. has assessed the Laboratory of:*

## *MicroVision Labs, Inc.*

***187 Billerica Road, Chelmsford, MA 01824***

*(Hereinafter called the Organization) and hereby declares that Organization is accredited in accordance with the recognized International Standard:*

## ISO/IEC 17025:2017

This accreditation demonstrates technical competence for a defined scope and the operation of a laboratory quality management system
(as outlined by the joint ISO-ILAC-IAF Communiqué dated April 2017):

## *Analytical Microscopy and Chemical Testing*

***(As detailed in the supplement)***

Accreditation claims for such testing and/or calibration services shall only be made from addresses referenced within this certificate. This Accreditation is granted subject to the system rules governing the Accreditation referred to above, and the Organization hereby covenants with the Accreditation body's duty to observe and comply with the said rules.

For PJLA:

Tracy Szerszen
President

Perry Johnson Laboratory Accreditation, Inc. (PJLA)
755 W. Big Beaver, Suite 1325
Troy, Michigan 48084

| *Initial Accreditation Date:* | *Issue Date:* | *Expiration Date:* |
|---|---|---|
| June 29, 2019 | July 21, 2023 | September 30, 2025 |

| *Accreditation No.:* | *Certificate No.:* |
|---|---|
| 98218 | L23-560 |

*The validity of this certificate is maintained through ongoing assessments based on a continuous accreditation cycle. The validity of this certificate should be confirmed through the PJLA website: www.pjlabs.com*

# *Certificate of Accreditation: Supplement*

**MicroVision Labs, Inc.**
187 Billerica Road, Chelmsford, MA 01824
Contact Name: John Knowles  Phone: 978-250-9909

*Accreditation is granted to the facility to perform the following testing:*

| FIELD OF TEST | ITEMS, MATERIALS OR PRODUCTS TESTED | SPECIFIC TESTS OR PROPERTIES MEASURED | SPECIFICATION, STANDARD METHOD OR TECHNIQUE USED | RANGE (WHERE APPROPRIATE) AND DETECTION LIMIT |
|---|---|---|---|---|
| Analytical Microscopy [F] | Particles, Nanoscale Particles, Bulk Materials, Biomedical Products, Semiconductors, MEMS Devices, Membranes | SEM, FE-SEM, Morphology, and Dimensions | ASTM E766, MVL 01, MVL 04, MVL 5, MVL 07 | 15 X to 500 000 X |
| | Particles, Dust, Fibers, Soot, Coal, Coal Ash | LM, PLM, Morphology, and Optical Properties | ASTM PDF-STP47926S, MVL 02, MVL 05, MVL 07 | 15 X to 1 800 X |
| Chemical [F] | Particles, Bulk Materials, Coal, Coal Ash, Lead Paint, Soot, Slag | EDS, Semi-Quantitative Elemental Analysis, Compositional Analysis and Elemental Maps | ASTM E1508, MVL 04, MVL 05, MVL 07, MVL 09 | 0.1 % to 1 % |
| | Polymers, Oils, Grease, Organic Compounds, Membranes | Micro-FTIR | ASTM E1252, MVL 07, MVL 21 | Qualitative |

1. The presence of a superscript F means that the laboratory performs testing of the indicated parameter at its fixed location. Example: Outside Micrometer [F] would mean that the laboratory performs this testing at its fixed location.
