1. SITE DESCRIPTION AND PROJECT SCOPE

1.1 INTRODUCTION

EA Engineering, P.C. and its affiliate EA Science and Technology (EA) has prepared this Data Usability Assessment Report (DUAR) Phase II in support of the Hazardous Toxic and Radioactive Waste (HTRW) Remedial Investigation (RI) at the Iona Island Naval Ammunition Depot Formerly Used Defense Site (FUDS) (FUDS Project Number [No.] C02NY074403) (Figure 1). The work is being performed under Contract No.W912DR-15-D-0014 Delivery Order No. W912DR18F0587, under the oversight of the U.S. Army Corps of Engineers (USACE) Baltimore and New England Districts.

The Iona Island Naval Ammunition Depot FUDS is located in Stony Point, Rockland County, New York, along the west bank of the Hudson River, The HTRW RI is being conducted at the site to characterize the nature and extent of hazardous substances in environmental media attributable to past Department of Defense (DoD) activities and evaluate potential risk to human health and ecological receptors. A two-phased approach was employed during this RI to facilitate data collection, evaluation, and discussion. Phase I was conducted in March-April 2021 to evaluate the presence/absence and/or nature and extent of hazardous in onsite soil within the FUDS boundary, evaluate the source-pathway-receptor interaction, and evaluate the subsequent risk to terrestrial receptors. Phase II was conducted in April 2022 to close data gaps identified after completion of Phase I, further evaluate contaminant migration pathways to the shoreline environment, evaluate impacts to shoreline media (surface water and sediment), and evaluate the subsequent risk to aquatic receptors.

The results of the Phase II investigation are the focus of this DUAR. Phase II field activities were conducted in accordance with the HTRW RI Uniform Federal Policy (UFP) – Quality Assurance Project Plan (QAPP) Addendum (EA 2022), in conjunction with the HTRW RI UFP-QAPP (EA 2020).

1.2 PROJECT SCOPE

Phase II field activities consisted of onsite soil sampling and onsite and background sediment and surface water sampling.

Phase II includes the following field activities:

- Collection of Incremental sampling methodology (ISM) soil samples from 8 previously established Phase I decision units (DUs) for analysis of physical parameter data (grain size, total organic carbon [TOC], oxidation-reduction potential [ORP], and cation-exchange capacity [CEC]). Samples from each DU were collected in triplicate (initial ISM sample plus two additional samples) (Figure 2);

- Collection of discrete surface water samples from 60 onsite locations for analysis of metals (Figure 3);

- Collection of ISM sediment samples from 3 onsite DUs for analysis of metals and physical parameter data (grain size, TOC, pH, and ORP). Samples from each DU were collected in triplicate (initial ISM sample plus two additional samples) (Figure 4);

- Collection of discrete surface water samples from 40 background locations for analysis of metals (Figure 5);

- Collection of ISM sediment samples from 2 background DUs, each consisting of 8 sampling units (SUs), for analysis of metals and physical parameter data (grain size, TOC, pH, and ORP). Single ISM samples were collected from each SU (Figure 5);

- Collection of discrete onsite shoreline sediment samples for analysis of acid volatile sulfide (AVS)/simultaneously extracted metals (SEM) (Figure 4).

1.3 PURPOSE AND ORGANIZATION OF THE DATA USABILITY ASSESSMENT REPORT

This DUAR provides a summary of the quality control (QC) practices employed in the production of definitive level data collected as part of Phase I RI sampling conducted in March–April 2020. The report summarizes the results of data validation and provides an assessment of the usability of the data for the intended purposes. Soil and sediment sampling and analysis and data validation were conducted according to the approved UFP-QAPP (EA 2020). Deviations from the UFP-QAPP are noted in this report.

The organization of the DUAR is as follows:

- ***Section 1 Site Description and Project Scope:*** Provides information regarding the history of the site and scope of the project, and the purpose of the DUAR.

- ***Section 2 Data Management and Reporting:*** Summarizes the sample management and data reporting procedures, and any deviations from the UFP-QAPP.

- ***Section 3 Chemical Data Quality Assessment:*** Summarizes the findings of the data validation and assesses the quality of the data.

- ***Section 4 Chemical Data Usability Assessment:*** Summarizes the usability of the data for each analysis.

- ***Section 5 References.***

2. DATA MANAGEMENT AND REPORTING

Phase II ISM soil samples and discrete sediment samples were collected in accordance with the standard operating procedures (SOPs) provided in the UFP-QAPP (EA 2020) and UFP-QAPP Addendum (EA 2022). Phase II ISM soil samples were screened in the field for ORP and submitted for offsite laboratory analysis of TAL metals, grain size, TOC, and CEC. Phase II discrete surface water samples were screened in the field for water quality parameters (i.e., pH, temperature, specific conductivity, dissolved oxygen [DO], ORP, turbidity, and salinity) and submitted for offsite laboratory analysis of TAL metals and hardness. Phase II ISM sediment samples were screened in the field for pH and ORP and submitted for offsite laboratory analysis of TAL metals, grain size, and TOC. Phase II discrete sediment samples were submitted for offsite laboratory analysis of AVS/SEM.

Laboratory analytical methods for samples collected during Phase II include the following:

- TAL Metals by U.S. Environmental Protection Agency (EPA) Methods 6010C/6020A
- Mercury by EPA Methods 7470A (water samples) and 7471B (soil samples)
- Hardness by Standard Method (SM) 2340B
- AVS/SEM by SM 4500-S2D and EPA Method 6010D[1]
- Grain size by ASTM International (ASTM) D422[2]
- TOC by Walkley-Black
- CEC by EPA SW-846 Method 9081.

2.1 SAMPLE MANAGEMENT

Laboratory analytical services Phase II were provided by the following laboratories:

- Eurofins TestAmerica Canton, OH: ISM sediment preparation
- Eurofins TestAmerica, Denver, CO: metals analyses (including mercury and hardness)
- Eurofins-Lancaster, PA: AVS/SEM analysis
- Eurofins TestAmerica, Corpus Christi, TX: CEC analysis
- Katahdin Analytical Services, LLC, Scarborough, ME: TOC and grain size analyses.

ISM sample preparation and laboratory analysis of CEC were conducted by laboratories that were not DoD-accredited but had been deemed acceptable by the USACE project chemist. The project team was unable to identify a DoD ELAP accredited laboratory with capacity to perform the ISM processing with ball milling. DoD has not accredited any laboratories for CEC by EPA SW-846

[1] AVS/SEM involves acidification of the sediment to release the AVS. Sulfide from the AVS was analyzed using SM 4500-S2D. SEM liberated during the acidification process were analyzed via EPA Method 6010D.
[2] The most recent version of ASTM-D422 was withdrawn in 2016 because it was not updated within the required period of time. At the time of the Phase II laboratory analysis, ASTM D422 has not yet been replaced, and DoD still accredited labs for ASTM D422. ASTM D422 was used to analyze grain size during Phase I and was used during Phase II for consistency.

Method 9081. Laboratories that are not DoD-accredited were required to follow QA/QC requirements per the DoD Quality Systems Manual (QSM), Version 5.3 (DoD 2019 and DOE 2019) to the extent possible.

The laboratories logged the samples into their laboratory information management systems and sent the work orders to EA for review and correction of any issues, if there were any (e.g., typos in sample names). Laboratory data were then generated in accordance with the laboratory SOPs listed in Worksheet #23 and included in Appendix E of the UPF-QAPP Addendum (EA 2022).

2.2 DATA REPORTING

The samples covered by this data quality assessment include 23 ISM soil samples, 105 discrete surface water samples (including 5 field duplicates), 25 ISM sediment samples, and 10 discrete sediment AVS/SEM samples (including 1 field duplicate). These samples were sent to the laboratories as part of 15 sample delivery groups. Separate laboratory analytical reports were provided for each sample delivery group. Laboratory reports are included in Appendix B of the RI Report.

Data reporting requirements included quality assurance/QC reviews of the data by the laboratory prior to data upload into the FUDSChem database. When the laboratory loaded the staged electronic data deliverables (SEDD) files into FUDSChem, they were automatically checked against the sample chains-of-custody to ensure that the correct sample designations and analyses were included. If any non-conformances were found, the SEDD was corrected and re-checked before being accepted into the FUDSChem database.

Level 4 PDF data packages from the laboratory were also uploaded to the FUDSChem library. Grain size data were not uploaded via SEDD, but instead were included in the PDF laboratory reports uploaded to FUDSChem.

Environmental measurement data (e.g., water quality parameters for surface water, soil and sediment pH) were transcribed from field notes into table format and uploaded to FUDSChem via the data submission tool.

2.3 DEVIATIONS FROM THE UFP-QAPP

This section details deviations from the UFP-QAPP Addendum (EA 2022) that relate to the collection of validated data:

- One Phase II triplicate sample collected from DU-11 (IINY-DU-11C)was screened in the field for pH and ORP. However, the sample was misplaced and was not shipped to the analytical laboratory for analysis of TOC, CEC, and grain size. Laboratory analytical results are not available for this triplicate sample. Results from the two other samples

collected from DU-11 (IINY-DU-11A and IINY-DU-11B) were used to evaluate bioavailability of metals in soil at DU-11.

This page left intentionally blank

3. CHEMICAL DATA QUALITY ASSESSMENT

This section summarizes the findings of the data review and validation, assesses whether data quality objectives were achieved, and describes the field and laboratory oversight activities and other measures used to ensure data reliability.

3.1 FIELD DATA QUALITY ASSESSMENT RESULTS

Field screening data were reviewed and verified to ensure correct reporting of information and completeness. No errors were noted and data are usable for the intended purposes. Detailed findings of the review are provided below.

3.1.1 ISM Soil and Sediment Sample Field Screening Data Quality Review

Soil and sediment pH and ORP field screening results for each DU were compared to evaluate accuracy and precision. No issues were noted with pH data. Inconsistencies were noted for soil ORP in one of three samples collected from DU-07 and for sediment ORP for one of three samples collected from the Iona Island Hudson River shoreline. ORP results for these samples were elevated compared to the replicate readings as follows:

- DU-07: field ORP measurements of 402, 310, and 307 millivolts (mV) (calculated standard hydrogen electrode corrected ORP results were 607, 515, and 512 mV). The 402 mV field screening value (607 mV calculated standard hydrogen electrode corrected ORP value) was elevated compared to the replicate readings. This elevated reading was also outside the range of ORP values for the remaining 14 upland ORP field screening values (field readings of 225 to 322 mV and calculated standard hydrogen electrode corrected ORP values of 430 to 527 mV).

- Iona Island Hudson River shoreline sediment: field ORP measurements of 493, 512, and 754 mV (calculated standard hydrogen electrode corrected ORP results were 698, 717, and 959 mV). The 754 mV field screening value (959 mV calculated standard hydrogen electrode corrected ORP value) was elevated compared to the replicate readings.

Elevated ORP results were considered anomalous. ORP and pH data were not used in any quantitative calculations. Data was used incorporated into a qualitative assessments to evaluate background representativeness and bioavailability of metals in onsite media. The single anomalous ORP readings in soil and sediment did not impact the assessments or change the conclusions for the background representativeness and bioavailability evaluations.

3.1.2 Discrete Surface Water Field Screening Data Quality Review

Surface water pH, temperature, specific conductance, DO, ORP, turbidity, and salinity field screening parameters collected during Phase I and Phase II were reviewed and verified to ensure correct reporting of information and completeness. In addition, water quality parameters for each

of the 20 samples collected within each onsite and background area (AOC #16 – Area D [former Dumping Area], Iona Island Hudson River shoreline, Iona Marsh shoreline, Con Hook Hudson River shoreline, and Con Hook Marsh shoreline) were compared to evaluate accuracy and precision. No errors or issues were noted with the surface water quality parameter dataset.

3.2 LABORATORY DATA QUALITY ASSESSMENT AND VALIDATION RESULTS

Table 1 provides a tabular summary that lists all the samples that were submitted to the laboratory, the sample delivery group number, sample depth, matrix, sampling method, validation level, and analysis.

Field QC samples by media and analyte are summarized in the table below. The quantities collected are consistent with the UFP-QAPP Addendum (EA 2022), with one exception. Although MS/MSDs for CEC were included in the QAPP, the laboratory subsequently indicated that MS/MSDs are not part of the CEC method.

Analytical Method	Matrix	# Discrete Samples	# ISM Decision Units (triplicates)	# ISM Survey Units (1 sample each)	# MS/MSD Pairs	# Field Duplicates
Metals (SW6010C, SW6020A, SW7470A)	Surface Water	100	NA	NA	5	5
Water Hardness (SM2340B)	Surface Water	100	NA	NA	5	5
AVS/SEM	Sediment	9	NA	NA	1	1
Metals (SW6010C, 6020A, SW7471B)	Sediment	NA	3	16	2	NA
TOC (WBLACK)	Sediment	NA	3	16	2	NA
Grain Size (ASTM D422)	Sediment	NA	3	16	NA	NA
Grain Size (ASTM D422)	Soil	NA	8	NA	NA	NA
TOC (WBLACK)	Soil	NA	8	NA	2	NA
CEC (SW9081)	Soil	NA	8	NA	NA	NA

Laboratory QC samples analyzed included matrix spikes (MSs) and matrix spike duplicates (MSDs), laboratory replicates (LR), method/preparation and calibration blanks, continuing calibration verification samples, interference check samples, serial dilutions, and laboratory control samples (LCSs).

Laboratory data were validated in accordance with DoD General Data Validation Guidelines (DoD 2019) and Module 2: Data Validation Procedure for Metals by ICP-OES, using the method

requirements specified in the UFP-QAPP Addendum (EA 2022) and the DoD QSM Version 5.3 (DoD and DOE 2019). Stage 2B Validation Electronic and Manual (S2BVEM) was completed using the FUDSChem software. Automated Data Review in FUDSChem was used to perform a Stage 2A data validation. The EA project chemists then performed a Stage 2B data validation, which included reviewing the Stage 2A validation report against the PDF laboratory report, verifying/modifying qualifiers applied during the Stage 2A review, and manually reviewing QC elements that were not included in the Stage 2A review. Stage 2A validation evaluates sample specific information and Stage 2B evaluates instrument performance as described in the DoD General Data Validation Guidelines (DoD 2019). Validation was performed in accordance with the DoD Quality System Manual Version 5.3 (2021). The specific validation procedures are detailed in the validation reports included in Appendix C of the HTRW RI Report.

The field and laboratory QC samples listed above were reviewed as part of data validation, and the chain-of-custody records, holding times, instrument performance records, initial calibrations, and data qualifiers were also reviewed. Sample results, with validation qualifiers and qualifier reason codes, are included in Table 2. The data assessed for precision, accuracy, representativeness, completeness, comparability, and sensitivity (PARCCS) are discussed in the following sections.

3.2.1 Data Validation Qualifiers

The analytical data were qualified and appropriately flagged during data validation. The qualifications were made by assessing the results submitted by the laboratory in terms of the technical requirements of the analytical methods (including QA/QC criteria) and data validation requirements. Qualifiers that were applied during data validation are discussed in detail in each data validation report. The data usability assessment focused on results that were qualified due to QC issues. The following qualifiers were applied to the reported data (Table 2):

- No qualifier: The analyte was positively identified at the specified numerical value exceeding the LOQ, and no data quality issues necessitating validation were identified

- U: The analyte was not detected at a level greater than or equal to the associated numerical value (LOD)

- J: The analyte was positively identified, and the associated numerical value is the approximate concentration of the analyte in the sample
- UJ: The analyte was not detected; however, the associated numerical value (LOD) is approximate and may be inaccurate or imprecise

- -: Result may be biased low. May be applied to J or UJ qualified data

- +: Result may be biased high. May be applied to J or UJ qualified data

The laboratory LOD is defined as the lowest concentration for reliable reporting of a non-detect of a specific analyte in a specific matrix with a specific method at 99 percent confidence (DoD 2017). The smallest concentration that produces a quantitative result with known and recorded precision and bias is known as the LOQ (DoD 2017). Instrument-specific detection limits (DLs) (e.g., the smallest analyte concentration that can be demonstrated to be different from zero or a blank concentration with 99 percent confidence [DoD 2017]), as provided for each analyte by the laboratory, are reported along with the LODs and LOQs in the laboratory analytical reports. Non-detect (U qualified) data are reported to the LOD.

Analytical results reported at estimated concentrations between the DL and LOQ were qualified as estimated (J) with a qualifier reason code of TR. Various data were also qualified as estimated (J or UJ) during data validation due to minor QC issues as follows:

- MS/MSD RPDs outside control limits (qualifier reason code = D)
- LR RPDs outside control limits (qualifier reason code = D1)
- FD RPDs outside control limits (qualifier reason code = D3)
- Serial dilutions outside QC limits (qualifier reason code = A)
- Sample preservation/collection requirement not met (qualifier reason code = P)
- Improper preparation/extraction (qualifier reason code = P2)
- %R outside QC limits in MS/MSDs (qualifier reason code = M)
- %R outside QC limits in the post digestion spike (qualifier reason code = M2)
- Detections in the laboratory blank (blank contamination) (qualifier reason code = L)
- Exceedance of test hold time (qualifier reason code = H1).

3.2.2 Measurement Performance Criteria

The following sections present the results of the data quality indicators used to validate and assess the data produced during the project (precision, accuracy/bias, representativeness, completeness, comparability, and sensitivity).

3.2.2.1 Precision

The precision of the analytical data was assessed through calculation of relative percent difference (RPD) for laboratory duplicates, field duplicates and serial dilutions. Assessment was performed during data validation, as recorded in the validation reports included in Appendix C of the RI Report. QC deficiencies in laboratory duplicate and serial duplicate runs that resulted in qualification of data are summarized below:

- The MS/MSDs ran on samples from IINY-CHHRS-SU-07-SEDIS, IINY-CHHRS-SW-02, and IINY-IHRS-DU-01A-SEDIS had RPDs outside QC limits for a subset of metals. Results for the parent samples were J qualified due to RPDs outside control limits (qualifier reason code = D; Table 2).

- The LR ran on samples from IINY-DU-04A-SSIS, IINY-DU-04B-SSIS, and IINY-DU-04C-SSIS had RPDs outside QC limits for cation-exchange capacity. Results were J qualified due to RPDs outside control limits (qualifier reason code = D1; Table 2).

- Field duplicate pair IINY-IHRS-SW-04 / IINY-IHRS-SW-FD1 had a RPD outside QC limits for copper, and field duplicate pair IINY-RRDS-FD1/ IINY-RRDS-SED-03 had a RPD outside QC criteria for SEM nickel. Results were J qualified due to RPDs outside control limits (qualifier reason code = D3; Table 2).

- Results for samples IINY-DUMP-SW-18, IINY-IHRS-DU-01A, and IINY-RRDS-SED-01, and IINY-CHHRS-SU-07were J qualified due to serial dilutions outside QC limits for metals and SEM (qualifier reason code = A; Table 2).

Note that the relative standard deviation (RSD) was calculated for detected results for each analyte in each DU where triplicate samples were collected and for background DUs where multiple SUs were sampled. RSDs for Phase II data are presented in Tables 5-2a, 5-5a, 6-12, 6-13, and 6-16 of the RI Report. As described in the current ITRC guidance for ISM sampling (ITRC 2020), RSD provides information about measurement precision but does not provide an indication of the accuracy of the estimate of the mean or the 95UCL. Therefore, a comment from the USACE Center of Expertise, provided on 1 August 2019 during preparation of the Phase 1 UFP-QAPP, indicated that an acceptance criterion for the RSD was unnecessary for this project because inferences about contamination are being made using a statistical approach that inherently takes the total measurement variability into account. Because no acceptance criterion was included in the UFP-QAPP, no data were qualified based on RSD.

3.2.2.2 Accuracy and Bias

The accuracy of the analytical data was assessed by comparing the results for spiked samples (MS, MSD, LCS, and post-digestion spikes), field, trip, and laboratory blanks, surrogates, and continuing calibration verifications to the project control limits. Percent recoveries and percent differences, and were within control limits, with the following exceptions.

Data for LCSs and laboratory control spike duplicates are generated to provide information on the accuracy of the analytical method and on the laboratory performance independent of the sample matrix effects. Recoveries of target analytes from the LCS associated with the analysis of all the samples collected during the reporting period were found to be within QC limits, and no qualifiers were applied for LCS recovery issues.

Data for the MS/MSD and post digestion spikes are generated to assess the effects of the sample matrix on analytical efficiency and to evaluate the analytical accuracy. QC deficiencies in MS/MSD and post-digestion spike recoveries that resulted in qualification of data are summarized below:

- Metals and SEM had %R outside QC limits in MS/MSDs associated with sediment samples IINY-TWS-SED-01, IINY-CHHRS-SU-07-SEDIS, IINY-CHMS-SU-02-SEDIS, and IINY-IHRS-DU-01A-SEDIS. Detected results for the affected metals were J qualified (qualifier reason code = M). Recoveries for some metals were high, and others were low; corresponding bias is indicated in Table 2.

- Metals (manganese and zinc) had a %R below QC limits in a MS/MSD associated with surface water sample IINY-CHMS-SW-17. The detected results for these two metals were J qualified (qualifier reason code = M). Low bias based on low %R is indicated in Table 2.

- TOC had a %R above QC limits in a MS/MSD associated with soil sample IINY-DU-19C-SSIS. The result for TOC in this sample was J qualified (qualifier reason code = M). High bias based on high %R is indicated in Table 2.

- Lead had a post spike %R outside QC limits for sediment sample IINY-IHRS-DU-01A-SEDIS, and SEM nickel and/or zinc had post spike %R outside QC limits for sediment samples IINY-RRDS-SED-01 and IINY-RRDS-FD1. Results for the affected metals were J qualified (qualifier reason code = M2).

Samples, blanks, and laboratory QC samples analyzed for organic compounds are spiked with surrogate compounds prior to extraction. Surrogate recoveries provide a means to evaluate the effects of individual sample matrices on analytical efficiencies. Surrogate recoveries outside QC limits can indicate that the sample matrix impacted analytical efficiency. The specific %Rs reported for each sample are evaluated to assess data quality and usability. There were no QC deficiencies in surrogate compound recoveries that resulted in qualification.

The stability of the analytical system is monitored by analysis of continuing calibration standards at concentrations near the mid-point of the instrument calibration range. The %D values between the relative response factor in the initial calibration and the relative response factor in the continuing calibration are reviewed to ensure instrument calibration criteria are within method control limits. There were no QC deficiencies in initial and continuing calibration verifications that resulted in qualification.

QA blanks, such as method, calibration, and preparation blanks, are prepared to identify any contamination that may have been introduced into the samples at the laboratory. The purpose of method blank analysis is to determine the presence and magnitude of contamination resulting from laboratory activities. Method blanks that indicate potential contamination during sample preparation or analysis and resulted in qualification of data are listed below:

- Metals were detected in the laboratory blanks associated with analysis of surface water samples. Results less than the LOQs were U qualified due to the blank contamination and results greater than the LOQ but less than 5 times the blank detection were J qualified with a high bias (qualifier reason code = L).

3.2.2.3 Representativeness

Representativeness is the measure of the degree to which data accurately and precisely represent a characteristic of a population, a parameter variation at a sampling point, a process condition, or an environmental condition. Representativeness is a qualitative parameter that is dependent upon the proper design and implementation of the sampling program and proper laboratory protocol. In order to meet the needs of the data users, project data must meet the measurement performance criteria for sample representativeness specified in the UFP-QAPP Addendum Worksheets #12 and #28 (EA 2022). Representativeness of the samples submitted for analysis is ensured by adherence to standard sampling techniques and standard analytical method protocols. Exceedances of maximum holding times that may have affected representativeness and resulted in qualification of data are summarized below:

- Sediment samples were extracted outside of the maximum hold time for acid volatile sulfide (AVS). AVS extractions and analyses were performed outside the 7-day hold time. The AVS results were non-detect and were UJ qualified (qualifier reason code = H1; Table 2).

Issues with laboratory preparation of samples that could affect the representativeness of the samples were also identified, as summarized below:

- TOC results for several background ISM sediment samples from Con Hook were qualified due to improper preparation at the laboratory. The ISM samples were dried and ground at the laboratory and then subsampled per ISM protocols to produce 9-11 gram sample aliquots that were provided for TOC analysis. However, those aliquots had to be further subsampled prior to analysis due to high carbon content; this subsampling was performed by manually mixing the sample and then taking a grab sample, rather than in accordance with ISM protocols. Sample results were J qualified due to the additional subsampling, combined with the fact that field triplicates were not collected for the background samples; triplicates could have allowed evaluation of representativeness (qualifier reason code = P2; Table 2).

- The cation exchange capacity (CEC) results for soil samples were qualified due to concerns regarding how sample processing at the laboratory may have affected the results. Initially, the samples had to be reanalyzed due to an error in CEC preparation. When the results of the reanalysis were reviewed, the project team identified some uncertainty in the results based on the ISM sample preparation methodology. Specifically, although it was not expected that the air drying would impact the results, there was concern that the drying process could have affected the cation exchange properties of the soil. Therefore, CEC results for all samples were J qualified as estimated concentrations (qualifier reason code = P; Table 2).

3.2.2.4 Completeness

The completeness goal for this project is 100 percent for each DU. Completeness for each analyte is calculated as the percentage of usable data points relative to all data obtained. There were no rejected sample data; therefore, the analytical completeness for the Phase II data is 100 percent.

One triplicate ISM sample (IINY-DU-11C-SSIS) planned for analysis of TOC, CEC, and grain size was collected but was not analyzed. Means for these parameters were calculated using data from samples IINY-DU-11A-SSIS and IINY-DU-11B-SSIS. The overall completeness for TOC, CEC, and grain size data is 96%.

3.2.2.5 Comparability

Comparability is the degree to which different methods, data sets, and decisions agree or can be represented as similar. Comparability describes the confidence (expressed qualitatively or quantitatively) that two data sets can contribute to a common analysis and interpolation. In order to meet the needs of the data users, project data must meet the measurement performance criteria for comparability specified in the UFP-QAPP Addendum (EA 2022) Worksheets #12 and #28.

The extent to which the analytical data will be comparable depends on the similarity of sampling and analytical methods. This objective is met by using standard methods for sampling and analysis and by following techniques and methods set forth in the UFP-QAPP Addendum (EA 2022).

3.2.2.6 Sensitivity

Sensitivity is the capability of a test method or instrument to discriminate between measurement responses representing different levels (e.g., concentrations) of a variable of interest. Examples of QC measures for determining sensitivity include laboratory fortified blanks, an MDL study, and calibration standards at the quantitation limit.

To meet the needs of the data users, the LODs for non-detects and LOQs for detections need to be less than the project action levels included in Worksheet #15 of the UFP-QAPP Addendum (EA 2022). Several results were reported from diluted analysis, and LODs and LOQs were adjusted accordingly for the diluted results. The dilutions were necessary to bring the target analytes within the calibration range. Additionally, the results for internal standards must meet the measurement performance criteria specified in Worksheet #12 of the UFP-QAPP Addendum. No sensitivity problems were noted for this Phase II dataset; therefore, the sensitivity objectives set forth in the project UFP-QAPP Addendum were met. Some metals were reported with LOQs greater than the project action limits, consistent with the UFP-QAPP Addendum. Uncertainties associated with these cases are addressed in Section F of the Human Health Risk Assessment (Appendix F to the RI Report) and Section 7.2.2 of the Ecological Risk Assessment (Appendix G).

3.3 SUMMARY OF VALIDATION RESULTS BY ANALYTE GROUP

The objective of the HTRW RI is to collect environmental analytical data at the Iona Island Naval Ammunition Depot FUDS that are scientifically defensible and representative of site conditions. The Phase II data will be used to evaluate the nature and extent of environmental impact and determine if concentrations of contaminants pose an unacceptable risk to human health and/or ecological receptors. The Phase II sampling was conducted to fill data gaps identified after completion of the Phase I sampling, as described in the QAPP Addendum (EA 2022).

3.3.1 Acid Volatile Sulfide

The sediment samples analyzed for AVS are indicated in Table 1. Sediment samples were extracted and analyzed outside the 7-day hold time. The results were non-detect and were UJ qualified. The total number of results for AVS is 10 and the total number of qualified results due to minor QC issues is 10. All results with the validation qualifiers and validation reason codes are included in Table 2.

3.3.2 Metals and Water Hardness

Metals were analyzed using Methods SW6010C, SW6010D, SW6020A, SW7471B, and SW7470A. Water hardness was calculated using Method SM2340B, from the results for calcium and magnesium by SW6010C. The samples analyzed by these methods are indicated in Table 1. Various results for metals, and one associated result for water hardness, were J qualified due to MS/MSD RPDs and %R, serial dilution %R, and field dup RPDs outside control limits. Several metals were detected in laboratory blanks associated with the surface water samples. Results less than the LOQ were U qualified due to the blank contamination and results greater than the LOQ but less than 5 times the blank detection were J qualified with a high bias as indicated on Table 2. The total number of results for metals Method SW6010C is 680 and the total number of qualified results due to minor QC issues is 85. The total number of SEM results for metals Method SW6010D is 50 and the total number of qualified results due to minor QC issues is 11. The total number of results for metals Method SW6020A is 2080 and the total number of qualified results due to minor QC issues is 53. The total number of results for mercury Method SW7471B is 25 and the total number of qualified results due to minor QC issues is 0. The total number of results for mercury Method SW7470A is 105 and the total number of qualified results due to minor QC issues is 0. The total number of results for hardness Method SM2340B is 105 and the total number of qualified results due to minor QC issues is 1. All results with the validation qualifiers and validation reason codes are included in Table 2.

3.3.3 Cation Exchange Capacity

CEC was analyzed using Method SW9081. Initial CEC analytical results for Phase II soil reported by the analytical laboratory (Eurofins TestAmerica, Corpus Christi, TX) ranged from 1,500 to 1,800 milliequivalents per 100 grams of soil (meq/100g). Typical values should be 0 to 100

meq/100g. These results were deemed abnormally high by several orders of magnitude by the EA ecological risk assessor. The analytical laboratory was informed of the issue with analytical results, which made the initial data unusable. The analytical laboratory conducted an internal audit and identified a discrepancy stemming from incorrect labeling for reagents used during the preparation of the samples. A corrective action was implemented, CEC samples were re-analyzed, and results were presented in a revised laboratory report.

The soil samples analyzed for CEC are listed in Table 1. CEC results were also qualified due to issues with sample handling. Two results for CEC were also qualified J due to lab replicate RPD outside QC limits. The total number of results for CEC is 23 and the total number of results qualified due to sample handling issues that could have affected results is 23. All results with the validation qualifiers and validation reason codes are included in Table 2.

3.3.4 Total Organic Carbon

TOC was analyzed using the Walkley-Black (WBLACK) method. The soil and sediment samples analyzed for TOC are listed in Table 1. One soil sample result for TOC was qualified J due to MS/MSD %R outside QC limits. TOC results for several background sediment samples were also qualified J due to improper preparation at the laboratory. The total number of results for TOC is 48 and the total number of qualified results due to minor QC issues is 17. All results with the validation qualifiers and validation reason codes are included in Table 2.

4. CHEMICAL DATA USABILITY ASSESSMENT

This section summarizes the usability of the Phase II data based on the data validation findings, the PARCCS data quality assessment, and achievement of data quality objectives.

As stated in Worksheet #11 Project Quality Objective of the UFP-QAPP (EA 2020), the purpose of the HTRW RI is to collect environmental analytical data at the Iona Island Naval Ammunition Depot FUDS that are scientifically defensible and representative of site conditions to:

- Evaluate the nature and extent of potential impacts associated with former structures and/or operations
- Evaluate potential risks to human health and ecological receptors
- Collect sufficient data to complete a feasibility study, if necessary.

Various data from Phase II were qualified as estimated (J or UJ) or non-detect (U) during data validation due to minor QC issues, as summarized in Section 3 and in the table below. Of the 3,126 results that were reported, 200 were qualified during validation due to minor QC issues. Overall, 6.4 percent of the dataset was qualified due to data quality issues. Reasons for data qualification included sample preparation and handling issues encountered during analyses by multiple laboratories, matrix interferences, and detections of metals in laboratory blanks associated with surface water samples. No results were rejected during data validation. Based on evaluation against the project DQOs specified in the UFP-QAPP Addendum (EA 2022), the Phase II data, as qualified are usable for the intended purposes. The potential impacts of data qualification will be addressed in uncertainty discussions in the human health and ecological risk assessments.

Summary of Results Qualified During Validation

Method/Analyte Group	Total Results	Rejected Results	Qualified Results	J Qualified Detected Results	Qualified Results Greater than LOQ	Bias of Qualified Results		
						Low Bias	High Bias	Unknown Bias
SM2340B/Water Hardness	105	0	1	1	1	0	0	1
AVS	10	0	10	0	0	0	0	10
SW6010C/Metals	680	0	85	5	12	0	7	78
SW6010D/SEM	50	0	11	11	10	4	0	7
SW6020A/Metals	2080	0	53	32	27	16	4	33
SW7470A/SW7471B/ Mercury	130	0	0	0	0	0	0	0
SW9081/CEC	23	0	23	23	23	0	0	23
WBLACK/TOC	48	0	17	17	17	0	1	16

Data Usability Summary

QA objectives for measuring data are expressed in terms of precision, accuracy, representativeness, comparability, completeness, and sensitivity (PARCCS). The QA objectives provide a mechanism for ongoing control and evaluating and measuring data quality throughout the project.

A review of the collected data is necessary in order to identify if data measurement objectives established in the seven-step data quality objective (DQ.O) process have been met. In general, the following data measurement objectives were considered:

•Specification of particular analytical method and reporting detection limit requirements
•Identification of the appropriate laboratory analytical QC requirements
•Verify if appropriate levels of other PARCCS criteria for the data has been met
•Delineation of specific sample-handling issues or other project-specific issues

The data validation review of the QA objectives verifies if the collected data are of sufficient quality to support their intended use.

A total of 0 results (0.00 %) out of the 3126 results (sample and field QC samples) reported have had qualifiers modified during this Data Usability Assessment and 0 results (0.00 %) have been rejected or deemed a serious deficiency. 1980 results were qualified during the data review process. Trace values, defined as results that are qualified as estimated because they fall between the detection limit and the reporting limit/limit of quantitation, are not counted as qualified results in the above count.

Narrative Comments

Iona Island Phase II Sampling April 2022

Review Questions	Yes	No	NA	Comment
Review Objective/Sampling Design				
Is the Final UFP QAPP associated with the event present in the Planning folder of the FUDSChem library for the project?	•			
Were key outputs defined during systematic planning (e.g.,PQOs or DQOs and MPCs) reviewed to make sure they are still applicable? Refer to the UFP QAPP for the projects, and to the worksheets found in REPORTS | UFP QAPP Worksheets.	•			
Refer to summary reports found in REPORTS | Event Tracking Reports | Event Status: All Data Types, Event Status: Chemistry Detail, and Unplanned Samples to review planned and unplanned samples and test methods.	•			ISM triplicate sample IINY-DU-11C-SSIS-041822 was collected, but the laboratory reported that it was not received; it was either lost during packing coolers or lost by the laboratory. CEC and TOC data for this triplicate sample are the only data that were planned but are not part of the final data set. In the FUDSChem Event Tracking: All Data Types report, there are 6 sediment samples shown as missing Environmental Measurement Information (EMI). These 6 sediment samples were collected for AVS/SEM analysis only and EMI was not planned for these locations. In the FUSDChem Chemistry Detail Report there are a few lab QC samples listed as awaiting data. These include a lab replicate for CEC, which was performed on a different sample, and MD/MSDs for water hardness, which were not required.
Was the sampling design reviewed for consistency with stated objectives? Refer to MAPS | Export to Google Earth to review sampling locations.	•			The sampling design was developed with the project team and is consistent with stated objectives. All Iona samples were collected at the planned locations/DUs. For background at Con Hook, the surface water sample locations had to be moved from planned locations due to lack of water at the planned locations. The field team moved samples to locations that had water and were consistent with observed conditions in Iona Marsh. Revised sampling locations are consistent with project objectives for background data collection.
Were data quality indicators (DQIs) from the DoD QSM used for this event? Review and discuss any DQIs that deviated from the DoD QSM. Refer to the UFP QAPP and to REPORTS | Environmental Setup Reports | Analyte Criteria, which highlights items that were modified from the original templates based on the DoD QSM.	•			DQIs from DoD QSM 5.3 were used for this event where available, as described in the QAPP.
Review Data				
If Event Planning was performed in FUDSChem, were all samples and measurements identified in REPORTS | Event Tracking Reports | Event Status: All Data Types completed and approved (all checked cells are green)?		•		There are 6 sediment samples shown in the Event Status: All Data Types Report as missing EMI. These 6 sediment samples were collected for AVS/SEM analysis only and EMI was not planned for these locations.

Data Usability Summary

Review Questions	Yes	No	NA	Comment
Review Data				
If Event Planning was performed in FUDSChem, were all samples identified in REPORTS | Event Tracking Reports | Event Status: Chemistry Detail collected and approved (all checked cells are green), or notated to explain discrepancies?	•			The Event Status: Chemistry Detail report shows MS/MSDs for water hardness as Awaiting Lab Data. However, this is a calculation method and does not require a MS/MSD. The Chemistry Detail report also indicates sample IINY-DU-11C-SSIS-041822 is awaiting lab data for CEC and TOC. This sample was lost while packing coolers or at the lab, and was therefore not analyzed.
If Event Planning was performed in FUDSChem, were all samples identified in REPORTS | Event Tracking Reports | Unplanned Samples reviewed to ensure correct completeness calculations?	•			No samples are listed in the unplanned samples report.
Were deviations from planned activities (e.g., number and locations of samples, holding time exceedances, damaged samples, non-compliant PT sample results, and SOP deviations) reviewed to determine their impacts on the data usability? If Event Planning was performed in FUDSChem, refer to REPORTS | Data Usability Assessment Reports | Project Completeness.	•			As indicated above, CEC and TOC data for one ISM triplicate sample are the only data that were planned but are not part of the final data set. Project completeness was 99.9%.
Have all Location related placeholders, such as centroid coordinates, been resolved? Review REPORTS | Data Assessment Reports | Locations.	•			
Were laboratory and data review reports for each Sample Delivery Group (SDG) associated with the event present in the FUDSChem library for the project? Refer to the list of SDGs listed on the cover page of the Data Usability Assessment Summary Report found under REPORTS | Data Usability Assessment Reports.	•			
Were all data review reports reviewed? Look for patterns, trends, and anomalies (e.g., unexpected results). Refer to the Data Review Reports in the project library as well as the event summary reports located in REPORTS | Data Usability Assessment Reports.	•			No anomalies were identified.
Were all data review reports associated with an approved eQAPP? Review the footer of the Data Review report in the Library to identify the version of the eQAPP that was used.	•			
Were there any implications of unacceptable QC sample results and does this impact sample results? If so, did any qualifiers require revision using the Sample Qualification tab of this interface?		•		Data were qualified as appropriate during data validation. No additional revision of qualifiers was required as part of this assessment.
Were sensitivity requirements met, as compared to regulatory Project Action or Screening Limits? Review REPORTS | Data Usability Assessment Reports | Sensitivity Summary.	•			LOQs were less than PALs except for certain metals in surface water, consistent with the QAPP.
Were any sample results recommended for rejection during validation (X qualified)? If so, have all X qualifiers been revised to R or J using the Sample Qualification tab of this interface?		•		
Were all LTM related parameters required for the project, such as groundwater measurements, environmental parameters, and well screen intervals found to be complete and correctly reported?			•	
Have all sections of the Dashboard linked Project Tracking Report been documented as complete?	•			

Data Usability Summary

Review Questions	Yes	No	NA	Comment
Document Usability/Draw Conclusions				
Based on the previous 'Review Data' documentation, are there any limitations on the use of the data associated with this event?		•		
Describe the conclusions reached during this Data Usability Assessment.	•			All data are usable as reported.
Lessons Learned/Recommendations				
Were any Program level Lessons Learned identified? (e.g., SW8330 was not the best fit for this site and MS/MS should be considered)	•			The lack of DoD certification for CEC analysis resulted in a lot of back and forth with the lab and minimal QC reporting. The lab reported unusable results with the first deliverable, but a corrective action was completed and the laboratory will conduct additional QC in the future.
Were any Project level Lessons Learned identified? (e.g., ISM sampling resulted in anomalies to be resolved in the future, or current locations not comparable to historical data)	•			CEC results were inconsistent with real-world values. The laboratory corrective action included review of results for reasonableness relative to these values, but it would avoid delay if validators are also made aware of expected ranges. Recommend either noting these in the QAPP or adding the question to the checklist for validation.
Are there any additional items associated with this sampling event that need clarification?		•		
Were any Sample level Lessons Learned identified? (e.g., a particular well may be expected to be dry in the future)		•		Conditions encountered in the field were appropriately accounted for in the QAPP (tidal influences on the shoreline, needing a boat to access Con Hook, etc.).

SUBJECT: Iona Island Shoreline Reconnaissance Survey

On 6-7 April 2020, two scientists from EA Engineering, Science, and Technology, Inc., PBC (EA) conducted a Shoreline Reconnaissance Survey at the Iona Island Naval Ammunition Depot, Formerly Used Defense Site. The project site is located in Stony Point, Rockland County, New York (Figure 1). Prior to conducting the survey, four "Recon Areas" were established (Figure 2) in the Hazardous Toxic and Radioactive Waste (HTRW) Remedial Investigation (RI) Uniform Federal Policy (UFP) - Quality Assurance Project Plan (QAPP) for the project site (EA, 2020). These areas include:

- Area 1 – Hudson River Shoreline
- Area 2 – Iona Marsh Shoreline
- Area 3 – Western Shoreline between Iona and Round Island
- Area 4 – CSX Railroad Tracks (West and East side)

In addition to surveying the four identified shoreline Recon Areas, EA personnel also generally characterized the upland conditions throughout Iona and Round Islands and conducted a reconnaissance of potential background sediment sampling locations.

The purpose of the Shoreline Reconnaissance Survey was to identify potential areas of sediment accumulation that could be suitable for sampling along the shoreline, identify and document habitat areas for potential ecological receptors, and identify potential preferential pathways to the shoreline from the upland portion of the island.

Should the results of the Phase I soil sampling investigation on the uplands portion of Iona Island indicate source-pathway-receptor interaction, including a pathway from Iona Island to the shoreline, potential habitat and/or receptors, and if physical parameters indicate a sink of contaminants, then sediments samples will be collected for chemical parameters as part of the Phase II investigation to evaluate potential site impacts to the Iona Island shoreline that are representative of significant habitat, could present a potential exposure pathway to human or ecological receptors, and could potentially be impacted by site-related contaminants.

During the survey, EA personnel traversed the shoreline areas on foot to identify potential areas of interest. EA marked areas of interest with orange and white survey flagging which were also recorded with a sub-meter accurate GPS unit. The areas of interest were geo-referenced on an aerial photograph provided in Attachment A (Figure 3). Photographs of key features are presented in Attachment B and the location of each photograph was mapped on Figure 4.

Area 1 – Hudson River Shoreline

Recon Area 1 consists of the shoreline along the Hudson River, which is located on the east side of Iona Island. The majority of the shoreline in this Recon Area consists of a stone river wall which was measured as approximately 6 feet in height (Photo 5). EA identified approximately 1,100 feet of river wall, although the wall is not contiguous along the shoreline—three large breaks in the wall were identified where the wall has partially collapsed (Photo 6). Additionally, small gaps between the stones were also observed along the length of the wall where the Hudson River passes through the wall at high tide and forms pockets of water behind the wall. EA observed large areas of cobble and boulder-sized stone at the northern and southern ends of the river wall as well as at the identified wall breaks. The large stones were mostly submerged during high tide but exposed during low tide (Photos 1 and 2). EA identified amphipods and aquatic snails on the underside of many of the large stones when flipped over (Photos 3 and 4). However, there was little silty or fine sediment in this area, with the majority of the substrate consisting of cobble and course-grained sand.

The majority of the area along the river wall consists of exposed bedrock (Photo 11) and gravel with the exception of some small pockets of sediment deposition. EA identified three small distinct areas of sediment deposition along the shoreline of Recon Area 1 (Photos 14 and 17). Each of these areas was identified for sediment sampling for grain size and total organic carbon (TOC). Sediment sampling was conducted on 7 April 2020.

EA also identified 6 potential outfall pipes along the river wall area of Recon Area 1. Pipe 1 was identified as an 18-inch concrete pipe located on the northern end of the river wall (Photo 6). This outfall pipe extends approximately 8 feet into the Hudson River during high tide. Pipe 2 was identified as a 12-inch steel pipe located in the central portion of Recon Area 1, near the historic causeway/pier (Photo 8). Additional steel piping and cables were observed in this area. It was unclear during the survey if this 12-inch pipe was part of the causeway road infrastructure (conduit piping) or an outfall discharge pipe. Approximately 30 feet south of Pipe 2, three additional discharge pipes were observed—two 8-inch steel pipes were identified in the wall and one 10-inch terracotta pipe was identified partially exposed in the ground above the wall (Photos 9 and 10). Lastly, Pipe 3 is a 14-inch concrete pipe identified at the southern end of the wall (Photo 12).

The pipes were identified as potential preferential pathways leading to the shoreline although their origins could not be identified at the time of the field survey. Based on the locations of mapped former buildings/structures identified on Figure 2, Pipes 1 and 3 appear to be in the areas of former buildings/structures. Pipe 2 does not appear to be in an area with former buildings/structures.

Area 2 – Iona Marsh Shoreline

Recon Area 2 consists of the shoreline area along the west side of Iona Island. This area is divided by a railroad embankment which supports an active CSX rail line. The western side of the railroad tracks and south of the entrance road consists of a tidal marsh (Photo 23) dominated by cattails (*Typha spp.*); the area east of the railroad tracks (Photo 18) is dominated by an extremely dense monotypic stand of common reed (*Phragmites australis*). The western side of the railroad tracks and north of the entrance road is dominated by phragmites as well. Recon Area 2 consists of typical tidal marsh areas common along the Hudson River. A fine-grained sediment bottom is present throughout the marsh (Photo 30). Three sediment sample locations were selected in this area to document sediment characteristics.

Although no outfall pipes were identified during the recon survey along the shoreline of Recon Area 2, a potential preferential pathway was identified. One groundwater seep was observed on the northwestern portion of Recon Area 2, in the vicinity of the entrance road to Iona Island (Photo 23). This groundwater seep was identified along the upland slope between the marsh and the existing railroad tracks. EA staff observed groundwater discharge along the upland slope into the marsh and a sediment sample was taken at this location. An outfall pipe was not observed in this location.

Area 3 – Western Shoreline Between Iona and Round Island

Recon Area 3 consists of the shoreline area on the southwest side of Iona Island and western portion of Round Island. This area includes the low portion of land between the two islands. Unlike Recon Areas 1 and 2, this area is not a true shoreline, as historic fill and disturbance has significantly altered this area. Recon Area 3 consists of a mix of *Phragmites* tidal wetland on the southern and western end of the area, a tidal wetland swale consisting of various plant species, and a rip-rap filled drainage swale.

Although no outfall pipes were identified during the survey along the shoreline of Recon Area 3, two potential preferential pathways were identified. The southern end of Iona Island appears to drain down towards the *Phragmites* dominated low point between Iona Island and Round Island. This area slopes slightly to the south east to a rip-rap filled drainage swale (Photo 20) that directs flow to the south, towards the tidal marsh associated with Recon Area 2. A tidal wetland swale also identified along Recon Area 3 appears to convey flow to the west toward the tidal marsh associated with Recon Area 2.

Just north of Recon Area 3, EA identified a *Phragmites* filled wetland depression on the north side of the Iona Island perimeter road. This depression appears to collect surface runoff from Iona Island, but EA staff were unable to identify a culvert beneath the road connecting this depression to the tidal wetland swale within Recon Area 3.

Area 4 – CSX Railroad Tracks (West and East Side)

Recon Area 4 includes the areas along the east and west side of the railroad track embankment and primarily consists of rip-rap along an upland embankment. The northern portion of Recon Area 4 includes a scrub-shrub upland along the edge of the rip-rap (Photo 24); the southern end of the recon area includes a transition from rip-rap to existing marsh areas associated with Recon Area 2 (Photo 19).

EA did not identify any discharge outfall pipes along Recon Area 4. No culverts were identified beneath the railroad embankment that could connect drainage from Iona Island on the east of the railroad embankment to the marsh on the western side of the railroad embankment. EA identified only one hydrological connection through the railroad embankment, connecting the cattail marsh to the west with the *Phragmites* marsh on the east. This connection is located outside the project area at an embankment opening (i.e., shallow bridge) approximately 1,500 feet away, across the marsh from Round Island.

Flora and Fauna Observations

In addition to identifying potential pathways and characterizing the shoreline conditions of the site, EA's environmental scientists also documented wildlife to determine potential ecological receptors at the site. Wildlife observations included incidental observations and did not include a formal survey for specific species. In general, the observations made are consistent of what would be expected for the habitat areas described above. A list of wildlife observations along with the general recon area depicting where each species was identified is provided in Table 1.

Table 1. Wildlife Observations

Common Name	Scientific Name	Recon Area Observed				
		Area 1	Area 2	Area 3	Area 4	Upland
White tailed deer	*Odocoileus virginianus*		X	X		X
Grey squirrel	*Sciurus carolinensis*				X	X
Northern water snake	*Nerodia sipedon*			X		
Black rat snake	*Panthrophis obsoletus*		X	X		
Painted turtle	*Chrysemys picta*		X			
Terrestrial snail	--	X				
Aquatic snail	--	X				
Amphipod	--	X				
Turkey vulture	*Cathartes aura*	X	X	X	X	X
Osprey	*Pandion haliaethus*	X	X	X		X
American crow	*Corvus brachyrhynchos*	X			X	X
Red-winged blackbird	*Agelaius phoeniceus*		X	X		
Mourning dove	*Agelaius phoeniceus*					X
Northern cardinal	*Cardinalis cardinalis*					X
Northern bluejay	*Cyanocitta cristata*			X		X
Great scaup	*Aythya marila*	X				
Pileated woodpecker	*Dryocopus pileatus*					X
Ring-billed gull	*Larus delawarensis*	X				X

As previously mentioned, *Phragmites* and cattail were the dominant aquatic vegetation. The upland habitat consists primarily of invasive species including Japanese barberry (*Berberis thunbergii*), multiflora rose (*Rosa multiflora*), wineberry (*Rubus phoenicolasius*), and Japanese honeysuckle (*Lonicera japonica*). Other dominant species located within the upland areas included maples (*Acer spp.*), *Forsythia spp*., devil's walkingstick (*Aralia spinosa*), and red cedar (*Juniperus virginiana*). Milkweed (*Asclepias syriaca*) was also identified.

Sediment Sampling

EA collected sediment samples on 7 April 2020 from areas identified as depositional. EA identified seven sediment sampling locations, including three locations in Recon Area 1 (SD 04, SD 05, and SD 06), three locations in Recon Area 2 (SD 01, SD 02, SD 03), and one location in Recon Area 3 (SD 07). The seven sediment locations are depicted on Figure 3. Sediment samples were collected for analysis of grain size and TOC. Grain size appears to vary from coarse sand and cobbles in Recon Area 1 to fine silts and clays in Recon Areas 2 and 3.

Potential Sediment Background Locations

EA identified two potential upstream background sediment sampling locations (Figure 5). The first potential background sampling location was identified as Constitution Island, which is located approximately 7 miles upstream of Iona Island on the eastern bank of the Hudson River. The island consists of approximately 175 acres of upland habitat and another 240 acres of marsh, similar to that of Iona Island. A gate prevented access to the island and signs indicated it is government property with restricted access and is believed to be part of West Point Military Academy.

The second potential background location was identified as Con Hook, which is a peninsula located approximately 3 miles upstream of Iona Island on the western side of the Hudson River. It consists of approximately 7 acres of upland

habitat and another 12 acres of a *Phragmites*-dominated marsh land, similar to that of Iona Island. Access appears only possible via boat. A boat ramp is located approximately 2 miles south of Con Hook in Mine Dock Park.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

1. Northernmost portion of Recon Area 1 at high tide, before start of river wall.

2. Northernmost portion of Recon Area 1 at low tide.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

3. Amphipod observed under shoreline rocks during low tide.

4. Snail observed under shoreline rocks during low tide.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

5. River wall located along the majority of Recon Area 1.

6. Pipe #1 identified along the northern portion of Recon Area 1.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

7. Sediment area observed at low tide at sample area SD-06.

8. Pipe #2 observed along Recon Area 1.

Photographic Record

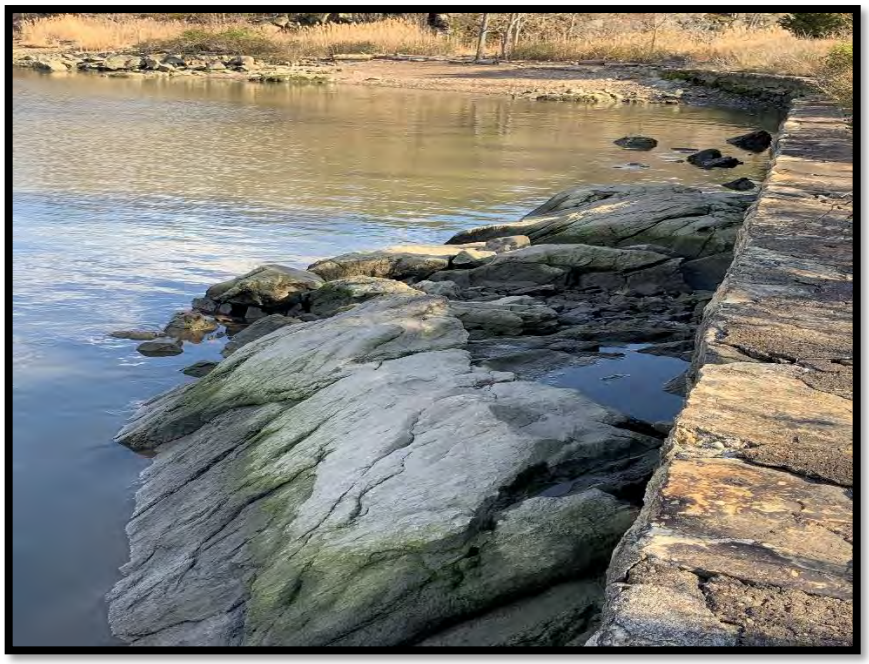
Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

9. Terracotta pipe identified partially buried near the historic causeway in Recon Area 1.

10. Two additional metal pipes identified along the river wall, near the historic causeway in Recon Area 1.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020



11. Sample location SD-05 located between the exposed bedrock and beach area in Recon Area 1.

12. Pipe #3 located along the river wall in Recon Area 1.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

13. Coarse sand, beach glass and pebble material along the beach area on the southern portion of Recon Area 1.

14. Southernmost portion of Recon Area 1 at high tide at sediment location SD-04.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

15. Southernmost portion of Recon Area 1 at low tide.

16. Water depth of approximately 5 feet along the river wall in Recon Area 1 at high tide.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

17. Northern shoreline of Round Island.

18. *Phragmites* dominated marsh in Recon Area 2, on the eastern side of railroad tracks.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

19. Rip-rap slope and water depth of three feet along the eastern side of railroad tracks, across from Round Island.

20. Potential pathway located between Round Island and the existing fill area.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

21. View of Recon Area 3 from Round Island.

22. View of *Phragmites* dominated marsh between Iona Island and Round Island.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

23. Potential groundwater seep area along Recon Area 2 (Location of SD 02).

24. Typical view of railroad tracks in Recon Area 4.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

25. Top of river wall with evidence of historic railing or fence posts.

26. Typical metal piping observed in Recon Areas 1 and 3 which appear to be from historic railing or fence structure.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

27. Observed fence and wall drainpipe identified on Round Island.

28. Sediment sample location SD-01.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

29. Sediment Sample Location SD-03 at hightide.

30. Sediment sample location SD-07 at low tide.

1. For each test, 10,000 permutation resamples were used to yield a stable p-value. When the value shown in “Right Tailed Prob” is less than 0.05, the H0 is rejected. If the resulting value in the Conclusion column is Do Not Reject H0, then the H0 is true and site concentrations are less than or equal to background. If the result is Reject H0, then site concentrations are greater than background.

Appendix F2

1. Kaplan-Meier estimator used for data sets with non-detect results.

2. Difference between site and background means reported as an interval if either site or background mean is a non-detect.

3. Right-tailed probability of permutation test of difference between site and background means. Adjusted p-values computed with Benjamini-Hochberg procedure for controlling false discovery rate (FDR). Asterisks indicate significance level (<0.05, <0.01, <0.001).

4. If the resulting value in the Conclusion column is Do Not Reject H0, then the H0 is true and site concentrations are less than or equal to background. If the result is Reject H0, then site concentrations are greater than background.

NOTES:

µg/L = micrograms per liter

CAS = Chemical Abstracts Service

DUMP = AOC #16 – Area D (former Dumping Area)

IHRS = Iona Hudson River Shoreline (along eastern boundary of AOC #16 – Area D)

RRDS = Riprap Filled Drainage Swale (Iona Marsh shoreline at outlet of riprap filled drainage swale)

TWS = Tidal Wetland Swale (Iona Marsh shoreline at outlet of tidal wetland swale)

CHHRS = Con Hook Hudson River Shoreline

CHMS = Con Hook Marsh Shoreline

1. Kaplan-Meier estimator used for data sets with non-detect results.

2. Difference between site and background means reported as an interval if either site or background mean is a non-detect.

3. Right-tailed probability of permutation test of difference between site and background means. Adjusted p-values computed with Benjamini-Hochberg procedure for controlling false discovery rate (FDR). Asterisks indicate significance level (<0.05, <0.01, <0.001).

4. If the resulting value in the Conclusion column is Do Not Reject H0, then the H0 is true and site concentrations are less than or equal to background. If the result is Reject H0, then site concentrations are greater than background.

NOTES:

CAS = Chemical Abstracts Service

mg/kg = milligrams per kilogram

DUMP = AOC #16 – Area D (former Dumping Area)

IHRS = Iona Hudson River Shoreline (along eastern boundary of AOC #16 – Area D)

RRDS = Riprap Filled Drainage Swale (Iona Marsh shoreline at outlet of riprap filled drainage swale)

TWS = Tidal Wetland Swale (Iona Marsh shoreline at outlet of tidal wetland swale)

CHHRS = Con Hook Hudson River Shoreline

CHMS = Con Hook Marsh Shoreline

1. INTRODUCTION

The Hazardous Toxic and Radioactive Waste (HTRW) Remedial Investigation (RI) has been conducted at the Iona Island Naval Ammunition Depot Formerly Used Defense Site (FUDS), (FUDS Project Number [No.] C02NY074402), located in Stony Point, Rockland County, New York (Figure 1). The RI has been conducted to characterize the nature and extent of hazardous substances in environmental media at the Iona Island Naval Ammunition Depot FUDS attributable to historical Department of Defense (DoD) operations and evaluate potential risk to human health and ecological receptors. This Human Health Risk Assessment (HHRA) for the Iona Island Naval Ammunition Depot FUDS has been prepared on behalf of the U.S. Army Corps of Engineers (USACE) to evaluate the potential for adverse effects to human health from exposure to FUDs eligible site-related contaminants of potential concern (COPCs) detected in media affected by past DoD site use.

The Navy used the site as an Ammunition Depot from 1900 to 1947, with the major effort consisting of assembling naval ammunition for World War II. Although no ammunition was manufactured at Iona, various types of explosives were assembled on site. Activities included preparing, assembling, maintaining, inspecting, and testing ammunition; storing bulk explosives, ammunition, and ordnance material; and issuing ammunition to the fleet, shore establishments, armed merchantmen, transport, and district forces (U.S. Army Geospatial Center [USAGC] 2018). The former depot was excessed by the Navy in 1957 and transferred to the General Services Administration (GSA). GSA conveyed the FUDS property to the Palisades Interstate Park Commission (PIPC) in 1965. The majority of buildings and structures, including building foundations, were demolished and removed by PIPC between November 1965 and December 1973 (USAGC 2018).

Investigations have been ongoing at the Iona Island Naval Ammunition Depot FUDS since 1992. Two previous investigations (the 1996 Data Collection Activities [Greeley-Polhemus Group, Inc. 1997] and 2007 Site Inspection [Alion Science and Technology Corporation 2008]) reported widespread detections of metals and polycyclic aromatic hydrocarbons (PAHs) in surface soil and/or subsurface soil.

Existing data from previous investigations were insufficient to evaluate nature and extent of contaminants in environmental media attributable to historical DoD operations and to evaluate whether concentrations of contaminants pose an unacceptable risk to human health and/or ecological receptors. The HTRW RI was proposed to address these insufficiencies and is the first comprehensive investigation of the Iona Island Naval Ammunition Depot FUDS.

1.1 OBJECTIVES OF THE HUMAN HEALTH RISK ASSESSMENT

An HHRA is a qualitative and quantitative process that characterizes site conditions and determines applicable risk to human health based on potential exposure scenarios. This HHRA is being conducted in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended by Title 42 of the U.S. Code Sections 9601 through 9675. Specifically, the objectives of the HHRA include the following:

- Outline the regulatory basis and guidance for conducting the HHRA
- Outline the methods for determining COPCs in site media
- Present the exposure setting that details land use, nearby human populations, and potential site activities
- Develop a conceptual site model (CSM) that characterizes relevant complete contaminant exposure pathways and receptors of concern
- Calculate potential carcinogenic and non-carcinogenic risk to receptors of concern (e.g., any human contact at the site under current or future scenarios)
- Identify areas that pose no unacceptable risks to human health and require no further action
- Determine contaminants of concern in site media that contribute significantly to potential risk concerns, which will be used to evaluate risk management decisions.

1.2 GENERAL APPROACH

The HHRA follows procedures and methodologies set forth by the U.S. Environmental Protection Agency (EPA) and USACE. Specific guidance documents used to evaluate potential risks to human health include the following:

- Risk Assessment Guidance for Superfund (RAGS), *Volume 1: Human Health Evaluation Manual (Part A) (Interim Final)*, EPA/540/1-89/002). December 1989.
- RAGS, *Volume 1: Human Health Evaluation Manual Supplemental Guidance – "Standard Default Exposure Factors" (Interim Final)*, Publication 9285.6-03. 25 March 1991a.
- RAGS, *Volume I – Human Health Evaluation Manual (Part B – Development of Risk-based Preliminary Remediation Goals)*. EPA/540/R-92/003. December 1991b.
- *Guidelines for Data Usability in Risk Assessment (Part A)*. Office of Solid Waste and Emergency Response (OSWER), Publication OSWER 9285.7-09A. December 1992.
- RAGS, *Volume I: Human Health Evaluation Manual (Part D, Standardized Planning, Reporting and Review of Superfund Risk Assessments)*. Office of Emergency and Remedial Response. December 2001.
- *Human Health Toxicity Values in Superfund Risk Assessments*. OSWER 9285.7-53. Office of Emergency and Remedial Response. December 2003a.

- RAGS, *Volume I: Human Health Evaluation Manual (Part E: Supplemental Guidance for Dermal Risk Assessment)* Final, EPA/540/R/99/005, OSWER 9285.7-02EP, Office of Superfund Remediation and Technology Innovation. July 2004.

- *Guidelines for Carcinogen Risk Assessment*. Risk Assessment Forum. EPA/630/P-03/001F. March 2005a.

- *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens*. Risk Assessment Forum, EPA/630/R-03/003F. March 2005b.

- *Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual (Part F: Supplemental Guidance for Inhalation Risk Assessment) Final*. Office of Superfund Remediation and Technology Innovation, EPA-540-R-070-002. January 2009a.

- *Exposure Factors Handbook, 2011 Edition*. EPA/600/R-090/052F. September 2011.

- *Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Exposure Factors*, OSWER Directive 9200.1-120-Update. 6 February 2014.

- *Risk Assessment Handbook Volume I: Human Health Evaluation*. USACE Engineering Manual 200-1-4. 31 January 1999.

- *Standard Scopes of Work for Environmental Risk Assessments*. USACE Engineer Pamphlet 200-1-15. 30 June 2016.

- *Environmental Quality – Formerly Used Defense Sites (FUDS) Program Policy*. USACE Engineer Regulation 200-3-1. 10 May 2004.

- *Tri-Service Position Paper on Background Levels in Risk Assessment*. USACE, Environmental and Munitions Center of Expertise, Omaha, NE. October.

1.3 REPORT ORGANIZATION

The HHRA consists of the following Sections:

- ***Section 1***—Introduction
- ***Section 2***—Data Handling and Evaluation
- ***Section 3***—Identification of COPCs
- ***Section 4***—Exposure Assessment
- ***Section 5***—Toxicity Assessment
- ***Section 6***—Risk Characterization
- ***Section 7***—Risk Assessment Uncertainties
- ***Section 8***—Conclusions
- ***Section 9***—References

1.4 SITE HISTORY AND BACKGROUND

The Iona Island Naval Ammunition Depot FUDS property consists of approximately 124 acres of land and inland water located on Iona Island and Round Island along the west side of the Hudson River, in the Town of Stony Point, Rockland County, New York (Figure 1). Iona Island is located within the Lower Hudson River Valley region, which includes all of Putnam, Rockland, and Westchester counties and is considered part of the downstate New York region due to its geographical and cultural proximity to New York City.

Prior to use by the military, Iona Island was utilized as a resort hotel during the Civil War. There was no documented evidence available of past use of ordnance-related items on Iona island prior to use by the military. The Navy acquired Iona Island from the L.H. Mace Brokerage Company of New York City in 1899 for construction of the Iona Island Naval Ammunition Depot (USACE 1998). In 1942, an additional approximately 13 acres of marshland, Round Island, was purchased and used for ammunition storage (USACE 1998).

During World War I, almost all the depth bombs and ammunition used in the Atlantic area passed through Iona. All submarines were sent to Iona Island to be filled with explosives, in addition to the regular work conducted. In 1915, over 2 million pounds of powder were made up in charges, about 327 carloads of material were handled during the year, and large shipments were made by transport, tug, and barge. A 1919 annual report to the Secretary of the Navy states that most of the 14-inch (in.) ammunition for the Army and Navy Railroad battery was prepared at Iona Island.

After World War I, although Iona Island was one of two of the Navy's main depots on the east coast, a program of reducing personnel and material and keeping active work to a minimum was followed under the United States' general program of limitation of arms treaty. In the 1930s, Iona Island supplied ammunition of various calibers to the fleet for service allowances, target practice, and reserve war requirements.

Between 1941 and 1945, the major activity conducted on Iona Island was assembling naval ammunition for World War II. More than 2,300 Navy ships and 2,300 merchant ships received their ammunition from Iona Island during World War II. In addition, 77 bases, 500 shore stations and 700 foreign naval ships were serviced with ammunition.

After World War II, use of Iona island as an ammunition depot became obsolete because of lack of expansion room to accommodate new types of ammunition. In 1947, the Department of the Navy decided to deactivate the Iona Island Naval Ammunition Depot and made the property available for restricted lease. The FUDS was re-designated as an Annex to the United States Naval Ammunition Depot, Earle, New Jersey, and in 1957, declared the Annex excess. In 1955 and 1960, the GSA utilized the Iona Island Naval Ammunition Depot FUDS through a permit for stockpile materials such as rubber and copper. In 1960, the GSA received official jurisdiction of the property, and other agencies under GSA control utilized the property for record storage during the 1960s. These agencies included the following: Maritime Administration, Atomic Energy Commission, Civil Service Commission, USACE, and the Navy's Bureau of Ships. The Maritime Administration also conducted occasional trans-shipments of heavy freight at the main wharf on

an occasional basis. On 30 March 1965, Iona Island was deemed evacuated after the last load of stockpiled materials left the property. In 1965, PIPC acquired both Iona and Round islands (USACE 1998).

In 1924, a total of 106 buildings including two water storage tanks and one standpipe were present on Iona Island (USACE 1998). In the late 1920s through the 1930s, various programs of maintenance and remodeling were carried out by the Bureau of Yards and Docks in addition to several other buildings being built. For example, ten magazine buildings were remodeled for fireproofing; three black-powder magazines and a railroad track to serve them were ordered; and two water tanks were provided, the water system enlarged, and two engine-driven generators installed. In addition, a 0.85-acre Dump Area is first identified between Round Island and Iona Island on a 1930-dated U.S. Navy layout plan (USAGC 2018).

Round Island, the southernmost portion of the depot, was utilized by the Navy for ammunition storage. The Navy filled in the area between Iona Island and Round Island to provide a connection between the two islands. Subsurface magazines were quarried out of rock on Round Island, and the rock removed was used to create a blast barrier between the magazine storage and the depot activities on Iona Island (Bluestone Environmental Group, Inc. 2018).

In 1951 when the depot was deactivated, there were 146 buildings on Iona Island (USAGC 2018). A 22 June 1965 letter presented in the Archive Search Report provides information on the site layout at the time of DoD transfer to PIPC. Roads on Iona Island were in poor condition, with many of the buildings not served by roads. Buildings were served by railroad with spurs from the West Shore Railroad that led to each warehouse and to the pier. Most buildings had been built between 1914 and 1918 and were made of brick while additional buildings constructed in 1941 were made of concrete-faced cinder block. Most buildings had no natural or artificial lighting, heating, or other utilities; they were large, open warehouses with high ceilings and no partitions or separation of floors. Several homes were also present on Iona Island, and previously served as residences for naval officers. Redevelopment for industrial or warehousing use would have required extensive renovation of buildings, clearance of structures, and construction of roads, parking lots, and new sewer system and utility lines; therefore, use of Iona Island was discontinued (USACE 1998).

Most buildings and structures were demolished and removed between November 1965 and December 1973 (USAGC 2018). It is possible that fill material was used during regrading following demolition and excavation/removal of foundations, and that surface and subsurface soil was significantly reworked/mixed across much of the former operations area. The FUDS has remained undeveloped since its transfer from DoD ownership to PIPC in 1965. PIPC developed demolition plans for the remaining buildings and for construction of a recreational park; however, the plans to develop Iona Island into a recreational park were not executed. The only construction that occurred on Iona Island was the parking lot located directly west of Iona Island and outside of the FUDS boundary. The contract plans illustrate the locations of the former buildings, which PIPC removed except for a few buildings which currently remain onsite. The plans also illustrate a fill area (believed to be building demolition debris) that currently provides access between Iona Island and Round Island (Alion Science and Technology Corporation 2008).

Original structures still standing include Building 201 (Empty Projectile Magazine); Building 212 (former Marine Barracks); Building 217 (Fire Station and Labor Office), Building 222 (Miscellaneous Storage Building), Building 508 (Bag Charge Magazine); and Building 603 (Pyrotechnic Magazine) (Bluestone Environmental Group, Inc. 2018). Figure 2 details the location of the remaining buildings. Building 222 (Store House) is utilized by Bear Mountain State Park for shipping and receiving. Building 212 is in disrepair but has not been demolished due to concerns with asbestos. The old roads in the main part of the former depot (near former Buildings 123 and 410) are still accessible by vehicle. The fill area between Round Island and Iona Island is vegetated, and solid ground allows the area to be traversable by foot.

2. DATA HANDLING AND EVALUATION

The RI was conducted to characterize the nature and extent of impacts to environmental media associated with 19 areas of concern (AOCs) identified as being eligible for further investigation under the FUDS HTRW project, and to assess potential exposure pathways and risk to human receptors and/or ecological receptors. HTRW RI field activities were conducted in accordance with the Uniform Federal Policy (UFP)-Quality Assurance Project Plan (QAPP) (EA Engineering, P.C. and its affiliate EA Science and Technology [EA] 2020) and the UFP-QAPP Addendum (EA 2022a). A two-phased approach (Phase I and Phase II) was employed to facilitate data collection, evaluation, and discussion.

2.1 PHASE I REMEDIAL INVESTIGATION SAMPLING

Phase I field activities were completed in March–April 2020. The Phase I investigation area at Iona Island covered the majority of the former operational area, the eastern (Hudson River) and western (Iona Marsh) shorelines of Iona Island, and the eastern and western sides of the active River Subdivision (CSX Transportation) railroad tracks. Field activities consisted of onsite and background soil sampling and a shoreline reconnaissance along Iona Island. Onsite field activities completed during Phase I included the following:

- Surface and subsurface soil sampling using incremental sampling methodology (ISM).
  - Establishment of 32 onsite decision units (DUs) to address HTRW AOCs, locations where elevated concentrations of Target Analyte List (TAL) metals and/or PAHs were detected during previous investigations, and former explosive storage and filling operations buildings identified as having potential for exposure risk to human and ecological receptors from remaining explosives residues in environmental media (DU-1 through DU-25 and EXDU-1 through EXDU-7) (Figure 3).
  - Surface soil sampling (0-6 in. below ground surface [bgs]) within a total of 30 onsite DUs (DU-1 though DU-7, DU-9 through DU-23, DU-25, and EXDU-1 through EXDU-7) with triplicate samples collected at each DU. Samples were analyzed for TAL metals, PAHs, polychlorinated biphenyls (PCBs), and/or explosives.
    - DU-8 was not sampled due to the presence of non-DoD-related 55-gallon drums and other debris within the DU.
    - DU-24 was not sampled as the majority of the DU consists of exposed bedrock with little, thin soil cover.
  - Shallow subsurface soil sampling (6 to maximum of 36 in. bgs) within 5 DUs (DU-17 through DU-21), with triplicate samples at each DU. Samples were analyzed for TAL metals, PAHs, PCBs, explosives, and/or benzene, toluene, ethylbenzene, and xylene. Subsurface soil at the remaining DUs was not sampled due to shallow depth to refusal (less than 12 in. bgs) at each DU.

- Completion of a shoreline reconnaissance survey to identify potential pathways that lead to the shoreline environment, evaluate whether there are barriers to overland transport from Iona Island to the shoreline, and conduct a receptor and resource inventory evaluation.

- A background soil investigation was conducted to establish regional background metal and PAH concentration ranges in surface and subsurface soil. Background soil sampling was conducted using ISM and included the following investigation field activities:

  — Establishment of 8 background DUs in Bear Mountain State Park outside the influence of the Iona Island Naval Ammunition Depot FUDS (Background and Decision Unit [BADU]-1 through BADU-8) (Figure 4).

  — Background surface soil sampling (0-6 in. bgs) within each of the background DUs. Samples were analyzed for TAL metals and PAHs.

  — Subsurface soil was not sampled at background DUs due to shallow depth to refusal (less than 12 in. bgs) at each DU.

Detailed sample collection information is presented in Section 2 of the RI Report (EA 2022b).

2.2 PHASE II REMEDIAL INVESTIGATION SAMPLING

Elevated metals concentrations were detected within AOC #16 – Area D (former Dumping Area) Phase I soil samples. As a result, Phase II was conducted to close data gaps identified in complete migration pathways from AOC#16 after completion of Phase I and support decision making. Defined surface water migration pathways were identified during Phase I leading from AOC #16 – Area D (former Dumping Area) to the Hudson River and Iona Marsh shorelines. These pathways include overland flow with tidal water and stormwater runoff to the Hudson River, a tidal wetland swale that appears to convey flow to the west toward Iona Marsh, and a riprap-filled drainage swale that directs flow south towards Iona Marsh.

Based upon potential migration pathways, it was determined there is potential for chemicals within soil at AOC #16 – Area D (former Dumping Area) to be mobilized during tidal inundation and transported via surface water to the Hudson River shoreline. In addition, the tidal wetland swale and riprap-filled drainage swale leading to Iona Marsh during the shoreline reconnaissance may convey water and associated contaminants during storm events.

Phase II field activities were completed in April 2022. The Phase II investigation area at Iona Island included the Hudson River shoreline along the eastern boundary of AOC #16 – Area D (former Dumping Area), and the outlets of two surface water migration pathways leading from AOC #16 – Area D (former Dumping Area) to Iona Marsh (including a riprap-filled drainage swale and tidal wetland swale). Onsite field activities completed during Phase II included the following:

- Surface water samples were collected using discrete sampling methods, with a total of 60 discrete surface water samples collected for analysis of dissolved (field filtered)

TAL metals, hardness, and water quality parameter data (temperature, pH, specific conductivity, dissolved oxygen, oxidation-reduction potential, turbidity, and salinity) (Figure 5)

— 20 samples within AOC #16 – Area D (former Dumping Area) during tidal inundation (DUMP-SW-01 to DUMP-SW-20) to evaluate whether contaminants are being mobilized from soil within the source area to tidal water.

— 20 samples along the Hudson River shoreline along the eastern boundary of AOC #16 – Area D (former Dumping Area) (IHRS-SW-01 to IHRS-SW-20) to evaluate the potential for migration of metals from AOC #16 – Area D (former Dumping Area) to the river shoreline.

— 20 samples along the Iona Marsh shoreline at the outlets of drainages identified during Phase I, including the riprap-filled drainage swale (RRDS-SW-01 to RRDS-SW-10) and tidal wetland swale (TWS-SW-01 to TWS-SW-10) to further evaluate these swales as contaminant migration pathways.

- Sediment sampling was conducted using ISM and included the following:

— Establishment of 3 sediment DUs at the ends of preferential flow pathways from AOC #16 – Area D (former Dumping Area) to the Hudson River and Iona Marsh shorelines, with one DU established along the Hudson River shoreline (IHRS-DU-01) and two DUs established along the Iona Marsh shoreline (RRDS-DU-01, and TWS-DU-01) (Figure 6).

— Sediment sampling within each onsite sediment DU, with a total of 9 ISM sediment samples (3 per DU) collected for analysis of TAL metals and physical parameter data (grain size, total organic carbon, pH, and oxidation-reduction potential)

Additionally, background surface water and sediment samples were collected to determine whether COCs in shoreline sediments on Iona Island are consistent with or exceed background. Background field activities completed during Phase II are presented in the bulleted list below. Con Hook, located approximately 3 miles upstream of Iona Island on the western side of the Hudson River, was selected to represent background surface water and sediment concentrations. Con Hook has similar depositional environments to Iona Island, with approximately 7 acres of upland habitat and another 12 acres of a Phragmites-dominated tidal marsh (Con Hook Marsh) (Figure 7). The Active River Subdivision (CSX Transportation) railroad tracks parallels the western boundary of Con Hook Marsh. Similar to Iona Marsh, Con Hook Marsh adjoining the railroad right-of-way may be impacted by contaminants associated with normal operation of the rail line.

- Background surface water sampling using discrete sampling methods at Con Hook for analysis of dissolved (field filtered) TAL metals, hardness, and water quality parameter data (temperature, pH, specific conductivity, dissolved oxygen, oxidation-reduction potential, turbidity, and salinity). A total of 40 surface water samples were collected, with

samples split between the Con Hook Hudson River shoreline and Con Hook Marsh shoreline to serve as background samples for the Iona Island Hudson River and marsh shoreline depositional environments (Figure 7).

— 20 discrete background surface water samples along the Con Hook Hudson River shoreline (CHHRS-SW-01 through CHHRS-SW-20).

— 20 discrete background surface water samples along the Con Hook Marsh shoreline, (CHMS-SW-01 through CHMS-SW-20).

- Background sediment sampling using ISM for analysis of TAL metals and physical parameter data (grain size, TOC, pH, and oxidation-reduction potential).

— Establishment of 2 DUs at Con Hook (upstream island within the Hudson River with similar depositional environments to Iona Island), with 1 DU on the Con Hook Hudson River shoreline and 1 DU on the Con Hook Marsh shoreline to serve as background areas for the Iona Island Hudson River and marsh shoreline depositional environments. Each DU was comprised of 8 non-contiguous sampling units (SUs) (CHHRS-SU-01 through CHHRS-SU-08 and CHMS-SU-01 through CHMS-SU-08) (Figure 7).

— Background sediment sampling within each background sediment SU, with a total of 16 ISM sediment samples collected for analysis, including 8 ISM sediment samples along the Con Hook Hudson River shoreline (CHHRS-SU-01 through CHHRS-SU-08) and 8 ISM sediment samples along the Con Hook Marsh shoreline (CHMS-SU-08 through CHMS-SU-08).

2.3 DATA EVALUATION AND USABILITY ASSESSMENT

Analytical data packages were reviewed to ensure that required laboratory components were included, quality assurance (QA)/quality control (QC) requirements were performed, and data use restrictions were well defined. The analytical data were qualified and appropriately flagged during data validation, and a data usability assessment was conducted to review the analytical results and data qualifiers. The data usability assessments for Phase I and Phase II analytical results are presented in Appendix D of the RI Report (EA 2022b). The following qualifiers were applied to the reported data:

- No qualifier: The analyte was positively identified at the associated numerical value, which is the concentration of the analyte in the sample.

- J: The analyte was positively identified, and the associated numerical value is the approximate concentration of the analyte in the sample.

- J-: The result is an estimated quantity, but the result may be biased low.

- J+: The result is an estimated quantity, but the result may be biased high.

- U: The analyte was not detected at a level greater than or equal to the associated numerical value (limit of detection [LOD] or limit of quantitation [LOQ]).

- UJ: The analyte was not detected; however, the associated numerical value (LOD or LOQ) is approximate and may be inaccurate or imprecise.

- R: The data are unusable. The sample results are rejected due to serious deficiencies in meeting the QC criteria. The analyte may or may not be present in the sample.

Various data were qualified as estimated (J or UJ) during data validation due to QC issues as discussed in the data usability assessments, Appendix D of the RI Report. Overall, the data generated for the Phase I and Phase II investigation meet the data quality objectives specified in the UFP-QAPP and UFP-QAPP Addendum (EA 2020, 2022a) and are considered sufficiently accurate to meet the project objectives. The potential impact of the estimated values is addressed in Section 7 of this HHRA. With the exception of the 1 rejected result (dibenz[a,h]anthracene at BADU-4), the results are deemed of sufficient quality for use in the HHRA.

2.4 DATA EVALUATED IN THE HUMAN HEALTH RISK ASSESSMENT

Data that had no qualifier was used as reported. For data with analytical qualifiers, the inclusion or exclusion of data was based upon EPA (1992) and USACE (2004) guidance. The following procedures were followed for sample results identified with data qualifiers:

- Analytical results bearing the U and UJ qualifiers (indicating that the analyte is not detected at the given LOD) were retained in the data set and considered non-detects. Each non-detected COPC was assigned a numerical value equal to its LOD.

- Analytical results bearing the J, J+, J- qualifiers (indicating that the reported value is estimated because the analyte is detected at a concentration below the LOQ or for other reasons), was retained at the reported concentration.

- Analytical results bearing the R qualifier (indicating that the data was rejected) were not evaluated in the HHRA.

Analytical results for all samples (including background results) are presented in Tables A-1 through A-13, **Attachment 1.**

3. IDENTIFICATION OF CONTAMINANTS OF POTENTIAL CONCERN

Identifying COPCs is a critical step in the risk assessment process. Screening criteria serve to focus the HHRA on COPCs that have the potential to significantly contribute to potential human health risks. Constituents that cannot be eliminated by screening are identified as COPCs and are then quantitatively evaluated in the HHRA. This section describes the risk-based screening as well as the background evaluation conducted to identify COPCs at the site.

3.1 RISK-BASED SCREENING

Risk-based screening identifies analytes that warrant further evaluation in the HHRA. When an analyte is detected at a concentration less than its respective risk-based criteria, exposure is not expected to result in health effects or concerns, and the analyte is not considered further in the HHRA. Analytes detected at concentrations that exceed their respective risk-based screening criteria do not necessarily represent a health concern. Instead, the results of the screening identify those analytes that warrant a more detailed, site-specific evaluation to determine whether health effects may occur. Risk-based screening was conducted by comparing detected analyte concentrations within each DU to risk-based screening concentrations. Any analyte in any medium for which the measured concentration exceeded the risk-based screening concentration was retained as an initial COPC.

EPA's regional screening levels (RSLs) were used for risk-based screening purposes in the HHRA (EPA 2022a). The EPA RSLs combine human health toxicity values with default exposure scenarios to estimate analyte concentrations in environmental media that are considered by EPA to be protective of human exposures (including sensitive populations) over a lifetime. For instance, a residential scenario assumes a default exposure of 350 days per year over a 26-year duration. EPA residential soil RSLs were used to screen the soil data. A restrictive clause is in place for Iona island that it shall be used for recreational purposes only; therefore, residential development is unlikely to occur at the site (USACE 1995). However, EPA residential soil RSLs are included to evaluate potential child receptors at the site.

The RSLs are based on specific, conservative, fixed levels of risk. For carcinogens, this is 10^{-6}, which is the lower bound for excess lifetime potential carcinogenic risk as defined by the National Contingency Plan (EPA 1990). For non-carcinogens, the RSLs are based on a hazard quotient (HQ) of 0.1, to account for potential cumulative effects of multiple contaminants affecting the same target organ. The EPA RSL table identifies some carcinogenic contaminants where the carcinogenic RSL is greater than one-tenth the non-carcinogenic RSL (identified in the EPA RSL tables as "c**"). In these instances, the more conservative one-tenth the non-carcinogenic RSL was used.

For soil and sediment ISM results, the 95 percent upper confidence limit (95UCL) on the mean for each DU was compared to screening criteria. For the ISM samples, triplicate samples were collected for each DU. A 95UCL was calculated from the triplicate results to represent the DU chemical concentration. For the Phase I soil ISM results, the 95UCL was calculated using the Interstate Technology Regulatory Council (ITRC) (2012) calculator as discussed in Section 2.5 of the Phase I RI Data Summary Report (EA 2021). The ITRC calculator uses two candidate upper

confidence limit (UCL) equations that can accommodate ISM datasets: the Student's-t and Chebyshev. The Chebyshev UCL is generally considered to be a conservative estimate of the 95UCL because it generally achieves or exceeds the desired coverage rates, even for non-normal distribution (ITRC 2012). Therefore, the Chebyshev UCL was selected as the 95UCL for use for Phase I results. For the Phase II sediment DUs, the updated ITRC Calculator was used to determine the 95UCL (ITRC 2020). The ITRC Calculator recommends the 95UCL from either the Student's-t or Chebyshev method based upon coefficient of variation (CV). The calculator recommends the Student's-t 95UCL for data sets where the CV of increments is low (defined as CV < 1.5), and the Chebyshev 95UCL for data sets where the CV is medium (defined as 1.5 < CV < 3) or high (defined as CV > 3) (ITRC 2021). The CV of increments is estimated based on summary statistics of the replicates. Therefore, the 95UCL was selected as either the Students-t or Chebyshev 95UCL based upon the recommendation from the ITRC calculator.

For the discrete surface water results, the maximum detected concentration is compared to the screening criteria. Soil and sediment analytical results were compared to the EPA residential soil RSLs. Surface water results were compared to the EPA tap water RSL and the EPA maximum contaminant level. Risk-based screening criteria are presented in Tables A-1 through A-13, **Attachment 1**.

3.2 COMPARISON TO BACKGROUND

3.2.1 Soil and Sediment COPC Background Comparison

Permutation test of means (Student t-Test with adjusted p-value) at the 95 percent confidence level was used to evaluate whether soil metals and PAH concentrations and sediment metals concentrations exceeded regional background concentration ranges.

Permutation tests are a subset of nonparametric statistics. The two-sample permutation test of means evaluates the difference between two group means, and the permutation test does not require that the data from each group follow a normal distribution or that the two groups have the same variance. For this reason, the permutation test is suitable for evaluating both small datasets and non-normal data distributions. Also, this permutation test does not require that the distribution of the two data groups have the same shape in order to be a central value test.

The permutation test assumes only that the data from the two are "exchangeable" when H_0 is true. For a two-sample permutation test of means, the test statistic is the observed difference in the two group means (i.e., site versus background). If the H_0 is true, the group assignment is arbitrary, as there is no difference in the means and the data in essence come from the same population. Therefore, the data are randomly rearranged regardless of group assignment to produce a different set of group means in each rearrangement. The difference in group means is computed and stored after each rearrangement, and this process is repeated for either all possible rearrangements (if possible) or several thousand permutations for larger data sets. The proportion of differences from the rearrangements that equal or exceed the one observed difference from the original data is the permutation p-value of the test (Helsel et al. 2020).

Concentrations for constituents within each DU for soil and sediment were compared to background concentrations using a two-sample hypothesis test with the following H_0.

$$H_0: \text{Site} \leq = \text{Background}$$
$$H_a: \text{Site} > \text{Background}$$

For each test, 10,000 permutation resamples were used to yield a stable p-value. Results of the permutation tests are presented in **Attachment 2**.

3.2.2 Surface Water COPC Background Comparison

A quantitative statistical approach (statistical hypothesis tests) using the two-sample hypothesis test described in Section 3.2.1 was used to compare onsite and background surface water metals concentrations. Mean concentrations from each onsite surface water area [Former Dump Area, Iona Hudson River shoreline, riprap drainage swale, and tidal wetland swale] were compared to mean concentrations from the applicable background depositional environment [Con Hook Hudson River shoreline and Con Hook Marsh shoreline]. The comparisons were made between similar environments. Mean concentrations in the Former Dump Area were compared to both the Con Hook Hudson River shoreline and Con Hook Marsh shoreline. Mean concentrations within the Hudson River shoreline were compared to only the Con Hook Hudson River shoreline. Mean concentrations within the riprap drainage swale, and tidal wetland swale were compared to the Con Hook Marsh shoreline. Results of the permutation tests are presented in **Attachment 2**.

3.3 SELECTION OF CONTAMINANTS OF POTENTIAL CONCERN

COPCs were identified as those analytes exceeding both EPA RSLs and background concentrations. Tables 1a through 1c present a summary of the COPCs identified within soil, sediment, and surface water, respectively. COPCs are presented in Tables 1a through 1c if they exceed risk-based concentrations as presented on Tables A-1 through A-13, **Attachment 1**.

For surface water, arsenic exceeds the EPA tap water RSL (0.052 microgram per liter [µg/L]) within the Former Dump Area (DUMP DU), Iona Hudson River Shoreline (IHRS DU), Tidal Wetland Swale (TWS DU), and Rip Rap Drainage Swale (RRDS DU). However, arsenic surface water detections do not exceed the arsenic maximum contaminant level of 10 µg/L. The following presents a comparison to background surface water results:

Insert #1. Arsenic Surface Water Descriptive Statistics

Decision Unit	Frequency of Detection	Mean Concentration (µg/L)
Dump	10/20	0.401
IHRS	20/20	0.491
RRDS	10/10	0.559
TWS	10/10	0.97
CHHRS	16/20	0.376
CHMS	19/20	0.711

Hypothesis tests for centrality comparing site DUs to background (**Attachment 2**) demonstrate that only IHRS DU has surface water arsenic concentrations exceeding background at the 95% confidence level. The arsenic surface water detections within the Former Dump Area (DUMP DU), the suspected source area for contaminants in IHRS DU, do not exceed background locations (Con Hook Hudson River shoreline and Con Hook Marsh shoreline) at the 95% confidence level. Therefore, the arsenic surface water concentrations within the IHRS DU are considered background levels and are not an indication of release to surface water. As a result, arsenic is not considered a COPC within surface water.

4. EXPOSURE ASSESSMENT

The exposure assessment is conducted to identify the persons or receptors that are or may be exposed to the site, the pathways through which they are potentially exposed, and the magnitude of these potential exposures. To quantify the magnitude of exposure, required information must include the COPC concentrations in various exposure media to which receptors are exposed (exposure point concentrations [EPCs]) and receptor-specific exposure or intake factors that determine the amount of chemical that enters the body (either orally, absorbed through the skin, or inhaled).

The exposure assessment includes several steps:

- Evaluating the exposure setting, which includes a description of the land use and the potentially exposed human populations.

- Developing the CSM, identifying the source of contamination, the contamination transport and release mechanisms, the exposure media, the exposure routes, and the potentially exposed populations.

- Calculating EPCs for each COPC for each of the complete exposure pathways identified in the CSM.

- Identifying the exposure models and parameters with which to calculate the exposure intakes.

- Calculating exposure intakes.

Based upon the site history and current and anticipated site use, a CSM was used to identify complete, potentially complete, or incomplete exposure pathways. Figure 8 presents the CSM. An exposure pathway is the course a chemical or physical agent takes from a source to a receptor. The CSM evaluates the potential sources of contamination, routes of migration, and potential receptors. Exposure pathways begin from potential source areas and progress through the environment via various fate and transport processes to potential human receptors. The exposure pathways may also include a release mechanism and a transport medium if the point of exposure is not at the same location as the source. A completed exposure pathway requires the following four components:

- A source and mechanism of chemical release to the environment
- An environmental transport medium for the released chemical
- A point of potential human contact with the contaminated medium
- A human exposure route at the point of exposure

All four components must exist for an exposure pathway to be complete and for exposure to occur. Incomplete exposure pathways do not result in actual human exposure and are not included in the

exposure assessment and resulting risk characterization. The HHRA exposure pathways are receptor-specific and address all potential human receptors of concern.

4.1 EXPOSURE SETTING

The Iona Island Naval Ammunition Depot FUDS property is located on Iona Island and Round Island along the west side of the Hudson River, in the Town of Stony Point, Rockland County, New York, (Figure 1). The approximately 124.2-acre site is connected to the mainland by a narrow two-lane road. A gate is present along this road; however, access to Iona island is still possible on foot. A busy freight rail line is located immediately east of Iona Island along the point of access.

Iona Island is part of the Hudson River National Estuarine Research Reserve and is under the administration of PIPC who operates the adjacent Bear Mountain State Park property. GSA conveyed the property to PIPC under a "restrictive clause" (recreational purposes only) (USACE 1995). The Hudson River National Estuarine Research Reserve is managed under New York's Coastal Management Program. For the portions of Bear Mountain State Park that are open to the public, recreational opportunities include hiking, boating, and bird watching. There is a parking lot and scenic overlook located directly west of Iona Island, outside of the FUDS boundary.

The majority of Iona Island consists of open space. The site is closed to the public seasonally from December through March when bald eagles are common. Park staff primarily use the existing buildings on Iona Island for storage. The shoreline along the Hudson River areas consists primarily of riprap, gravel, cobbles, boulders, and exposed bedrock. A limited area of exposed sand and gravel shoreline area is present along the shoreline of AOC #16. This area of shoreline is a likely area for boaters or kayakers to access the site. This shoreline area changes to cobbles and boulders (riprap) extending southward along Round Island and a retaining wall spanning the shoreline north of this area is present, with large boulders in the river. The wall is not present along the shoreline in the area of the northern dock. Due to these physical constraints, access to Iona island from the Hudson River is not likely in AOC #16 areas between AOC #16 and the northern dock area or south of AOC #16 towards Round Island.,

The section of the Hudson River at Iona Island is very narrow and deep, with strong currents that scour the shoreline leaving a rocky bottom substrate. The Hudson River in this area has a depth of approximately 165 ft. Tidal influence at Iona Island is approximately 3.5 ft, consequently, the shorelines may not be accessible during high tide conditions (Alion 2008). In addition, a shallow bedrock shelf is present along the Hudson River shoreline. The shelf extends eastward into the river channel, with depths ranging from 0 to approximately -10 ft shoreline below the river surface. The shelf along the shoreline of AOC #16 – Area D (former Dumping Area) extends 250 to 350 ft into the Hudson River channel before sloping steeply downward to a depth of approximately -95 ft below the river surface. Northwest of AOC #16 – Area D (former Dumping Area) the shelf narrows to less than 100 ft along the majority of the eastern shoreline of Iona Island.

Groundwater and surface water at Iona Island are not used as potable water. In the 1990s, the water supply line that supplied Iona Island ruptured on the causeway (near NYS Route 9W). Bear

Mountain State Park did not repair the waterline break and a bedrock well was installed (March 1997) behind the existing storehouse (Building 222). Per Charlie Tonneson, Bear Mountain Park Engineering Department, this new well is not treated and is used for non-potable purposes only (bottled water is brought onto Iona Island for drinking purposes).

Due to the Iona Island restrictive clause that it shall be used for recreational/park purposes only, residential development is not a possible future use (USACE 1995). Recreational use at the site is limited to educational outings and history tours (6–8 times per year with approximately 50 people). Additionally, Iona Island has been used for camping, notably by the Boy Scouts of America (Boy Scouts), who have used the site for activities within the past 5 years (EA 2020). In addition, researchers are presently working in the marshes. Potential trespassers are a possibility because the shoreline is not fenced and residents who live nearby may access the site during boating season from the Hudson River or walk along the access road. Local residents have been observed walking dogs and fishing along the Hudson River shoreline of the site.

Canoers can also access Iona Island, but canoeing is by permit only. There is no intent to put in a trail system associated with the state park. There were plans in the 1970s to develop part of Iona Island as a retreat/nature center, and a sewer system was installed in the early 1970s but was never used. There is no plan for utility work and construction work activities are limited. There are no anticipated construction plans beyond potentially converting existing buildings for other use or constructing a new storehouse. However, if parts of the site were developed for recreational use, construction workers could be potential future receptors.

4.2 SOURCE AREAS

Source areas at the Iona Island FUDS include the 19 AOCs identified as being eligible for further inclusion in the HTRW project and locations where filling or possible spilling of explosive-containing materials could have occurred. The AOCs include the locations/footprints of 16 former buildings, 4 former aboveground storage tanks (ASTs), a former dumping area, 2 former coal storage areas, and 3 former transformers where contaminants related to the facilities or from historic processes during the site's commission as an ammunition depot may be present. In addition, 7 former explosive storage and filling operations buildings were identified as potential source areas. Figure 2 presents the locations of the AOCs and other source areas.

4.3 RELEASE MECHANISMS

Release mechanisms include those physical processes that contribute to the introduction and distribution of a contaminant in the environment. The primary release mechanisms for site contaminants from former buildings/structures at the Iona Island FUDS during operational use included spills, direct releases to the ground, and improper disposal including dumping. These primary release mechanisms may have resulted in contamination of soil at and/or beneath former buildings/structures.

Contaminants in surface and shallow subsurface soil may have been transported to a range of exposure media (including air, subsurface soil, surface water, and sediment) through secondary

and tertiary release mechanisms. Secondary release mechanisms from surface and shallow subsurface soil to other media include the following:

- Soil removal/reworking
- Leaching and infiltration into the subsurface via gravity and/or percolation of precipitation/surface water
- Overland runoff and erosion to surface water bodies or drainage swales
- Wind erosion

The majority of buildings and structures, including building foundations, were demolished and removed by PIPC between November 1965 and December 1973, and imported fill may have been placed over much of the former operational areas (USAGC 2018). Contaminants in surface and subsurface soil were likely mobilized beyond the footprint of the AOCs during demolition of former buildings/structures and reworking of surface and subsurface soil.

Potential contaminants may also have leached/infiltrated into the subsurface through gravity and/or percolation of precipitation/surface water, thus migrating to the subsurface soil. Leaching/infiltration may be ongoing if a soil source is present at Iona Island, particularly at AOC #16 – Area D (Dumping Area). In addition, contaminants may have been transported along the surface via overland runoff and erosion and ultimately deposited in shoreline environments.

4.4 MEDIA OF CONCERN

Soil is the primary medium of concern. Surface soil samples were collected at each DU at 0 to 6 in. bgs. Subsurface soil samples were collected from 6 to 36 in. bgs at select DUs where subsurface soil was encountered. Samples were collected within a wet area, DU-17 through DU-19, which is identified as AOC #16 – Area D (former Dumping Area). Samples collected from DU-17 through DU-19 were considered soil samples for this HHRA.

Groundwater was not encountered during sampling within any of the DUs evaluated. Surface water and sediment samples were collected in select area based upon an evaluation of Phase I soil analytical results that revealed potential concern for the migration of chemicals from AOC#16 – Area D (former Dumping Area) to surface water and sediment. Migration pathways include tidal flow to the Hudson River shoreline and defined surface water channels leading to Iona Marsh (riprap-filled drainage swale and tidal wetland swale). No COPCs were determined for surface water (see Section 3.3). Therefore, only soil and sediment are considered a potential media of concern.

4.5 RECEPTORS OF CONCERN

Within the exposure assessment, EPA guidance (1989, 1991a, 1991b) requires that plausible exposure under both current and future land use be evaluated in the HHRA. Accordingly, potential

receptors were identified for both current and future use scenarios. Potential receptors identified include park personnel, researcher, construction worker, adult recreator, adolescent recreator, child recreator, adolescent trespasser, and camper.

Park Personnel

Park personnel are assumed to be adults who work for PIPC. Park personnel may perform maintenance activities such as grass mowing, site inspections, and general maintenance of the buildings. The Park Personnel are expected to contact the entire site, including the shoreline portions. The park personnel are not expected to dig at depths greater than 6 inches or perform other excavation activities. Therefore, contact is limited to surface soil. These workers may also perform maintenance or similar activities to the swales (RRDS and TWS) and within the IHRS. Therefore, there is a potential for contact to sediment within these areas. The following exposure pathways were considered complete or potentially complete for the park personnel:

- Incidental ingestion of soil and sediment
- Dermal contact with soil and sediment
- Inhalation of windblown particulates from soil

The particulate pathway assumes COPCs are attached to soil particles and become airborne through wind action. Sediments were assumed to remain inundated with water and not expected to produce particulates through wind action.

Researcher

The researcher was also assumed to be an adult and work at the site on a limited or part-time basis. They are not full-time employees with PIPC. The researcher was assumed to work or plant within the marshes so contact with soils within the marsh is expected. Sediment within the marshes was assumed as a contact similar to soil. Plantings within the marsh are assumed within the top 6 inches of soil/sediment. Researchers may also contact other areas of the site. Additionally, the researchers are not expected to perform other subsurface activities. Therefore, contact is limited to surface soil. Researchers are not anticipated to contact sediment collected within the drainage swales (RRDS and TWS) or along the Hudson River (IHRS). The following exposure pathways were considered complete for the researcher:

- Incidental ingestion of soil
- Dermal contact with soil
- Inhalation of windblown particulates from soil

The particulate pathway assumes COPCs are attached to soil particles and become airborne through wind action. Sediments were assumed to remain inundated with water and not expected to produce particulates through wind action.

Construction Worker

The construction worker was also assumed to be an adult and work at the site during short-term construction projects (i.e., 1 year or less). They are expected to dig and perform other subsurface activities, including installation of utilities. Therefore, they may contact all soil depths. Construction worker contact with the Site is expected to be variable. They may contact just one DU during specific construction activities, such as re-development, or move around the Site and contact many DUs during multiple construction activities. The following exposure pathways were considered complete or potentially complete for the construction worker:

- Incidental ingestion of soil
- Dermal contact with soil
- Inhalation of windblown particulates from soil

Recreational Users

The recreational user represents a multiple age-range family that may visit the site from canoeing or access from the road that connects to Iona Island. The adult recreational user was assumed at over 18 years of age. The adolescent recreational user was assumed from 6 to 16 years. The child recreational user was assumed from 2 to 6 years. Recreational users younger than 2 years of age are not anticipated due to site access and site conditions that are not conducive to playgrounds or other play areas. The recreational user is not expected to dig or perform other subsurface activities and is representative of other low frequency receptors that may visit the site during tours or other group events. Additionally, recreational users may contact sediment along the Hudson River shoreline (IHRS). Risk results for the recreational user are protective of other low frequency visitors. The following exposure pathways are considered complete for the recreational user:

- Incidental ingestion of soil and sediment
- Dermal contact with soil and sediment
- Inhalation of windblown particulates from soil

Sediments were assumed to remain inundated with water and not expected to produce particulates through wind action.

Trespasser

The trespasser represents a receptor who may visit the site while boating along the eastern shoreline (Hudson River), boating along the western shoreline, or hiking in the state park. An adult or an adolescent trespasser are expected; however, only an adolescent was evaluated to provide a protective evaluation. The adolescent trespasser was assumed to be 12 to 18 years of age and represents a slightly older adolescent trespasser who may be alone or in the presence of similarly aged individuals. A trespasser is not expected to dig or perform other subsurface activities. The following exposure pathways are considered complete or potentially complete for the trespasser:

- Incidental ingestion of soil and sediment

- Dermal contact with soil and sediment
- Inhalation of windblown particulates from soil

Sediments were assumed to remain inundated with water and not expected to produce particulates through wind action.

Boy Scouts/Camper

The Boy Scouts were assumed at an age from 5 to 18 years who would visit the site to camp and may perform other activities, such as planting or clean-up. The Boy Scouts/Camper may dig or perform other subsurface activities, so they were expected to contact deeper soils. The Boy Scouts may also contact sediment along the IRHS. The following exposure pathways were considered complete or potentially complete for the Boy Scouts/camper:

- Incidental ingestion of soil and sediment
- Dermal contact with soil and sediment
- Inhalation of windblown particulates from soil

4.6 DETERMINATION OF EXPOSURE AREAS

The initial evaluation of DU analytical results was performed on a DU-basis to inform potential decisions that relate to the DU. However, it is acknowledged that all potential site receptors may not remain within one DU because none of the DUs present an attractive area for any of the receptors to spend a majority of time while onsite. Therefore, all receptors may visit various areas of Iona Island during their visit.

However, DU-17 through DU-19 within AOC #16 – Area D (former Dumping Area) are different from the remainder of the Iona Island DUs. The former Dumping Area is a marshy area that is covered with vegetation and subject to tidal influence from the Hudson River that makes access difficult. The Former Dump Area is also identified as a future nature preserve/wetland area. No construction or other activities are expected in this area and actual contact with this area is likely minimal due to vegetation and tidal influences. Additionally, DU-17 through DU-19 were the only DUs with COPCs within the deeper soil samples of 6 to 36 in. bgs. As a result of the site layout and DU locations, two separate exposure areas were identified in the HHRA, in addition to each individual DU.

The first exposure area was identified as the Iona Island Exposure Area. The Iona Island Exposure Area is an upland area exposure to site soils and includes all DUs, except DU-17 through DU-19 within AOC #16 – Area D (Former Dumping Area). The second exposure area, identified as the Former Dump Area Exposure Area, includes only DUs 17 through 19. All receptors identified for Iona Island were evaluated for contact with each exposure area.

The sediment DUs, IHRS, RRDS, and TWS, were not evaluated within an exposure area. The physical condition and location of these DUs are very different than the exposure areas. The IHRS DU consists of exposed sand and gravel shoreline area that is very different than the uplands Island

Exposure Area and the Former Dump Area Exposure Area (DU-17 through DU-19). The drainage swales, RRDS and TWS, represent small areas that lead to the Iona Tidal Marsh. Due to the fact they are drainage swales and are physically separate from other areas, these DUs are evaluated as separate DUs.

4.7 EXPOSURE POINT CONCENTRATIONS

To determine potential doses, EPCs were derived to quantify COPC concentrations within onsite soil. The EPC represents the concentration of COPC in media of concern that a potential receptor is expected to contact over a designated exposure period. Site receptors move randomly across areas of the site over an exposure time, so the EPC was represented by a conservative estimate of the average concentration of the area of exposure.

For ISM samples, triplicate samples were collected for each DU. A 95UCL was calculated from the triplicate results to represent the DU chemical concentration. For the Phase I soil ISM results, the 95UCL was calculated using the Interstate Technology Regulatory Council (ITRC) (2012) calculator. The ITRC calculator uses two candidate upper confidence limit (UCL) equations that can accommodate ISM datasets: the Student's-t and Chebyshev. The Chebyshev UCL is generally considered to be a conservative estimate of the 95UCL because it generally achieves or exceeds the desired coverage rates, even for non-normal distribution (ITRC 2012). Therefore, the Chebyshev UCL was selected as the 95UCL for use for Phase I soil results. Tables A-1 through A-6, **Attachment 1**, present the 95UCL for each soil DU.

For each soil exposure area, which represents combined DUs as discussed in Section 4.4, the EPC was represented by the 95UCL of all the DUs within the respective exposure area combined. The 95UCL for each exposure area was calculated using the ITRC (2020) area weighted calculator. For the exposure areas, all COPCs identified for the individual DUs were evaluated in the exposure area evaluation. **Attachment 3** presents the 95UCL for each exposure area.

For the sediment ISM results, the updated ITRC Calculator was used to determine the 95UCL (ITRC 2020). The ITRC Calculator recommends the 95UCL from either the Student's-t or Chebyshev method based upon coefficient of variation (CV). The calculator recommends the Student's-t 95UCL for data sets where the CV of increments is low (defined as $CV < 1.5$), and the Chebyshev 95UCL for data sets where the CV is medium (defined as $1.5 < CV < 3$) or high (defined as $CV > 3$) (ITRC 2021). The CV of increments was estimated based on summary statistics of replicates. For the Phase II sediment DUs, the 95UCL was selected as either the Students-t or Chebyshev 95UCL based upon the recommendation from the ITRC calculator. Tables A-12 and A-13, **Attachment 1**, present the 95UCL for each sediment DU.

4.8 QUANTIFICATION OF DOSE FROM CHEMICAL EXPOSURES

To determine potential concerns for human health, an estimate of chemical dose was calculated. Two different measures were evaluated, depending on the nature of the effect. When evaluating longer-term (i.e., chronic) exposures to chemicals that produce adverse non-carcinogenic effects, intakes are averaged over the period of exposure (i.e., the averaging time [AT]) (EPA 1989). This measure of intake is referred to as the average daily intake and is a less than lifetime exposure. For

chemicals that produce carcinogenic effects, intakes are averaged over an entire lifetime and are referred to as the lifetime average daily intake (LADI) (EPA 1989).

Detailed equations for determining intake are described below.

Intake Equations for Soil and Sediment

Intake for the incidental ingestion of soil or sediment was estimated using the following equation:

$$(L)ADI = \frac{EPC \; x \; IR \; x \; EF \; x \; ED \; x \; CF}{BW \; x \; AT}$$

where:

(L)ADI = (Lifetime) Average daily intake (milligram per kilogram [mg/kg]-day)
EPC = Concentration of COPC in soil or sediment (mg/kg)
IR = Ingestion rate (milligram(s) per day [mg/day])
EF = Exposure frequency (days/year)
ED = Exposure duration (years)
CF = Conversion factor (10^{-6} kilogram per milligram [kg/mg])
BW = Body weight (kilogram [kg])
AT = Averaging time (days)
For non-carcinogens, AT = ED x 365 days/year
For carcinogens, AT = 70 years x 365 days/year

Exposure associated with dermal contact of soil or sediment was estimated based upon the following equation:

$$(L)ADI = \frac{EPC \; x \; SA \; x \; AF \; xA \; BS \; x \; EF \; x \; ED \; x \; CF}{BW \; x \; AT}$$

where:

(L)ADI = (Lifetime) Average daily intake (mg/kg-day)
EPC = Concentration of a COPC in a soil or sediment (mg/kg)
SA = Surface area for Contact (square centimeters [cm^2])
AF = Skin adherence factor (milligrams per square centimeter [mg/cm^2-event])
ABS = Absorption factor (dimensionless)
EF = Exposure frequency (days/year)
ED = Exposure duration (years)
CF = Conversion factor (10^{-6} kg/mg)
BW = Body weight (kg)
AT = Averaging time (days)
For non-carcinogens, AT = ED x 365 days/year
For carcinogens, AT = 70 years x 365 days/year

The inhalation of particulates from soil was calculated using the following equation (EPA 2009a):

$$EC = \frac{EPC_{air} \; x \; ET \; x \; EF \; x \; ED \; x \; CF_1}{AT \; x \; CF_2}$$

where:

EC = Exposure concentration (microgram(s) per cubic meter [µg/m^3])
EPC$_{air}$ = Concentration of COPC in air (milligrams per cubic meter [mg/m^3])
ET = Exposure time (hours)
EF = Exposure frequency (days/year)
ED = Exposure duration (years)
CF$_1$ = Conversion factor (1,000 micrograms per milligram [µg/mg])
CF$_2$ = Conversion factor (24 hours/day)
AT = Averaging time (days)
For non-carcinogens, AT = ED x 365 days/year x 24 hours/day
For carcinogens, AT = 70 years x 365 days/year x 24 hours/day

The concentration of COPCs in air resulting from particulate emissions from soil was developed following procedures presented in EPA's Soil Screening Guidance (EPA 2002). The COPC concentration in air was calculated from:

$$EPC_{air} = EPC_{soil} \; x \left[\frac{1}{PEF}\right]$$

where:

EPC$_{air}$ = Concentration of COPC in air (mg/m^3)
EPC$_{soil}$ = COPC concentration in soil (mg/kg)
PEF = Particulate emission factor (cubic meters per kilogram [m^3/kg])

The PEF relates the concentration of a COPC in soil with the concentration of dust particles in air. For all receptors, except the construction worker, a PEF value of 1.21×10^9 m^3/kg is used.

The PEF for the construction worker considers particulate matter emissions from wind erosion, excavation soil dumping, dozing, grading, and tiling. The EPA RSL calculator (EPA 2022b) was used to determine the PEF for the construction worker. The PEF is based upon potential construction that may occur at the site assuming excavation, grading, and tilling at the site, which results in a PEF from other than vehicle traffic assuming 1 acre is disturbed during construction. Outputs from the calculator are provided in **Attachment 4**.

4.9 EXPOSURE PARAMETERS

The second step in quantifying chemical intakes requires the identification of exposure parameters. Exposure parameters include rates of contact (e.g., ingestion rates, skin surface areas), exposure

frequency and duration, BW, and averaging time. The contact rate reflects the amount of contaminated media contacted per unit time or event. Exposure frequency and duration are used to estimate the total time of exposure to COPC in media of concern. The BW represents the average BW over an exposure period (EPA 1989). Specific exposure parameters for each receptor are selected based on EPA guidance (EPA 1989, 1991a, 1991b, 2002, 2004, 2011, and 2014) and professional judgment. The receptor-specific exposure parameters used in the HHRA are shown in **Table 2**.

For all adult receptors (i.e., park personnel, researcher, adult recreational user, and construction worker), the BW was assumed at 80 kg (EPA 2014). For the child recreational user, the BW was assumed at 16 kg. This is based on values in Table 8-1 of EPA's Exposure Factors Handbook (EFH) (EPA 2011) and is the average BW for the age ranges of 2 to less than 3 years (13.8 kg) and 3 to less than 6 years (18.6 kg). For the adolescent recreational user, the Boy Scouts/camper, and the adolescent trespasser, the BW was based on the average of the age range evaluated in EPA's EFH Table 8-1.

The ED for each receptor was based upon EPA guidance (2011, 2014), professional judgement, and the age range evaluated. Park personnel are assumed to be long-term, career park employees working at the site for 25 years (EPA 2011, 2014). The researcher was assumed to be a short-term, part-time park employee. Table 16-105 of EPA EFH presents the occupational tenure of employed individuals by employment status. The median duration for a part-time employee is 3.1 years (EPA 2011). Construction workers were assumed to be at the site for a 1-year duration (EPA 2014). For all other receptors, the exposure duration was based upon the age-range evaluated.

4.9.1 Soil Exposure Parameters

For each receptor, the EF, incidental ingestion rates, and skin surface areas available for contact were assumed to be the same for both surface soil and subsurface soil. The soil skin adherence factor and dermal absorption factor were expected to differ for each receptor between surface soil and subsurface soil.

The EF for the park personnel and construction worker were based on EPA (2011, 2014) guidance. Park personnel are similar to the default composite worker (both indoor and outdoor exposure) listed in EPA guidance (1991a, 2014). EF for the researcher, trespasser, and Boy Scouts/camper were based upon professional judgement. The EF for the recreational user was based on professional judgement.

The construction worker was assumed to contact soil for 250 days per year, which is 5 days per week for 50 weeks (EPA 2014). Park personnel were assumed to contact soil for 5 days per week for 32 weeks (approximately 6 months) or 160 days per year. The recreational user was assumed to visit the site 1 day per week during the warmer months, or approximately 31 weeks, this results in an exposure frequency of 31 days/year. This was assumed to occur over a 10-year exposure duration based upon the age range of 6 to 16 years for the adolescent recreational user, 4-year duration for the child, and a 20-year duration for the adult. The camper EF was estimated based upon a typical number of days Boy Scouts spend camping. A merit badge requirement for camping

within the Boy Scouts is for 20 nights per year (Boy Scouts of America 2023). While this requirement is more likely for an older age range than the age range evaluated in this HHRA, the estimate of 20 nights per year was selected. The ED for the camper was based upon the age range evaluated. The EF for the trespasser assumes a visit 1 day per week, twice per month from April to November, which equals 16 days per year. The 1 day per week visit was typical for all users at New York State Parks (New York State Office of Parks, Recreation & Historic Preservation 2016) and is site-specific. This EF for the trespasser was expected to occur over a 6-year ED based upon the age range evaluated for the trespasser. The researcher was assumed to visit the site 2 days per week, 6 months per year (primarily in growing season to maintain marsh or other areas) for a total of 52 days per year.

The ingestion rate for the construction worker was obtained from guidance for the calculation of the EPA RSLs and Supplemental Guidance for Developing Soil Screening Levels (EPA 2002, 2022a). A construction worker soil ingestion rate of 330 mg/day was assumed. For the park personnel and researcher, a soil ingestion rate of 100 mg/day was assumed to account for primarily outdoor activities (EPA 2011, 2014, 2022a). For the adult, adolescent, and child recreational user, soil ingestion rates of 100 mg/day, 200 mg/day, and 200 mg/day were assumed, respectively, which are equal to typical ingestion rates used for the resident adult and child (EPA 2011, 2014, 2022a). For the Boy Scouts/campers, a soil ingestion rate equal to the resident child, 200 mg/day, was assumed to account for expected high-contact rate with soil. The adolescent trespasser has a lower contact rate with soil; therefore, a soil ingestion rate of 100 mg/day was assumed.

Dermal exposure to soil was assumed for exposed body surface areas only. The SA available for contact generally assumes hands, forearms, head, lower legs, and feet for the resident. The construction worker and park personnel were only assumed to contact soil with hands, forearms, and head with a mean SA of 3,527 cm^2 (EPA 2014). The adult recreational user SA available for contact was set to the SA for the adult resident of 6,032 cm^2 (EPA 2014, 2022a). For the adolescent recreational user, child recreational user, adolescent trespasser, and camper the mean SA was determined for the head, hands, forearms, and lower legs from Table 7-2 of the EPA EFH (EPA 2011). To account for the forearm and lower leg only, these body parts were assumed at 45 percent of the full arm and leg mean surface areas. For the child recreational user, the mean SA for the head, hands, forearms, and lower legs for the age groups of 2 to less than 3 years and 3 to less than 6 years was determined to be 2,107 cm^2 (EPA 2011). For the adolescent recreational user and trespasser, the mean SA for the head, hands, forearms, and lower legs for the age groups of 11 to less than 16 years was determined to be 4,645 cm^2 (EPA 2011). For the Boy Scouts/camper, the mean SA for the head, hands, forearms, and lower legs for the age groups of 6 to less than 11 years and 11 to less than 16 years was determined to be 3,947 cm^2 (EPA 2011).

Adherence factors for surface soil were obtained from EPA guidance for workers and residents (EPA 2011, 2014, 2022a). The researcher and construction worker were expected to have higher contact with surface soil, so the skin adherence factor was set to the EPA default for a construction worker of 0.3 mg/cm^2. Additionally, the adherence factor for the adolescent and child recreational user, trespasser, and Boy Scouts were set to the EPA default of 0.2 mg/cm^2 for a recreator (EPA 2022a). The adherence factor for the park personnel was set to the EPA default for a composite worker (0.12 mg/cm^2) to account for indoor and outdoor work (EPA 2022a).

Adherence factors for subsurface soil were based upon the expected activities for the construction worker and Boy Scouts since they are the only receptors expected to contact the subsurface. Exhibit 3-3 of RAGS E (EPA 2004) presents soil adherence factors based upon activities. For the construction worker, the 95th percentile adherence factor for a utility worker of 0.9 mg/cm^2 was selected (EPA 2004a). For the Boy Scouts, the adherence factor for children playing in wet soil (3.3 mg/cm^2) was selected (EPA 2004).

The inhalation of soil particulates assumed a 24-hour exposure period for the Boy Scouts/camper and an 8-hour workday for the researcher and park personnel. For the construction worker, the workday was determined from Table 16-20 of EPA EFH (EPA 2011), which presents the time spent in select outdoor locations and outdoor at construction sites. The 90th percentile time spent at a construction site for 18 to 64 years of age is 687 minutes per day. The 90th percentile time spent at a construction site for the Northeast Region is 695 minutes per day. Both of these times are similar and are approximately 11.5 hours per day. The recreational user and trespasser were assumed to only be present at the site for 4 hours per day. This is based upon a comparison of outdoor recreation times for doers only from Tables 16–25 and 16–26 of EPA EFH (EPA 2011). The 50 percentile and 90 percentile times for both the 11 to 16 age range (Table 16-25) and the 50 percentile and 90 percentile times for the Northeast Region ranged from 2 to 6 hours. Therefore, a value of 4 hours was selected. The PEF for all receptors, except the construction worker, was set to 1.21×10^9 m^3/kg. This PEF is specific to New York State and averages meteorological data for four cities (Cleveland, Ohio; Harrisburg, Pennsylvania; Hartford, Connecticut; and Philadelphia, Pennsylvania) based upon the two climatic zones for New York State (zones #7 and #8) [New York State Department of Environmental Conservation (NYSDEC) 2006]. A review of this PEF confirms it is appropriate for site-specific use for the site exposure. The PEF for the construction worker was determined using the EPA RSL calculator and is provided in **Attachment 4**.

4.9.2 Sediment Exposure Parameters

Exposure frequencies for contact with sediment were assumed equal to those for soil due to the low number of days per year the recreational user and Boy Scouts contact the site. It is reasonable that they may contact sediment for these same number of days. However, park personnel were assumed to be at the site for 160 days per year. This receptor contact with sediment was assumed at half of the days they are estimated to be onsite. Incidental ingestion rates for sediment are not available, so soil incidental ingestion rates are usually used as a surrogate. However, the soil ingestion rates account for ingestion of dust (EPA 2011). To determine the sediment ingestion rate for all receptors, only the soil ingestion rates (i.e., no dust ingestion), 50 mg/day, were used from Table 5-1 of the EPA 2011 EFH (EPA 2011). For dermal contact, the skin surface area available for contact used for surface soil was assumed to be similar because this accounts for exposed skin surfaces of the receptor, so these areas will also be available for sediment contact. The adherence factor used for subsurface soil for similar aged receptors were assumed similar since they take into account a wetter soil with a higher adherence factor.

5. TOXICITY ASSESSMENT

The toxicity assessment considers the types of potential adverse health effects associated with exposures to COPCs in onsite soil, the relationship between the magnitude of exposure and potential adverse effects, and the related uncertainties, such as the weight of evidence of a particular COPCs carcinogenicity in humans.

5.1 HEALTH EFFECTS CLASSIFICATION AND CRITERIA

EPA (1989) specifies that the assessment be accomplished in two steps: hazard identification and dose-response assessment. Hazard identification is the process of determining whether studies demonstrate that exposure to a COPC may cause the incidence of an adverse effect. EPA specifies the dose-response assessment, which involves: (1) quantitative evaluation of the existing toxicity information, and (2) characterization of the relationship between the dose of the COPC administered or received, and the incidence of potentially adverse health effects in the exposed population. From this quantitative dose-response relationship, specific toxicity values are derived that can be used to estimate the incidence of potentially adverse effects occurring in humans at different exposure levels (EPA 1989).

Toxicity values will be selected according to EPA (2003a) and USACE (2016) guidance. The following hierarchy for human toxicity values will be used in the HHRA:

- **Tier 1 values** – EPA's Integrated Risk Information System (IRIS) (EPA 2022c)
- **Tier 2 values** – EPA's Provisional Peer Reviewed Toxicity Values
- **Tier 3 values** – Toxicity values from other sources. Priority will be given to sources of information that use sound science and are the most current, peer-reviewed, transparent, and publicly available.

The primary source of toxicity information is IRIS (EPA 2022c). When toxicity information and factors are not available in IRIS, a secondary value is sought. Tier 2 values, EPA's Provisional Peer Reviewed Toxicity Values, are developed by the Office of Research and Development, the National Center for Environmental Assessment, and the Superfund Health Risk Technical Support Center on a chemical-specific basis when requested by the Superfund program. Tier 3, other toxicity values, are considered when Tier 1 or Tier 2 toxicity values are not available. These toxicity values are taken from additional EPA and non-EPA sources and are chosen based on the most current and best peer-reviewed source available. The California EPA (CalEPA) Office of Environmental Health Hazard Assessment Toxicity Criteria Database (CalEPA 2022), the CalEPA Cancer Potency Values (CalEPA 2009), the Agency for Toxic Substances and Disease Registry (ATSDR) Minimal Risk Levels (ATSDR 2022), and the Health Effects Assessment Summary Tables (EPA 1997) are potential Tier 3 sources for this HHRA.

For this HHRA, two toxicological endpoints are considered: carcinogenic and non-carcinogenic. The following sections detail how each endpoint is determined.

Toxicity Assessment for Non-Carcinogens

The methodology used by EPA for deriving non-cancer reference values for non-carcinogens, and site-specific considerations for modifying or using these concentrations are discussed in detail in Barnes and Dourson (1988) and EPA guidance (EPA 2022c). Non-carcinogens are typically judged to have a threshold daily dose below which deleterious or harmful effects are unlikely to occur. This concentration is called the no-observed-adverse-effect-level (NOAEL), and may be derived from either animal laboratory experiments or human epidemiology investigations (usually workplace studies). In developing a toxicity value or human NOAEL for non-carcinogens (i.e., a reference dose [RfD]), the regulatory approach is to (1) identify the critical toxic effect associated with chemical exposure (i.e., the most sensitive adverse effect); (2) identify the threshold dose in either an animal or human study; and (3) modify this dose to account for interspecies variability (where appropriate), differences in individual sensitivity (within-species variability), and other uncertainty and modifying factors. For the reference concentration (RfC), experimental exposures are extrapolated to a human equivalent concentration (HEC). The HEC is determined through a two-step process that begins with a point-of-departure, which is adjusted (multiplied) by a dosimetric adjustment factor (DAF) (EPA 2009a). The point-of-departure can represent a NOAEL, lowest-observed-adverse-effect-level (LOAEL), benchmark concentration, lower confidence limit, and the lower limit on an effective concentration using a 10 percent response level (LEC_{10}). The DAF is for the specific site of the chemical's effects (e.g., respiratory tract). The DAF is dependent upon the nature of the contaminant and the target site of the toxic effect.

Uncertainty factors (UFs) are intended to account for specific types of uncertainty inherent in extrapolation from the available data. The UFs are generally 10-fold, default factors used in operationally deriving the RfD and RfC from experimental data. UFs less than 10 can be used. A UF of 3 can be used in place of one-half power ($10^{0.5}$), when appropriate. The UFs are intended to account for (1) variation in susceptibility among the members of the human population (i.e., inter-individual or intraspecies variability); (2) uncertainty in extrapolating animal data to humans (i.e., interspecies uncertainty); (3) uncertainty in extrapolating from data obtained in a study with less-than-lifetime exposure (i.e., extrapolating from subchronic to chronic exposure); (4) uncertainty in extrapolating from a LOAEL rather than from a NOAEL; and (5) uncertainty associated with extrapolation when the database is incomplete. The maximum UF for the derivation of the RfCs used in this HHRA is 1,000. The maximum UF for the derivation of the RfDs used in this HHRA is 3,000. To calculate the RfD, the appropriate NOAEL is divided by the product of all the applicable UFs. This is expressed as:

$$RfD = NOAEL / (UF_1 \times UF_2 \times UF_3 \times UF_4)$$

The resulting RfD is expressed in units of milligrams of chemical per kilogram of body weight per day (mg/kg-bw/day). To calculate the RfC, the HEC is divided by UFs and is expressed in units of mg/m^3. Tables 3 and 4 present the non-carcinogenic toxicity values used in this HHRA.

Toxicity Assessment for Carcinogenicity

Unlike non-carcinogens, carcinogens are generally assumed to have no threshold. There is presumed to be no level of exposure below which carcinogenic effects will not manifest

themselves. This "non-threshold" concept supports the idea that there are small, finite probabilities of inducing a carcinogenic response associated with every level of exposure to a potential carcinogen. EPA uses a two-part evaluation for carcinogenic effects. This evaluation includes the assignment of a weight-of-evidence (WOE) classification and the quantification of a cancer toxic potency concentration.

EPA has established five recommended standard hazard descriptors: "*Carcinogenic to Humans*," "*Likely to Be Carcinogenic to Humans*," "*Suggestive Evidence of Carcinogenic Potential*," "*Inadequate Information to Assess Carcinogenic Potential*," and "*Not Likely to Be Carcinogenic to Humans*" (EPA 2005a). The WOE classification is based on a thorough scientific examination of the body of available data. Only compounds that have a WOE classification of B2 or above are considered to have carcinogenic potential in this risk assessment. Compounds with a WOE classification of C will be discussed in the uncertainty section.

Since the revised cancer guidelines (EPA 2005a) are not yet incorporated into many of the IRIS chemical profiles, the WOE classifications defined by EPA (EPA 1989) and shown in the toxicity profiles on the IRIS system will still be used when interpreting carcinogenic toxicity of COPCs. The WOE classification system assigns a letter or alphanumeric (A through E) to each potential carcinogen that reflects an assessment of its potential to be a human carcinogen. This WOE classification that will be used in the HHRA is defined as follows:

- ***Group A*** – Known human carcinogen
- ***Group B –*** Probable human carcinogen
- ***Group B1 –*** Limited evidence of carcinogenicity in humans
- ***Group B2 –*** Sufficient evidence in animals, but inadequate evidence in humans
- ***Group C –*** Possible human carcinogen (limited evidence of carcinogenicity in animals in the absence of human data)
- ***Group D –*** Human carcinogenicity not classifiable because of lack of data
- ***Group E*** – Evidence of non-carcinogenicity in humans (no evidence in at least two adequate animal tests in different species or in both epidemiological and animal studies)

Quantification is expressed as a slope factor (SF) for oral and dermal exposures and an inhalation unit risk (IUR) for inhalation exposures, which reflects the dose-response data for the carcinogenic endpoint(s) (EPA 1989, 2009a). The SF and the IUR are the upper 95^{th} percentile confidence limit of the probability of response per unit daily intake of a chemical over a lifetime. The SF is expressed in units of proportion (of a population) affected per mg/kg-day. The IUR is expressed in $\mu g/m^3$. Typically, the SF and the IUR are used to estimate the upper-bound lifetime probability of a person developing cancer from exposure to a given concentration of a carcinogen. SFs and IURs are generally based on experimental animal data unless suitable epidemiological studies are

available. Due to the difficulty in detecting and measuring carcinogenic endpoints at low exposure concentrations, SFs and IURs are typically developed by using a model to fit the available high-dose, experimental animal data, and then extrapolating downward to the low-dose range to which humans are typically exposed. EPA recommends the linear multistage model to derive an SF and IUR. The model is conservative and provides an upper bound estimate of excess lifetime cancer risk. These methods and approaches are discussed in greater detail within the EPA *Cancer Guidelines* (EPA 2005a). Tables 5 and 6 present the carcinogenic toxicity values used in this HHRA.

Carcinogenic compounds were assessed for mutagenic modes of action. COPCs identified as mutagenic have sensitivity pertaining to cancer risks associated with early-life exposures. Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-c,d)pyrene are the COPCs with a mutagenic mode of action. Tables 5 and 6 present the COPCs with a mutagenic mode of action. The mutagenic mode of action is assessed with a linear approach (EPA 2005b). To account for the early-life exposure and the mutagenic mode of action, the cancer potency estimates will be adjusted by an age-dependent adjustment factor (ADAF). EPA recommends, for mutagenic chemicals, when no chemical-specific data exist, a default approach using estimates from chronic studies (i.e., cancer slope factors) with appropriate modifications to address the potential for differential risk of early life stage exposure (EPA 2005a, 2005b). An ADAF modification for early life stage exposure to mutagenic COPCs is required because available studies indicate higher cancer risks resulting from a given exposure occurring early in life when compared with the same amount of exposure during adulthood (EPA 2005b). The intakes for COPCs identified with a mutagenic mode of action will be modified by an ADAF for the following exposures (EPA 2005b):

- For exposures before 2 years of age (i.e., spanning a 2-year time interval from the first day of birth up until a child's second birthday), a 10-fold adjustment

- For exposures between 2 and less than 16 years of age (i.e., spanning a 14-year time interval from a child's second birthday up until their sixteenth birthday), a 3-fold adjustment

- For exposures after turning 16 years of age, no adjustment

For this HHRA, the adolescent recreational user, child recreational user, and adolescent trespasser are within the age range that requires adjustment for a mutagenic mode of action.

5.2 ADJUSTMENT FOR DERMAL ABSORPTION

Toxicity values specific to dermal exposures are not available and require adjustment of the oral toxicity values (oral RfDs or SFs). This adjustment accounts for the difference between the daily intake dose through dermal contact as opposed to ingestion. Most toxicity values are based on the actual administered dose and must be corrected for the percent of chemical-specific absorption that occurs across the gastrointestinal tract prior to use in dermal contact risk assessment (EPA 1989, 2004). EPA recommends utilizing oral absorption efficiency factors in converting oral toxicity values to dermal toxicity values (EPA 2004). This adjustment accounts for the absorption

efficiency in the "critical study," which is utilized in determining the RfD and SF. Where oral absorption in the critical study is essentially complete (i.e., 100 percent), the absorbed dose is equivalent to the administered dose, and no adjustment of oral toxicity values is necessary when evaluating dermal exposures. When gastrointestinal absorption of a chemical in the critical study is poor (e.g., 1 percent), the absorbed dose is much smaller than the administered dose, and toxicity values for dermal exposure are adjusted to account for the difference in the absorbed dose relative to the administered dose. To account for the differences between the administered (oral) and the absorbed (dermal) dose, RfDs and SFs are modified by the gastrointestinal dermal absorption factor (GI ABS).

In addition to the GI ABS modification of the toxicity values for dermal contact, dermal contact rates are also evaluated based upon a chemical's ability to be absorbed through the skin surface. This absorption rate is dependent upon the medium evaluated. For soil, EPA has identified a dermal ABS that is chemical-specific. The ABS value reflects the desorption of a chemical from soil and the absorption of the chemical across the skin and into the blood stream. Recommended values are presented that consider ranges of values that result from different soil types, loading rates, chemical concentrations, and other conditions. ABSs specific to sediment have not been set forth, so soil ABSs are used as surrogates for sediment. Chemical-specific adjustment for dermal absorption is presented on Table 7.

5.3 SPECIAL CHEMICAL: LEAD

Lead is classified as a B2-probable human carcinogen. However, EPA has not published an SF or IUR for quantifying carcinogenic risks. Lead is not regulated as a carcinogen because it appears to be more potent as a toxicant to the hemopoietic system by inhibiting heme synthesis. Much of the toxicological data collected on the effects of lead in humans relates to exposure and effect in terms of the amount of lead in blood associated with an observed effect, expressed as micrograms of lead per deciliter of blood (µg lead/dL blood). EPA and the Centers for Disease Control and Prevention (CDC) have determined that there is no safe level of lead in children (CDC 2012). CDC recommended a reference value based on the 97.5^{th} percentile of the National Health and Nutrition Examination Survey (NHANES)-generated blood-lead level in children 1–5 years old (CDC 2012). The 97.5^{th} percentile blood-level level was identified as 5 µg/dL. Therefore, blood lead levels are the indicator of excess lead exposure in humans.

6. RISK CHARACTERIZATION

The characterization of human health risk involves combining information from the exposure assessment with that from the toxicity assessment. Chemical intakes for each receptor and each exposure pathway are combined with toxicity information to derive cumulative excess lifetime cancer risks (ELCRs) and cumulative non-cancer hazard indexes (HIs). The ELCRs and HIs are presented in EPA RAGS D format (EPA 2001). These tables also present cumulative cancer risks or HIs for COPCs, pathways, and receptors.

The methodologies used to estimate carcinogenic risks and chronic and subchronic risks for non-carcinogens are described further in the sections below.

6.1 HAZARD INDEX FOR NON-CARCINOGENIC EFFECTS

Potential human health risks associated with exposures to non-carcinogenic COPCs are calculated by comparing the intake or the EC with the chemical-specific RfD or RfC, as per EPA Guidance (EPA 1989, 2009a). An HQ is derived for each COPC, as shown in the equation below:

$$HQ = \frac{Intake}{RfD} \qquad \text{or} \qquad HQ = \frac{EC}{RfC \times (1{,}000 \mu g/mg)}$$

where:

HQ	=	Hazard quotient (unitless)
Intake	=	Calculated non-carcinogenic average daily intake (mg/kg-day)
EC	=	Exposure concentration (µg/m^3)
RfD	=	Reference dose (mg/kg-day)
RfC	=	Reference concentration (mg/m^3)

If the average daily dose (intake) exceeds the RfD or RfC, the HQ will exceed a ratio of one (1.0) and there may be concern that potential adverse systemic health effects will be observed in the exposed populations. If the average daily dose (intake) does not exceed the RfD or the RfC, the HQ will not exceed 1.0 and there will be no concern that potential adverse systemic health effects will be observed in the exposed populations. In general, the greater the value of the HQ is above 1.0, the greater the level of concern. However, the HQ does not represent a statistical probability that an adverse health effect will occur. To evaluate the potential for exposure to multiple chemicals for each exposure pathway, an HI is calculated.

This approach assumes that the exposure to more than one chemical is additive; and therefore, sums the HQs of all the COPCs:

$$HI = \Sigma HQ_n$$

In this aspect, synergistic and antagonistic interactions are not considered. Similar to the HQs, if the HI exceeds 1.0, the potential for non-carcinogenic adverse effects may exist. The overall receptor-specific HI is the sum of the HIs for all exposure pathways. If the HI is less than 1.0, then

no adverse health effects are likely to be associated with exposures at the site. However, if the total HI is greater than 1.0, separate endpoint-specific HIs may be calculated based on toxic endpoint of concern or target organ (e.g., HQs for neurotoxins are summed separately from HQs for renal toxins). Only if an endpoint-specific HI is greater than 1.0 is there reason for concern about potential health effects for that endpoint.

6.2 CARCINOGENIC RISK

Carcinogenic risk is calculated as the incremental probability of an individual developing cancer over a lifetime as a result of exposure to a potential carcinogen. The numerical estimate of ELCR is calculated by multiplying the lifetime cancer average daily intake (LADI) by the risk per unit dose (the SF) or multiplying the EC by the IUR.

This is shown in the following equation:

$$ELCR_n = LADI \times SF$$
$$ELCR_n = EC \times IUR$$

where:

$ELCR_n$ = chemical-specific excess lifetime cancer risk for chemical "n"
$LADI$ = Lifetime average daily intake (mg/kg-day)
EC = Exposure concentration ($\mu g/m^3$)
SF = Cancer slope factor $(mg/kg\text{-}day)^{-1}$
IUR = Inhalation unit risk $(\mu g/m^3)^{-1}$

Since the SF and the IUR are the statistical 95th percent upper-bound confidence limit on the dose-response slope, this method provides a conservative, upper-bound estimate of risk. It should be noted that the interpretation of the significance of the cancer risk estimate is based on the appropriate public policy. EPA in the National Contingency Plan (40 CFR Part 300) (EPA 1990) states that:

> *"...For known or suspected carcinogens, acceptable exposure levels are generally concentration levels that represent an excess upper bound lifetime cancer risk to an individual of between 10^{-4} and 10^{-6}."*

To evaluate the potential for exposure to multiple chemicals for each exposure pathway, risks resulting from exposure to multiple carcinogens are assumed to be additive. Therefore, the pathway-specific ELCR is estimated by summing the risks estimated for each COPC in each environmental media and for each pathway:

$$ELCR_{total} = \Sigma ELCR_n$$

where:

$ELCR_{total}$ = total lifetime cancer risk across all exposure pathways
$ELCR_n$ = chemical-specific excess lifetime cancer risk for chemical "n"
n = various individual carcinogenic COPCs

The overall receptor-specific $ELCR_{total}$ is the sum of the risk for all exposure pathways. This risk is presented as one significant figure (EPA 1989).

6.3 LEAD RISKS

For lead in soil, lead risks were modeled using *Recommendations of the Technical Review Workgroup for Lead, An Interim Approach to Assessing Risks Associated with Adult Exposures to Lead in Soil* (EPA 2003b, 2009b, 2017). The adult lead model (ALM) is developed to model the most sensitive receptor which is the fetus of a worker who develops a body burden as a result of non-residential exposure to lead. The model assumes levels of lead that are protective of a fetus will also afford protection for male or female adult workers. To achieve a specific level of protectiveness, EPA has established a limit to exposure to soil lead levels such that a typical (or hypothetical) child would have an estimated risk of no more than 5 percent exceeding the reference blood-lead level.

For the adult receptors, the baseline blood-lead level (PbB_0) and geometric standard deviation of the blood-lead level (GSDi) based upon the NHANES 2009–2014 data were used (EPA 2017).

The ALM is recommended for use to evaluate potential concerns for exposure to lead for adolescents, which includes the site receptors adolescent recreational users and trespassers EPA 2022d). EPA notes, "The adolescent population may be considered sensitive since exposures during these years may result in a body burden of lead that is available to transfer to the fetus later in life. Given the limitations of currently available modeling tools, it is reasonable to apply the ALM to adolescent receptors…" (EPA 2022d). To evaluate adolescents, specific model parameters in the ALM are changed to better model the adolescent population; these parameters include the exposure frequency, exposure duration, baseline blood lead (PbB_0), and absorption fraction.

EPA notes that potential lead absorption is higher in adolescents than in adults. A range from 12 to 30 percent absorption is identified. However, an absorption fraction of 12 percent is selected for all receptors based upon the expected activities that will occur at the site and the infrequent exposures. The baseline blood lead level for the adolescent was taken from the CDC report *National Report on Human Exposure to Environmental Chemicals* (CDC 2022). The report using individual and pooled blood or urine samples tested by Centers for Disease Control and Prevention from people who took part in CDC's NHANES. The report determined a geometric mean of blood lead levels for adolescents (age 12 to 19 years) from years 2017 and 2018 as 0.411 µg/dL (CDC 2022). The CDC report does not specify a GSD_i for this blood-lead level. Therefore, ALM default GSD_i was used.

For the soil ingestion rate, EPA notes, "a soil ingestion rate of 50 mg/day is recommended as a plausible central tendency value for non-contact-intensive activities. Either commercial or

industrial workers may work primarily indoors, so that exposure to soil occurs primarily via indoor dust. Workers' limited and occasional contact with outdoor soils (e.g., picnicking, walking to parking lots, standing on a loading dock) should be adequately accounted for via the 50 mg/day incidental soil ingestion. If an individual is performing a contact-intensive activity with soil, then a soil ingestion rate greater than 50 mg/day would be expected (EPA 2022c)." For all receptors, except the construction worker, contact with the site was assumed to consist of only non-contact-intensive activities; therefore, a soil ingestion rate of 50 mg/day was assumed. The construction worker exposure to soil is expected to be contact intensive. For this type of exposure, EPA notes, "Because central tendency values are recommended inputs for both the IEUBK [Integrated Exposure Uptake Biokinetic] model and the ALM, a more plausible range for a soil lead ingestion rate is 50 mg/day to 200 mg/day for adult contact-intense soil exposures. Thus, there is reasonable support for use of 100 mg/day as a soil ingestion rate for the contact-intense worker scenario in the ALM (EPA 2022d)."

EPA also notes for the ALM, "If exposures are expected to occur over a shorter time interval, then EF should not be prorated over the entire year (EPA 2022d)." For recreational user receptors, contact with the site is not expected to occur over the entire year (i.e., 12 months) but rather during warmer months (e.g., 6 months). As a result, the averaging time used in the ALM reflects the shorter time period these receptors are present at the site (EPA 2003b).

The following is a summary of some default parameters and site-specific parameters used in the ALM:

- Lead concentration in soil = mean concentration (DU specific)
- Mother's Blood Lead Concentration at Childbirth = 0.6 µg of lead/dL
- GSD_i of lead in blood = 1.8 (EPA 2017)
- Soil ingestion rate = 100 mg/day (construction worker); 50 mg/day (worker and recreational user)
- Absorption fraction = 0.12 (default)
- Exposure frequency = Receptor specific (Table 2)
- Baseline blood lead (PbB_0) = 0.411 µg/dL (adolescent), 0.6 µg/dL (adults)

6.4 RISK ASSESSMENT RESULTS

Calculations are presented for each individual DU and for the two exposure areas. The Iona Island Exposure Area includes DU-1 through DU-07 and DU-09 through DU-22, which encompass

15 AOCs (locations/footprints of 16 former buildings, 4 former ASTs[1], 2 former coal storage areas, and 3 former transformer locations). The Former Dump Area Exposure Area is the second exposure area and includes DU-17 through DU-19, which includes AOC #16 – Area D (Former Dumping Area).

The following sections and tables present the non-carcinogenic hazards and carcinogenic risks. No receptor exposures exceeded the acceptable cancer risk range of 10^{-4} to 10^{-6}. Additionally, all receptors exposure were below the non-cancer hazard index of 1.0 for exposure to DUs-13 through -18, except for the construction worker. However, a breakdown by target organ did not reveal any target organ HIs greater than 1.0. Potential risk concerns were determined for lead; these are discussed in Section 6.4.25.

6.4.1 DU-1 Risk Assessment Results

Calculations for receptors evaluated for DU-1 are presented in Tables 8 through 15. Estimates of cumulative risks across all pathways for non-carcinogenic and carcinogenic effects are presented in Tables 16 through 23. The following table presents a summary of the results:

Insert #2. DU-1 Risk Assessment Results

Receptors	HHRA Results	
	Carcinogenic Risk	Non-carcinogenic Hazards
Park Personnel	3E-06	0.04
Researcher	2E-07	0.01
Construction Worker	7E-07	0.4
Adult Recreator	5E-07	0.007
Adolescent Recreator	7E-07	0.03
Child Recreator	9E-07	0.07
Adolescent Trespasser	1E-07	0.006
Camper	7E-07	0.02

[1] The ASTs themselves are not the AOCs. The FUDS-eligible AOCs are the former AST locations/footprints. The ASTs were removed but the sites were not formally closed and were not included in the Containerized HTRW project.

6.4.2 DU-2 Risk Assessment Results

Calculations for receptors evaluated for DU-2 are presented in Tables 24 through 31. Estimates of cumulative risks across all pathways for non-carcinogenic and carcinogenic effects are presented in Tables 32 through 39. The following table presents a summary of the results:

Insert #3. DU-2 Risk Assessment Results

6.4.25 Lead

Lead was identified as a COPC based upon a comparison to the EPA residential soil RSL (400 mg/kg) (Table 1a). Lead was identified as a COPC for the individual DU-7, DU-17 (surface and subsurface soil), DU-18 (surface and subsurface soil), and IHRS DU. Since these individual DUs had maximum detected concentrations of lead above the residential soil RSL, lead was identified as a COPC within the combined exposure areas, Iona Island Exposure Area (including DU-1 through DU-7, DU-9 through DU-15) and Former Dump Exposure Area (DU-17 through DU-19). Potential concerns for workers, recreational adults and adolescents exposure to lead in soil were evaluated using the EPA ALM. The ALM evaluates the percentage of a target population that will have blood-lead levels above a reference concentration of 5 µg/dL. Outputs of the ALM are presented in **Attachment 5**.

Insert #26. Results of ALM

Receptor	% Exceeding	95th percentile Fetal Blood Lead Level (µg/dL)
DU-7 – surface soil

IHRS DU – sediment		
Park Personnel	**87.8**	**26.1**
Adult Recreational	**38.1**	**11.0**
Adolescent Recreational	**35.4**	**10.6**

The models indicate mean blood-lead levels exceed a level of concern for a construction worker at all areas evaluated. Mean blood-lead levels exceeded a level of concern for the park personnel at DU-17 surface and subsurface soil, DU-18 subsurface soil, the Former Dump Area and IHRS DU. For the recreational user, only the IHRS (Hudson River Shoreline) DU exceeded the

acceptable mean blood-lead level. It is noted that the Former Dump Area Exposure Area, which includes DU-17 and DU-18, is a marshy area that is covered with vegetation and subject to tidal influence that makes access difficult. The Former Dump Area is also identified as a future nature preserve/wetland area. No construction or other activities are expected in this area and actual contact with this area is minimal and unlikely to result in human health concerns.

7. RISK ASSESSMENT UNCERTAINTIES

There are numerous uncertainties inherent in the HHRA process. Risk assessment methods as specified by guidance (EPA 1989) are precautionary; as such, they are protective but may over-estimate risks to assure protectiveness of public health. Where uncertainties exist, conservative parameters were used in the HHRA process to ensure that the resulting risk characterization represents an "overestimate" of potential human health concerns. This ensures adequate protection of human health so that risks are not underestimated.

7.1 SAMPLING AND ANALYSIS UNCERTAINTIES

Of the potential uncertainties associated with environmental sampling, the sample design is likely to have the greatest impact on the evaluation of risks to receptors. The soil sampling design was developed based on the available historical information regarding the activities that occurred at the site. Focusing the study design to provide analyses for certain chemicals specific to suspected source areas is a valid and accepted means of maintaining a practical and efficient limit on the field effort. However, there is always a possibility that the study design could miss sampling where these chemicals are present or miss other types of chemicals in a specific sample.

The ISM sampling design was used to prevent missing areas where site-related chemicals are present. However, only 1-acre grids were sampled across the site in areas of suspected historical activities. The areas where no grids were sampled present an uncertainty in that, over time, as the soils have been reworked and spread across the site, these areas that were not sampled may contain chemicals. However, ISM sampling design better predicts the average concentration across an area than discrete samples.

In an effort to address the uncertainties just discussed, and in accordance with the conservative nature of HHRAs, the 1-acre and smaller DUs established in areas most likely to contain the highest levels of contamination. However, each DU was sampled randomly. Therefore, the sample design is likely to overestimate potential long-term human health risk concerns for exposure to the Site.

The 95UCL was used as an upper estimate of mean exposures for all Phase I ISM results. In almost all cases, both the Student's-t and Chebychev calculated 95UCL from the triplicate samples produced results that were higher than any of the detected replicate concentrations. Due to the distribution of the data, variability in the results, and the apparent heterogeneity of site soil, the Chebychev value was recommended over the Student's-t value, which was generally a lower number. There were no cases where the Chebychev value resulted in an HQ greater than 1 where the Student's-t would not. However, both values are typically higher than the triplicate sample results, are conservative, and may overestimate risks. However, these uncertainties would not change the overall results of the HHRA because no risk concerns were determined for any receptor exposure to the site.

As discussed in Section 3.2 of the Phase I RI Data Summary Report (EA 2021), approximately 20 percent of the sample results were J-flagged for minor laboratory interferences including matrix interference, trace contamination in blank samples, and/or exceeding holding times. J qualifiers

indicate estimated values. In some cases, the J qualifier is biased low, indicating the reported result may be lower than the actual concentration. In these cases, risks may be underestimated. For instance, due to the potential low bias in the PAH concentrations at DU-13 as a result of holding time exceedances during laboratory preparation, concentrations of PAHs could be higher than those reported. As such, potential risks at DU-13 could also be higher. In the cases where the J qualifier is biased high, then the potential risks associated with these data may be overestimated because the reported result is potentially higher than the actual concentration. This occurs for several metals and PAHs in DUs 9, 11, 14, 19, and 20. However, these uncertainties would not change the overall results of the HHRA. For the biased high PAH results, potential risk concerns were not identified for any receptors' exposure to PAHs at the site. For the biased low PAH results, risk results for all receptors' exposure to PAHs were at least an order of magnitude below levels considered unacceptable.

Section 3.3.2 of the Phase II RI Data Summary Report (EA 2023) notes some metals were reported with LOQs greater than the project action limits. This occurred only within the surface water analytical results. The metals that had LOQs greater than the project action limits are shaded gray in Tables A-7 through A-11 in Attachment 1. The metals that exceeded were antimony, arsenic, mercury, and thallium. The following table compares the LOQs and the project action levels:

Insert #27. LOQs and Project Action Levels

Chemical	LOQ (µg/L)	Project Action Level (µg/L)
Antimony	1.0	0.78
Arsenic	1.0	0.052
Mercury	0.08	0.063
Thallium	0.2	0.02

The project action levels for these chemicals are based upon an HQ=0.1, except for arsenic. Arsenic is based upon a cancer risk level of $1x10^{-6}$. The LOQs for antimony, mercury, and thallium are within or less than an order of magnitude (i.e., 10 times) of the project action levels. This reveals that the LOQs would not result a non-cancer hazards above a level of 1. For arsenic, the LOQ represents an approximate cancer risk level of $2x10^{-5}$, which is within the acceptable cancer risk range of $1x10^{-6}$ to $1x10^{-4}$. Additionally, detected concentrations of antimony, arsenic, mercury, and thallium were reported as estimated (i.e., "J" flagged) concentrations below the LOQs. Therefore, the LOQs above the project action levels would not result in potential risk concerns and would not affect the overall conclusions of the HHRA.

7.2 EXPOSURE ASSESSMENT UNCERTAINTIES

Potential receptor exposure to environmental media at Iona Island does not adhere to "typical" default exposure scenarios that are modeled for a recreational area. The site is remote, and use of the site is intermittent. While the site is used by PIPC and there is evidence of local residents visiting the site, the actual exposure and contact with the site media is difficult to quantify. A majority of the exposure parameters determined for each receptor are based upon professional judgement and EPA guidance. The exposure parameter that presents the most uncertainty is the

exposure frequency (EF), or number of days a receptor visits/contacts the site. Conservative EFs were determined for each receptor to provide a protective evaluation. The EFs are likely overestimated, especially when evaluating a long-term exposure to the site.

The HHRA did not reveal any risk concerns for receptor exposure to any of the DUs evaluated, except potential concerns for lead in soil and sediment within DUs 7, 17, 18, the Former Dump Area Exposure Area, and IHRS DU. DU-7 only revealed potential concerns for a construction worker exposure. DUs 17 and 18 revealed potential concerns for the park personnel, and IHRS DU revealed potential concerns for all receptors (park personnel, adult/adolescent recreational users). While it is likely that site receptors would visit random areas of the site and not one specific DU, it is reasonable that a construction worker may perform construction activities within the one-acre DU area, or a recreational user would specifically spend time within the IHRS DU due to its accessibility from the Hudson River. However, the park personnel is more likely to visit the entire area of Iona island to perform maintenance activities such as grass mowing, site inspections, and general maintenance. As a result, the concentration of lead would not be specific to a DU for the park personnel but better represented as a mean concentration across the DUs. The mean lead concentration across all DUs is 667 mg/kg. This mean lead concentration includes the sediment DUs (i.e., IHRS, RRDS, and TWS). It is noted that determining a mean concentration using just the DU lead concentrations likely results in a overestimate of the mean lead concentration across the entire Iona Island. The DUs only represent approximately 25 acres out of the 124 acres of the Iona Island Naval Ammunition Depot FUDS. The determination of the lead DU mean concentration is similar to method used to determine EPCs for the combined exposure areas (i.e., the Former Dump Exposure Area and the Iona Island Exposure Area). However, this provides a protective evaluation of potential contact.

The DU mean lead concentration was evaluated using the ALM. Attachment 6 contains the outputs for the determination of the mean concentration and the ALM model. The following table presents the results of the ALM model:

Insert #28. Results of ALM for All DUs

Receptor	% Exceeding	95th percentile Fetal Blood Lead Level (µg/dL)
Entire Site		
Park Personnel	0.7	3.1

The results of the ALM modeling for the entire site reveal there are no potential concerns for park personnel exposure to lead in soil. This reveals that potential risk concerns determined for the park personnel exposure to lead within a specific DU is likely overestimated and expected park personnel exposures across Iona island would be much lower and are not expected to be a concern.

Additionally, the HHRA evaluated the potential relative bioavailability (RBA) of lead within soil and sediment using the default value of 60% in both the IEUBK and ALM models. Both models use the RBA of lead in soil/sediment and the absorption of soluble lead (20% in the ALM and 50% in the IEUBK) to determine absolute gastrointestinal absorption factor (AF_{Pb}) for lead in soil and

sediment. The AF_{Pb} is a significant variable in the determination of resulting blood-lead levels. However, the lead concentrations within the areas of concern, especially the IHRS, were high enough that the RBA of lead in soil and sediment would have to be around 20% (as opposed to the default 60%) to result in blood-lead levels that are below a level of concern.

7.3 TOXICITY ASSESSMENT UNCERTAINTIES

There are numerous uncertainties associated with the toxicity assessment. These are generally due to the unavailability of data to thoroughly calculate the toxicity of COPCs. These uncertainties are described in more detail in the following sections.

7.3.1 Uncertainties Associated with Non-Carcinogenic Effects Interspecies Extrapolation

Most toxicological information is developed through experiments with laboratory animals. Regulatory agencies rely on experimental animal data to assess the hazards of chemical exposures to humans. Interspecies differences in chemical absorption, metabolism, excretion, and toxic response are not well understood; therefore, conservative assumptions are applied to animal data when extrapolating to humans. These assumptions probably result in an overestimation of toxicity.

7.3.2 Intraspecies Extrapolation

Differences in individual human susceptibilities to the effects of chemical exposures may be caused by such variables as genetic factors (e.g., glucose-6-phosphate dehydrogenase deficiency), lifestyle (e.g., cigarette smoking and alcohol consumption), age, hormonal status (e.g., pregnancy), and disease. Considering the diversity of human populations and their differing susceptibilities to chemically induced injury or disease, a safety factor is used. EPA uses a factor between 1 and 10. This uncertainty may lead to overestimates or underestimates of human health effects at given doses.

7.3.3 Uncertainties Associated with Carcinogenic Effects Interspecies Extrapolation

Most toxicological information for carcinogenic assessments is derived from experiments with laboratory animals. There is uncertainty about whether animal carcinogens are also carcinogenic in humans. While many chemical substances are carcinogenic in one or more animal species, only a very small number of chemical substances are known to be human carcinogens. The fact that some chemicals are carcinogenic in some animal species but not in others raises the possibility that not all animal carcinogens are human carcinogens. Regulatory agencies assume that humans are as sensitive to carcinogens as the most sensitive animal species. This policy decision, designed to prevent underestimation of risk, introduces the potential to overestimate carcinogenic risk.

7.3.4 High-Dose to Low-Dose Extrapolation

Typical cancer bioassays provide limited low-dose data on responses in experimental animals for chemicals being assessed for carcinogenic or chronic effects. The usual dose regime involves three dose groups per assay. The first dose group is given the highest dose that can be tolerated, the second is exposed to one-half that dose, and the third group is unexposed (control group) (National

Research Council [NRC] 1983). Since this dosing method does not reflect how animals would react to much lower doses of a chemical, a dose-response assessment requires extrapolation from high to low doses using mathematical modeling that incorporates, to varying degrees, information about physiologic processes in the body (NRC 1983).

A central problem with the low-dose extrapolation models is that they often fit the range of data from animal bioassays equally well, and it is not possible to determine their validity based on goodness of fit. Several models may fit experimental data equally well, but all may not be equally plausible biologically. The dose-response curves derived from different models diverge substantially in the dose range of interest (NRC 1983). Therefore, low-dose extrapolation is more than a curve-fitting process, and considerations of biological plausibility of the models must be considered before choosing the best model for a particular set of data.

7.3.5 Modification for Mutagenic Compounds

Carcinogenic slope factors for compounds identified with a mutagenic mode of action for early-life exposure (i.e., PAHs) are modified by a default adjustment factor. The default adjustment factors are used because chemical-specific data are not available to directly assess cancer susceptibility from early-life exposure to a carcinogen acting through a mutagenic mode of action. The default adjustment factors are derived from a weighted geometric mean tumor incidence ratio. Therefore, the use of the default adjustment factors may both over-estimate and under-estimate the potential potency for early-life exposure for chemicals with a mutagenic mode of action for carcinogenesis (EPA 2005b). However, the analysis of potential exposure over a lifetime reduces the effects and uncertainty of the mutagenic adjustments on estimated lifetime cancer risk. Carcinogenic risks for receptors identified within the early-life exposure age range are determined based upon a lifetime exposure. The resulting uncertainty in the use of the mutagenic default adjustment factors is reduced but some uncertainty still remains in the use of default factors over a specified age range rather than chemical-specific data. This uncertainty is evident in the carcinogenic risk calculations for benzo(a)pyrene. The use of the mutagenic adjustment factor for benzo(a)pyrene results in significantly higher carcinogenic risks for all receptors younger than 16 years (e.g., child resident and adolescent recreational user). Benzo(a)pyrene has shown sufficient evidence in animals for a mutagenic mode of action; however, the adjustment factors used in this HHRA are standard values that are not specific to benzo(a)pyrene. This results in additional uncertainties and potential overestimate of carcinogenic risks for benzo(a)pyrene, and other PAHs.

7.4 RISK CHARACTERIZATION UNCERTAINTIES

Uncertainties in the risk characterization can stem from the inherent uncertainties in the data evaluation, the exposure assessment process, including any modeling of EPCs in secondary media from primary media, and the toxicity assessment process. The individual uncertainties in these respective processes were addressed in the previous sections.

7.5 UNCERTAINTY CONCLUSIONS

For each step of the risk assessment process, conservative assumptions were made that are intended to be protective of human health and to ensure that risks are not underestimated. All uncertainties discussed in this section revealed that the risk results in the HHRA are likely overestimated. The overestimation of potential risks from exposure to the site would not change the overall conclusions of the HHRA, except for lead. For all chemicals, except lead, the HHRA revealed no potential risk concerns for any receptors' exposure to the site. The following table presents an updated table of the lead model results based upon the exposure discussion for the park personnel presented in Section 7.2:

8. CONCLUSIONS

Potential receptors evaluated in the HHRA included park personnel, researcher, construction workers, recreational users (adult, adolescent, and child), adolescent trespasser, and camper/Boy Scout. The HHRA quantitatively evaluated all receptor's exposure to each DU at the site that revealed potential COPCs in onsite soil and sediment. The evaluation of DU analytical results was performed on a DU-basis to inform potential decisions that relate to the DU. In addition, two separate combined exposure areas for soil were evaluated to represent expected receptor exposure to the entire island: the Iona Island Exposure Area and the Former Dump Area Exposure Area. The first exposure area (Iona Island Exposure Area) included the AOCs, ASTs, and former transformers. The second exposure area (Former Dump Area Exposure Area) included DU-17 through DU-22.

The HHRA indicates there are no exceedances of the carcinogenic risk thresholds for any receptors evaluated for any of the individual DUs or the two exposure areas. The non-cancer hazard index thresholds were below the acceptable threshold of 1.0 for all receptors evaluated for all of the individual DUs and the two exposure areas, except the construction worker exposure to DU-13, DU-18, and the Former Dump Exposure Area (DU-17 through DU-19). A breakdown by target organ did not reveal any target organs above the acceptable threshold of 1.0 for the construction workers exposure to DU-13 and DU-18. Therefore, the HHRA did not reveal potential concerns for carcinogenic risks or non-cancer hazards for any receptor's exposure to each DU or the two combined exposure areas.

Lead was evaluated separately from the carcinogenic risks and non-cancer hazards. Lead was evaluated through the use of the EPA's ALM. Lead was identified as a COPC in DU-7, DU-17, DU-18, and the Former Dump Exposure Area (which includes DU-17 and DU-18). To achieve a specific level of protectiveness, EPA has established that a typical (or hypothetical) child would have an estimated risk of no more than 5 percent exceeding the reference blood-lead level of 5 µg/dL. Results of the ALM revealed greater than 5 percent of the population exceeded the reference blood-lead level of 5 µg/dL for the following receptors:

- Construction workers exposed to surface soil at DU-7 in the upland area, and surface and subsurface soil at DU-17 and DU-18 covering the eastern portion of AOC #16 - Area D (former Dumping Area), the Former Dump Area Exposure Area, and sediment from IHRS-DU-01 (Iona Island Hudson River shoreline adjacent to AOC #16 – Area D [former Dumping Area])

- Park personnel exposed to surface and subsurface soil at DU-17 and DU-18 and sediment within IHRS-DU-01

- Recreational users exposed to sediment within IHRS-DU-01.

It is noted that the Former Dump Area Exposure Area, which includes DU-17 and DU-18, is a marshy area that is covered with vegetation and subject to tidal influence that makes access difficult. The Former Dump Area is also identified as a future nature preserve/wetland area. No

construction or other activities are expected in this area and actual contact with this area is minimal and unlikely to result in human health concerns. Additionally, construction worker exposure represents exposures that are usually controlled using standard health and safety protocols and personal protective equipment. Potential lead risk concerns identified for the construction worker within DU-7, DU-17, DU-18, and the Former Dump Exposure Area do not warrant further evaluation or risk management decisions.

As noted in Section 7.2, the park personnel potential exposure to one specific DU for an entire year is not an expected scenario. The park personnel are more likely to be exposed to environmental media over the entire island for activities such as grass mowing, site inspections, and general maintenance. For this reason, the exposure to the entire island is better represented by an average (or mean) concentration of the DUs across the site, which includes all DUs sampled (i.e., DU-1 through DU-7, DU-9 through DU-19, IHRS, RRDS, and TWS). It is noted that this mean concentration does not include the areas of the site not sampled and likely overestimates the true mean lead concentration across the Site. The mean soil lead concentration across all DUs is 667 mg/kg, revealing less than 5% of the population exceeds the target blood-lead level. The results of the ALM modeling for the mean lead concentration across the DUs show no potential concerns for the park personnel exposure to lead based upon expected exposures. Therefore, the park personnel exposure to Iona Island does not warrant further evaluation or risk management decisions.

The recreational user exposure to lead within the IHRS DU did reveal significant exceedance of the acceptable blood-lead threshold. Unlike the park personnel expected exposure, the recreational user may spend a significant amount of time at the IHRS DU. This DU is located along the Hudson River and is a flat area where boaters may visit, and the recreational user exposure is an exposure that is difficult to control on Iona Island. While sediments in this area are generally sandy with larger grain size that is difficult to adhere to the skin surface, there is a potential for contact, sample results from the IHRS DU reveal potential transport of contaminants from AOC #16 (Dumping Area) along the surface via overland runoff and erosion and into shoreline sediments. As a result, there are sufficient potential concerns for a recreational user exposure to the IHRS DU to warrant additional evaluation and/or risk management decisions in a Feasibility Study. Sample results from the RRDS and TWS DUs on the tidal marsh side of Iona Island do not reveal impacts from AOC #16 or potential risk concerns for receptors, which reveals the tidal marsh area is disconnected from the Former Dump Area.

In conclusion, based upon potential receptors and their expected exposure to the site, there are no risk concerns for potential receptor exposures to Iona Island associated media, except the recreational user exposure to the IHRS DU.

LEGEND

● Complete Pathway; confirmed receptor and media interaction (i.e., a source, migration route, and receptor have been identified).

◑ Potentially Complete Pathway; receptor and media interaction; however, the exposure may be limited, either due to the type of receptor or the nature of the source, and has not been confirmed.

○ Incomplete Pathway; no receptor and media interaction. No evaluation is conducted.

NOTES

Surface soil = defined as the interval from 0 to 6 inches bgs.
Subsurface soil = defined as the interval from 6 to 36 inches bgs.
VOC = Volatile Organic Compound

1. EPA Regional Screening Levels Table, EPA, November 2019. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
2. A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

DU-8 (AOC #5: Former Building 207 – Marine Garage Building) was not sampled because it would not be possible to separate metals and PAH contaminants originating from former Building 207, from contaminants originating from drums and other debris observed in DU-8.

NOTES:

mg/kg = milligrams per kilogram
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
PCB = Polychlorinated biphenyl
RSL = regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high

Red concentrations exceed EPA Residential Soil RSL.
Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

Validation Reason Codes:

A	Serial dilution
C	LCS Recovery
D	MS RPD
H2	Prep Hold Time
I	Surrogate recovery outside project limits
L	Lab Blank
M	MS Recovery
M2	Post Spike
P1	Column RPD
TR	Trace Level Detect
V2	CCV

(a) EPA Regional Screening Levels Table, EPA, November 2019. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.

(b) A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

DU-8 (AOC #5: Former Building 207 – Marine Garage Building) was not sampled because it would not be possible to separate metals and PAH contaminants originating from former Building 207, from contaminants originating from drums and other debris observed in DU-8.

NOTES:

mg/kg = milligrams per kilogram
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
PCB = Polychlorinated biphenyl
RSL = regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated.
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate.
- Bias low
+ Bias high

Validation Reason Codes:

A Serial dilution
C LCS Recovery
D MS RPD
H2 Prep Hold Time
I Surrogate recovery outside project limits
L Lab Blank
M MS Recovery
M2 Post Spike
P1 Column RPD
TR Trace Level Detect
V2 CCV

Red concentrations exceed EPA Residential Soil RSL.

Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

1. EPA Regional Screening Levels Table, EPA, November 2019. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
2. A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

NOTES:
mg/kg = milligrams per kilogram
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
PCB = Polychlorinated biphenyl
RSL = regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high
Red concentrations exceed EPA Residential Soil RSL.
Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

Validation Reason Codes:
A Serial dilution
C LCS Recovery
D MS RPD
H2 Prep Hold Time
I Surrogate recovery outside project limits
L Lab Blank
M MS Recovery
M2 Post Spike
P1 Column RPD
TR Trace Level Detect
V2 CCV

(a) EPA Regional Screening Levels Table, EPA, November 2019. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
(b) A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

NOTES:
mg/kg = milligrams per kilogram
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
PCB = Polychlorinated biphenyl
RSL = regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high
Red concentrations exceed EPA Residential Soil RSL.
Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

Validation Reason Codes:
A Serial dilution
C LCS Recovery
D MS RPD
H2 Prep Hold Time
I Surrogate recovery outside project limits
L Lab Blank
M MS Recovery
M2 Post Spike
P1 Column RPD
TR Trace Level Detect
V2 CCV

(a) EPA Regional Screening Levels Table, EPA, November 2019. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
(b) A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

NOTES:
mg/kg = milligrams per kilogram
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
PCB = Polychlorinated biphenyl
RSL = regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high
Red concentrations exceed EPA Residential Soil RSL.
Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

Validation Reason Codes:
A Serial dilution
C LCS Recovery
D MS RPD
H2 Prep Hold Time
I Surrogate recovery outside project limits
L Lab Blank
M MS Recovery
M2 Post Spike
P1 Column RPD
TR Trace Level Detect
V2 CCV

1. EPA Regional Screening Levels Table, EPA, November 2019. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
2. A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

NOTES:
mg/kg = milligrams per kilogram
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
PCB = Polychlorinated biphenyl
RSL = regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high
Red concentrations exceed EPA Residential Soil RSL.
Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

2. A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

DU-24 (T2 near AOC #16 – Area Dumping Area) was not sampled. The majority of DU-24 contained exposed bedrock with little to thin soil cover. Any PCBs that may have been released from former transformers would have been transported via runoff and overland flow across the bedrock outcrop of Round Island to the Hudson River. While sediment and soil was noted along the northeastern edge of DU-24 off the bedrock outcrop of Round Island, this sediment/soil was along the shoreline of the tidally influenced Hudson River. The Hudson River itself is a PCB source. Therefore, collecting PCBs from soil/sediment along the Hudson River would not provide information that could be used to evaluate a potential release related to former transformers.

1. EPA Regional Screening Levels Table, EPA, November 2019. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
2. A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

NOTES:
mg/kg = milligrams per kilogram
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
RSL = regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high

Validation Reason Codes:
A Serial dilution
C LCS Recovery
D MS RPD
H2 Prep Hold Time
I Surrogate recovery outside project limits
L Lab Blank
M MS Recovery
M2 Post Spike
P1 Column RPD
TR Trace Level Detect
V2 CCV

Red concentrations exceed EPA Residential Soil RSL.
Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

1. EPA Regional Screening Levels Table, EPA, November 2019. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
2. A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

NOTES:
mg/kg = milligrams per kilogram
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
NS = No standard
PCB = Polychlorinated biphenyl
R = The data are unusable The sample results are rejected due to serious deficiencies in meeting the QC criteria The analyte may or may not be present in the sample
RSL = regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high

Red concentrations exceed EPA Residential Soil RSL.
Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

Validation Reason Codes:

A	Serial dilution
C	LCS Recovery
D	MS RPD
H2	Prep Hold Time
I	Surrogate recovery outside project limits
L	Lab Blank
M	MS Recovery
M2	Post Spike
P1	Column RPD
TR	Trace Level Detect
V2	CCV

1. EPA Regional Screening Levels Table, EPA, May 2022. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
2. EPA Maximum Contaminant Levels.

NOTES:
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
RSL = regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated

Red concentrations exceed EPA Tapwater RSL.
Concentrations highlighted in yellow exceed EPA Tapwater RSL and MCL.

Validation Reason Codes:
A Serial dilution
L Lab Blank
TR Trace Level Detect

1. EPA Regional Screening Levels Table, EPA, May 2022. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
2. EPA Maximum Contaminant Levels.

NOTES:
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
RSL = regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated
Red concentrations exceed EPA Tapwater RSL.
Concentrations highlighted in yellow exceed EPA Tapwater RSL and MCL.

Validation Reason Codes:

A	Serial dilution
L	Lab Blank
TR	Trace Level Detect

1. EPA Regional Screening Levels Table, EPA, May 2022. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
2. EPA Maximum Contaminant Levels.

NOTES:
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
RSL = regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated

Red concentrations exceed EPA Tapwater RSL.
Concentrations highlighted in yellow exceed EPA Tapwater RSL and MCL.

Validation Reason Codes:
A Serial dilution
L Lab Blank
TR Trace Level Detect

(a) EPA Regional Screening Levels Table, EPA, May 2022. Value shown is equal to HI=0.1. Carcinogenic values equal to $1x10^{-6}$.
(b) A deed restriction is in place noting that there is to be no residential development at the site (USACE 1995); however, EPA residential soil RSLs are included to assess for children receptors including site visitation for nature walks and potential camping.

NOTES:
mg/kg = milligrams per kilogram
mV = millivolts
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
RSL = regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated

Validation Reason Codes:
A Serial dilution
D MS RPD
M MS Recovery
M2 Post Spike
TR Trace Level Detect

Red concentrations exceed EPA Residential Soil RSL.
Concentrations highlighted in yellow exceed EPA Industrial Soil RSL.

1. For each test, 10,000 permutation resamples were used to yield a stable p-value. When the value shown in "Right Tailed Prob" is less than 0.05, the H0 is rejected. If the resulting value in the Conclusion column is Do Not Reject H0, then the H0 is true and site concentrations are less than or equal to background. If the result is Reject H0, then site concentrations are greater than background.

1. Kaplan-Meier estimator used for data sets with non-detect results.

2. Difference between site and background means reported as an interval if either site or background mean is a non-detect.

3. Right-tailed probability of permutation test of difference between site and background means. Adjusted p-values computed with Benjamini-Hochberg procedure for controlling false discovery rate (FDR). Asterisks indicate significance level (<0.05, <0.01, <0.001).

4. If the resulting value in the Conclusion column is Do Not Reject H0, then the H0 is true and site concentrations are less than or equal to background. If the result is Reject H0, then site concentrations are greater than background.

NOTES:

			Site Data				Background Data				Permutation Test (H0: Site <= Background)				
Analyte Name	Analyte Code	CAS	Units	Decision Unit	Number of Samples Collected	Number of Analyte Detections	Mean [1]	Decision Unit	Number of Samples Collected	Number of Analyte Detections	Mean[1]	Site Mean - Background Mean [2]	Right-Tailed Probability[3]	Adjusted Right-Tailed Probability[3]	Conclusion[4]

CAS = Chemical Abstracts Service

mg/kg = milligrams per kilogram

DUMP = AOC #16 – Area D (former Dumping Area)

IHRS = Iona Hudson River Shoreline (along eastern boundary of AOC #16 – Area D)

RRDS = Riprap Filled Drainage Swale (Iona Marsh shoreline at outlet of riprap filled drainage swale)

TWS = Tidal Wetland Swale (Iona Marsh shoreline at outlet of tidal wetland swale)

CHHRS = Con Hook Hudson River Shoreline

CHMS = Con Hook Marsh Shoreline

Phase II Surface Water Background Comparison Permutation Tests

1. Kaplan-Meier estimator used for data sets with non-detect results.

2. Difference between site and background means reported as an interval if either site or background mean is a non-detect.

3. Right-tailed probability of permutation test of difference between site and background means. Adjusted p-values computed with Benjamini-Hochberg procedure for controlling false discovery rate (FDR). Asterisks indicate significance level (<0.05, <0.01, <0.001).

4. If the resulting value in the Conclusion column is Do Not Reject H0, then the H0 is true and site concentrations are less than or equal to background. If the result is Reject H0, then site concentrations are greater than background.

NOTES:

µg/L = micrograms per liter

CAS = Chemical Abstracts Service

DUMP = AOC #16 – Area D (former Dumping Area)

IHRS = Iona Hudson River Shoreline (along eastern boundary of AOC #16 – Area D)

RRDS = Riprap Filled Drainage Swale (Iona Marsh shoreline at outlet of riprap filled drainage swale)

TWS = Tidal Wetland Swale (Iona Marsh shoreline at outlet of tidal wetland swale)

CHHRS = Con Hook Hudson River Shoreline

CHMS = Con Hook Marsh Shoreline

1. INTRODUCTION

The Hazardous, Toxic, and Radioactive Waste (HTRW) Remedial Investigation (RI) was conducted at the Iona Island Naval Ammunition Depot Formerly Used Defense Site (FUDS, [FUDS Project No. C02NY074402]) to characterize the nature and extent of hazardous substances in environmental media at the FUDS that are attributable to historical Department of Defense (DoD) operations and to evaluate potential risk to human health and ecological receptors. The HTRW RI is the first comprehensive investigation of the Iona Island Naval Ammunition Depot FUDS.

A brief historical context of the background follows. This site was actively used from 1900 to 1947, with significant activity for assembling naval ammunition and explosives for World War II. This included ammunition related activities such as assembling, maintaining, inspecting, and testing; storing bulk explosives; issuing ammunition to fleets among other activities (U.S. Army Geospatial Services Administration [USAGC] 2018). The former Iona Island Naval Ammunition Depot was excessed by the U.S. Navy in 1957 and transferred to the General Services Administration (GSA), which conveyed the FUDS to the Palisades Interstate Park Commission (PIPC) in 1965. Most of the buildings and structures were demolished and removed by 1973 (USAGC 2018). For more information on site history and description, please see Section 2.1.1 (Environmental Setting and Constituents at the Site).

Previously at this site, two investigations were conducted in 1997 and 2007, which reported detections of metals and polycyclic aromatic hydrocarbons (PAHs) in multiple media (Greeley-Polhemus Group, Inc. 1997; Alion Science and Technology Corporation [Alion] 2008). These investigations were not comprehensive enough to establish the nature and extent of contamination and therefore the HTRW RI was proposed. A two-phased approach was employed to facilitate data collection, evaluation, and discussion. Phase I field activities were conducted in March and April 2020 and consisted of soil sampling using incremental sampling methodology (ISM). Phase II field activities were conducted in April 2022 and consisted of shoreline surface water and sediment sampling as well as additional soil sampling to provide information to complete this ecological risk assessment (ERA).

This ERA was prepared on behalf of the U.S. Army Corps of Engineers (USACE) by EA Engineering, PC. and Its Affiliate EA Science and Technology (EA) to evaluate the potential for adverse effects to ecological receptors exposed to site-related constituents of potential ecological concern (COPECs). The overall objective of the ERA was to quantitatively and qualitatively evaluate exposure and risks to ecological receptors and to provide risk managers with information necessary to achieve management goals and evaluate remedial decisions, if necessary.

1.1 GENERAL APPROACH

The ERA followed the procedures and methodologies set forth by the U.S. Environmental Protection Agency (EPA) and USACE. Specific EPA guidance documents included the following:

- *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments – Interim Final.* EPA 540-R-97-006, Office of Solid Waste and Emergency Response (OSWER) 9285.7-25, PB97-963211. June 1997.

- *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments Eco Update.* OSWER. Publication 9345.0-14. EPA 540/F-01/014. June 2001.

- *Wildlife Exposure Factors Handbook.* Volumes 1 and 2. EPA/600/R-93/187. December 1993.

- *Guidelines for Ecological Risk Assessment.* EPA/630/R95/002F. April 1998.

- *Guidance for Developing Ecological Soil Screening Levels (EcoSSLs).* OSWER Directive 9285.7-55. Revised February 2007, including separate contaminant EcoSSL documents.

- *Framework for Metals Risk Assessment*. EPA 120/R-07/001. March 2007.

Additionally, the applicable USACE guidance documents included the following:

- *Risk Assessment Handbook Volume II: Environmental Evaluation of the USACE Engineering Manual 200-1-4*. EM 200-1-4. 31 December 2010.

- *Environmental Quality, Standard Scopes of Work for Environmental Risk Assessment.* USACE Engineer Pamphlet EP 200-1-15. 30 June 2016.

- *A Guide to Screening-Level Ecological Risk Assessment TriService Environmental Risk Assessment Working Group.* Technical Paper. TG-090801. September 2008.

1.1.1 EPA's 8-Step Ecological Risk Assessment Process

This ERA followed EPA's *Ecological Risk Assessment Guidance for Superfund* (EPA 1997), which includes an 8-Step ERA process (**Figure 1-1**). Steps 1 and 2 of the process include a screening-level ecological risk assessment (SLERA). In Step 1, COPECs are identified in environmental media (e.g., soil) through a conservative screening process. In this process, screening benchmarks are used for comparison to site-specific analytical results and are based on conservative assumptions. In Step 2, risk estimates are refined using informed assumptions (such as area use and life history-traits for modeled receptors) for exposure and toxicity of the previously identified COPECs. If the results of the SLERA indicate potential adverse ecological effects, a scientific-management decision point allows the process to continue to a baseline ecological risk assessment (BERA), if warranted. The BERA consists of Step 3 (Problem Formulation) through Step 8 (Risk Management) and would use additional site-specific information (e.g., analytical tissue data, toxicity testing, habitat evaluations, community analysis, population metrics) to characterize risk to ecological receptors.

1.1.2 U.S. Army Corps of Engineers Flowcharts

USACE New England District has drafted ERA flowcharts (**Attachment A**) to provide a breakdown of the ERA process for project managers, team members, and communication purposes. The process is 3-steps, consisting of: (1) a preliminary screening level, consistent with step 1 of EPA's process introduced above 2) a refined screening level, consistent with step 2 of EPA's process and 3), a baseline assessment, consistent with steps 3 through 8 of EPA's process, to evaluate ecological risks, as outlined below:

- ***Step 1—Screening-Level Risk Assessment*** (**Attachment A, Flowchart/Figure 1**): The SLERA consists of preliminary screening steps. The preliminary screen evaluates constituent concentrations against generic, conservative screening values.

- ***Step 2—Refined Screening-Level Risk Assessment*** (**Attachment A, Flowchart/ Figure 2**): If potential risk exists after the preliminary evaluation, a refined screen is conducted to incorporate more readily available site-specific information such as adjustments to the exposure point concentrations (EPCs), toxicity information/effects of the identified COPECs, exposure scenarios to ecological receptors, and other input parameters that make the evaluation more site-specific. Only receptors/pathways that show potential risk in the SLERA or for which insufficient information is available to address risk are carried through to the refined screening-level ecological risk assessment (RSLERA).

- ***Step 3—Baseline Ecological Risk Assessment*** (**Attachment A, Flowchart/Figure 3**)***:*** If results of the RSLERA indicate potential risk, additional data may be collected to refine the potential risks in the BERA for specific COPEC(s), environmental media, and receptor(s). Such data could include analyses of porewater samples, toxicity testing, tissue constituent concentrations, population studies, and/or benthic community metrics to understand actual site-specific risk. Only those receptors remaining at the completion of the RSLERA are carried forward for further evaluation in the BERA.

1.2 REPORT ORGANIZATION

This ERA is organized into the following sections:

- **Section 1, Introduction** – presents the purpose and objectives of the ERA and guidance documents that were followed as part of the process.

- **Section 2, Screening-Level Problem Formulation** – presents a description of the site, the ecological conceptual site model (CSM), ecological receptors and pathways for analysis, and the assessment and measurement endpoints (Step 1).

- **Section 3, Ecological Risk Assessment Dataset** – presents the data collected as part of the Phase I and Phase II investigations and the EPCs used in the ERA.

- **Section 4, Screening-Level Ecological Risk Assessment**– presents the results of Step 1 of EPA's 8-step process/Flowchart 1, which includes a screen of constituent concentrations and concludes with a list of COPECs for further evaluation in the RSLERA.

- **Section 5, Refined Screening-Level Ecological Risk Assessment Methodology** – describes the process for conducting the RSLERA, which includes combining elements of ecological exposure and effects to refine risk estimates for each COPEC, corresponding to Step 2 of EPA's process and Flowchart 2.

- **Section 6, Uncertainty Assessment** – presents the inherent uncertainties that are associated with evaluating risk.

- **Section 7, Refined Screening Level Ecological Risk Assessment Results and Risk Characterization** – presents and interprets the RSLERA results considering multiple measurement endpoints, lines of evidence, and uncertainties.

- **Section 8, Refined Screening Level Ecological Risk Assessment Conclusions** – presents the conclusions of the RSLERA.

- **Section 9, References**

2. SCREENING-LEVEL PROBLEM FORMULATION

The problem formulation is part of the initial screening assessment (Step 1). As part of this step, the ecological CSM is developed. For this initial step, site-specific information for determining the nature and extent of contamination and for characterizing ecological receptors at the site is limited to analytical chemistry data evaluated from environmental media. The problem formulation presents the ecological CSM, a description of the site, ecological receptors and pathways for analysis, and the assessment and measurement endpoints.

2.1 ECOLOGICAL CONCEPTUAL SITE MODEL

During the screening-level problem formulation, an ecological CSM is developed to address the five key issues presented in the EPA Ecological Risk Assessment Guidance for Superfund (EPA 1997):

- The environmental setting and constituents known or suspected to exist at the site (Section 2.1.1)
- Fate and transport pathways that might exist at the site (Section 2.1.2)
- Exposure potential and ecotoxicity associated with constituent, site ecology, and categories of receptors that could be affected (Sections 2.1.3 and 2.1.4)
- Identification of complete exposure pathways (Section 2.1.5)
- Selection of ecological receptors and endpoints to evaluate (Section 2.1.6)

The following sections describe these five key issues presented by EPA (1997) that contribute to the development of the CSM, which is presented in Section 2.1.7.

2.1.1 Environmental Setting and Constituents at the Site

The Iona Island Naval Ammunition Depot FUDS property is an approximately 124.2-acre site located on Iona Island and Round Island along the west side of the Hudson River, in the Town of Stony Point, Rockland County, New York, as presented in **Figure 2-1.** A busy freight rail line is located immediately east of Iona Island along the point of access.

Iona Island is located in Bear Mountain State Park on the east side of U.S. 202/Route 9W, 6 miles south/downstream of West Point Military Academy, one mile south/downstream of the Bear Mountain Bridge, and 41.2 miles north/upstream from the mouth of the Hudson River. Round Island, the southeastern part of Iona Island, was once cut off by marshes and was attached to Iona Island with fill in the early 20th century (New York State Department of Environmental Conservation and U.S. Department of Commerce 1992).

Iona Island is connected to the mainland by a narrow two-lane road off U.S. 202/Route 9W near Doodletown. The island is accessed by crossing active River Subdivision (CSX Transportation) railroad tracks and entering through an unmanned gate.

The Iona Island Naval Ammunition Depot was used by the U.S. Navy between 1900 and 1947, with the major effort consisting of assembling naval ammunition for World War II. Although no ammunition was manufactured there, various types of explosives were assembled on site. Activities included preparing, assembling, maintaining, inspecting, and testing ammunition; storing bulk explosives, ammunition, and ordnance material; and issuing ammunition to the fleet, shore establishments, armed merchantmen, transport, and district forces (USAGC 2018).

After World War II, use of the island as an ammunition depot became obsolete because of lack of expansion room to accommodate new types of ammunition. In 1947, the U.S. Navy deactivated the Iona Island Naval Ammunition Depot and made the property available for restricted lease. The FUDS was re-designated as an Annex to the U.S. Naval Ammunition Depot, Earle, New Jersey. In 1957, the Annex was declared excess. In 1955 and 1960, GSA utilized the Iona Island Naval Ammunition Depot FUDS through a permit for stockpile materials such as rubber and copper. In 1960, GSA received official jurisdiction of the property. Other agencies under GSA control utilized the property for record storage during the 1960s, including the following: Maritime Administration, Atomic Energy Commission, Civil Service Commission, Army Corps of Engineers, and U.S. Navy's Bureau of Ships. The Maritime Administration also conducted trans-shipments of heavy freight at the main wharf on an occasional basis. On 30 March 1965, Iona Island was deemed evacuated after the last load of stockpiled materials left the property. In 1965, PIPC acquired both Iona and Round Islands (USACE 1998).

The majority of buildings and structures, including building foundations, were demolished and removed by PIPC between November 1965 and December 1973 (USAGC 2018). Fill material may have been used during re-grading following demolition and excavation/removal of foundations, and surface and subsurface soil was significantly reworked/mixed across much of the former operations area. The FUDS has remained undeveloped since its transfer from DoD ownership to PIPC in 1965. PIPC developed demolition plans for the remaining buildings and for construction of a recreational park; however, the plans to develop the island into a recreational park were not executed. The only construction that occurred on the island was that of the parking lot located directly west of Iona Island and outside of the FUDS boundary.

Historical constituents from on-site operations include metals and semivolatile organic compounds (SVOCs) such as PAHs, explosives, and polychlorinated biphenyls (PCBs). More detailed descriptions about the site's history, uses, and constituents can be found in the main text of the RI Report, to which this appendix is attached.

2.1.2 Fate and Transport Pathways

The potential primary release mechanisms for site-related constituents from operational use include accidental spills, direct releases to the ground from testing activities, and improper disposal including dumping. These primary release mechanisms may have resulted in contamination of soil

at and/or beneath former buildings/structures and the surroundings. The Iona Island Naval Ammunition Depot was deactivated in 1947, and the majority of buildings and structures, including building foundations, were demolished and removed. Soil has been significantly reworked during demolition, excavation, and regrading following the demolition of former structures.

Constituents released through deposition may have remained in surface soil by adsorbing to soil particles. When released to the environment, constituents such as some metals and SVOCs including PAHs tend to sorb to soil, sediment, and other organic materials. Some toxic forms of metals (e.g., methyl mercury) accumulate in animal tissue, while others (e.g., arsenic) accumulate in plants. Natural processes such as adsorption, ion exchange, complexation, and precipitation can cause metals to become immobilized and, therefore, not be bioavailable.

Constituents in surface soil may have been transported to a range of exposure media (including air, subsurface soil, groundwater, surface water, and sediment). Secondary release mechanisms from surface soil to other media include the following:

- Infiltration and leaching to underlying subsurface soil and shallow groundwater
- Overland runoff and erosion into surface water and sediment
- Surface and subsurface soil removal/reworking

Reworking of surface and subsurface soil during demolition is a major mechanism by which constituents that bind to soil particles, such as metals and PAHs, can be widely dispersed across the site. For example, site demolition and regrading potentially released and mixed lead-based paint particles into the soil. While metals may generally sorb/bond to soils, very fine paint chips/particles would result in a more sporadic hit-or-miss distribution of contamination.

Due to the non-volatile properties of the site constituents and time elapsed since potential releases, active physical processes such as diffusion and volatilization would not be considered significant contributors to constituent migration. Vapors and particulates in ambient air could be potential exposure media. However, due to the vegetative cover present throughout the site, time since release, and non-volatile properties of the constituents, this transport pathway is unlikely to contribute to significant exposure pathways under current or future land use conditions. In addition, inhalation pathways are considered not significant for ecological receptors in comparison to ingestion pathways (EPA 2007a).

The types of constituents previously detected or potentially present at the site would be bound to soil particles but could migrate via advective transport (bulk movement) of soil particles or desorption (leaching) with the flow of surface water or groundwater toward the adjacent marshes and the Hudson River shoreline. Desorption would be dependent on the solubility of the individual constituent and the properties of the soil. For example, explosives with high solubility such as 2,4-dinitrotoluene could have leached into subsurface soil and groundwater being transported to the shoreline and deposited in the sediments along the island.

Tertiary release mechanisms from contaminated secondary media may include the following:

- Discharge from groundwater to sediment and surface water
- Infiltration from subsurface soil and shallow groundwater to deeper bedrock groundwater
- Uptake of constituents from abiotic media (e.g., soil, sediment, and surface water) into prey tissue that is consumed by wildlife.

2.1.3 Constituent Descriptions

As discussed above, constituents from on-site operations include primarily metals and organic compounds such as SVOCs (primarily PAHs), PCBs, and explosives. Each of the constituent groups are discussed in the sections below.

2.1.3.1 Metals

Metals are naturally occurring constituents in the environment and vary in concentrations across geographic regions. Since metals are naturally occurring, many organisms have evolved mechanisms to regulate accumulations, especially accumulations of essential metals. Some metals (e.g., copper, selenium, and zinc) are nutritionally essential elements at low levels but toxic at higher levels, and others (e.g., lead, arsenic, and mercury) have no known biological functions. For metals to become available for uptake into organisms and cause adverse effects, the metals must be freely dissolved. For example, aluminum toxicity is dependent on soil pH and is considered potentially toxic when the soil has a pH less than 5.5 (EPA 2003). Certain metal compounds bioaccumulate in tissues (e.g., methyl mercury), and this bioaccumulation may be correlated to toxicity depending on the exposure concentrations (EPA 2007b).

Metals are neither created nor destroyed by biological or chemical processes, rather these processes can transform metals from one species to another (valence states) and can convert them between inorganic and organic forms (e.g. methylation). The form of the metal (chemical species, compound, matrix, and particle size) influences the bioaccessibility, bioavailability, and toxicological effects of the metal(s). The form of the metal is influenced by environmental properties such as pH, grain size, moisture content, redox potential, total organic carbon (TOC) content, cation exchange capacity (CEC), and acid volatile sulfide (AVS) (EPA 2007b).

Toxicity in wildlife from metal exposures in field settings is rarely documented (EPA 2007b). Most metals express multiorgan toxicity, resulting in a decrease in overall vigor, as opposed to well-defined mechanisms of action documented from organic constituents such as pesticides (EPA 2007b). In raptors collected from the field, lead toxicity resulting in neurological impacts and emaciation has been documented (Franson and Russel 2014). However, correlation between field exposures and other confounding factors make evaluation of constituent-specific toxicity challenging. Therefore, toxicological data used to assess the risk of metals to wildlife are derived from laboratory species such as rats, mice, or domestic livestock (e.g., cattle and chickens) exposed to soluble metal salts that are typically more toxic than naturally occurring metals. Furthermore, toxicological studies tend to focus on one metal rather than the mixture of metals that often occur in the environment. Some metals have similar modes of action and are typically assumed to have

additive effects, whereas others may be antagonistic (EPA 2007b). As such, there is some uncertainty with the evaluation of potential risks from exposure to metal mixtures.

2.1.3.2 Organic Compounds

Some organic compounds of potential toxicological concern (e.g., PCBs) are anthropogenic and do not occur naturally. PCBs are a group of synthetic organic constituents that exist as oily liquids or solids. PCBs enter the environment as mixtures containing a variety of individual congeners and are often referred to by their trade name, Aroclor. For example, the name Aroclor 1254 means that the mixture of individual PCB congeners contains approximately 54 percent chlorine by weight, as indicated by the second two digits in the name. PCBs were used widely as coolants and lubricants in transformers, capacitors, and other electrical equipment. The manufacture of PCBs stopped in the United States in 1977 because there was evidence that PCBs accumulate in the environment and may cause harmful effects (Agency for Toxic Substances and Disease Registry [ATSDR] 2000).

There are more than 100 different PAHs that generally occur as complex mixtures (e.g., as part of combustion products such as soot), not as single compounds (ATSDR 1995). A targeted list of 18 PAHs are typically analyzed in environmental media for the following reasons: (1) information on these PAHs is available, (2) they are suspected to be more toxic and exhibit harmful effects that are representative of PAHs as a whole, 3) they are detected more frequently in environmental media relative to other PAHs and 4) these are PAHs identified as priority pollutants at Superfund Sites (ATSDR 1995).

Explosives are compounds or mixtures that decompose or re-arrange with extreme rapidity when heat or shock is applied, resulting in releases of gas and heat (Juhasz and Naidu 2007). Military use of explosives may have resulted in contamination on military installations, such as Iona. Explosives and residues that may contain production impurities or decomposition by-products may enter the environment following explosives manufacture, assembly, packing, and detonation (Juhasz and Naidu 2007).

One of the most important factors affecting fate of organic compounds in environmental media is their affinity for binding to fine grained soils/sediment and organic matter. PCBs, particularly the higher chlorinated congeners, adsorb strongly to sediment and soil, where they tend to persist with half-lives of months to years. This decreases the mobility of these compounds, preventing them from dissolving in groundwater. However, while the hydrophobicity of these compounds may decrease solubility, it also increases the potential for uptake into the tissues of biota and the potential for bioaccumulation. Alternatively, some constituents such as high molecular weight (HMW) PAHs (e.g., benzo[a]pyrene) do not bioaccumulate significantly because they are large molecules and cannot transport easily into tissue cells (ATSDR 1995, 2000).

Specific chemical properties of explosives (e.g., solubility in water and rate of degradation) can vary with the compound. Many explosives are characterized by moderate to high mobility in soil. These explosives are unlikely to adsorb strongly to soils, and therefore can lead to contamination of groundwater. The most common explosives have low Log Kow values (<2), which may be used

as a surrogate metric of bioaccumulation potential (See RI Table 7-2). Chemicals with Log Kow values >5 are potentially bioaccumulative, while Log Kow <5 are less likely to bioaccumulate into animal tissue (Government of Canada 1995). However, a limited number of studies investigating the bioaccumulation of various explosives have demonstrated bioaccumulation from soil by earthworms and plants and from surface water by fish (Juhasz and Naidu 2007).

Harmful effects following exposure to organic compounds may occur in wildlife and aquatic receptors. PCB exposure has been shown to induce a suite of deleterious effects including immunological, neurological, reproductive, and developmental toxicity, as well as disruption of thyroid function in various animal models (Arena et al. 2003; Boas et al. 2012; Fernie et al. 2001; Monosson 2000). Consequently, data from animal studies suggests that PCBs are endocrine disrupting chemicals (Djordjevic et al. 2020). Similarly, PAH exposure has been shown to impact the reproduction and development of terrestrial and aquatic wildlife (Cousin and Cachot 2014; Fernie et al. 2018; Zychowski et al. 2017), as well as having genotoxic and immunological effects (Matson et al. 2009; Reynaud and Deschaud 2006). For the nitroaromatic explosive compounds, effects on growth, reproduction, and the hematological system have been recorded for invertebrates, fish, and reptiles, though fewer studies have been conducted in mammalian species compared to the PCBs and PAHs (reviewed in Lotufo 2012).

The following sections discuss the site ecology and habitats that have the potential to be impacted by organic and inorganic constituents.

2.1.4 Site Ecology

Iona Island is part of the much larger Hudson River National Estuarine Research Reserve and Significant Coastal Fish and Wildlife Habitat Area, managed under New York's Coastal Management Program (Alion 2008). The Iona Island Marsh became a registered National Natural Landmark in 1974, and the island is considered a bald eagle sanctuary (Levine 2011). Habitats surrounding Iona Island include brackish intertidal mudflats, brackish tidal marsh, and freshwater tidal marsh. Terrestrial habitats on the island consist of deciduous forested uplands. Specific habitats are described in more detail in the following paragraphs.

An intertidal marsh encompasses approximately 225 acres between Iona Island and the western shore of the Hudson River and is one of the largest, undeveloped tidal wetlands along the river (Yozzo et al. 2005). The marsh is separated from the FUDS by a non-climbable steel fence on top of a rubble wall and the CSX railroad. The National Wetlands Inventory (U.S. Fish and Wildlife Service [USFWS] 2018a) classifies the marsh as an estuarine and marine wetland (E2EM1N6 – estuarine, intertidal, emergent, persistent, regularly flooded, oligohaline 0.5–5 parts per thousand salinity) (**Figure 2-2**).

The southern end of Iona Island has two wetland areas. The marshes that separate Iona Island and Round Island from the mainland were partially filled in the early 20th century, with a U.S. Navy dumping area located along the Hudson River side of the islands and an area of fill on the western shoreline placed by Palisades Interstate Park Commission (PIPC) following U.S. Navy transfer of the FUDS in 1965. A portion of the marshes remains tidally flooded and currently comprises the

"Former Dump Area". There is also a small (0.35-acre) freshwater emergent wetland on the western side of the island. Field observations indicate this area is dominated by persistent emergent vegetation such as *Phragmites australis* and cattails. The Hudson River is classified as estuarine and marine deep water (estuarine, subtidal, unconsolidated bottom, subtidal, oligohaline 0.5-5 parts per thousand salinity) (USFWS 2018a).

Vegetation within Iona Island Marsh is dominated by narrow leaf cattail (*Typha* spp.) with common reed (*Phragmites australis*) and swamp rose mallow (*Hibiscus moscheutos*). Crack willow (*Salix fragilis*) is present at the mouth of Doodletown Brook within the tidal swamp. In 2017, PIPC restored approximately 50 percent of the marsh from invasive species (including *Phragmites australis*) to native vegetation (pers. comm. Mr. Matthew Shook, Bluestone Environmental Group, Inc. 2018). Iona Island Marsh is especially important for marsh-nesting birds. Probable or confirmed breeding species include more than one species of heron, least bittern (*Ixobrychus exilis*), Canada goose (*Branta canadensis*), mallard (*Anas platyrhynchos*), wood duck (*Aix sponsa*), Virginia rail (*Rallus limicola*), belted kingfisher (*Ceryle alcyon*), marsh wren (*Cistothorus palustris*), and red-winged blackbird (*Agelaius phoeniceus*) (Yozzo et al. 2005, Levine 2011).

The upland terrestrial areas of the island consist of deciduous, rocky woodland communities including oaks (*Quercus* spp.), ashes (*Fraxinus* spp.), birches (*Betula* spp.), willows (*Salix* spp.), red maple (*Acer rubrum*), and elms (*Ulmus* spp.). Compaction of soil and site disturbance have resulted in a significant presence of invasive species (estimated at 60 percent of the vegetation on the island) including multiflora rose (*Rosa multiflora*), autumn olive (*Elaeagnus umbellate*), Norway maple (*Acer platanoides*), oriental bittersweet (*Celastrus orbiculatus*), and black swallow-wort (*Vincetoxicum nigrum*) (Yozzo et al. 2005). During the visual inspection of vegetation performed during the 2020 Shoreline Reconnaissance Survey (discussed below in Section 2.1.4.2), a high density of invasive species was observed including Japanese barberry (*Berberis thunbergii*), multiflora rose (*Rosa multiflora*), wineberry (*Rubus phoenicolasius*), and Japanese honeysuckle (*Lonicera japonica*).

The woodlands are maintained for their value as cover, perch sites, and buffer zones. Toward the center of the island, where historical buildings once stood, open grasslands and low-lying shrubs dominate the landscape. Resident wildlife species of Iona Island Marsh that could be present include muskrat (*Ondatra zibethicus*), white-tailed deer (*Odocoileus virginianus*), box turtle (*Terrapene carolina*), northern water snake (*Nerodia sipedon*), timber rattlesnake (*Crotalus horridus*), red fox (*Vulpes vulpes*), rat snake (*Pantherophis* spp.), and green frog (*Rana clamitans*) (Yozzo et al. 2005). Incidental observations of two mammals, three reptiles, and a number of birds were made during the 2020 Shoreline Reconnaissance Survey (discussed below in Section 2.1.4.2).

2.1.4.1 Threatened and Endangered Species

Under the Endangered Species Act of 1973 (ESA), threatened species are species that may become endangered if conditions surrounding the species begin, or continue, to deteriorate. Endangered species are species whose prospects for survival in an area are assumed to be in immediate danger because of a loss or change in habitat, over-exploitation, predation, competition, or disease. In

addition to threatened and endangered species, the state of New York also identifies species of special concern as any species that does not meet the criteria of an endangered or threatened species but is particularly vulnerable and could easily become an endangered, threatened, or extirpated species. Special concern species are established by policy, not by regulation, and are used for planning and informational purposes; they do not have the legal weight of endangered and threatened species. There are several protected species that may occur at the site and these species and their status are provided in the insect below. Additionally, there are 10 migratory birds of conservation concern known to use the Island as habitat.

Insert 2-1. Protected Animal Species at Iona Island[1]

Group	Species	Common Name	Status	Jurisdiction
Fish	*Acipenser brevirostrum*	Shortnose sturgeon	Endangered	Federal/State
Fish	*Acipenser oxyrhynchus*	Atlantic sturgeon	Endangered	Federal/State
Birds	*Haliaeetus leucocephalus*	Bald eagle	Threatened[1]	State
Birds	*Ixobrychus exilis*	Least bittern	Threatened	State
Birds	*Setophaga cerulea*	Cerulean warbler	Special Concern	State
Birds	*Vermivora chrysoptera*	Golden-winged warbler	Special Concern	State
Birds	*Pandion haliaetus*	Osprey	Special Concern	State
Birds	*Circus cyaneus*	Northern harrier	Threatened	State
Birds	*Podilymbus podiceps*	Pied-billed grebe	Threatened	State
Plants	*Isotria medeoloides*	Small whorled pogonia	Threatened/Endangered	Federal/State
Mammals	*Myotis sodalis*	Indiana bat	Endangered	Federal/State
Mammals	*Myotis septentrionalis*	Northern long-eared bat	Endangered[2]	Federal/State
Reptiles	*Clemmys muhlenbergii*	Bog turtle	Threatened/Endangered	Federal/State

Sources: USFWS ECOS-IPaC system Iona Island project request 10/8/2018 (USFWS 2018b), NYSDEC Environmental Resource Mapper (NYDEC 2019), and NOAA 2023a.

1) Bald eagles are also federally protected under the Bald and Golden Eagle Protection Act.
2) On 29 November 2022, USFWS published a ruling reclassifying northern long-eared bat from threatened to endangered under the federal Endangered Species Act. This rule is effective 30 January 2023. The change to endangered in New York will take place at the same time as the Federal listing.

Atlantic sturgeon (*Acipenser oxyrhynchus*) and shortnose sturgeon (*Acipenser brevirostrum*) are classified as Endangered by National Marine Fisheries Service and are protected in the State of New York (National Oceanic and Atmospheric Association [NOAA] Fisheries 2023a; NYSDEC 2019). These species of sturgeon live primarily in the ocean but migrate to coastal rivers for spawning. In New York, spawning and nursery grounds for juveniles are located in the Lower Hudson River, such as near Iona Island (Edinger et al. 2014). As adults, they will spend time at the fresh water/salt-water interface, which fluctuates near Iona Island. Sturgeon are known to shelter in deep holes (i.e., deep Hudson River channel), and in their adult and juvenile life stages foraging occurs in mucky substrate for crustaceans, worms, and mollusks (NOAA 2023b). Suitable foraging habitat would be expected in the estuaries surrounding Iona Island.

2.1.4.2 Shoreline Reconnaissance Survey Results

A Shoreline Reconnaissance Survey was conducted by EA as part of the Phase I investigation on 6–7 April 2020 to characterize the shoreline and document potential constituent migration and exposure pathways, ecological resources, and receptors. Field reconnaissance was conducted, and the results of the investigation are presented in **Attachment B**. As part of the field reconnaissance,

the type of material and environment along the shoreline was documented and photographed (**Attachment B**).

Sediments consisting of fine-grained particles and high organic matter (i.e., TOC) are more likely to present a "sink" for historical constituents and serve as a source of continuous exposure to organisms as opposed to coarser-grained particles (e.g., sand and gravel) with low TOC that are less likely to accumulate historical constituents. As such, seven sediment samples were collected and analyzed for physical parameters (TOC and grain size) to evaluate their potential for accumulating constituents. Samples were collected along the Hudson River shoreline as well as along the Iona Marsh and in accordance with Worksheet 11 of the Uniform Federal Policy (UFP)-Quality Assurance Project Plan (QAPP) (EA 2020)[1].

Results of the physical data in sediments can be found in the Phase I Data Summary Report (EA 2021) and indicate that the shoreline of the Hudson River contains pockets of sandy sediments with little organic matter (i.e., low TOC), whereas the shoreline on the marsh side of the island contains very soft, mucky sediments, with high organic matter, silty clays, and finer grained sediments. As such, it is anticipated that the marsh shoreline contains more of a depositional environment than the Hudson River shoreline and may be a "sink" for constituents.

Wildlife and vegetation observed on-site during the Shoreline Reconnaissance were documented to determine potential ecological receptors. In general, the observations made are consistent with what would be expected for the habitat areas described in Section 2.1.4 and include the following:

- Mammals:
  - White tailed deer (*Odocoileus virginianus*)
  - Grey squirrel (*Sciurus carolinensis*)

- Reptiles:
  - Northern water snake (*Nerodia sipedon*)
  - Black rat snake (*Panthrophis obsoletus*)
  - Painted turtle (*Chrysemys picta*)

- Birds:
  - Turkey vulture (*Cathartes aura*)
  - Osprey (*Pandion haliaethus*)
  - American crow (*Corvus brachyrhynchos*)
  - Red-winged blackbird (*Agelaius phoeniceus*)
  - Mourning dove (*Zenaida macroura*)
  - Northern cardinal (*Cardinalis cardinalis*)
  - Northern blue jay (*Cyanocitta cristata*)
  - Greater scaup (*Aythya marila*)

[1] EA Engineering, P.C. is affiliated with EA Engineering, Science, and Technology, Inc., PBC, who does business as EA Science and Technology in State of New York.

— Pileated woodpecker (*Dryocopus pileatus*)
— Ring-billed gull (*Larus delawarensis*)

In the wetland areas, phragmites *(Phragmites australis)* and cattail *(Typha spp.)* were the dominant aquatic vegetation. The upland habitat consists primarily of open grassland dominated by graminoid vegetation. The visual inspection found a high density of invasive species including Japanese barberry (*Berberis thunbergii*), multiflora rose (*Rosa multiflora*), wineberry (*Rubus phoenicolasius*), and Japanese honeysuckle (*Lonicera japonica*). Other species observed within the upland areas included maples (*Acer spp.*), *Forsythia spp*., devil's walkingstick (*Aralia spinosa*), and Eastern red cedar (*Juniperus virginiana*). Milkweed (*Asclepias syriaca*) was also identified.

2.1.5 Exposure Pathway Analysis

Exposure pathway analysis provides insight into the potential constituent exposure to wildlife receptors that may exist and/or visit the site. In general, an exposure pathway consists of the following components:

- Source and mechanism of constituent release to the environment (e.g., spill)
- Environmental transport medium (e.g., surface soil)
- Point-of-contact with the contaminated medium (exposure point)
- Exposure route at the exposure point (e.g., dermal contact with surface soil)

If all four components are present, the pathway is considered complete. Not all complete exposure pathways are quantitatively evaluated as pathways may be less significant than primary exposure pathways that account for nearly all exposure or, in some cases, the means to accurately evaluate exposure quantitatively are not available. Each pathway defines a unique mechanism by which potential receptors are directly or indirectly exposed to constituents. The following definitions are used to identify exposure pathways:

- ***Complete Exposure Pathway***—There is confirmed receptor and media interaction (i.e., a source, migration route, and receptor have been identified). Exposure is evaluated quantitatively.

- ***Complete Pathway, but not Significant***—There is confirmed receptor and media interaction. However, pathway is not significant and exposure is not evaluated quantitatively.

- ***Incomplete Exposure Pathway***—There is no receptor and media interaction. No evaluation is conducted.

Media of concern and ecological receptors are evaluated to identify potential exposure routes linking the two and to determine which pathways are complete. The sections below identify the major routes of exposure and their applicability to each of the identified receptor groups.

2.1.5.1 Groundwater

No groundwater was identified or sampled as part of the Phase I or II investigations. Exposure to groundwater is considered an incomplete pathway for terrestrial receptors because they are not exposed to groundwater directly. The Former Dump Area is low lying and the surface water sampled is subject to groundwater discharge and surface water inundation depending on tides. Aquatic receptors may be exposed to groundwater but only after it is transported to the Hudson River and becomes mixed with river water at which point this becomes surface water. Consequently, this exposure pathway was assessed by consideration of surface water exposure in aquatic receptors.

2.1.5.2 Terrestrial Exposure Pathways

Plants may absorb constituents from surface and subsurface soil via roots. They may also absorb constituents from air or airborne particles through the stomata in leaves, although the waxy surfaces of leaves may limit this exposure. Soil invertebrates may ingest constituents in soil and also may be exposed to constituents in soil through direct contact. Some plant roots may exist in deeper soil layers and invertebrates such as earthworms have the potential to burrow deeper into the soil. Therefore, exposure pathways linking plants and soil invertebrates to surface and subsurface soil are complete and relevant for assessment. As part of the base of the food web, plants and invertebrates also provide food/prey items for foraging by upper-trophic level wildlife (e.g., birds and mammals).

The major exposure route for wildlife (i.e., birds, mammals, and herptiles) is ingestion of constituents in contaminated media (EPA 2007a). The surface water ingestion pathway is a complete but not significant exposure pathway as constituents tend to bind to suspended sediments and settle out of the water column. Surface water ingestion is not likely to be a risk driving exposure route. Wildlife may ingest constituents by incidentally ingesting soil while grooming or foraging. Some constituents may bioaccumulate in animal tissues. Therefore, wildlife may also ingest constituents through the prey items that they consume as food. Ingestion of constituents in soil and/or food are considered complete exposure pathways for wildlife.

Wildlife may be exposed to constituents in air, surface water, or soil via direct contact during foraging. Birds and mammals have protective outer coverings (feathers and fur) that prevent or limit the dermal absorption of constituents from environmental media (EPA 2007a, U.S. Army Center for Health Promotion and Preventative Medicine [USACHPPM] 2004). EPA guidance identifies that, in most cases, dermal exposures are likely to be less significant than exposures through ingestion, and their evaluation involves considerable uncertainty (EPA 2007a, USACHPPM 2004). Therefore, the dermal exposure route is considered complete but not significant for birds and mammals and therefore is not quantitatively evaluated in the ERA. Since herptiles may be more sensitive to dermal exposure (Weir et al. 2010), the dermal exposure route is considered a complete exposure pathway for herptiles.

Some mammals burrow into the soil to create dens and burrows which serve, not only as a home for these species, but also benefit the environment by aerating the soil. As a result, these mammals

may be exposed to and incidentally ingest both surface and subsurface soil. Foxes have been observed on the island and likely burrow in dens, which were observed during a site visit in October 2018. As such, mammals are assumed to burrow and be exposed to both surface and subsurface soil.

Inhalation is a complete pathway for wildlife that may inhale constituents that have volatilized or that are adsorbed to airborne particulates. EPA guidance indicates that, in general, the inhalation pathway is complete but not significant compared to ingestion pathways (EPA 2007a) and therefore is not quantitatively evaluated in the ERA.

In summary, the following terrestrial exposure pathways are complete and quantitatively evaluated in the ERA:

- direct contact to constituents in soil for plants;
- ingestion and direct contact to constituents in soil for soil invertebrates and herptiles; and
- ingestion of constituents in soil and food for wildlife (birds, mammals, and herptiles).

2.1.5.3 Aquatic Exposure Pathways

Results of the Shoreline Reconnaissance indicate that much of the shoreline along the Hudson River consists of boulders and riprap and does not contain suitable sediments or benthic habitats to support infaunal organisms. Faunal amphipods were observed on the underside of rocks, so these organisms are likely exposed primarily to surface water rather than sediments. Sediments along the Hudson River are characterized by sands or cobbles with low TOC content. On the other side of the island within Iona Marsh, the sediments are characterized by fine-grained organic muck and exhibit higher TOC content.

Based on the results of the Shoreline Reconnaissance Survey, there is the potential for runoff from the partially filled area between Round and Iona Islands to travel to the marsh side of the island. This area floods frequently with high tides, which could transport constituents from soil out into Iona Marsh. Sediments in the marsh appear conducive for accumulation of constituents.

Sediments are ingested by benthic invertebrates, demersal (bottom-feeding) fish, pelagic fish (within the water column) and incidentally by wildlife (i.e., bird, mammals, and herptiles) that feed in the aquatic environment. These receptors are also directly exposed to the sediment. Pelagic fish exposure to sediment is complete but not significant compared to exposure captured by demersal fish exposure to sediment and this exposure pathway is not quantitatively evaluated.

EPA guidance indicates that dermal exposures from direct contact are likely to be less significant than exposures through ingestion for birds and mammals due to protective outer coverings (EPA 2007a, USACHPPM 2004). Therefore, the sediment dermal exposure route is considered complete but not significant for birds and mammals. Since herptiles may be more sensitive to dermal exposure (Weir et al. 2010), the dermal exposure route is considered a complete exposure pathway for herptiles.

Food web models are typically not conducted for benthic invertebrates as exposure parameters are not readily available in EPA's Wildlife Exposure Factors Handbook (1993) or for fish due to the lack of site fidelity (see Section 2.1.6.2 for more information). Sediment quality criteria are expected to be protective of benthic invertebrates and fish via all exposure routes.

Aquatic and wetland plants have root systems that are also directly exposed to sediment. Areas with dense *Phragmites* root mats will limit wildlife exposure to sediment. Desorption of constituents from sediment to the water column can occur, impacting water column invertebrates (i.e., zooplankton) and pelagic (predacious) fish.

Demersal and pelagic fish as well as aquatic-feeding wildlife (e.g., birds, mammals, and herptiles) may ingest constituents through the prey items that they consume as food. For instance, insectivorous birds and demersal fish consume benthic invertebrates; herbivorous birds and mammals consume wetland aquatic plants; pelagic fish, large piscivorous mammals (e.g., river otter), and birds (e.g., bald eagle and heron) consume fish; and herptiles may consume any of the aquatic biota items. Ingestion of constituents in sediment and aquatic biota are considered complete exposure pathways for aquatic wildlife and are evaluated quantitatively in the food web models.

Ingestion of aquatic biota is considered complete for fish, but this pathway is not evaluated quantitatively in the food web models due to fish being transient in nature. Moreover, modeling exposures and ultimate associations with toxicity for aquatic receptors is limited. For example, US EPA's Aquatox model is available but is limited to organic contaminants and is therefore not applicable for sites impacted by heavy metals such as Iona Island and the Hudson River. Additionally, another model available for quantifying exposure/toxicity to aquatic receptors is US EPA's Web-ICE; however, this is limited to acute exposure scenarios as outputs focus on acute endpoints (i.e. mortality), thus the application of such a model for legacy impacted sediments will not yield applicable information for an exposure characterization of persistent contaminants from sediments, such as the case for Iona Island sediment at the Hudson River littoral zone. Finally, in the context of contaminant exposures, food web models are unlikely the most representative exposure route as fish are predominantly exposed at the gill-water interface (Evans 1987). Ingestion of aquatic biota is considered a complete but not significant exposure pathway for demersal and pelagic fish. For more information on how exposure is evaluated for aquatic receptors by taxa see Section 2.1.6.2.

Ingestion and direct contact with surface water is a complete pathway for each of the aquatic receptors (aquatic plants [direct contact only], benthic invertebrates, zooplankton, demersal fish, pelagic fish, and wildlife [birds, mammals, and herptiles]). The surface water ingestion pathway is a complete but not significant exposure pathway for wildlife as constituents tend to bind to suspended sediments and settle out of the water column. Surface water ingestion is not likely to be a risk driving exposure route. Benthic invertebrate and aquatic plant exposure to surface water is complete but not significant compared to exposure to sediment. Surface water quality criteria are expected to be protective of benthic invertebrates, fish, and aquatic plants via all exposure routes.

As discussed above, EPA guidance indicates that dermal exposures from direct contact are likely to be less significant than exposures through ingestion for wildlife (birds and mammals) due to protective outer coverings (EPA 2007a, USACHPPM 2004). The direct contact exposure pathway for surface water was considered complete but not significant and was not quantitatively evaluated for birds and mammals. Since herptiles may be more sensitive to dermal exposure (Weir et al. 2010), the dermal exposure route is considered a complete exposure pathway for herptiles.

In summary, the following aquatic exposure pathways are considered complete and quantitatively evaluated in the ERA:

- direct contact to sediment for aquatic plants;
- ingestion and direct contact to sediment for benthic invertebrates;
- ingestion and direct contact to sediment and surface water for demersal fish and herptiles;
- ingestion and direct contact to surface water for zooplankton and pelagic fish;
- ingestion of constituents in sediment and food for aquatic wildlife (birds, mammals, and herptiles).

2.1.6 Ecological Receptors

Selection of representative ecological receptor species for evaluation is based primarily on the following (EPA 1997):

- The likelihood of a species to use the site and the area immediately surrounding it
- The potential for exposure to constituents based on the feeding habits and life history of the organisms/feeding guild represented by the receptor species
- Life history and exposure information for the selected receptor species
- Toxicity information for the representative receptor species
- The societal importance of the species (e.g., threatened and/or endangered species, species of special concern).

2.1.6.1 Terrestrial Receptors

Based on the ecological setting and media of concern discussed above, ecological receptors selected for evaluation include terrestrial organisms such as plants, soil invertebrates, mammals, birds, and herptiles, are discussed further below.

Terrestrial Plant Community

No protected terrestrial plant species have been observed or are known to inhabit Iona Island. However, the small whorled pogonia (*Isotria medeoloides*) is believed or known to occur in

Rockland County, New York, and is federally listed as threatened and listed as endangered by the state of New York. The plant species is an orchid and grows in open-canopy forests and woodlands (North American Orchid Conservation Center 2023). Thus, it is possible the small whorled pogonia could be at upland portions of the site, most likely on the slopes of Round Island beneath the forest canopy and along drainage features in shallow soils where it is not being outcompeted by shrubs or other herbaceous vegetation. Based on the general nature of available plant toxicity data, no specific plant species are selected for evaluation. Instead, the assessment evaluates the potential for adverse effects to terrestrial plant communities by comparing soil data to soil screening values protective of plants. Also, terrestrial plants are an important component of the food web as food for herbivorous wildlife.

Soil Invertebrate Community

The earthworm was selected as the representative receptor species for the soil invertebrate community. Earthworms are an ideal receptor because they are in constant contact with the soil and can accumulate some constituents; as such, they represent a conservative estimate of exposure. They will be evaluated by comparing soil data to soil screening values protective of earthworms. Also, soil invertebrates are an important component of the food web as prey for insectivorous wildlife.

Herbivorous Wildlife

The meadow vole (*Microtus pennsylvanicus*) was selected as a representative receptor species to evaluate the potential for adverse effects to small herbivorous mammals from the ingestion of constituents in plants. The meadow vole was selected as a representative receptor because it is likely to occur in the study area, has a relatively small foraging range (which increases the potential for exposure to localized areas of potential contamination), uses underground tunnels and burrows (University of Kentucky 2023), and has a diet consisting solely of plant material. Also, the meadow vole is an important component of the food web as a common prey species for upper-trophic level predatory birds and mammals. In addition to the ingestion of constituents in food items, the incidental ingestion of constituents in soil is also evaluated.

Insectivorous Wildlife

The American robin (*Turdus migratorius*) was selected as a representative receptor species to evaluate the potential for adverse effects to insectivorous birds. The American robin is an appropriate receptor because it is common in a wide range of habitat types, likely to be present at the site, feeds primarily on invertebrates, and has a life history similar to that of many other passerine birds, including the red-winged black bird which were noted by both citizen scientists and EA field staff in the reconnaissance survey. Also, sufficient data are available for this species to support quantitative evaluation of food web exposures for passerine birds. For this evaluation, American robins are conservatively assumed to predominantly ingest earthworms and other invertebrates as well as some incidental ingestion of soils to account for diets that align with the protected species noted below and the red-winged black bird.

The cerulean warbler (*Setophaga cerulea*) and the golden-winged warbler (*Vermivora chrysoptera*) are both considered species of special concern by the state of New York. The cerulean warbler prefers deciduous forest habitats (Cornell Lab of Ornithology 2023a) the golden-winged warbler prefers mosaic forest near wetlands (Cornell Lab of Ornithology 2023b), and since both habitat types exist on-site, both species may be present at the site. However, due to the lack of an available food web exposure model for these birds, both species will be represented by the American robin (Cornell Lab of Ornithology 2023c). The American robin is an appropriate surrogate receptor because both warblers and the robin eat a wide variety of insects, and all have similar nesting behaviors. However, the American robin has a more generalist life history, meaning it can utilize a wider range of resources and habitats, and is approximately twice the size of the warbler. Smaller birds are required to feed more frequently and have larger energy requirements relative to body size; thus, contaminant doses normalized to body weight (e.g., in the denominator) may be greater compared to larger species. As such, potential risks to the smaller warbler species may be underestimated using the larger American robin as a surrogate receptor. The uncertainty associated with using surrogate receptors to evaluate risk to protected species is discussed further in Section 6.4.

The northern short-tailed shrew (*Blarina brevicauda*) is identified as a representative receptor species for evaluation of the potential for adverse effects to insectivorous mammals. Shrews consume a diet consisting almost entirely of insects and, thus, have a high rate of incidental soil ingestion while foraging. Sufficient data are available for this species to support quantitative evaluation of food web exposures. In addition, given their life history, feeding habits, use of burrows and tunnels, and high ingestion rates, shrews are expected to be a precautionary representative of other partially or predominantly carnivorous mammals, including skunks, mice, coyotes, and fisher cats.

The Indiana bat (*Myotis sodalis*) and northern long-eared bat (*Myotis septentrionalis*) are both federal and state-listed endangered species. Both species spend winters hibernating in areas such as caves or mines that are not present at or near the site, however both species choose summer roost sites opportunistically, roosting under exfoliating bark or in tree cavities, and therefore both bats may be present on-site during the summer (USFWS 2023a, 2023b). However, due to the lack of an available food web exposure model for bats, both species will be represented by the northern short-tailed shrew. The northern short-tailed shrew is an appropriate surrogate receptor for the two bat species because all are mostly nocturnal mammals with a similar diet that is largely insectivorous and opportunistic, and all have high energy demands requiring individuals to eat very high volumes of insect matter relative to their body size. However, the shrew is significantly heavier than the bats and has some important life history differences, such as that shrews do not fly or hibernate (University of Virginia 2010). Therefore, potential risks to these bats may be underestimated or overestimated using the northern short-tailed shrew as a surrogate receptor. For example, the larger body size and associated food ingestion rate for shrews may underestimate dietary exposure doses for bats. Bats are known to hibernate in the winter in habitats that are not present at the site, meaning the habitat use assumption with shrews as a surrogate would likely lead to overestimation of risk. The uncertainty associated with using surrogate receptors to evaluate risk to protected species is discussed further in Section 6.4.

Predatory Wildlife

The red-tailed hawk (*Buteo jamaicensis*) was selected as the representative receptor for predatory birds because it is likely to be present at the site and feeds predominantly on small mammals (such as mice, shrews, voles, rabbits, and squirrels). Also, sufficient data are available for this species to support quantitative evaluation of food web exposures.

The northern harrier (*Circus cyaneus*) is a state-listed threatened species. They prefer open grassland, therefore it is possible they may be found on-site. Due to the lack of an available food web exposure model for this species, it will be represented by the red-tailed hawk. The red-tailed hawk is a suitable surrogate receptor for the northern harrier because the species are closely related, and both have highly similar diets and life histories (Cornell Lab of Ornithology 2023d). The species are of fairly similar size, however the red-tailed hawk is slightly larger on average and more of a generalist, so it is possible that risks to the northern harrier may be underestimated using the red-tailed hawk as a surrogate receptor due to differences in food intake and contaminant dose relative to body size (i.e., in the denominator). The uncertainty associated with using surrogate receptors to evaluate risks to protected species is discussed further in Section 6.4.

Red fox (*Vulpes vulpes*) was selected as the representative receptor for predatory mammals because it was observed at the site, feeds primarily on small mammals, burrows in dens, has a high potential for exposure due to bioaccumulation though the food web, and is a valuable component to ecosystem structure by regulating the abundance, reproduction, distribution, and recruitment of lower-trophic level prey. Also, sufficient data are available for this species to support quantitative evaluation of food web exposures.

Herptiles

Reptiles and amphibians could inhabit terrestrial areas and be exposed to soil and prey. However, due to the lack of toxicological information, exposure factors, and ecological screening values for these species, only a qualitative evaluation of potential risks is possible. Risks to reptiles and amphibians are assumed to be similar to other receptors such as birds based on studies comparing toxic thresholds between the two groups (Salice et al. 2009).

EPA guidance on risk assessment suggests that birds can be used as surrogates for reptiles (EPA 2004). It has been demonstrated that for reptile exposure specifically to lead, growth effects were seen at a similar exposure dose to the lead EcoSSL Toxicity reference value (TRV) for avian ground insectivores (Salice et al. 2009), indicating the risk due to lead could occur at similar thresholds for birds and reptiles. The dietary exposure (ingestion of prey as well as incidental ingestion of soil during foraging) to birds is expected to be greater than that for reptiles since reptiles have lower energetic demands (Weir et al. 2010). As long as birds are as, or more, sensitive than reptiles to a given constituent, using birds (and other receptors such as mammals) as surrogates for the evaluation of risk to herptiles should be a conservative evaluation. However, in some cases the evaluation may not be as conservative. For example, herptiles may be more sensitive to a given constituent than other receptors, and there is a possibility that dermal exposure may be a more important pathway for herptiles as compared to other receptors (Weir et al. 2010).

Although use of surrogate receptors for the evaluation of potential risk to herptiles is uncertain, given the lack of available information, risk characterization via food web models is not possible. The uncertainty in the evaluation of risks to herptiles is also discussed in Section 6.4.2.

Summary

In summary, terrestrial receptors for evaluation are based on feeding guilds and availability of quantitative wildlife exposure models. As described above there are some instances noted where protected species may be present at the site (i.e., Northern Harrier, Long-eared Bat and Indiana Bat). In such cases, potential exposures to these species are modeled using the best representative receptors with similar life history traits that are data rich for use in exposure modeling. The terrestrial receptors selected for evaluation include the following:

- Terrestrial plant community
- Soil invertebrate community, represented by earthworms (*Lumbricus terrestr*is)
- Populations of herbivorous mammals, represented by meadow vole (*Microtus pennsylvanicus*)
- Populations of insectivorous mammals, represented by short-tailed shrew (*Blarina brevicauda*)
- Populations of insectivorous birds, represented by American robin (*Turdus migratorius*)
- Populations of predatory (carnivorous) mammals, represented by red fox (*Vulpes vulpes*)
- Populations of predatory (carnivorous) birds, represented by red-tailed hawk (*Buteo jamaicensis*)
- Populations of herptiles (i.e., amphibians and reptiles)

2.1.6.2 Aquatic Receptors

Potential aquatic ecological receptors include aquatic plants, benthic invertebrates, zooplankton, demersal fish, pelagic fish, aquatic birds, mammals, and herptiles.

Aquatic Plant Community

Based on the general nature of available plant toxicity data, no specific aquatic plant species were selected for evaluation. Instead, the assessment evaluated the potential for adverse effects to aquatic plant communities. There are no screening values protective of aquatic plants; therefore, plant communities were evaluated by comparing constituent concentrations in sediment to sediment screening benchmarks. Despite the lack of specific screening levels, an evaluation was

still performed given the importance of aquatic plants in the food web for aquatic herbivorous wildlife.

Benthic Invertebrate Community

Based on the general nature of available benthic invertebrate toxicity data, no specific species were selected for evaluation. Instead, the assessment evaluated the potential for adverse effects to benthic invertebrate communities (i.e., benthos). Benthic invertebrate communities were evaluated by comparing constituent sediment concentrations to sediment screening benchmarks. Although benthic invertebrates may be exposed to surface water and porewater, exposure to sediment via direct contact is considered the primary exposure pathway and was evaluated quantitatively. Also, benthic invertebrates are an important component of the food web as food for demersal fish and aquatic insectivorous wildlife.

Zooplankton Community

Based on the general nature of available invertebrate toxicity data, no specific species were selected for evaluation. Instead, the assessment evaluated the potential for adverse effects to water column invertebrate communities. Zooplankton communities were evaluated by comparing constituent concentrations in surface water to relevant surface water quality criteria.

Fish Community

Fish are exposed to COPECs through gills and dietary exposure routes. Bioconcentration occurs via exposure from water (typically through passive diffusion at the gill), and bioaccumulation of a COPEC may occur from both dietary and water compartments (Barber et al. 1991). The fish that may inhabit the shoreline of Iona Island can include demersal and pelagic fish species that may also be anadromous (e.g., see Steimle et al. 2000). Thus, fish could be resident or transient at Iona Island shoreline. The endangered, demersal, and anadromous shortnose sturgeon (*Acipenser brevirostrum*) and Atlantic sturgeon (*Acipenser oxyrhynchus*) may be a transient fish as maturation of this fish occurs in the lower Hudson River (NYDEC 2023a).

Exposures to site related COPECs for fish that are transient in nature are expected to be limited to time spent near the site shoreline. Otherwise, fish ranges, especially those that are anadromous, will be within water further from the site, thus reducing continuous exposure scenarios. Importantly, while some exposure models exist (i.e., US EPA Bioaccumulation and Aquatic System Simulator [BASS] and Food and Gill Exchange of Toxic Substance [FGETS]), application of such models would be limited in the context of this ecological risk assessment. Exposure without a metric for comparison of hazard yields limited information relevant to potential risk scenarios. Outputs from these models could help understand potential exposures to fish; however, utility would be limited to exposure alone as there are no standards or criteria appropriate for comparison. Therefore, comparisons to USEPA chronic surface water quality criteria (derived by US EPA following established guidelines for the protection of aquatic organisms) and sediment screening benchmarks (threshold effect concentrations (TECs) that are below concentrations expected to cause harmful effects to aquatic organisms (MacDonald et al. 2003) will be conducted. These

comparisons are conservative as these assume continuous chronic exposures. Resident fish communities will also be compared to chronic screening benchmarks.

Herbivorous Wildlife

Populations of herbivorous birds were represented by the mallard duck (*Anas platyrhynchos*), which are common dabbling (surface-feeding) ducks of freshwater and saltwater wetlands. They feed by dabbling and tipping up in shallow water, often filtering through soft sediments for food. They primarily feed on seeds, leaves, buds, stems, roots, and tubers of aquatic plants (EPA 1993). Herbivorous birds were evaluated by calculating a daily dose of constituents from sediment and aquatic biota (aquatic plants). Exposure from ingestion of surface water was not included for aquatic receptors, as constituents tend to bind to suspended sediments that settle out of the water column, resulting in minimal risk from this pathway (see Section 2.1.5.3 above). The daily dose was compared to TRVs for birds.

Populations of herbivorous mammals were represented by muskrat (*Ondatra zibethicus*). These rodents spend most of their lives in or near bogs, marshes, lakes, or streams. They are primarily herbivorous and feed upon roots, shoots, bulbs, tubers, stems, and leaves of aquatic plants. They construct dens in riverbanks or along shores of waterways and have a small home range (EPA 1993). Herbivorous mammals were evaluated by calculating a daily dose of constituent from sediment and aquatic biota (aquatic plants). The daily dose was compared to TRVs for mammals.

Insectivorous Wildlife

Populations of insectivorous birds were represented by lesser scaup (*Aythya affinis*), which is a common diving duck that primarily consumes invertebrates from the water column and surfaces of aquatic plants and other substrates. Common prey includes snails, clams, water fleas, amphipods, midges, chironomids, and leeches. When seeds are abundant, they may also be consumed in large quantities (EPA 1993). Insectivorous birds were evaluated by calculating a daily dose of constituent from sediment and aquatic biota (benthic invertebrates). The daily dose was compared to TRVs for birds.

The pied-billed grebe (*Podilymbus podiceps*) is a state-listed threatened species. It prefers wetland habitats with both open water and aquatic vegetation cover available, and so may be present on-site. However, due to the lack of an available food web exposure model for the grebe, the species will be represented by the lesser scaup. The lesser scaup is a suitable surrogate receptor for the pied-billed grebe because both species have highly similar diets, habitat requirements, and life histories. However, the lesser scaup is significantly larger than the pied-billed grebe, and as such it is possible that risk to the grebe will be underestimated due to the differences in ingestion rates and contaminant doses relative to body size (i.e., in the denominator). The uncertainty associated with using surrogate receptors to evaluate risk to protected species is discussed further in Section 6.4.

Piscivorous Wildlife

COPECs that do accumulate in fish tissue and those that are expected to transfer to higher trophic levels are evaluated using food web models. Piscivorous birds and mammals are evaluated in those food web models with COPEC specific bioconcentration factors (BCFs) used to estimate total fish concentrations that are consumed as prey. Populations of piscivorous mammals were represented by river otter (*Lontra canadensis*), which are found in freshwater, estuarine, and some marine environments from coastal areas to mountain lakes. They inhabit food-rich coastal areas such as lower portions of streams and rivers, estuaries, non-polluted waterways, lakes, tributaries that feed rivers, and areas of little human impact. The bulk of their diet is fish, but they feed on a variety of prey depending on availability and ease of capture. They may also consume crustaceans, insects, amphibians, and reptiles (EPA 1993). Piscivorous mammals were evaluated by calculating a daily dose of constituents from sediment and aquatic biota (demersal fish). The daily dose was compared to TRVs for mammals.

Populations of piscivorous birds were represented by the great blue heron (*Ardea herodias*). These birds have long legs, necks, and bills that are adapted for wading in shallow water and stabbing prey. Most heron species build their nests in trees near their foraging habitat. Herons range in size from the least bittern to the great blue heron (EPA 1993). Great blue herons are assumed to consume demersal fish. Piscivorous birds were evaluated by calculating a daily dose of constituent from sediment and aquatic biota. The daily dose was compared to TRVs for birds.

The least bittern (*Ixobrychus exilis*) is a protected species under the Migratory Bird Act, and habitat for the species has been noted on the island. However, due to the lack of an available food web exposure model for the bittern, the species was represented by the great blue heron, which is a similar wading, piscivorous heron species that shares similar habitats and feeding behaviors. Both birds have long necks and spear-like bills. They feed primarily on aquatic life (e.g., fish) and are common along the margins of waterbodies and wetlands. Their long legs, necks, and bills are adapted for wading in shallow water and stabbing prey. The least bittern is the smallest of the wading birds, whereas the great blue heron is the largest (EPA 1993). Using an established allometric equation (Nagy 2001), the ingestion rate and contaminant dose normalized to body weight (i.e., in the denominator) of the least bittern would be approximately threefold higher than the blue heron; therefore, potential risks to the least bittern may be underestimated using the great blue heron as a surrogate receptor. The uncertainty associated with using surrogate receptors to evaluate risk to protected species is discussed further in Section 6.4.

The bald eagle (*Haliaeetus leucocephalus*) is a state and federal protected species that roosts along the Hudson River shoreline on Iona Island, especially during the winter months. Bald eagles are primarily opportunistic, consuming a variety of prey including ducks and birds or whatever prey is available and easiest to obtain (including carrion). They also consume dead and dying fish when available but will capture live fish swimming near the surface or fish in shallow water (EPA 1993). Due to the large home range and lack of site fidelity, the bald eagle was not evaluated in the ERA. However, evaluation of great blue heron, another piscivorous species, is considered to be protective of bald eagles due the heron's smaller home range and greater site fidelity (EPA 1993).

The osprey (*Pandion haliaetus*) is considered a species of special concern by the state of New York. It is an obligate piscivore (NYDEC 2023b), meaning it consumes only fish. Evaluation of the great blue heron, another obligate piscivore (though notably larger), will be considered protective of osprey.

Herptiles

Reptiles and amphibians could inhabit aquatic (marsh) areas and be exposed to site-related constituents through direct contact with sediments, surface water and ingestion of prey. In addition, the bog turtle *(Clemmys muhlenbergii*) is a federal and state listed threatened species with a range that overlaps with the site. In New York, the bog turtle is generally found in open wet meadows or boggy areas dominated by sedges or sphagnum moss, and they rely on a complex habitat featuring microhabitats for different parts of their life cycle (NYDEC 2023c). However, due to the lack of toxicological information, exposure factors, and ecological screening values for reptile and amphibian species, only a qualitative evaluation of potential risks is possible. Risks are assumed to be similar to other receptors evaluated. See Section 2.1.6.1 for the discussion of the use of surrogate receptors to evaluate risk to herptiles.

Summary

In summary, the aquatic receptors for evaluation are based on feeding guilds and availability of wildlife exposure models. As described above there are some instances noted where protected species may be present at the site (i.e., Least Bittern, Pie-billed Grebe), potential exposures to these species are modeled using the best representative receptors with similar life history traits that are data rich for use in exposure modeling. The aquatic receptors selected for evaluation include the following:

- Aquatic plant community
- Benthic invertebrate community (i.e., benthos)
- Aquatic life (zooplankton, demersal fish, and large pelagic fish)
- Populations of herbivorous birds, represented by mallard duck (*Anas platyrhynchos*)
- Populations of herbivorous mammals, represented by muskrat (*Ondatra zibethicus*)
- Populations of insectivorous birds, represented by lesser scaup (*Aythya affinis*)
- Populations of piscivorous mammals, represented by river otter (*Lontra canadensis*)
- Populations of piscivorous birds, represented by great blue heron (*Ardea herodias*)
- Populations of herptiles (i.e., amphibians and reptiles)

2.1.7 Conceptual Site Models

A graphical representation of the ecological CSM is depicted on **Figure 2-3**.

2.2 ASSESSMENT AND MEASUREMENT ENDPOINTS

Assessment and measurement endpoints are identified for each representative receptor species evaluated at the site. EPA guidance stresses the importance of ecologically significant endpoints. According to EPA (1998), "Assessment endpoints are explicit expressions of the actual environmental value that is to be protected, operationally defined by an ecological entity and its attributes." Failure to select appropriate assessment and measurement endpoints can result in the inability to answer the risk questions. Several criteria are applicable for endpoint selection (Suter 2007, EPA 1998):

- Unambiguous Definition—Assessment endpoints should indicate a subject and a characteristic of the subject (e.g., fish reproduction).

- Accessibility to Prediction and Measurement—Assessment endpoints should be reliably predictable from measurements.

- Susceptibility to the Hazardous Agent/Stressor—Susceptibility of an organism (plant or animal) results from the combination of potential for exposure and the sensitivity to the concentrations of constituents or other stressors of concern.

- Biological Relevance—Biological relevance of impacts to an individual organism is determined by the importance of the impact to higher levels of biological organization (e.g., populations or communities).

- Social Relevance and Policy Goals—Assessment endpoints should be of value to decision-makers and the public. The assessment endpoints should represent effects that would warrant consideration of site remediation or alteration of project plans. Assessment endpoint selection should also include endpoints that may be mandated legally (e.g., protected species).

For the Iona Island FUDS, the terrestrial assessment endpoints (AE) include the following:

- AE1: Protection and maintenance (i.e., survival, growth, and reproduction) of terrestrial plant community from adverse effects to survival, growth, or reproduction from exposure to COPECs in soil

- AE2: Protection and maintenance (i.e., survival, growth, and reproduction) of soil invertebrate community from adverse effects to survival, growth, or reproduction from exposure to COPECs in soil

- AE3: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of herbivorous mammals, represented by meadow vole (*Microtus pennsylvanicus*), from exposure to COPECs in soil and biota (i.e., plant tissue)

- AE4: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of insectivorous birds, represented by American robin (*Turdus migratorius*), from exposure to COPECs in soil and biota (i.e., earthworms)

- AE5: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of insectivorous mammals, represented by short-tailed shrew (*Blarina brevicauda*), from exposure to COPECs in soil and biota (i.e., earthworms)

- AE6: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of carnivorous (predatory) mammals, represented by red fox (*Vulpes vulpes*), from exposure to COPECs in soil and biota (i.e., small mammal tissue)

- AE7: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of carnivorous (predatory) birds, represented by red-tailed hawk (*Buteo jamaicensis*), from exposure to COPECs in soil and biota (i.e., small mammal tissue)

For the Iona Island FUDS, the following assessment endpoint is relevant to terrestrial and aquatic environments:

- AE8: Protection of and maintenance (i.e., survival, growth, and reproduction) of populations of herptiles (amphibians and reptiles) from exposure to COPECs in soil, surface water, and sediment (qualitative evaluation due to minimal toxicological endpoints)

For the Iona Island FUDS, the aquatic assessment endpoints include the following:

- AE9: Protection and maintenance (i.e., survival, growth, and reproduction) of aquatic plant community from exposure to COPECs in sediment and surface water

- AE10: Protection and maintenance (i.e., survival, growth, and reproduction) of benthic invertebrate community from COPECs in sediment

- AE11: Protection and maintenance (i.e., survival, growth, and reproduction) of zooplankton community from exposure to COPECs in surface water

- AE12: Protection and maintenance (i.e., survival, growth, and reproduction) of demersal fish community from exposure to COPECs in surface water and sediment

- AE13: Protection and maintenance (i.e., survival, growth, and reproduction) of pelagic fish community from exposure to COPECs in surface water

- AE14: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of herbivorous birds, represented by mallard duck (*Anas platyrhynchos*), from exposure to COPECs in sediment and biota (i.e., plant tissue)

- AE15: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of herbivorous mammals, represented by muskrat (*Ondatra zibethicus*), from exposure to COPECs in sediment and biota (i.e., plant tissue)

- AE16: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of insectivorous birds, represented by lesser scaup (*Aythya affinis*), from exposure of COPECs in sediment and biota (i.e., benthic invertebrates)

- AE17: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of piscivorous mammals, represented by river otter (*Lontra canadensis*), from exposure to COPECs in sediment and biota (i.e., fish tissue)

- AE18: Protection and maintenance (i.e., survival, growth, and reproduction) of populations of piscivorous birds, represented by great blue heron (*Ardea herodias*), from exposure to COPECs in sediment and biota (i.e., fish tissue).

Measurement endpoints are measurable ecological characteristics that are related to the assessment endpoints (EPA 1998). Since it is difficult to "measure" assessment endpoints, measurement endpoints are selected to allow inference regarding the assessment endpoints described above. Measurement endpoints are used to assess the potential for effects on the assessment endpoints through their comparison to screening-level concentrations or toxicity values. The overall measurement endpoints are provided below. **Table 2-1** presents specific measurement endpoints for each assessment endpoint.

- Chemistry Data for Soil—The measurement of COPEC concentrations in soil provides the means, when compared to conservative (based on chronic or no effects levels) ecotoxicological-based screening concentrations, for drawing inferences regarding the assessment endpoints for terrestrial plants and soil invertebrates.

- Chemistry Data for Sediment—The measurement of COPEC concentrations in sediment provides the means, when compared to conservative (based on chronic or no effects levels) ecotoxicological-based screening concentrations, for drawing inferences regarding the assessment endpoints for aquatic plants, benthic invertebrates, and demersal fish.

- Chemistry Data for Surface Water—The measurement of COPEC concentrations in surface water provides the means, when compared to conservative (based on chronic or no effects levels) ecotoxicological-based screening concentrations, for drawing inferences regarding the assessment endpoints for zooplankton and demersal and pelagic fish.

- Modeled Doses of COPECs—The estimated dose of COPECs ingested by wildlife (birds and mammals) using chemistry data in site media when compared to wildlife TRVs provides the means for drawing inferences regarding the assessment endpoints for wildlife (i.e., birds and mammals).

- Quantitative measurements of physical parameters in site media assist with evaluating the bioavailability potential of each COPEC. Data for grain size, TOC, pH, CEC, and AVS/simultaneously extracted metals (SEM) are used to assess the potential bioavailability of each COPEC.

3. ECOLOGICAL RISK ASSESSMENT DATASET

3.1 REMEDIAL INVESTIGATION SAMPLING

A two-phased investigation approach was conducted as part of the RI to facilitate data collection, evaluation, and discussion. Phase I field activities were conducted in March and April 2020 and consisted of surface soil and subsurface soil sampling using ISM. Phase I field activities were conducted in accordance with the HTRW RI UFP-QAPP (EA 2020) and are presented in the Phase I RI Data Summary Report (EA 2021).

Phase II field activities were conducted in April 2022 following the HTRW RI UFP-QAPP Addendum (EA 2022) and are documented in the RI Report to which this document is appended. Activities included surface water and sediment sampling to evaluate the potential for inorganic constituents to impact the shoreline of Iona Island. In addition, physical parameters in soil were collected in select upland decision units (DUs) to help evaluate potential terrestrial risk as part of the RSLERA.

3.1.1 Phase I Investigation

Surface soil ISM samples (0-6 inches [in.] below ground surface [bgs]) were collected in triplicate from 30 DUs: DU-1 through DU-7, DU-9 through DU-23, DU-25, and EXDU-1 through EXDU-7. Due to shallow bedrock and general lack of subsurface soil across much of the site, subsurface soil samples (6 in. to a maximum of 36 in. bgs) were collected from only 5 DUs (DU-17 through DU-21). Soil samples were submitted to an analytical laboratory for analysis of Target Analyte List (TAL) metals; PAHs; polychlorinated biphenyls (PCBs); explosives residues; and/or benzene, toluene, ethylbenzene, and xylenes (BTEX). DUs are presented in **Figure 3-1**. Most DUs were approximately 1 acre (200 feet [ft] x 200 ft) in size. A few smaller DUs were sized at 60 ft x 60 ft. In addition, surface soil ISM samples (0-6 in. bgs) were collected from 8 background DUs in Bear Mountain State Park to establish regional background concentrations of TAL metals and PAHs (**Figure 3-2**). A total of 90 surface soil samples (initial and replicates), 15 subsurface soil samples (initial and replicates), and 8 background surface soil samples were collected via ISM for laboratory analysis.

3.1.2 Phase II Investigation

Based on the results of the Phase I investigation, additional soil parameters, sediment, and surface water data were collected as part of the Phase II investigation. Following a preliminary evaluation of the Phase I data, which indicated that metals were the primary constituent in soil, only metals were evaluated in the shoreline media (i.e., aquatic habitats). Therefore, sediment and surface water samples were evaluated for metals only. Soil data were collected to help further evaluate the potential bioavailability of metals in soil at eight DUs: DU-4, DU-7, DU-9, DU-11, DU-13, DU-17, DU-18, and DU-19 (**Figure 3-3**). The following parameters were collected in triplicate: oxidation reduction potential (ORP) (field-measurement), TOC, CEC, and grain size.

To evaluate the potential transport of metals to the shoreline, particularly from the Former Dump Area (DU-17, DU-18, and DU-19), sediment and surface water data were collected from three shoreline DUs: the Iona Island Hudson River Shoreline (IHRS), a Riprap Drainage Swale (RRDS) that leads out from the Former Dump Area to the Round Island shoreline, and a Tidal Wetland Swale (TWS) that leads out from the Former Dump Area to the Iona Marsh shoreline (**Figure 3-3**). Each of these areas consists of about one-half acre. Sediment samples were collected using ISM. Surface water samples were collected as individual grab samples. TAL metals were analyzed in both surface water (dissolved) and sediment. Additional parameters in surface water included temperature, pH, dissolved oxygen (DO), ORP, specific conductivity, turbidity, salinity, and hardness. Additional parameters in sediment included pH, ORP, TOC, grain size, and AVS/SEM.

In addition, background sediment ISM and surface water grab samples were collected from an upstream location called Con Hook. Con Hook is similar to Iona Island in that it is an outcrop of land in the Hudson River with a marsh and a riverine shoreline, but it has not been impacted by former military activities (**Figure 3-4**). Eight ISM sediment samples were collected from the Con Hook Marsh Shoreline, and eight sediment samples were collected from the Con Hook Hudson River Shoreline. Sediment samples from Con Hook were analyzed for the same constituent and physical parameters as the Iona Island sediment samples, except for AVS/SEM, which was not collected from Con Hook. AVS/SEM is used to predict site-specific bioavailability of the metals cadmium, copper, nickel, lead, and zinc based on AVS and TOC content. Information on the bioavailability of metals from the background area is not needed to evaluate the bioavailability of these metals at the site. Twenty surface water grab samples were collected from each of the Con Hook Marsh and Con Hook Hudson River Shorelines and were analyzed for the same constituent and physical parameters as those analyzed in the Iona Island surface water. Following analysis, data were evaluated for usability.

3.2 DATA EVALUATION AND USABILITY ASSESSMENT

Analytical data packages were reviewed to ensure that required laboratory components were included, quality insurance and quality control (QC) requirements were performed, and data use restrictions were well defined. During data validation, the analytical data were qualified and appropriately flagged if criteria were not met as indicated below, and a data usability assessment was conducted to review the analytical results and data qualifiers. The data usability assessments are presented in the data summary reports included in Appendix D of the RI Report to which this document is appended. Overall, the data meet the data quality objectives and with few exceptions are deemed usable for the ERA. Additional detail on Phase 1 and Phase II data evaluations are provided in the subsequent sections.

The following qualifiers were applied to the reported data:

- No qualifier: The analyte was positively identified at the specified numerical value exceeding the limit of quantitation (LOQ), and no data quality issues requiring validation were identified

- U: The analyte was not detected at a level greater than or equal to the associated numerical value (limit of detection [LOD])

- J: The analyte was positively identified, but the associated numerical value is approximate and may be inaccurate or imprecise

- UJ: The analyte was not detected; however, the associated numerical value (LOD) is approximate and may be inaccurate or imprecise

- -: Result may be biased low. May be applied to J qualified data

- +: Result may be biased high. May be applied to J qualified data

- R: The analytical result was rejected.

The inclusion or exclusion of data for the ERA was based upon the analytical qualifiers. The following procedures were followed for sample results with data qualifiers:

- Analytical results bearing the U and UJ qualifiers (indicating that the analyte is not detected at or above the concentration presented) were retained in the dataset and considered non-detects. In nearly all cases, each non-detected COPC was assigned a numerical value equal to its LOD. For silver non-detected results in soil, the assigned numerical value was equal to the LOQ

- Analytical results bearing the J, J+, J- qualifiers (indicating that the reported value is estimated because the analyte is detected at a concentration below the LOQ or for data quality limitations identified during data validation) were retained at the reported concentration

- Analytical results bearing the R qualifier were not evaluated in the ERA.

PAHs were grouped into HMW and low molecular weight (LMW) classifications, and their concentrations were summed for evaluation (EPA 2007f). If an individual PAH was not detected in a sample, the concentration was assumed to be zero for the purposes of summing LMW and HMW PAHs. Concentrations of the following LMW PAHs were summed: acenaphthene, acenaphthylene, anthracene, fluorene, 1-methylnaphthalene, 2-methylnaphthalene, naphthalene, and phenanthrene. Concentrations of the following HMW PAHs were summed: benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(g,h,i)perylene, benzo(a)pyrene, chrysene, dibenz(a,h)anthracene, fluoranthene, indeno(1,2,3-c,d)pyrene, and pyrene.

3.2.1 Phase I Data

Some soil data were qualified as estimated (J, J-, J+ or UJ) and one result was rejected during data validation due to QC issues, as discussed in the Phase I data usability assessment in Appendix D of the RI Report. Of the 3,848 results that were reported, 1,058 results were qualified during validation. Overall, approximately 28 percent of the dataset was qualified as estimated due to minor QC issues.

PAHs had the greatest number of qualified results. Of the 1,278 PAH results in soil, approximately half (660) of the results were qualified during data validation due to minor QC issues. Of these, 237 were J or UJ qualified because sample preparation exceeded holding times and 143 results were J qualified as they were below the LOQ. The majority of J qualifiers have a potential low bias, meaning the reported result may be lower than the actual concentration. Despite these qualifiers, the concentrations of PAHs are not anticipated to be impacted by holding times. PAHs, particularly HMW PAHs, are more tightly bound to soils than volatile organic compounds and LMW PAHs and are unlikely to be volatilized during sample holding. Additionally, one result for dibenz(a,h)anthracene in the background dataset was R qualified (rejected) due to a QC issue and was not used in the ERA. The seven remaining detected results were sufficient to calculate the 95th percent upper confidence limit (95UCL) of the mean for the background dataset.

Based on evaluation against the project data quality objectives specified in the UFP-QAPP (EA 2020) the Phase I data as qualified are usable for the intended purposes. The potential impact of the estimated values is addressed in Section 6. With the exception of the one rejected result, the results are deemed usable for the ERA. Results from the Phase I Investigation are presented in **Attachment C**.

3.2.2 Phase II Data

Various sediment and surface water data were qualified as estimated (J or UJ) during data validation due to QC issues as discussed in the Phase II data usability assessment in Appendix D of the RI Report. Of the 3,126 results that were reported, 200 results were qualified during validation. Overall, approximately 6 percent of the dataset was qualified as estimated due to minor QC issues. An additional 611 results (approximately 20 percent) that were reported at estimated concentrations between the LOD and LOQ were qualified as estimated. Based on evaluation against the project data quality objectives specified in the UFP-QAPP and UFP-QAPP Addendum (EA 2020, 2022), the Phase II data as qualified are usable for the intended purposes. The potential impact of the estimated values is addressed in Section 6 of this ERA. However, with the exception of the rejected CEC data (discussed below), the results are deemed of sufficient quality for use in the ERA.

Initial laboratory CEC results for soil collected during the Phase II investigation were rejected due to laboratory error, which resulted in values orders of magnitude greater than expected (e.g., 1,500 to 1,800 milli-equivalents per 100 grams [meq/100g]). No other soil physical parameters were affected. As such, CEC results were deemed unusable during data validation. Samples were reanalyzed for CEC by the laboratory, and results ranged from 23 to 39 meq/100g in the upland

soil, which is similar to estimated CEC in soils typical for New York State agricultural land (12-25 meq/100g) (Cornell University 2007). Soil samples reanalyzed for CEC were flagged as estimated (J) due to drying occurring between initial and reanalysis, which may influence CEC values (Meyer and Arp, 1994; Phillips et al. 1986). Samples were stored 140–144 days (20 weeks) at the laboratory prior to reanalysis. Meyer and Arp (1994) found that CEC values in soil increased slightly with storage time (up to 14 weeks) but were closely related to values obtained with non-dried samples. Conversely, Phillips et al. (1986) found that oven drying of soil samples significantly decreased CEC from original measurements, but that air drying had no significant effect; the latter is how these samples were dried. These data are considered usable in the ERA based on the supporting literature.

3.3 DATA SUMMARY BY MEDIA

The samples analyzed and detections of constituents are summarized below for each medium analyzed, including soil (surface and subsurface), sediment, and surface water.

3.3.1 Soil Dataset

Analytical data tables for soil collected via ISM from the Phase I investigation are presented in **Attachment C**. No soil analytical data were collected as part of the sampling design for Phase II. However, additional physical parameters evaluated in soil as part of the Phase II investigation are provided in **Attachment D (Table D-8).**

Attachment C tables provide the triplicate soil sample results (surface and subsurface) and their associated data qualifiers, as well as the calculated EPC for each DU, as discussed in Section 3.4. The lowest EcoSSL is presented to screen the data, as discussed in Section 4.4. In addition, the arithmetic mean, standard deviation, and relative standard deviation (RSD) were calculated for detected results for a subset of analytes that were selected for the RSLERA by DU where triplicate samples were collected (**Attachment E**). Constituents that were not analyzed in a DU are depicted as NA on the tables; constituents that were not detected in a DU are depicted as ND on the tables (**Attachment C**).

3.3.1.1 Surface Soil

Surface soil samples (0–6 in. bgs) were collected from 27 upland DUs (DU-1 through DU-7, DU-9 through DU-16, DU-20 through DU-23, DU-25, and EXDU-1 through EXDU-7) and 3 DUs encompassing Area of Concern (AOC) #16 – Area D (Former Dump Area, DU-17 through DU-19) for analysis of TAL metals, PAHs, PCBs, and/or explosives residues. Analytes detected in surface soil samples are presented in the list below:

- Up to 23 metals analytes (aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, total chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc) at each of the 15 on-site upland DUs (DU-1 through DU-7 and DU-9 through DU-16) and each of the 3 DUs in the Former Dump Area (DU-17 through DU-19)

- 18 PAH analytes (1-methylnaphthalene, 2-methylnaphthalene, acenaphthene, acenaphthylene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenz[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, naphthalene, phenanthrene, and pyrene) at each of the 13 upland DUs sampled for PAHs and each of the 3 DUs in the Former Dump Area

- 1 PCB Aroclor, Aroclor 1260, at both upland DUs sampled for PCBs (DU-23 and DU-25) and 2 PCB Aroclors detected in surface soil samples collected from the 3 DUs (Aroclor-1248 at DU-17 and DU-18, and Aroclor-1260 at each of the 3 DUs in the Former Dump Area)

- 4 explosives analytes (1,3,5-trinitrobenzene, 1,3-dinitrobenzene, 2,4,6-trinitrotoluene, and 2,4-dinitrotoluene) at 1 of 7 upland DUs sampled for explosives (EXDU-1 only)

At several DUs (DU-17 through DU-19, DU-23, DU-25, and EXDU-1 through EXDU-7), samples collected had reporting limits greater than the ecological screening level for some analytes. The analytes for which the reporting limit was higher than the ecological screening level are presented in the list below:

- 2 PCB Aroclors (Aroclor 1221 and 1242) at each of the 3 DUs in the Former Dump Area as well as both upland DUs sampled for PCBs

- 3 explosive residue analytes (1,3-dinitrobenzene, 3-nitrotoluene, and Tetryl) at each of the 3 DUs in the Former Dump Area, as well as each of the upland DUs sampled for explosive residues (EXDU-1 through EXDU-7)

Reporting limits of individual non-detect Aroclors that exceeded the ecological screening level ranged from 0.045 to 0.079 milligrams per kilogram (mg/kg), which is approximately 1 to 2 times the ecological screening level (0.041 mg/kg). Other Aroclors were detected, and total PCBs were modeled in the risk assessment with an EPC of 0.15 mg/kg. Therefore, though there is some uncertainty as to whether the concentrations of non-detect Aroclors are greater or less than the screening level, any potential risk has been captured by total PCBs in the risk assessment. The uncertainty associated with analytical data, including detection limits, is discussed in Section 6.2.

Reporting limits in samples with non-detect 1,3-dinitrobenzene that exceeded the ecological screening level ranged from 0.038 to 0.041 mg/kg, which is approximately 1.1 to 1.2 times the ecological screening level (0.034 mg/kg). Reporting limits in samples with non-detect 3-nitrotoluene ranged from 0.19 to 0.2 mg/kg, which is approximately 1.5 times the ecological screening level (0.13 mg/kg). Given the low magnitude of exceedance of the ecological screening level, non-detect concentrations of 1,3-dinitrobenzene and 3-nitrotoluene are not expected to pose risks to ecological receptors.

Reporting limits in samples with non-detect concentrations of Tetryl were approximately 0.1 mg/kg and were approximately 5.5 times the ecological screening level (0.018 mg/kg). The

ecological soil screening level is from EPA Region 4 (2018) and is based on risk to soil invertebrates. The screening level presented is derived from an equation based on equilibrium partitioning theory and water quality benchmarks predicted from EPA's Ecological Structure Activity Relationships Predictive Model. This model predicts toxicity for aquatic organisms, and the minimum chronic value was used as the screening value. Therefore, there is inherent uncertainty associated with the soil invertebrate screening level as it is based on a predicted level of toxicity. The Tetryl reporting limits fall below the other available EPA Region 4 screening levels for plants and mammals (25 mg/kg and 1.5 mg/kg, respectively). Tetryl was not detected above the reporting limit of approximately 0.1 mg/kg, which falls over an order of magnitude below plant and mammal soil screening levels (25 mg/kg and 1.5 mg/kg, respectively). Therefore risks to plant and mammal receptors from Tetryl is not expected, though the possibility for risks to soil invertebrates cannot be ruled out.

3.3.1.2 Subsurface Soil

Soil encountered across most of the upland area during the Phase I investigation was shallow, with exposed/shallow bedrock and depth to refusal ranging from 6–12 in. bgs. Deeper soil in the upland area was encountered at DU-20 and DU-21 only, with refusal at 18 and 24 in. bgs, respectively. On-site subsurface soil samples were collected from DU-20 (6–18 in. bgs) and DU-21 (6–24 in. bgs) for analysis of PAHs and BTEX. Subsurface soil was not sampled at additional upland DUs due to the shallow depth to refusal. Subsurface soil was sampled at the same 3 upland DUs in AOC #16 – Area D (Former Dump Area, DU-17 through DU-19) and analyzed for metals, PAHs, PCBs, and explosives residues. Analytes detected in subsurface soil samples are presented in the list below:

- 23 metals analytes (aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, total chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc) detected in subsurface soil samples collected from each of the 3 DUs in the Former Dump Area. Subsurface samples collected from the upland DUs (DU-20 and DU-21 only) were not analyzed for metals.

- 18 PAH analytes (1-methylnaphthalene, 2-methylnaphthalene, acenaphthene, acenaphthylene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenz[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, naphthalene, phenanthrene, and pyrene) were detected in subsurface soil samples collected from upland sites DU-20 and DU-21 and from each of the 3 DUs in the Former Dump Area.

- 2 PCB Aroclors detected in subsurface soil samples collected from the 3 DUs in the Former Dump Area (Aroclor-1260 at DU-17 and DU-19 and Aroclor-1262 at DU-18 only). Subsurface samples from the upland DUs were not collected.

- BTEX and explosives residues analytes were not detected in subsurface soil samples collected from any DU.

3.3.2 Sediment Dataset

Analytical data tables for sediment collected via ISM from the Phase II investigation are presented in **Attachment D.** These tables provide the triplicate ISM sediment sample results and their associated data qualifiers, as well as the calculated EPC for each DU, as discussed in Section 3.4. The ecological sediment screening value is presented to screen the data for identifying potential unacceptable risks, as discussed below in Section 4.4. In addition, the arithmetic mean, standard deviation, and the percent RSD of replicates was calculated for detected results for each analyte in each DU where triplicate samples were collected (**Attachment D**). The RSD was used in the calculation of the coefficient of variation (CV), which is used to measure the spread of data relative to sample size (EPA 2022a). Ultimately, the CV is determined to be low, medium, or high, which influences the selection of the 95UCL from the Student's t-test or Chebyshev calculation (see Interstate Technology and Regulatory Council [ITRC] 2020 for criteria definitions). The EPCs selected for sediment were derived from Chebyshev 95UCL following the approach outlined in ITRC Calculator (ITRC 2020; see section 3.4 below for details).

Metals samples were collected from three on-site sediment DUs established at the ends of preferential surface water migration pathways leading from AOC #16 – Area D (Former Dump Area) to the Hudson River and Iona Marsh shorelines as follows: IHRS-DU-01 along the Hudson River shoreline adjacent to AOC #16 – Area D (Former Dump Area), RRDS-DU-01 along the Iona Marsh shoreline at the outlet of the riprap drainage swale, and TWS-DU-01 along the Iona Marsh shoreline at the outlet of the tidal wetland drainage swale. Metals analytes detected in sediment from each DU are presented below:

- IHRS-DU-01: 17 metals analytes (aluminum, antimony, arsenic, barium, beryllium, cadmium, total chromium, cobalt, copper, iron, lead, manganese, nickel, silver, thallium, vanadium, and zinc)

- RRDS-DU-01 and TWS-DU-01: 18 metals analytes (aluminum, antimony, arsenic, barium, beryllium, cadmium, total chromium, cobalt, copper, iron, lead, manganese, nickel, selenium, silver, thallium, vanadium, and zinc).

In one area, Iona Island Hudson River Shoreline, non-detect sediment samples analyzed for selenium had reporting limits (0.77 mg/kg) that just exceeded the ecological screening level for selenium (0.72 mg/kg). Due to the very low magnitude of exceedance of the screening level, selenium in sediment at Iona Island Hudson River Shoreline is not expected to pose risk to ecological receptors.

3.3.3 Surface Water Dataset

Analytical data tables for dissolved surface water from grab samples collected as part of the Phase II investigation are presented in A**ttachment D**. These tables provide the results for individual samples collected as well as the calculated EPC for each area. The ecological surface water screening value is presented to screen the data for potential unacceptable risks, as discussed below in Section 4.4.

A total of 60 on-site discrete surface water samples were collected for analysis of dissolved TAL metals to evaluate the surface water migration pathways leading from AOC #16 – Area D (Former Dump Area) to the Hudson River and Iona Marsh shorelines, with 20 samples collected from each of the following areas:

- Source area at –OC #16 - Area D (Former Dump Area) (DUMP-SW-01 through DUMP-SW-20)
- Hudson River shoreline adjacent to –OC #16 - Area D (Former Dump Area) (IHRS-SW-01 through IHRS-SW-20)
- Iona marsh at the outlets of the Riprap Drainage Swale (RRDS-SW-01 through RRDS-SW-10) and Tidal Wetland Swale (TWS-SW-01 through TWS-SW-10)

Metals analytes detected in one or more surface water samples collected from each area are presented in the list below:

- AOC #16 – Area D (Former Dump Area): 18 metals analytes (aluminum, antimony, arsenic, barium, beryllium, calcium, total chromium, cobalt, copper, lead, magnesium, manganese, nickel, potassium, selenium, sodium, thallium, and zinc)
- Iona Island Hudson River Shoreline: 19 metals analytes (aluminum, antimony, arsenic, barium, calcium, total chromium, cobalt, copper, iron, lead, magnesium, manganese, nickel, potassium, selenium, silver, sodium, thallium, and zinc)
- Iona Marsh shoreline: 17 metals analytes (aluminum, antimony, arsenic, barium, beryllium [Tidal Wetland Swale only], calcium, total chromium [Tidal Wetland Swale only], cobalt, copper, magnesium, manganese, nickel, potassium, sodium, thallium [Tidal Wetland Swale only], vanadium [Riprap Drainage Swale only], and zinc [Tidal Wetland Swale only]).

At several areas (AOC #16 – Area D, Iona Island Hudson River Shoreline, Riprap Drainage Swale, Tidal Wetland Swale, Con Hook Hudson River Shoreline [CHHRS], and Con Hook Marsh Shoreline [CHMS]), non-detect samples collected had reporting limits greater than the ecological screening level for certain analytes. The analytes for which the reporting limit was higher than the ecological screening level are presented in the list below:

- Cadmium at AOC #16 – Area D, Iona Island Hudson River Shoreline, Riprap Drainage Swale, Tidal Wetland Swale, CHHRS, and CHMS
- Lead at Iona Island Hudson River Shoreline

The reporting limits for the cadmium non-detect surface water samples were 0.75 micrograms per liter (µg/L), 1.25 times the ecological screening level (0.6 µg/L). There were no detections of cadmium evaluated in the ERA. The single non-detect lead sample with a reporting in exceedance

of the ecological screening level (2.057 µg/L) was 3 µg/L, approximately 1.5 times the screening level. The maximum detection of lead was 1.0 µg/L, and all other reporting limits for lead fell below 1.0 µg/L. Sample concentrations evaluated in the ERA were lower than the reporting limits of these non-detect samples. However, given the relatively low magnitude of exceedance of the ecological screening levels, risk due to non-detected cadmium and lead in surface water is not expected.

3.4 EXPOSURE POINT CONCENTRATIONS

The datasets described above were used to calculate EPCs for each detected analyte within each media (soil, sediment, surface water). An EPC is defined as the concentration of a COPEC in site media to which a receptor may be exposed.

The use of ISM results is a more precise estimate of the average concentration within an exposure area than would be calculated by collecting multiple discrete samples. ISM data have less variance than discrete samples and provides a more comprehensive characterization of COPEC distribution and extent. Each DU provides constituent analytical results in triplicate. A 95UCL of the mean was calculated for each soil and sediment DU based upon the results of the triplicate samples, and for background samples. The 95UCL is defined as a value that, when calculated repeatedly for randomly drawn subsets of site data, equals, or exceeds the true mean 95 percent of the time. The 95UCL provides a conservative estimate of the average (or mean) concentration and a reasonable confidence that the true site average will not be underestimated. The following sections discuss the process and procedures used to calculate EPCs for each media. Results are presented in the data tables in **Attachment** C (Phase I data) **and Attachment D (**Phase II data**).** ISM calculator outputs for grouped exposure areas for soil and ProUCL outputs for surface water EPCs are provided in **Attachment E.**

Soil and sediment samples were both collected via ISM, and EPCs were calculated using the ITRC. Soil samples were collected during Phase I, and EPCs were calculated prior to the release of the ITRC Calculator updates in 2020. Sediment samples were collected during Phase II, and EPCs were calculated with the updated ITRC Calculator (2020). The 2012 ITRC Calculator defaults to the Chebyshev 95UCL, which is generally higher than the Student's t-test 95UCL. Though the Phase I data would have slightly lower 95UCLs in some cases if EPCs were rerun using the updated calculator, the project team determined that data did not need to be rerun as the conclusions of the ERA were not likely to change.

3.4.1 Soil Exposure Point Concentrations

Soil 95UCLs were calculated from the ISM data using the (2012) ITRC Calculator. Two candidate equations that can accommodate ISM datasets were used to calculate the 95UCL: the Student's t-test and Chebyshev. The Student's t-test UCL is expected to provide valid 95UCL values when the distribution of means is approximately normal. The Chebyshev UCL is generally considered to be a conservative estimate of the 95UCL because it generally achieves or exceeds the desired coverage rates, even for non-normal distribution (ITRC 2012). ITRC (2012) guidance recommends using the Chebyshev 95UCL, which is generally higher than the Student's t-test 95UCL.

Therefore, the Chebyshev UCL was selected as the 95UCL for use for Phase I soil results. The implications of this are further discussed in Section 6. The resulting 95UCLs are presented in the Phase I soil data tables in **Attachment C**. Backup information (e.g., ISM 2012 ITRC Calculator results) are presented in **Attachment E**.

3.4.2 Sediment Exposure Point Concentrations

For sediment ISM results, the updated ITRC Calculator was used to calculate the 95UCL (ITRC 2020). The updated ITRC Calculator recommends the 95UCL from either the Student's t-test or Chebyshev method based upon CV. The ITRC Calculator recommends the Student's t-test 95UCL for datasets where the CV of increments is low (defined as CV < 1.5), and the Chebyshev 95UCL for datasets where the CV is medium (defined as 1.5 < CV < 3) or high (defined as CV > 3) (ITRC 2020). The CV of increments was estimated based on summary statistics of replicates. For the Phase II sediment DUs, the 95UCL for each analyte was selected as either the Student's t-test or Chebyshev 95UCL based upon the recommendation from the ITRC Calculator. The sediment EPCs were calculated within the Excel macros following ITRC (2020) and are presented in **Attachment D**.

3.4.3 Surface Water Exposure Point Concentrations

Surface water was collected as discrete grab samples and not incremental samples. Therefore, surface water EPCs (95UCLs) were calculated using EPA's ProUCL 5.2 (EPA 2022a) software for the 20 surface water sample results in each area. Surface water EPCs are presented in **Attachment D**. Results from ProUCL are provided in **Attachment E**.

The calculated EPCs for soil, sediment, and surface water were used to evaluate potential ecological risks in the SLERA and RSLERA, Sections 4 and 5, respectively.

This page intentionally left blank

4. SCREENING-LEVEL ECOLOGICAL RISK ASSESSMENT

The SLERA represents a conservative initial assessment of potential risk and is consistent with Step 1 of EPA's 8-Step ERA Process (**Figure 1-1**) and the decision process depicted on Flowchart 1 (**Attachment A**). The following sections discuss the evaluation conducted as part of the SLERA:

- Evaluating if the constituents are related to DoD activities (Section 4.1),
- Selecting ecological risk-based screening values (Section 4.2)
- Determining the methodology for evaluating whether concentrations of constituents are similar to background or regional reference concentrations (Section 4.3)
- Comparing selected and screening values to the EPCs calculated in Section 3.4 and results of the background comparison for DoD-related COPECs (Section 4.4)

The SLERA concludes with a list of constituents that meet all criteria (DoD related, greater than background, and exceed screening values) to identify COPECs to be further evaluated in the RSLERA.

4.1 DEPARTMENT OF DEFENSE-RELATED CONSTITUENTS

The RI report, to which this appendix is attached, contains detailed descriptions of the site's history, uses, and constituents. The RI identified the following metals as preliminary contaminants of potential concern based on the prior site use: aluminum, antimony, arsenic, barium, beryllium, calcium, cadmium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc. Inorganic constituents, except for essential nutrients (calcium, magnesium, iron, potassium, and sodium) and aluminum, are assumed to be associated with DoD activities since historical constituents from on-site operations include metals (see Section 2.1.1 for brief description of prior site use).

Essential nutrients (calcium, magnesium, iron, potassium, and sodium) are necessary for metabolic processes in organisms; therefore, they are considered essential for wildlife. At naturally occurring concentrations, receptors are able to regulate uptake and metabolism of these elements. As such, they have been eliminated from further evaluation in this SLERA. The uncertainty associated with the toxicity of essential nutrients is discussed in Section 6.

In addition, only constituents considered to be Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) hazardous substances per the Code of Federal Regulations (CFR) 40 CFR §302.4 are evaluated further. This eliminates the following inorganic constituents for which there are no CERCLA Reportable Quantity limits:

- Aluminum
- Barium

- Cobalt
- Manganese
- Vanadium

The RI also included PAHs, BTEX, PCBs, and explosives residues as preliminary contaminants of potential concern. Detected concentrations of these organic constituents are reportable under CERCLA and are assumed to be associated with former DoD activities; therefore, these constituents were evaluated further.

4.2 SCREENING VALUE COMPARISONS

Conservative ecological screening values, based on no effect levels, are available from the literature and government documents (see Sections below) for each media (soil, sediment, and surface water). EPCs were compared to screening values as described below. Screening value comparisons are only applicable to analytes found to be greater than background. Methods for comparison to background levels are described in Section 4.3. A hazard quotient (HQ) is the ratio of the EPC to the screening value. HQs greater than 1.0 indicate the potential for risk, and the analyte is retained as a COPEC for further evaluation in the RSLERA. It should be noted that the higher the HQ, the greater the potential for adverse effects; likewise, the lower the HQ, the lower potential for adverse effects.

4.2.1 Ecological Soil Screening Levels

Screening values used in the SLERA to screen the soil data and select COPECs for further evaluation are presented in **Table 4-1,** which were selected as part of the UFP-QAPP (EA 2020). Values are presented for plants, soil invertebrates (i.e., earthworms), mammals, and birds. The values were compiled by EPA Region 4 (EPA 2018) from various sources including the following in order of preference:

- EPA. 2007a. Ecological Soil Screening Levels. https://www.epa.gov/risk/ecological-soil-screening-level-eco-ssl-guidance-and-documents

- Los Alamos National Laboratory. 2018. Development of Ecological Preliminary Remediation Goals for Los Alamos National Laboratory. Revision 1.1 LA-UR-18-20670. EP2018-0017 February. https://permalink.lanl.gov/object/tr?what=info:lanl-repo/eprr/ESHID-602891

- Efroymson, et al. 1997a. Toxicological Benchmarks for Screening Contaminants of Potential Concern for Effects on Terrestrial Plants: 1997 Revision. Oak Ridge National Laboratory, Oak Ridge, TN. ES/ER/TM-95/R4. https://rais.ornl.gov/documents/tm85r3.pdf

- Efroymson, et al. 1997b. Toxicological Benchmarks for Screening Contaminants of Potential Concern for Effects on Soil and Litter Invertebrates and Heterotrophic Process: 1997 Revision. Oak Ridge National Laboratory, Oak Ridge, TN. ES/ER/TM-126/R2. https://rais.ornl.gov/documents/tm126r21.pdf

- Efroymson, et al. 1997c. Preliminary Remediation Goals for Ecological Endpoints. Oak Ridge National Laboratory, Oak Ridge, TN. 50 pp. ES/ER/TM-162/R2. https://rais.ornl.gov/documents/tm162r2.pdf

- Ecological Structure-Activity Relationship Model Version 2 (EPA 2017) and the Region 4 food-web soil model (EPA 2018).

4.2.2 Ecological Sediment Screening Values

Ecological sediment screening values (ESVs) are primarily based on chronic effects to benthic invertebrates. Since there are no sediment screening benchmarks specifically for aquatic plants or demersal fish that also live close to the sediments, the ESVs are used to evaluate these endpoints as well. In general, ESVs are based on constituent concentrations associated with a low probability of unacceptable risks to ecological receptors (EPA 2018). Exceedance of ESVs may indicate the need for further evaluation of the potential ecological risks. EPCs for sediment in each DU were compared to ESVs to select sediment COPECs during the SLERA.

Table 4-2 presents the sediment ESVs, which were selected as part of the UFP-QAPP Addendum for the Phase II Investigation (EA 2022) and were selected from the following sources identified by EPA (2018):

- Long et al. 1991. The Potential for Biological Effects of Sediment-Sorbed Contaminants Tested in the National Status and Trends Program. NOAA Technical Memorandum NOS OMA 52.

- MacDonald et al. 2003. Development and Evaluation of Numerical Sediment Quality Assessment Guidelines for Florida Inland Waters. Florida Department of Environmental Protection, Tallahassee, FL. Development and Evaluation of Numerical Sediment Quality Assessment Guidelines for Florida Inland Waters.

- MacDonald, D.D. 1994. Approach to the Assessment of Sediment Quality in Florida Coastal Waters. Florida Department of Environmental Protection. 1994 Florida Sediment Quality Assessment Guidelines for Florida Coastal Waters.

- Persaud et al. 1993. Guidelines for the protection and management of aquatic sediment quality in Ontario. Ontario Ministry of the Environment. Queen's Printer of Ontario.

4.2.3 Surface Water Screening Values

The latest available National Recommended Water Quality Criteria (NRWQC), continuous criteria for chronic effects are used to select surface water COPECs. Surface water EPCs are compared to these water quality criteria. For analytes without currently available NRWQC, additional values were selected from EPA compilations. Due to a lack of compiled EPA surface water screening values for Region 2 (the State of New York's EPA region), screening values from EPA Regions 3 and 4 were compared. These values include compilations from the following:

- The Great Lakes Initiative. 2013. Clearinghouse resources Tier II criteria revised 2013 http://www2.epa.gov/gliclearinghouse/
- Suter et al. 1996. Toxicological benchmarks for screening potential contaminants of concern for effects on aquatic biota: 1996 Revision. U.S. Department of Energy, Oak Ridge, Tennessee. ES/ER/TM-96/R2. https://rais.ornl.gov/documents/tm96r2.pdf
- Canadian Council of Ministries of the Environment (CCME). 2003. Canadian Environmental Quality Guidelines: Summary Table. December 2003. Canadian Council of Ministers of the Environment, Winnipeg, Manitoba. Available at: http://www.ccme.ca/en/resources/canadian_environmental_quality

The water quality criteria used to select surface water COPECs in the SLERA were selected as part of the UFP-QAPP Addendum for the Phase II Investigation (EA 2022b), and the selected values are presented in **Table 4-3**. The hierarchy for selection of criteria was identified as follows: NRWQC (current values), Great Lakes Initiative (2013), Suter et al. (1996), and CCME (2003). Note that CCME values were not selected as values from sources higher in the selection hierarchy were available for each constituent.

Surface water quality criteria for chronic effects (CCC; continuous chronic criteria) for cadmium, chromium, lead, nickel, and zinc are dependent on the water hardness. To calculate water quality criteria for these metals, the lowest confidence limit of the hardness data at the site and the background area [71 milligrams per liter (mg/L) of calcium carbonate] were incorporated into EPA's chronic equations (EPA 2022b) with the following form:

Equation 4-1

$$CCC = e^{[mC \times \ln(hardness) + bC]} \times CF$$

Where:

CCC	= continuous chronic criteria for dissolved metal (µg/L)
mC	= metal specific chronic parameter (EPA 2022b)
hardness	= site specific hardness (71 mg/L calcium carbonate)
bC	= metal specific chronic parameter (EPA 2022b)
CF	= freshwater chronic conversion factor, CFs for cadmium and lead are hardness-dependent

The site-specific hardness value was used in the following equations:

- **Cadmium:** EXP[0.7977 x ln(71)-3.909] x [1.101672-(ln(71) x 0.041838)] = **0.6 µg/L**
- **Chromium:** EXP[0.819 x ln(71)+0.6848] x 0.86 = **56 µg/L**
- **Lead:** EXP[1.273 x ln(71)-4.705] x [1.46203-[(ln(71) x 1.45712)] = **1.73 µg/L**
- **Nickel:** EXP[0.846 x ln(71) + 0.0584] x 0.997 = **38.9 µg/L**
- **Zinc:** EXP[0.8473 x ln(71) + 0.884] x 0.986 = **88.4 µg/L**

4.3 BACKGROUND COMPARISONS

Soil and sediment samples were collected via ISM, and surface water samples were collected via discrete grab samples. The different sample types require different statistical methods for comparison to background sample concentrations to determine if site concentrations are greater than background concentrations. The methodology for the soil and sediment background comparison is presented in Section 4.3.1, the methodology for the surface water background comparison is presented in Section 4.3.2, and the results of the comparisons are presented in Section 4.3.3.

4.3.1 Soil and Sediment Background Comparison

Permutation test of means (Student's t-test with adjusted p-value) at the 95 percent confidence level was used to evaluate whether on-site soil and sediment concentrations exceeded regional background concentration ranges for naturally occurring metals and PAHs. Concentrations for constituents within each DU were compared to background samples (for metals and PAHs) using a two-sample hypothesis test with the following null and alternative hypotheses:

$$H_0: \text{Site} \leq \text{Background}$$
$$H_1: \text{Site} > \text{Background}$$

Permutation tests are a subset of nonparametric statistics. The two-sample permutation test of means evaluates the difference between two group means, and the permutation test does not require that the data from each group follow a normal distribution or that the two groups have the same variance. For this reason, the permutation test is suitable for evaluating both small datasets and non-normal data distributions. Also, this permutation test does not require that the distribution of the two data groups have the same shape in order to be a central value test. For each test, 10,000 permutation resamples were used to yield a stable p-value.

The permutation test assumes only that the data from the two are "exchangeable" when H_0 is true. For a two-sample permutation test of means, the test statistic is the observed difference in the two group means (i.e., site versus background). If the H_0 is true, the group assignment is arbitrary, as there is no difference in the means and the data in essence come from the same population. Therefore, the data are randomly rearranged regardless of group assignment to produce a different set of group means in each rearrangement. The difference in group means is computed and stored after each rearrangement, and this process is repeated for either all possible rearrangements (if possible) or several thousand permutations for larger data sets. The proportion of differences from

the rearrangements that equal or exceed the one observed difference from the original data is the permutation p-value of the test (Helsel et al. 2020).

4.3.2 Surface Water Background Comparison

A quantitative statistical approach (statistical hypothesis tests) using the two-sample hypothesis test described above was also used to compare on-site and background metals concentrations in surface water. Mean concentrations from each on-site surface water area (Iona Island Hudson River Shoreline, Riprap Drainage Swale, and Tidal Wetland Swale) were compared to mean concentrations from the applicable background depositional environment (CHHRS and CHMS). Comparisons were made between similar environments. Mean concentrations from Iona Island Hudson River Shoreline were compared to only the CHHRS since they are both subject to influence as well as erosion from the Hudson River. Mean concentrations within the Riprap Drainage Swale and Tidal Wetland Swale were compared to the CHMS since these areas are more likely depositional and less likely impacted by the Hudson River. Mean concentrations in the Former Dump Area were compared to both the CHHRS and CHMS since the area is adjacent to the Hudson River but also may be less susceptible to scour and more of a depositional environment. If the Former Dump Area concentrations were similar to either background area (as described in 4.3.3), site concentrations were determined to not be greater than background.

4.3.3 Background Comparison Results

Summary statistics and the results of the permutation test are presented in **Attachment F**. When the value shown in "Right Tailed Prob" (the p-value) is less than 0.05, the null hypothesis is rejected for the alternative hypothesis the site mean is greater than the background mean. When the p-value > 0.05 there is insufficient evidence to reject the null hypothesis for the alternative hypothesis. If the resulting value in the Conclusion column is Do Not Reject H_0, then the null hypothesis is true and site concentrations are less than or equal to background. If the result is Reject H_0, then site concentrations are greater than background.

Adjusted p-values were computed with the Benjamini-Hochberg (1995) procedure to control the false discovery rate (FDR) at $\alpha = 5\%$. The FDR is the expected proportion of incorrectly rejected hypotheses among all rejected hypotheses. FDR-controlling methods are more powerful and reject more null hypotheses than adjustments controlling the familywise error rate (FWE) such as the Bonferroni adjustment. The Benjamini-Hochberg adjustment for ordered p-values $p_1 \leq \cdots \leq p_m$ is defined as

$$\tilde{p}_i = \begin{Bmatrix} p_m & \text{for } i = m \\ min\left(\tilde{p}_{i+1,} \frac{m}{i} p_i\right) & \text{for } i = m-1, \ldots, 1 \end{Bmatrix}$$

For example, the comparison to background of arsenic in sediment **(Table F-2, Attachment F)** consists of $m = 3$ independent tests corresponding to the three DUs (IHRS, RRDS, and TWS). The Benjamini-Hochberg adjusted p-values are computed from the above equation in step-up fashion starting with the largest unadjusted p-value as shown below.

Insert 4-1. Example of Benjamini-Hochberg Adjustment to p-values

i	DU	Unadjusted p-value	Adjusted p-value
3	TWS	0.008	$\tilde{p}_{i=m} = p_m = 0.008$
2	RRDS	0.004	$\tilde{p}_{i=2} = min\left(0.008, \frac{3}{2}0.004\right) = 0.006$
1	IHRS	0.004	$\tilde{p}_{i=2} = min\left(0.006, \frac{3}{1}0.004\right) = 0.006$

Table F-1 (Attachment F) depicts the analytes in soil that have concentrations that are greater than background and include the following DoD-related constituents: LMW and HMW PAHs, antimony, arsenic, cadmium, chromium, copper, lead, mercury, silver, thallium, and zinc. **Table F-2 (Attachment F)** depicts the analytes in sediment and surface water that have concentrations that are greater than background. The following DoD-related constituents in sediment were greater than background: antimony, arsenic, cadmium, chromium, copper, lead, nickel, silver, and zinc. The following DoD-related constituents in surface water were greater than background: arsenic, chromium, copper, and zinc. If they were found to exceed ecological screening values and were associated with the DoD, these constituents were carried forward for further evaluation in the RSLERA.

4.4 SCREENING LEVEL ECOLOGICAL RISK ASSESSMENT RESULTS

The COPEC selection table for soil is provided in **Table 4-4**. The COPEC selection table for sediment is provided in **Table 4-5**; and the selection table for surface water COPECs is provided in **Table 4-6**.

Overall, the following COPECs were retained for further evaluation in soil since the most conservative ecological soil screening level was exceeded in at least one DU: antimony, arsenic, cadmium, chromium, copper, lead, mercury, nickel (subsurface only) selenium (subsurface only) thallium, zinc, HMW and LMW PAHs (surface only), total PCBs, and 1,3-dinitrobenzene (surface only). With the exception of DU-20, DU-21, and DU-25, each DU had at least one COPEC in soil.

The following COPECs were retained for further evaluation in sediment: antimony, arsenic, cadmium, chromium, copper, lead, nickel, silver, and zinc. No COPECs were identified in surface water. Identification as a COPEC indicates potential for ecological risk and the COPECs were carried through the RSLERA process for receptor-specific evaluations, as described in Section 5.

As discussed in more detail in Section 5.1, though the SLERA was evaluated on a DU basis, for the terrestrial component of the RSLERA the DUs have been grouped into the Former Dump Area (DU-17 through DU-19) and Iona Island (all other DUs) exposure areas. In some cases, the constituent identified as a COPEC for one receptor in the SLERA did not exceed ecological soil screening levels for all receptors. The RSLERA is limited to those receptors that had exceedance of the receptor-specific screening level (or lacked a screening level) in at least one DU within the

exposure area. Further details are given in the following Section 5.1. The following table presents the COPECs that will be evaluated for specific terrestrial receptors in the RSLERA.

Insert 4-2. COPECs Identified in the Screening-Level Assessment

COPECs Identified in the Screening-Level Risk Assessment	Plants	Soil Invertebrates	Mammals	Birds
Iona Island

Notes:
"✓" indicates that the analyte-receptor was carried through to the RSLERA; "-" indicates that this analyte-receptor was not carried through to the RSLERA.

5. REFINED SCREENING LEVEL ECOLOGICAL RISK ASSESSMENT METHODOLOGY

The following section discusses the methodology used for the RSLERA. The RSLERA comprises the second step of an ERA. The RSLERA further evaluates the COPECs selected during the SLERA (Section 4.4) and refines the conservative assumptions to be more site-specific and based on quantifiable effects to apical endpoints rather than no effects levels. Additional parameters and lines of evidence considered during the RSLERA include receptor area use factors (AUFs), TRVs based on both no observed adverse effect levels (NOAELs) and lowest observed adverse effect levels (LOAELs), and constituent bioavailability. Additionally, refinement screening values (RSVs), another lowest observed effects threshold value, are used for assessing risk to the benthos at this stage. AUFs are calculated based on the habitat range of a given receptor and account for the amount of time receptors are likely to be in the site area and exposed to COPECs, whereas receptors are assumed to occupy only the site area in the initial screening step. While the SLERA considers only highly conservative benchmarks based on NOAELs, LOAELs are considered less conservative and represent a more realistic assessment of the potential for adverse effects. Finally, the initial SLERA step assumes constituents are readily bioavailable, which is a highly conservative assumption. Consideration of factors impacting bioavailability including soil/sediment cation exchange capacity (CEC), percent clay, soil pH and additional physical parameters provide a more site-specific assessment of receptor constituent exposure.

The following section, 5.1., describes the methodology for the RSLERA by individual receptor group. The equations used to calculate total doses of COPECs to receptors are given in Sections 5.1.6.3 to 5.1.6.5, with details on receptor site usage given in Section 5.1.6.5. The ecological effects evaluation, including soil and physical parameters and TRVs, are discussed in Section 5.2, with calculation of hazard quotients highlighted in Section 5.3. The uncertainties inherent to the RSLERA approach are described in Section 6, and the quantitative results of the RSLERA are discussed and potential risks are characterized in Section 7. At the conclusion of the RSLERA, the risk manager and risk assessment team will decide whether the RSLERA is adequate to determine that ecological threats are negligible, or if the process should continue to a BERA (Steps 3 through 7 in **Figure 1-1**; **Flowchart 3 in Attachment A**).

5.1 ECOLOGICAL EXPOSURE EVALUATION METHODOLOGY

The ecological exposure evaluation compares EPCs to TRVs to characterize risk. TRVs are literature-based toxicity values, most often based on toxicological laboratory studies. To evaluate potential impacts to lower trophic level receptors (plants, invertebrates), the EPC is compared directly to the TRV. Potential ecological impacts to wildlife receptors (mammals and birds) are assessed by comparing calculated doses of COPECs to conservative wildlife TRVs that are derived from available toxicological data. Additional discussion and the selection of TRVs is provided in Section 5.2.3.

Though the SLERA was evaluated on a DU basis, for the terrestrial component of the RSLERA the DUs have been grouped into the Former Dump Area (DU-17 through DU-19) and the Iona Island (all other DUs) exposure areas. These two areas were grouped on the basis of the Former

Dump Area representing a potential source area for the site. The three one-acre DU's grouped as the Former Dump Area (DU's 17-19, Figure 3-3) incorporate and extend beyond the boundary of the approximately 0.85-acre AOC #16 designated previously as the Dumping Area.

Limited subsurface soil samples were collected in the Iona Island exposure area due to shallow bedrock and results of all subsurface soil samples from this exposure area fell below screening levels. Therefore, the 95UCL EPCs calculated for the Iona Island exposure area include surface soil results only from all DUs analyzed (except DU-17 through DU-19). Surface and subsurface soil samples in the Former Dump Area (DU-17 through DU-19) were collected from 0 to 6 inches and 6 to 36 inches, respectively. Ecological receptors are generally assumed to be exposed to surface soil only as that is the biologically active zone and the depth of this zone varies based on site conditions. EPA has quantified soil biological activity in forests and grasslands as a function of depth and recommends that soil samples for assessment of ecological risk include the top 25 to 30 centimeters (approximately 10 to 12 inches) (EPA 2015). The surface soil interval collected was relatively shallow (6 inches) and ecological receptors may be exposed to soil deeper than the surface soil interval in the Former Dump Area (EPA 2015). Since the subsurface sample results had exceedances of the screening levels and relatively high concentrations of COCs, as a conservative measure, the 95UCL EPCs calculated for the Former Dump Area were based on surface soil and subsurface soil from DU-17 through DU-19. The methods for calculating weighted 95UCLs for the grouped exposure areas followed the ITRC guidance (ITRC). Further details and methods are given in **Attachment E**.

5.1.1 Terrestrial Plants and Soil Invertebrates

Consistent with EPA (1997), the 95UCL EPC for each exposure area was compared to TRVs for plants and soil invertebrates. This was also done for the aquatic plant community, where sediment EPCs were compared to TRVs for plants. If the EPC concentration was greater than the TRV, there is the potential for adverse effects. TRVs for plants and soil invertebrates are discussed in Sections 5.2.3.1 and 5.2.3.2.

5.1.2 Terrestrial Wildlife

Food web modeling was used to derive dose-based exposure estimates for terrestrial wildlife (i.e., which were then compared to literature-based TRVs. Food web modelling was conducted for all terrestrial receptors which includes herbivorous, insectivorous, and predatory birds and mammals, as described above in Section 2.1.6.1. Food web models are presented in **Attachment G**. The following Sections 5.1.6.1 to 5.1.6.4. presents the methods that were used to quantify the potential exposure of wildlife to constituents via the ingestion of food and soil or sediment. The methods are based on equations presented in EPA (1993) and Sample et al. (1996). The equations and exposure parameters discussed below are consistent with EPA (1997) guidance and standard risk assessment practice. The food web modeling was conducted for constituents that were selected as COPECs for birds and mammals, based on the results of the SLERA (Section 4).

5.1.3 Aquatic Plants and Benthos

To evaluate potential risks to the benthos (i.e., demersal fish, aquatic plants, and benthic invertebrates), the 95UCL EPC for each sediment DU was compared to the sediment RSV. If the EPC was greater than the RSV, then there is the potential for adverse effects to the benthic community. The sediment RSVs are discussed in Section 5.2.3.3.

5.1.4 Aquatic Life (Fish, Zooplankton, Birds and Mammals)

Since there were no COPECs identified in surface water as part of the SLERA, risk to fish and zooplankton is not expected and no further evaluation was necessary in the RSLERA. For the herbivorous, insectivorous, and piscivorous aquatic receptors (described in Section 2.1.6.2), food web modeling was conducted as described above for terrestrial wildlife in Section 5.1.2. Models are shown in Attachment G.

5.1.5 Herptiles

As highlighted above in Sections 2.1.6.1 and 2.1.6.2, there is a lack of information such as exposure factors and ecological screening values for herptiles. Consequently, risks are assumed to be similar to other receptors evaluated and are not evaluated directly. The uncertainty associated with the use of surrogate receptors is discussed further in Section 6.4.2.

5.1.6 Exposure Parameters

Input parameters for the food web models include receptor-specific soil or sediment ingestion rates, food ingestion rates, body weights, foraging range, and fraction/proportion of diet. The primary source of this information and specific parameters is the *Wildlife Exposure Factors Handbook* (EPA 1993), with other sources shown in **Tables 5-1 and 5-2**. These tables also provide the food web modeling exposure/input parameters for each wildlife receptor that was evaluated (described in Sections 2.1.6.1 and 2.1.6.2) and were presented in the UFP-QAPP Addendum for the Phase II investigation (EA 2022).

5.1.6.1 Bioaccumulation Factors

For COPEC uptake from soil, food prey tissue (biota) concentrations were estimated using bioaccumulation factors (BAFs) that were from EPA's EcoSSL documents. These documents compile values from various literature sources (**Table 5-3**) and include BAF values for general biota items (e.g., plants, soil invertebrates, and small mammals, EPA 2007a).

For sediments and water, biota concentrations were estimated or derived from laboratory and field measurements (EPA 1999) (**Table 5-4**). For surface water, fish BCFs were derived from laboratory and field data. If field data were used for the derivation of fish BCF, the BAFs were converted to BCFs based on trophic level position (EPA 1999). BCFs for sediment-to-benthic invertebrates were derived for cadmium, chromium, copper, lead, inorganic mercury, and zinc using laboratory and field data; all other BCFs are the arithmetic average of these metals (EPA 1999). All values

were converted to mg/kg dry weight assuming a moisture content of 80 and 83.3 percent for fish and invertebrates, respectively (Holcombe et al. 1976, Pietz et al. 1984)

The following sections provide the equations used to calculate doses of COPECs to upper-trophic level wildlife receptors.

5.1.6.2 Ingestion of COPECs from Soil or Sediment

Wildlife may ingest soil or sediment while foraging or grooming. Therefore, food web models account for incidental ingestion of soil or sediment. Equation 5-1 was used to calculate the dose of COPEC wildlife would obtain from the ingestion of soil or sediment ($Dose_s$, milligrams soil or sediment per kilogram body weight per day [mg/kg bw-d]):

Equation 5-1 $$Dose_s = SI \times C_s$$

Where:

$Dose_s$ = COPEC concentration ingested per day from soil or sediment (mg/kg bw-d)
SI = Soil or sediment ingestion rate (kilograms soil or sediment per kilogram body weight per day [kg/kg bw-d])
C_s = COPEC 95UCL concentration in soil or sediment (mg/kg)

Soil or sediment ingestion values were obtained from the scientific literature for the wildlife species of concern. The primary sources for soil and sediment ingestion values were Beyer (1994) and EPA (2007a). If soil or sediment ingestion values were obtained as percent incidental ingestion, values were converted to kilograms per kilogram body weight per day (kg/kg bw-day) by multiplying the percent value by the food ingestion rate.

5.1.6.3 Ingestion of COPECs from Food

Equation 5-2 was used to calculate the dose of COPEC that wildlife could obtain from the ingestion of food items including plants, invertebrates, and mammals. The equation for ingestion of fish is shown separately in Equation 5-3. The equation for fish considers a different moisture content and is focused on uptake from surface water only.

Equation 5-2 $$Dose_{biota} = FI \times \left(C_s \times \left[\frac{BCF}{0.167}\right]\right) \times \%$$

Where:

$Dose_{biota}$ = COPEC concentration ingested per day from food (mg/kg bw-d)
FI = Food ingestion rate (kg/kg bw-d)
C_s = COPEC 95UCL concentration in soil or sediment (mg/kg)
BCF = Bioconcentration factor from sediment to biota tissue (liters per kilogram wet weight). Converted to mg/kg dw, assuming 83.3% moisture content

% = Percentage of diet

For the ingestion of fish tissue, the following equation was used:

Equation 5-3 $$Dose_{biota} = FI \times \left(C_{sw} \times \left[\frac{BCF}{0.20}\right]\right) \times \%$$

Where:

$Dose_{biota}$ = COPEC concentration ingested per day from food (mg/kg bw-d)
FI = Food ingestion rate (kg/kg bw-d)
C_{sw} = COPEC 95UCL concentration in surface water (mg/L)
BCF = Bioconcentration factor from water to fish tissue (liters per kilogram wet weight). Converted to mg/kg dw, assuming an 80% moisture content
% = Percentage of diet.

For the SLERA, EPCs were compared to conservative soil screening levels to determine COPECs requiring further assessment, assuming 100% constituent bioavailability. In the RSLERA, food web modelling and realistic assumptions of receptor diet are included. For example, within the RSLERA, American robins were assumed to consume a diet that consists of both invertebrates (97%) and plant matter (e.g., seeds, fruit) (3%) at seasonally appropriate inhabitance of Iona Island (EPA 1993).

5.1.6.4 Total COPEC Ingestion

The total dietary exposure doses ($Dose_{total}$, mg/kg bw-d) to wildlife for the evaluated COPECs were estimated using Equation 5-4. Ingestion of water was not included as a significant exposure pathway (Section 2.1.5.3), therefore total doses were the sum of COPEC amounts in soil/sediment and dietary items.

Equation 5-4 $$Dose_{total} = (Dose_{biota} + Dose_s) \times AUF$$

Where:

$Dose_{total}$ = Total amount of COPEC ingested per day from food and soil or sediment (mg/kg bw-d)
$Dose_{biota}$ = Amount of COPEC ingested per day from food (mg/kg bw-d); refer to Equations 5-2 and 5-3
$Dose_s$ = Amount of COPEC ingested per day from soil or sediment (mg/kg bw-d)
AUF = Area use factor (1 or less).

5.1.6.5 Site Usage

The area use factor (AUF) was calculated based on the habitat range for each receptor. The following terrestrial receptors have habitat ranges that are approximately 1 acre: vole, shrew, and

robin. Therefore, an AUF based on habitat range was not applied to these receptors as they could spend 100 percent of life at the site, though a temporal adjustment based on migration was applied to the robin. Alternatively, for the remaining terrestrial receptors (fox and hawk), the home ranges are large (at least as large as the exposure areas) but due to the variability in home ranges, an AUF of 1 was selected to be conservative.

Average home ranges of the short-tailed shrew are less than 1 acre (EPA 1993; Blair 1940; Buckner 1966; Jones et al. 1983), thus, it is assumed they spend 100 percent of their life within an exposure area. However, home range size varies based on habitat type sampled (Jones et al. 1983) and there are recorded instances where an individual male short-tail shrew had a larger home range (4.5 acres; Blair 1940, Jones et al. 1983) and for those individuals the exposure estimates may be high. For example, the home range of a shrew may be greater than one acre in an area inundated with tidal waters twice daily as it is in the Former Dump Area, since this habitat is not ideal for the receptor's foraging requirements.

For the robin, a migratory receptor, a temporal adjustment was made to the AUF for the time the receptor is actually in the area. Robins are assumed to be in the northern United States and New York area for approximately 8 months of the year (i.e., March through October) (EPA 1993). The AUF was adjusted to 0.67 (8/12 months) to reflect this annual temporal use.

For all the aquatic wildlife receptors with a habitat range >1 acre (mallard, scaup, otter, and heron), the AUF was adjusted by dividing the habitat range for each receptor by the size of the sediment DU (0.5 acre). The muskrat has a small habitat range (<1 acre); therefore, the AUF was not adjusted.

The total dietary intakes were then compared to TRVs to evaluate if adverse effects are possible from exposure to COPECs in food and soil or sediment. Results are presented in Section 7. The following sections described the ecological effects evaluation (Section 5.2) and the calculation of hazard quotients (Section 5.3).

5.2 ECOLOGICAL EFFECTS EVALUATION

This section discusses the physical parameters that affect the bioavailability of constituents and selects TRVs for each receptor group. In general, the toxicities of constituents are related to their bioavailability, which is influenced by various physical and chemical characteristics. Many constituents may form complexes or compounds that bind them to soil and make them chemically inaccessible to ecological receptors. Alternatively, these elements and compounds may be present in forms that are easily dissolved and absorbed, or in forms that tend to bind to biological tissues. It is these forms of easily absorbed constituents that are most toxic. Most TRVs are based on forms of constituents that are readily bioavailable.

Toxicological benchmarks are often developed based on readily bioavailable forms of metals; these benchmarks may overestimate toxicity for less bioavailable forms or underestimate toxicity for more bioavailable forms. The primary factors controlling the potential bioavailability of metals are pH, the availability/characteristics of sorption sites on soil/sediment surfaces, and the content

of organic matter, and clay minerals. Acidity increases the bioavailability of many cationic metals, such as barium, chromium, copper, lead, vanadium, and zinc, which may become more soluble at pH below 5 (EPA 1992). Increasing the soil pH increases the sorption of metals to soil particles, making the metal less bioavailable. Some metals may also form complexes with iron oxides and hydroxides; this also causes the metals to be less bioavailable and less mobile. The following sections discuss the physical characteristics and properties of soil and sediment that can impact metals bioavailability in more detail.

5.2.1 Soil Physical Parameters

Soil physical parameters collected as part of the Phase II investigation are provided in **Attachment D (Table D-8**) and means are summarized by DU in **Table 5-5**. The importance of soil physical parameters in determining constituent bioavailability and potential risk to receptors is discussed throughout Section 7. To provide a quantitative assessment of the potential reduction in bioavailable concentrations for receptors, the EPA (2020) method for classifying metal bioavailability in soil based on percent clay and pH was used. This method was based on literature review of cadmium, cobalt, copper, nickel, lead, and zinc bioavailability studies to soil organisms (EPA 2020). Within the RSLERA, the percent bioavailability of the previously identified metals are refined based on the site-specific measured soil parameters following EPA (2020).

5.2.1.1 Total Organic Carbon and Clay Content

The soils are high in organic matter, with TOC values ranging from approximately 28,000 mg/kg at DU-4 to 230,000 mg/kg in DU-18. The soils primarily consist of sands and silts. Clay content ranges from 1.5 percent at DU-17 to 9.12 percent in DU-7. Comparing the Former Dump Area (DU-17 through DU-19) and Iona Island (all other DUs), TOC ranged from 33,000 – 233,333 mg/kg and 28,667 – 43,667 mg/kg at the Dump Area and Iona Island, respectively. Clay content was higher in Iona Island compared to the Dump Area, with ranges of 1.98 – 9.12 percent and 1.5 – 1.97 percent, respectively. Concentrations of metals can be evaluated as a function of effective clay fraction. Higher inorganic constituent concentrations are allowable for soils with higher effective clay fraction due to the adsorptive nature of clay and very small particles because of their large surface area, reactive surfaces, and edges. This higher binding capacity reduces the bioavailability of metals as they are bound tightly to clays. Clay and organic matter particles have a net negative charge, which attracts and binds cations (i.e., metals).

5.2.1.2 Soil Cation Exchange Capacity

A measure of the ability of soil to bind cations is referred to as CEC. If the CEC value is low, few cations are able to bind to the soil particles; if the CEC value is high, a larger number of cations can bind to the soil. The CEC of a soil is expressed in centimol positive charge per kilogram of soil ($cmol_c/kg$) or milli-equivalents per 100 grams of soil (meq/100g), and the expressions are numerically equivalent. Sandy soils low in organic matter have a very low CEC (i.e., less than 3 meq/100g) while heavier clay soils or soils high in organic matter generally have a much higher CEC (i.e., greater than 20 meq/100g) (Cornell University 2007). CEC values across all DUs ranged

from 24 – 53 meq/100g, with a range of 24 – 36 and 33 – 53 meq/100g in the Iona Island and Former Dump Area, respectively. Overall, the high CEC across the site indicates a high organic matter content and a high number of cations for binding to metals. The high organic matter content will restrict mobilization of metals and, therefore, the soils will tend to accumulate metals. Since the metals will be sorbed tightly to soil particles they will be less bioavailable for uptake into plants and soil invertebrates.

5.2.2 Sediment Physical Parameters

In sediments, sulfides, grain size, and TOC content play significant roles in the bioavailability and, ultimately, toxicity of metals. Sediment physical parameters collected during the Phase II investigation are provided in **Attachment D (Tables D-9 and D-10)**. Three replicate sediment samples from each area (Iona Island Hudson River Shoreline, drainage swale, and tidal wetland swale) were analyzed for each sediment parameter. A summary of average physical parameters in each sediment DU is provided in **Table 5-6**. The implications of the sediment physical parameters for potential risk to receptors is discussed throughout Section 7.

5.2.2.1 Grain Size and TOC

The sediments along the Iona Island Hudson River Shoreline differ from the swales located on the marsh side of the island. Along the river, the sediments have low organic content, with TOC of around 3,000 mg/kg. The sediments are primarily coarse and medium sands with an absence of silt and around 6 percent clay. However, along the marsh side of the island, the organic carbon content is much higher with TOC values ranging from 62,000 to 78,000 mg/kg. Sediments on this side of the island contain much higher clays (around 30 percent) and silts (around 50 percent) and minimal coarse sands (1 percent). Observations during the reconnaissance confirmed the differences in sediments on either side of the island. The marsh shoreline areas consisted of soft, mucky, marsh sediments; whereas the river side of the island was sandier and had much less organic matter.

5.2.2.2 Sediment Cation Exchange Capacity

Sediments typically have higher CEC than soil due to the high organic matter and water content. Sediment CEC values ranged from 30 to 91 meq/100g in DUs 17, 18, and 19, which contain the frequently flooded Former Dump Area (**Figure 3-1**).

5.2.2.3 Acid Volatile Sulfides/Simultaneously Extracted Metals

Sediments with similar concentrations of metals may have different toxic effects, depending on the amount of organic carbon and/or sulfide available to bind and render the metals non-bioavailable. The AVS/SEM approach developed by EPA (2005f) accounts for differences in sulfide and refines predictions of heavy metal toxicity in sediments. AVS/SEM predicts toxicity in sediments containing the following divalent metals: copper, cadmium, nickel, lead, and zinc.

In the laboratory, sulfide is volatilized from sediments by the addition of acid, and SEM are the metals extracted during the AVS procedure. One mole of SEM will react with one mole of AVS in sediments. The reaction forms an insoluble metal sulfide that is not available for uptake by benthic organisms. Therefore, the amount of AVS present in sediments serves a critical role in setting limits to metal availability and toxicity. The AVS/SEM method gives a better indication of sediment toxicity to benthic organisms than measurements of "total" metals by measuring only the "bioavailable" fraction of metals present. The difference between the sum of the molar concentrations of SEM minus the molar concentration of AVS, normalized to the fraction of organic carbon (f_{oc}) predicts which sediments are toxic. The equation is $(\sum SEM\text{-}AVS)/f_{oc}$ and the toxicity thresholds are as follows (EPA 2005f):

- If $(\sum SEM\text{-}AVS)/f_{oc}$ <130 micromoles per gram organic carbon ($\mu mol/g_{oc}$), metals are unlikely to be bioavailable/toxic.
- If 130 $\mu mol/g_{oc} < (\sum SEM\text{-}AVS)/f_{oc} < 3000\ \mu mol/g_{oc}$, metals may be bioavailable/toxic.
- If $(\sum SEM\text{-}AVS)/f_{oc} > 3000\ \mu mol/g_{oc}$, metals are likely to be bioavailable/toxic.

The field collection of sediments for AVS/SEM analysis requires limiting the sediment's exposure to oxygen, which can reduce the level of sulfides in the sample. Therefore, a discrete sediment sample (i.e., not homogenized, not ISM) is required. Three discrete samples were collected from each sediment exposure area, for a total of nine AVS/SEM samples. Results of AVS/SEM analyses at the three DUs are provided in **Table 5-7**.

Results from the marsh side of Iona Island (Riprap Drainage Swale and Tidal Wetland Swale) are less than 130 $\mu mol/g_{oc}$, which indicates that the metals in sediment are unlikely to be bioavailable; therefore, they are unlikely to cause toxicity to sediment-dwelling organisms. Results from Iona Island Hudson River Shoreline are much higher, with values over 25,000 $\mu mol/g_{oc}$, which indicates that the metals are likely to be bioavailable and cause toxicity.

5.2.3 Toxicity Reference Values and Refinement Screening Values

The RSLERA allows for more site-specific and less conservative evaluations of potential risk compared to the SLERA. The SLERA focused on comparison of constituents to highly conservative ecological soil screening levels that were not receptor-specific. The refinements at the RSLERA stage involve consideration of receptor-specific NOAELs and LOAELs for mammals and birds, RSVs for benthos, and benchmarks associated with a 20 percent effect for plants and soil invertebrates. This section describes the TRVs used in the RSLERA including both no-level effects thresholds and low-level effects thresholds, as discussed in the following sections. TRVs for plants and soil invertebrates are provided in **Table 5-8**. TRVs for benthos are based on the RSVs and are provided in **Table 4-2**. TRVs for mammals are provided in **Table 5-9**, and TRVs for birds are provided in **Table 5-10**.

5.2.3.1 Plants

To assess the potential for COPECs to adversely affect the plant community, EPCs were compared to concentration-based TRVs protective of plants (**Table 5-8**). Resources used included EcoSSLs that are protective of plants (EPA 2005a-e, 2006, 2007a-g, 2008) and Efroymson et al. (1997a) who established values associated with a 20 percent reduction in growth, reproduction, or other measured toxicological endpoints.

5.2.3.2 Soil Invertebrates

Similar to plant TRVs, to assess the potential for COPECs to adversely affect the soil invertebrate community, EPCs were compared to concentration-based TRVs protective of soil invertebrates (**Table 5-8**). Resources used included EcoSSLs protective of earthworms (EPA 2005a-e, 2006, 2007a-g, 2008) and Efroymson et al. (1997b). TRVs from studies listed in Efroymson et al. (1997b) were established at a level associated with a 20 percent mortality or other measured toxicological endpoints for earthworms.

5.2.3.3 Benthos

The RSV represents a probable effects level, above which adverse effects are expected to occur and are appropriate for use in the RSLERA (EPA 2018). To evaluate the potential for COPECs to adversely affect the benthos, which includes benthic invertebrates as well as benthic-feeding fish and rooted plants, EPCs were compared to RSVs for freshwater sediments (**Table 4-2**), as compiled by EPA Region 4 (2018) from the sources identified in Section 4.2.2. These values are less conservative than the ESVs and are appropriate for use in the RSLERA.

5.2.3.4 Wildlife Toxicity Reference Values

COPECs identified as having the potential to adversely affect wildlife species (based on comparison to the avian and/or mammalian EcoSSLs in the SLERA) were further evaluated using dose-based TRVs in the RSLERA. Two types of TRVs were used, each corresponding to a different level of potential ecological impacts for mammals and birds (**Tables 5-9 and 5-10**). No observed adverse effect levels (NOAELs) are doses that have been shown to cause no adverse impacts in test species. NOAELs were obtained from studies compiled for EPA's EcoSSLs (EPA 2005a-e, 2006, 2007a-g, 2008) and Oak Ridge National Laboratory (Sample et al. 1996). The Oak Ridge National Laboratory NOAELs were derived based on measurements of survival, growth, or reproduction in the laboratory. Values from EPA's EcoSSLs were derived through statistical analyses of results from multiple toxicological studies with multiple endpoints. NOAELs are conservative and considered protective which are appropriate for use in bounding the potential risk conclusions. Since NOAELs are associated with no observed effects in a test study, it is uncertain if the values are close to or far below the threshold value at which effects would first be observed.

Lowest observed adverse effects levels (LOAELs) are the lowest concentrations at which a significant adverse effect has been observed at an exposure concentration in comparison to a control. For risk assessments seeking to protect populations of organisms, LOAELs correspond to

an adverse effect in survival, growth, or reproduction. LOAELs are useful because there is considerable uncertainty associated with NOAELs. LOAELs serve to bound the range of NOAELs, and the threshold of toxic effects is considered to lie somewhere between the NOAEL and the LOAEL.
In some cases, LOAELs were available from EPA's EcoSSLs documents or by Oak Ridge National Laboratory studies (Sample et al. 1996). The corresponding LOAEL was used from the EPA EcoSSL document when available. When there was no corresponding LOAEL value, the geometric mean of the LOAELs for growth and reproduction was calculated; this approach is similar to that used to derive the EcoSSL NOAEL value. In the absence of LOAEL data for a specific receptor/COPEC, it was assumed that the LOAEL is 10 times the value of the NOAEL. Therefore, LOAELs are considered less conservative than NOAELs and present more realistic potential for adverse effects to an individual and potentially a population. LOAEL exceedances are the primary focus in the RSLERA.

In general, COPECs are evaluated on an individual basis. However, combined effects were evaluated for PAHs and PCBs. Since Aroclor PCBs are mixtures of individual PCB congeners, toxicity from PCBs is evaluated based on a mixture of total PCBs.

5.3 HAZARD QUOTIENTS

Quantitative risk was estimated using the exposure estimates and the toxicity values (EcoSSLs or TRVs). The HQ approach was used to estimate risk by comparing EcoSSLs, TRVs, or RSVs to EPCs. If the HQ was greater than 1, there was the potential for adverse effects and subsequently lines of evidence including bioavailability and magnitude of exceedance are used for further evaluation. EcoSSLs are equivalent to a documented and/or best conservatively estimated chronic NOAEL. However, since the RSLERA focuses on evaluating risk to populations of organisms and not individuals with the exception of protected species, the LOAEL is a more appropriate benchmark used for comparison, and risks were characterized based on LOAEL-based results. Therefore, both a conservative evaluation against the NOAEL, or no effect levels, and an evaluation against the lowest effect levels, or LOAEL, was conducted as provided in Equation 5-4 (EPA 1997).

Equation 5-4

$$HQ = \frac{Dose}{TRV_{NOAEL\ or\ LOAEL}}\ or\ HQ = \frac{EPC}{RSL}$$

Where:

HQ	= Hazard quotient (unitless)
Dose	= Estimated COPEC intake (mg/kg bw-d)
EPC	= Exposure point concentration (mg/kg)
$TRV_{NOAEL\ or\ LOAEL}$	= Toxicity reference value NOAEL or LOAEL-based (mg/kg bw-d)
RSL	= Refined screening level (mg/kg).

It should be noted that an HQ is not a statistical value or a defined measurement of risk. For example, an HQ of 0.01 does not indicate a 1 in 100 probability of adverse effects occurring. Rather, it indicates that the exposure-related dose is one hundred times less than the TRV for the constituent. In addition, the HQ does not infer a linear relationship (i.e., the hazards posed by exposure to the constituent do not increase linearly as the HQ increases) (USACE 2010).
Sometimes risks are evaluated using a hazard index (HI) approach, which sums individual HQs for similar constituent groups. Metals are not typically evaluated based on HIs, an approach that is consistent with EPA framework for metals (EPA 2007b). The calculation of HIs is primarily completed for constituent groups that exhibit a well-defined toxic action (e.g., organochlorine pesticides, Aroclors) and tend to occur as mixtures (PAHs). Most metals express multi-organ toxicity as opposed to well-defined mechanisms of toxicity such as organochlorine pesticides. Bioavailability can vary widely due to environmental factors including organometallic transformations. Toxicological responses to a given metal may vary among species due to differences in toxicokinetics (absorption, distribution, elimination) and toxicodynamics (relative potency). In addition, most TRVs are based on laboratory studies using metal salts as opposed to the species/complexes that are typically found in nature. USACE (2010) risk assessment guidance cautions on the use of HIs, which should only be calculated for constituents with the same toxic effect mechanisms (e.g., PAHs). As such, only HQs were calculated and used to evaluate potential risk in this RSLERA at the Iona Island FUDS." (Section 5.3).

The following Section, Section 6, provides the uncertainty analysis associated with environmental sampling, analytical data, exposure and toxicity estimates, and assessment of risks. The results and conclusions of the RSLERA are outlined in Sections 7 and 8, respectively.

6. UNCERTAINTY ASSESSMENT

It is important to document sources of uncertainty associated with the risk assessment process. This is because many conservative assumptions are built into the evaluation, from determining the appropriate EPC to uncertainty factors used to derive TRVs. Uncertainties have the potential to either underestimate or overestimate actual risk to receptors. The main areas of uncertainty associated with the ERA include:

- Environmental sampling
- Analytical data
- Estimated exposure and toxicity data
- Characterization of risk

This section provides a general discussion of the uncertainty associated with the risk assessment process and individual lines of evidence. The interpretation of the overall degree of uncertainty is the culmination of all lines of evidence which is discussed along with the findings in Section 7.

6.1 ENVIRONMENTAL SAMPLING

Of the potential uncertainties associated with environmental sampling, the sample design is likely to have the greatest impact on the evaluation of risks to ecological resources. The sample design was developed based on the available historical information regarding the activities that occurred at the site. Focusing the study design to provide analyses for certain constituents specific to suspected source areas is a valid and accepted means of maintaining a practical and efficient limit on the field effort. However, there is always a possibility that the study design could miss samples where constituents are present or miss other types of constituents in a specific sample. The ISM sampling design was used in efforts to prevent missing quantifiable constituents. However, only 1-acre grids were sampled across the site in areas of suspected historical activities. A total of 26 individual 1-acre DUs were targeted for soil sampling with the boundary of the site comprising approximately 125 acres of land and inland water. A total of 90 and 16 surface and subsurface ISM soil samples were collected respectively across all grids. Therefore, the areas where no grids were sampled present an uncertainty in that, over time, as the soils have been reworked and spread across the site, these areas were not sampled and may contain DoD-related constituents. The sampling areas were focused on previously identified areas of concern at the site, therefore ensuring the study design captured the most contaminated areas. Furthermore, the ISM sampling design has been shown to yield more reliable and reproducible results and better predict the average concentration across an area than discrete samples.

In an effort to address the uncertainties discussed above, and in accordance with the conservative nature of SLERAs, the 1-acre and smaller DUs established in areas of most likely to contain the highest levels of contamination, but each DU was sampled randomly. For example, the food web models assume that mammals and birds with small foraging ranges obtain all their food from within one DU, clearly a highly conservative assumption. With the exception of fixed or limited mobility receptors (e.g., plants), ecological receptors are unlikely to utilize only those areas of

highest contamination and are more likely to forage over a larger area that includes areas of contamination as well as less contaminated areas.

6.2 ANALYTICAL DATA

Additional uncertainties are associated with the analytical data used within the RSLERA, including the selection of EPCs, constituent detection limits, and data quality. These uncertainties are discussed within this section.

6.2.1 Exposure Point Concentrations

The 95UCL was used as an upper estimate of mean exposures. In almost all cases, both the Student's t-test and Chebyshev 95UCLs calculated from the triplicate ISM soil samples produced results that were higher than any of the each replicate concentrations. Due to the distribution of the data, variability in the results, and the apparent heterogeneity of site soil, the Chebyshev value was recommended over the Student's t-test value, which was generally a lower number. However, both values are typically higher than the replicate sample results, are conservative, and may overestimate risks. For sediment, an updated version of the ITRC Calculator was used to identify the appropriate 95UCL. Therefore, the conservatism was reduced in the calculation of EPCs for sediment. Given that the 95UCL still represents a conservative exposure estimate, no bias is expected as a result of using the updated calculator for sediment EPCs.

6.2.2 Detection Limits

There are some cases where a constituent is not detected at the LOD or LOQ, but the LOD or LOQ exceeds a screening value. In such cases, other lines of evidence including the magnitude of the HQ exceedance, properties of the constituent and its bioavailability, and other mitigating factors will be considered to identify potential risk. For instance, in soil, the LODs of non-detect results for Aroclor-1221, Aroclor-1242, 3-nitrotoluene, 1,3-dinitrobenzene, and Tetryl are greater than their respective ecological screening levels. Concentrations of Aroclor-1221 and Aroclor-1242 exceeded their screening values at DU-23 and DU-25. Several explosive compounds had concentrations that exceeded ecological screening levels in the DUs evaluated only for explosives. Based on the low detections of these compounds and their volatile nature, they are not anticipated to be present at concentrations that would cause adverse impacts to ecological receptors. However, there is some uncertainty with risks from these constituents as they cannot be quantified.

6.2.3 Data Quality

As discussed in Section 3.2, approximately 20 percent of the soil sample results were J-flagged for minor laboratory interferences including matrix interference, trace contamination in blank samples, and/or exceeding holding times. J qualifiers indicate estimated values. In some cases, the J qualifier is biased low, indicating the reported result may be lower than the actual concentration. In these cases, risks may be underestimated. In the cases where the J qualifier is biased high, then the potential risks associated with these data may be overestimated because the reported result is

potentially higher than the actual concentration. This occurs for several metals and PAHs in DUs 9, 11, 14, 19, and 20 and will be elaborated on in the risk characterization in Section 7.

Many of the soil background samples, particularly for PAHs, were J- flagged due to holding time exceedances. Per the UFP-QAPP (EA 2020), holding times for PAHs are 14 days until extraction. The long processing time for the ISM samples prevented their timely extraction, and the samples were not extracted until 25 or 26 days after receipt, which could bias values low for these constituents. For other constituent groups including metals and PCBs, maximum holding times were 180 – 365 days per the UFP-QAPP (EA 2020); thus, these groups were not impacted. While this adds some uncertainty to the background data, background samples that are biased low provide a more conservative evaluation than ones biased high.

6.3 ESTIMATES OF EXPOSURE AND TOXICITY

Additional uncertainty is associated with exposure assumptions and the toxicity benchmarks used to evaluate risk. These parameters are discussed in more detail in Sections 6.3.1 and 6.3.2.

6.3.1 Exposure Assumptions

A major source of uncertainty is associated with the estimation of each receptor's exposure to COPECs. Generally, food web models used to estimate exposure from soil/sediment and biota are created to represent a worst-case scenario of possible risks to the receptor groups; and thus, conservative assumptions are incorporated into the models. The models assume that receptors are exposed to the 95UCL concentrations of constituents in environmental media consistently on a daily basis. It is expected that such a conservative scenario would overestimate risk for highly mobile receptors.

Furthermore, the exposure parameters used in the food web models are not site-specific. Since site-specific habitat characteristics (e.g., availability, distribution, and quality of food) influence feeding strategies and, therefore, exposure parameters, there is uncertainty associated with using non-site-specific exposure parameters. Non-site-specific modeled uptake/bioaccumulation factors were utilized to estimate dietary tissue uptake, which introduces a high degree of uncertainty.

In addition, soil/sediment ingestion rates are literature-based (e.g., EPA 2007a, Beyer et al., 1994) and are not available for all species. For example, soil ingestion rates for the American robin were not available; thus, the value for American woodcock was used (Table 5-1). Dose estimates for wildlife are significantly affected by soil/sediment ingestion rates, which can over- or underestimate risk estimates depending on the accuracy of the soil/sediment ingestion rate.

6.3.2 Toxicity Reference Values

The assessment of risks was primarily based on the comparison of estimated doses to TRVs from the literature. There are many uncertainties associated with these evaluation tools and the assessment of risks based upon them. The quality of the TRV can influence the estimate of potential risk. With metals, TRVs are typically generated using the most bioavailable/toxic form

of the metal. Whereas the form of metal that is most likely present on-site would be a much less toxic, inert, or complexed form. The TRVs selected for this ERA are those most often recommended by EPA and allow for a conservative estimate of potential risk.

LOAEL TRVs are not always available and may be estimated from the NOAEL using an uncertainty factor. When insufficient studies are available, uncertainty factors are applied to NOAEL TRVs to estimate a LOAEL TRV. As such, these TRVs are highly uncertain. In addition, there is a paucity of toxicological data in the literature for soil invertebrates and plants, and TRVs (i.e., EcoSSLs) are generally developed to be extremely conservative for these receptors. Sporadic elevations of concentrations of metals in soil would not necessarily be toxic to communities or populations of plants and soil invertebrates, which is how these groups of receptors are typically evaluated. Many plants are tolerant of high concentrations of metals and will accumulate significant concentrations without demonstrating any adverse effects. Some metals, such as copper, are nutrients for plants.

Due to the lack of adequate toxicity studies, there are no EcoSSLs for chromium for soil invertebrates or plants. More current toxicological literature associated with chromium and zinc could not be found. There are also no EcoSSL values for mercury. Efroymson et al. (1997a) cautions that their plant "benchmarks are to serve primarily for contaminant screening" In addition, availability of constituents for uptake by earthworms is controlled by soil characteristics such as grain size, pH, organic carbon content, and moisture content (Efroymson et al. 1997b).

USACE's Risk Assessment Handbook (USACE 2010) cautions on the use of EcoSSLs for cleanup levels:

> *The USEPA EcoSSLs provide screening values for soil invertebrates and plants. It is emphasized that the EcoSSLs are soil screening numbers, and as such are not appropriate for use as cleanup levels. Screening ecotoxicity values are derived to avoid underestimating risk. Requiring a cleanup based solely on EcoSSL values would not be technically defensible.*

RSVs used to evaluate the benthos (benthic invertebrates, aquatic plants, and demersal fish) are primarily based on statistical evaluations of toxicological data for a few benthic invertebrate species. The values are based on bulk sediment toxicity tests from contaminated sediments throughout different areas of the United States. These bulk sediments were often from heavily industrialized areas and contained multiple constituents including both metals and organic compounds (e.g., PCBs, pesticides, PAHs). While the RSVs may be appropriate for the benthic invertebrate community, they are not truly reflective of toxicity values for aquatic plants or demersal fish. However, since there are no screening values for these species, available sediment benchmarks for benthic invertebrates are used as surrogates.

6.4 ASSESSMENT OF RISKS

6.4.1 Individual- vs. Population-Level Effects

Another uncertainty results from the extrapolation of assumptions about the potential for adverse effects from individual organisms to populations. The intent of ERAs, as set forth in the assessment endpoints, is to ultimately evaluate risks to populations. Few methods are available to extrapolate the potential for adverse effects from the individual level to the population level. This would include individual based population models that would incorporate demographic and density information on a selected population(s) at the study site. Following, stochasticity of model parameters (such as life history traits and exposure concentrations), population-level impacts may be evaluated in the context of risk assessment. Forbes et al. (2008) provides a critical review on incorporating population models into ERAs.

Without site-specific demographic data on targeted populations, the standard practice is to generally assume that if there is no potential for direct adverse effects to individual organisms then it is also unlikely for there to be the potential for direct adverse effects to populations. Similarly, it is assumed that if there is the potential for adverse effects to individual organisms there is also the potential for adverse effects to populations. However, it is conservative to assume that potential damage at the individual level will impact the populations in the surrounding ecosystem. See Sections 7.4 and 7.5 for context using site-specific parameters.

6.4.2 Surrogate Receptor

Protected species that may be present at the site were identified in Section 2.1.4.1. With the exception of the osprey, which was observed during the Shoreline Reconnaissance Survey in April 2020 (Section 2.1.4.2), the actual presence of these protected species on-site is an uncertainty. Surrogate receptors for which complete exposure information was available were selected to estimate exposure parameters for the listed species (Section 2.1.6). Efforts were made to select surrogate receptors with similar biology and life histories, with a focus on the life history aspects that would most influence exposure parameters, such as diet and foraging strategies. However, there is significant uncertainty inherent in the use of surrogate receptor species to estimate risk to represented species. Firstly, every species is unique, and special status species often have unique features of their life histories that have made them vulnerable to population declines which would not be reflected in the exposure parameters of the selected surrogate species. Also, it is not possible to select a "perfect" surrogate receptor for which exposure parameters are available. For instance, the size of the surrogate and protected species may vary even though diet and foraging strategies are similar. For example, the American robin was chosen as the surrogate receptor for the cerulean warbler, which is roughly half the size of a robin. This could lead to underestimates of risk to the protected species. Ultimately, in the absence of suitable research studies to determine species-specific exposure factors for each special status species, the uncertainty associated with the use of surrogate receptors cannot be eliminated.

There is also uncertainty regarding the assessment and characterization of risks to herptiles. With the exception of bioassays, there is a lack of adequate methods for assessing risks to amphibians

and reptiles. Consequently, these receptors were not evaluated quantitatively in the risk assessment. The greatest uncertainty with respect to the characterization of risks to amphibians and reptiles is the lack of receptor-specific chemical benchmarks, uptake data, and bioconcentration rates. Approved TRVs and other comparative values to measure adverse effects to amphibians and reptiles from chemicals in soil have not yet been developed from literature. Available toxicity literature and databases provide some usable information, though they are still under development and are not yet comprehensive or consistent enough to allow development of reliable TRVs. Thus, uncertainties associated with toxic effects of constituents at particular concentrations on adults, juveniles, larvae, or eggs, or the specific effects of chemical exposure on development, reproductive capacity, or survival remain unresolved. It has been demonstrated that for reptile exposure specifically to lead, growth effects were seen at similar exposure doses to the lead EcoSSL TRV for avian ground insectivores (Salice et al. 2009), indicating the risk would occur at similar thresholds for birds and reptiles. Therefore, risks from lead to other receptors, especially birds, may be used to indicate risk to reptiles and amphibians.

6.4.3 Hazard Quotient Approach

There are several limitations associated with the use of HQs to determine the potential for risk to ecological receptors. While the HQ is a standard tool in ERAs set forth in EPA guidance (EPA 1997), an article in the scientific literature points out a number of limitations to the use of this method (Tannenbaum et al. 2003). The use of the HQ identifies a potential for risk as opposed to an actual risk, because the HQ result is not a probability. The HQ identifies whether a dose or concentration exceeds a benchmark, and by how much; and therefore, it is not a linear or scalable metric. Also, the HQ cannot be used to quantitatively extrapolate between individual and population level effects. HQs based on NOAELs for the most sensitive species are often exceeded by concentrations that occur naturally in the environment. These limitations should be considered before using HQ-based estimates of the potential for risk to draw conclusions or make decisions based on assessment results.

6.5 SUMMARY

This section aimed to provide a generic discussion of the uncertainty associated with the risk assessment process, including sampling designs, analytical data, and parameters used for exposure and toxicity calculations. These uncertainties, along with other site-specific details, are incorporated into the following results section (Section 7) to characterize risks to receptors.

7. REFINED SCREENING-LEVEL ECOLOGICAL RISK ASSESSMENT RESULTS AND RISK CHARACTERIZATION

The quantitative results of the RSLERA and additional characterization that interprets the potential risk for each receptor group are provided in the sections below. Consistent with ERA guidance (EPA 1997), results of the RSLERA are designed to estimate an upper-bound potential for adverse effects to the selected representative receptor species. Therefore, exceedance of a TRV indicates the potential for adverse effects; however, it does not indicate that an adverse effect is occurring from the COPEC (Tannenbaum et al. 2003). It does, however, indicate that additional evaluation may be necessary.

In risk characterization, a qualitative weight of evidence approach is applied to understanding any HQs that are >1. Site-specific environmental data and life history traits of the potential ecological receptors at the site are used to understand risks that were identified (HQ >1) in the RSLERA. Those may include factors that influence bioavailability of the COPECs, expected habitat use of receptors, and other potential uncertainties such as limitations in available data (as identified in Section 6).

The text below characterizes risks for each assessment endpoint. For assessment endpoints with inconclusive findings, further evaluation was conducted using weights of evidence. The weight of evidence approach is the process by which measurement endpoints are related to an assessment endpoint to evaluate whether a significant risk of harm is posed to the environment. Results are presented by exposure area. Terrestrial exposure areas include the Former Dump Area and Iona Island. Aquatic exposure areas include Iona Island Hudson River Shoreline, Riprap Drainage Swale, and Tidal Wetland Swale.

7.1 AE1: TERRESTRIAL PLANT COMMUNITY

When the 95UCL EPCs for surface soil (Iona Island) and surface and subsurface soil (Former Dump Area) were compared to EcoSSLs (i.e., TRVs) for plants (**Table 7-1**), the following COPECs had HQs greater than 1:

Insert 7-1. Risk Characterization for Terrestrial Plants.

Receptor	Exposure Area	COPEC	HQ	Bioavailability Adjusted HQ	Risk Characterization Conclusions
Terrestrial Plants	Iona Island	Lead	3	1	No risk due to adjusted HQ≤1
		Thallium	3	-	No risk due to qualitative bioavailability assessment
		HMW PAHs	2	-	No risk due to qualitative bioavailability assessment
	Former Dump Area	Chromium	82	-	Potential for risk
		Copper	22	9	Potential for risk
		Lead	15	6	Potential for risk
		Mercury	6	-	Potential for risk
		Selenium	2	-	No risk due to low magnitude of exceedance
		Thallium	6	-	No risk due to low effect level HQ<1
		Zinc	21	9	Potential for risk

- Not calculated; bioavailability adjustment method was not developed for these analytes (EPA 2020).

In the Iona Island exposure area, though there are concentrations of metals in exceedance of plant TRVs (i.e., arsenic, chromium, copper, lead, mercury, selenium, thallium, and zinc) in individual DUs, the HQs for the combined 95UCL EPC are all 3 or less. Using the EPA's soil bioavailability classification procedure, Iona Island and the Former Dump Area soil can be classified as 'Medium-Low' metal bioavailability, based on pH levels > 6.5 in all soils and percent clay < 26 percent (EPA 2020). The corresponding percent bioavailability is 41 percent, which decreases the lead HQ to 1 for the Iona Island area. The soil bioavailability classification was not developed for thallium and HMW PAHs (Huang et al. 2018; Wick et al. 2020), which also showed exceedances at Iona Island; however, the high CEC values and organic carbon content are likely to reduce bioavailability of these compounds. Thus site-wide concentrations of COPECs are not expected to pose risk to terrestrial plants.

In the Former Dump Area, the HQ for the combined 95UCL EPC for selenium is 2. Due to the low magnitude of exceedance of the EcoSSL, site-wide concentrations of selenium in the Former Dump Area soil are not expected to pose risk to terrestrial plants. The HQs for the remaining COPECs range from 6 to 82, indicating risk may be more likely. To evaluate the potential magnitude of risk, a weight of evidence evaluation was conducted that incorporates multiple lines of evidence into the determination of risk.

Adjusting for an assumed 41 percent bioavailability of copper, lead, and zinc (EPA 2020), HQs remain above 1 for terrestrial plants in the Former Dump Area; thus, potential risk to terrestrial plants from these compounds at the Former Dump Area is anticipated. Though the soil bioavailability method was not developed based on literature for mercury, chromium, or thallium, pH and percent clay are major factors driving bioavailability of these compounds (Hussain et al. 2022; Huang et al. 2018; Wick et al. 2020; Reijonen and Hartikainen 2016; Sewart et al. 2003). Consequently, assuming a similar percent bioavailability for these compounds (i.e., 41 percent), HQs would still be above 1 for all compounds, indicating risk from chromium, mercury, and thallium to terrestrial plants at the Former Dump Area.

Importantly, significant uncertainty exists regarding the TRV used for thallium of 0.05 mg/kg. The TRV is lower than the mean background concentration of thallium measured in this assessment of 0.13 mg/kg (Table 4-4). When using the corresponding low effect level for thallium of 0.5 mg/kg (Los Alamos National Laboratory 2018), the HQ falls below 1. Consequently, risk to populations of terrestrial plants from thallium at the Former Dump Area is unlikely; however, risk from chromium, copper, lead, mercury, and zinc is potentially present.

As discussed in Section 2.1.6.1, the small whorled pogonia, which is federally listed as threatened and state listed as endangered, is not known to occur on the site but is believed to occur in Rockland County, New York, and could be present at upland forested portions of the site. The small whorled pogonia is a terrestrial plant that is sensitive to competition with other species. Therefore, this species would not use the frequently flooded Former Dump Area as habitat due to its moisture regime and predominance of *Phragmites australis* coverage. The risks to terrestrial plants from chromium, copper, lead, mercury, and zinc in the Former Dump Area are not expected to impact small whorled pogonia plants.

7.2 AE2: SOIL INVERTEBRATE COMMUNITY

When the 95UCL EPCs for surface soil (Iona Island) and surface and subsurface soil (Former Dump Area) were compared to EcoSSLs (i.e., TRVs) for soil invertebrates (**Table 7-2**), the following COPECs had HQs greater than 1:

Insert 7-2. Risk Characterization for Soil Invertebrates.

Receptor	Exposure Area	COPEC	HQ	Bioavailability Adjusted HQ	Risk Characterization Conclusions
Soil Invertebrates	Iona Island	Arsenic	2	-	No risk due to qualitative bioavailability assessment
		HMW PAHs	2	-	No risk due to qualitative bioavailability assessment
	Former Dump Area	Arsenic	2	-	No risk due to qualitative bioavailability assessment
		Chromium	205	-	Potential for risk
		Copper	19	8	Potential for risk
		Mercury	34	-	Potential for risk
		Zinc	28	12	Potential for risk

- Not calculated; bioavailability adjustment method was not developed for these analytes (EPA 2020).

In the Iona Island exposure area, though there are concentrations of metals in exceedance of soil invertebrate TRVs (i.e., arsenic, chromium, copper, lead, mercury, and zinc) in individual DUs, the HQs for the combined 95UCL EPC are all 2 or less. The high CEC values and organic carbon content of the soil are likely to reduce bioavailability of these compounds; thus, site-wide concentrations of COPECs in the Iona Island exposure area surface soil are not expected to pose risk to soil invertebrates.

In the Former Dump Area, the HQ for the combined 95UCL EPCs for arsenic is 2. Due to the low magnitude of exceedance of the EcoSSL and likely reduced bioavailability due to the soil physical parameters, the site-wide concentrations of arsenic in the Former Dump Area soil are not expected to pose risk to soil invertebrates. The HQs for the remaining COPECs range from 19 to 205, indicating risk may be more likely. Assuming a 41 percent bioavailability, HQs for all compounds excluding arsenic remain above 1, indicating that risk from chromium, copper, mercury, and zinc to soil invertebrates is potentially present at the Former Dump Area. As highlighted previously, the Former Dump Area is frequently inundated and includes areas with thick stands of *Phragmites* that may prevent habitation by soil invertebrates, though core samples taken from a tidally influenced phragmites marsh in NJ have found macroinvertebrate presence and community richness including Oligochaeta, Nematoda and Polychaeta (Angradi et al. 2001).

Therefore, based on the high HQ exceedances (HQs of 205, 19, 34, and 28 for chromium, copper, mercury, and zinc, respectively) and lack of site-specific information on the invertebrate community, potential risk to this receptor group cannot be ruled out.

7.3 AE3: TERRESTRIAL HERBIVOROUS MAMMALS

Potential risks to herbivorous mammals were evaluated using a food web model for meadow voles (**Table G-1**). Ingestion doses were calculated for each exposure area based on the 95UCL EPCs for surface soil (Iona Island) and surface and subsurface soil (Former Dump Area), which were used to predict the concentration in plant tissue that would be consumed by voles. The dose from soil and dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. HQs greater than 1 indicate potential risk. None of the constituents in any DU had NOAEL or LOAEL-based HQs greater than 1; therefore, there is no potential risk to herbivorous mammals in either exposure area.

7.4 AE4: TERRESTRIAL INSECTIVOROUS BIRDS

Potential risks to insectivorous birds were evaluated using a food web model for the American robin (**Table G-2**). Robins were assumed to be migratory, spending only a portion of their time (8 months) at the site. Ingestion doses were calculated for each exposure area based on the combined 95UCL EPCs for surface soil (Iona Island) and surface and subsurface soil (Former Dump Area), which were also used to predict a concentration in plant and invertebrate tissue that would be consumed by robins. The dose from soil and dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. HQs greater than 1 indicate potential risk. The table below presents the HQs ($HQ_{NOAEL,}$ HQ_{LOAEL}, and Bioavailability Adjusted HQ_{LOAEL}) as well as risk characterization conclusions for all COPECs that exceeded the NOAEL-based TRVs.

Insert 7-3. Risk Characterization for Terrestrial Insectivorous Birds.

Receptor	Exposure Area	COPEC	HQ_{NOAEL}	HQ_{LOAEL}	Bioavailability Adjusted HQ_{LOAEL}	Risk Characterization Conclusions
Insectivorous birds (American robin)	Iona Island	Lead	6	3	1	No risk due to adjusted HQ≤1
		HMW PAH	3	<1	-	No risk, HQ_{LOAEL}<1
	Former Dump Area	Cadmium	3	<1	<1	No risk, HQ_{LOAEL}<1
		Copper	21	7	3	Potential for risk
		Lead	29	15	7	Potential for risk
		Zinc	2	<1	<1	No risk, HQ_{LOAEL}<1

- Not calculated, bioavailability adjustment method was not developed for these analytes (EPA 2020).

When the doses are compared to the NOAEL-based TRVs, lead and HMW PAHs HQs exceed 1 in the Iona Island exposure area and cadmium, copper, lead, and zinc HQs exceed 1 in the Former Dump Area. When the doses are compared to the LOAEL-based TRVs, all HQs fall to 1 or below 1 with the exception of lead in the Iona Island exposure area and copper and lead in the Former Dump Area. It is important to consider that the LOAEL TRV for HMW PAHs is highly uncertain. EPA (2007f) did not derive a TRV for HMW PAHs due to a lack of data; thus, an uncertainty

factor was applied to the available NOAEL to estimate a LOAEL. Consequently, the HQ based on this value is uncertain.

Adjusting the soil EPC by 41 percent, the HQ based on the comparison of the LOAEL-based TRV for lead to the dose to insectivorous birds at Iona Island falls to 1. Consequently, site-wide concentrations of lead in the Iona Island exposure area surface soil are not expected to pose risk to terrestrial insectivorous birds.

Adjusting the soil EPC in the Former Dump Area by 41 percent, resultant HQs would be 3 and 7 based on comparison to the LOAEL-based TRVs for copper and lead, respectively. Consequently, measured soil physical parameters and the resultant lower bioavailability would not mitigate potential risks from copper and lead to insectivorous birds at the Former Dump Area.

Several uncertainties exist with regards to the models and assumptions used to assess risks to terrestrial insectivorous birds. In the absence of site-specific tissue, the oligochaete tissue concentrations are modeled based on an uptake factor and equation for copper and lead, respectively. The uptake factor and equations developed by Sample et al. (1998a) and suggested for use in EcoSSL guidance (EPA 2007a) are generalized, as they represent multiple oligochaete species, seasons, and soil types and characteristics, which have all been shown to affect uptake (Sample et al. 1998a). Therefore, the uncertainty with the oligochaete tissue estimate for any specific location may be high (Sample et al. 1998a), and thus the exposure estimates to the wildlife receptors that eat oligochaetes are also uncertain.

Further uncertainty exists relating to the suitability of the Former Dump Area habitat for soil invertebrate foraging by insectivorous birds. As highlighted previously, thick stands of *Phragmites* cover a limited area of the Former Dump Area, which may provide a barrier to soil invertebrate foraging by insectivorous birds. Though *Phragmites* colonization is likely to have a negative overall impact on bird communities, some species are known to have preference for *Phragmites* dominated habitat. A literature search found support for the use of *Phragmites* habitat by ecological receptors, including several species that have been identified on site such as the marsh wren, red-winged blackbird, and Virginia rail (Benoit and Askins 1999; Whyte et al. 2015).

The area is frequently inundated which may limit the presence of soil invertebrate prey items within the area. A previous study of *Phragmites* dominated marsh in New Jersey found presence of macroinvertebrates including Oligochaeta, Nematoda, and Polychaeta, suggesting that suitable prey items are likely present (Angradi et al. 2001). Macroinvertebrate densities were high in *Phragmites* reeds on Iona Island, based on surveys conducted in 1999 and 2000 (Yozzo and Osgood 2013). Though some of the species identified in the aforementioned studies were aquatic or semiaquatic, bioaccumulation of copper and lead in benthic macroinvertebrates would be higher in these species compared to terrestrial soil invertebrates based on bioaccumulation factors. In addition, bird species known to use *Phragmites* dominated habitat, such as the marsh wren, consume both terrestrial and aquatic invertebrates (Beaubien et al. 2020). Consequently, it is assumed that the Former Dump Area could support habitation and foraging by insectivorous birds.

The America robin was selected as the surrogate receptor for the cerulean warbler and the golden-winged warbler, which are both considered species of special concern by the state of New York. Both protected species are smaller than the robin and use of the robin as a surrogate receptor may underestimate risk to these species based on differences in ingestion rate relative to body weight. The diet of both cerulean and golden-winged warblers primarily consists of insects (NYDEC 2023); thus, the American robin model was adjusted to consume almost entirely insects to more closely represent the two state species of concern. The cerulean warbler prefers deciduous forest habitats (Cornell Lab of Ornithology 2023a) and the golden-winged warbler prefers mosaic forest near wetlands (Cornell Lab of Ornithology 2023b). Both habitat types exist on-site; thus, both species may be present at the site. Thick stands of *Phragmites australis* are not their preferred habitat, meaning it is unlikely either species will spend all their time inhabiting the Former Dump Area. Consequently, risks to these threatened species may be overestimated based on the lack of habitat suitability, though the use of the Former Dump Area for foraging by species of concern cannot be ruled out based on this assessment.

There is potential for population-level impacts to terrestrial insectivorous birds given LOAEL-based HQs exceed 1 for lead and copper even when bioavailability is incorporated into the exposure model. The LOAEL-based HQs for lead and copper are based on comparisons to TRVs that are derived from chronic exposures with effects on reproductive endpoints. Given this impact is directly linked to population sustainability (fecundity and recruitment), it is prudent to highlight the potential for population-level impacts to insectivorous avian species for lead and copper at the Former Dump Area. However, population-level effects on this receptor group cannot be determined or ruled out without further site-specific ecological data. Information on populations present within the Former Dump Area (abundance and density as well as other parameters) would be needed to reduce this uncertainty and to provide insight into population impacts from these metals. Equally important, species of concern may be present in the area, for which effects at the individual effect level are significant. Consequently, potential risks to species of concern from copper and lead exposure in the Former Dump Area cannot be ruled out. Therefore, it is concluded there is potential risk to insectivorous birds and consequently two bird species of special concern due to copper and lead at the Former Dump Area.

7.5 AE5: TERRESTRIAL INSECTIVOROUS MAMMALS

Potential risks to insectivorous mammals were evaluated using a food web model for short-tailed shrew (**Table G-3**). Ingestion doses were calculated for each exposure area based on the 95UCL EPCs for surface soil (Iona Island) and surface and subsurface soil (Former Dump Area), which were also used to predict a concentration in plant, small mammal, and invertebrate tissue that would be consumed by shrews. The dose from soil and dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. HQs greater than 1 indicate potential risk. The table below presents the HQs ($HQ_{NOAEL,}$ HQ_{LOAEL}, and Bioavailability Adjusted HQ_{LOAEL}) as well as risk characterization conclusions for all COPECs that exceeded the NOAEL-based TRVs.

Insert 7-4. Risk Characterization for Terrestrial Insectivorous Mammals.

Receptor	Exposure Area	COPEC	HQ_{NOAEL}	HQ_{LOAEL}	Bioavailability Based HQ_{LOAEL}	Risk Characterization Conclusions
Insectivorous mammals (shrew)	Iona Island	Lead	2	<1	<1	No risk, HQ_{LOAEL}<1
		HMW PAHs	10	<1	-	No risk, HQ_{LOAEL}<1
	Former Dump Area	Antimony	9	<1	-	No risk, HQ_{LOAEL}<1
		Cadmium	6	<1	<1	No risk, HQ_{LOAEL}<1
		Copper	12	7	3	Potential for risk
		Lead	7	4	2	Potential for risk
		Thallium	3	<1	-	No risk, HQ_{LOAEL}<1
		Zinc	2	<1	<1	No risk, HQ_{LOAEL}<1
		HMW PAHs	3	<1	-	No risk, HQ_{LOAEL}<1

- Not calculated, bioavailability adjustment method was not developed for these analytes (EPA 2020).

When the doses are compared to the NOAEL-based TRVs, lead and HMW PAHs HQs exceed 1 in the Iona Island exposure area and antimony, cadmium, copper, lead, thallium, zinc, and HMW PAHs HQs exceed 1 in the Former Dump Area. When the doses are compared to the LOAEL-based TRVs, all HQs fall below 1 except for copper and lead in the Former Dump Area. Accounting for bioavailability based on soil parameters as discussed previously (i.e., assuming 41 percent bioavailability), HQs still exceed 1 for both copper and lead when compared to NOAEL and LOAEL-based TRVs, indicating that the lower bioavailability could not mitigate the potential for risk to terrestrial insectivorous mammals.

The shrew was a surrogate receptor for the Indiana bat (*Myotis sodalis*) and northern long-eared bat (*Myotis septentrionalis*), which are both federal and state-listed endangered species. There is uncertainty associated with the use of the short-tailed shrew as a surrogate for these species based on differences in size and life history (Section 2.1.6.1). Additional uncertainty exists regarding the models used to estimate soil invertebrate tissue concentrations as discussed in the preceding section. The short-tailed shrew is assumed to spend all its time at the site based on the published home range (EPA 1993), which is a conservative assumption given that the area is inundated twice daily, with previous studies suggesting that short-tailed shrews favor forested habitats over tidally inundated marshes (Ekernas and Mertes 2006). As such, risks based on exposure within the Former Dump Area to this receptor group may be overestimated. In addition, the endangered bat species for which the shrew was a surrogate receptor are unlikely to forage entirely in the Former Dump Area; thus, risks may be further overestimated. Despite this, the potential for population-level effects on this receptor group cannot be determined or ruled out without further site-specific ecological data; though effects may be possible based on exceedance of TRVs associated with effects on reproduction. Risk to both federal and state-listed endangered species of bats (Indiana bat (*Myotis sodalis*) and northern long-eared bat (*Myotis septentrionalis*)) is based upon a conservative exposure scenario for the surrogate receptor, the shrew and as such may be overestimated. However, to be conservatively protective, it is concluded there is potential risk to protected bat species from copper and lead at the Former Dump Area.

7.6 AE6: CARNIVOROUS MAMMALS

Potential risks to carnivorous mammals were evaluated using a food web model for red fox (**Table G-4**). Ingestion doses were calculated for each exposure area based on the 95UCL EPCs for surface soil (Iona Island) and surface and subsurface soil (Former Dump Area), which were also used to predict a concentration in small mammal tissue that would be consumed by fox. The dose from soil and dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. HQs greater than 1 indicate potential risk. None of the HQs exceeded the threshold of 1 so risk to carnivorous mammals is not expected.

7.7 AE7: CARNIVOROUS BIRDS

Potential risks to carnivorous birds were evaluated using a food web model for red-tailed hawk (**Table G-5 in Attachment G**). Ingestion doses were calculated for each exposure area based on the 95UCL EPCs for surface soil (Iona Island) and surface and subsurface soil (Former Dump Area), which were also used to predict a concentration in small mammal tissue that would be consumed by hawks. The dose from soil and dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. HQs greater than 1 indicate potential risk.

When the doses were compared to the NOAEL-based TRVs, HQs were less than 1 except for the HQ for lead which was 3. The HQ for lead dropped to 1 when the dose was compared to the LOAEL-based TRV. Consideration of soil physical parameters and the associated reduced bioavailability of constituents would reduce risk further. Based on the lack of exceedance of the LOAEL-based TRVs, risk to carnivorous birds is not expected. The red-tailed hawk was a surrogate species for the northern harrier (*Circus cyaneus*), a state-listed threatened species. Risk to this protected bird species is not expected.

7.8 AE8: HERPTILE POPULATIONS

As discussed above in Section 2.1.6.1, herptiles (i.e., reptiles and amphibians) were evaluated based on a qualitative evaluation using other receptors as surrogate species. For reptiles, potential risks are expected to be most similar to that of birds (Salice et al. 2009), but risks to any receptor could indicate potential risks to herptiles. This assumption is made due to the lack of toxicological and exposure information for herptiles. The RSLERA results and risk characterization for terrestrial species are presented above in Section 7.1 through 7.7, and the risk characterization for aquatic species are presented below in Sections 7.9 through 7.18.

There is potential risk to herptiles in the Former Dump Area due to copper and lead in the soil because of the potential risk to terrestrial insectivorous birds as well as terrestrial plants and soil invertebrates (copper only). There are also potential risks to herptiles due to chromium, mercury, and zinc due to risks to plants and/or soil invertebrates.

Since there were no COPECs identified in surface water or potential risks to other aquatic life, there are no anticipated risks to herptiles due to concentrations of COPECs in surface water. There is potential risk to aquatic insectivorous birds, aquatic plants, benthic invertebrates, demersal fish, and, therefore, herptiles due to lead in the sediment at the Iona Island Hudson River Shoreline. There are also risks to herptiles due to antimony, cadmium, nickel, and zinc in the sediment at Iona Island Hudson River Shoreline due to risks to aquatic plants, benthic invertebrates, and demersal fish.

Given that box and painted turtles have been recorded in the study area, it is possible that bog turtles, a federally threatened and state endangered species, could be present on site. However, of the areas with potential risks to herptiles, adequate habitat is likely not present. The Former Dump Area is densely vegetated with primarily *Phragmites australis*, an invasive species known to eliminate the microhabitats important to the bog turtle (NYDEC 2023c). Iona Island Hudson River Shoreline also does not feature the preferred habitat of the bog turtles (open wet meadows and boggy areas). Therefore, bog turtles are not likely to be found in these areas of potential risk, and risk is not expected to bog turtles.

Overall, using other receptors as surrogates for herptiles, potential risk was identified for this group at the Former Dump Area from chromium, copper, lead, mercury, and zinc. At the Iona Island Hudson River Shoreline, potential risk from antimony, cadmium, lead, nickel, and zinc was identified for herptiles based on exceedances for other receptors including birds and soil invertebrates.

7.9 AE9: AQUATIC PLANT COMMUNITY

As discussed above in 2.1.6.2 and 4.2.2, there are no sediment screening values protective of aquatic plants. Therefore, aquatic plants rooted in sediments were evaluated by comparing EPCs for sediment to refined sediment screening benchmarks. See **Table 7-3** for the refined HQs. The HQs for six metals at Iona Island Hudson River Shoreline (antimony, cadmium, copper, lead, nickel, and zinc) exceeded 1. Only zinc exceeded its RSV in the Riprap Drainage Swale with an HQ of 3. Zinc in this area may be attributed to the metal debris (e.g., rebar, old fencing, and other metal pieces) observed in the Riprap Drainage Swale. AVS/SEM results from the Riprap Drainage Swale indicate that metals in sediment are unlikely to be bioavailable; therefore, zinc is not expected to pose risk in the Riprap Drainage Swale exposure area. No concentrations of metals exceeded RSVs in the Tidal Wetland Swale. In addition, none of the concentrations of metals in any surface water samples exceeded surface water quality criteria in any area. Therefore, aquatic plants are not at risk in the Riprap Drainage Swale or the Tidal Wetland Swale.

As discussed below in Section 7.10, metals in sediments are bioavailable at the Iona Island Hudson River Shoreline based on AVS/SEM results and low TOC content. Despite the low concentrations in surface water, due to the exceedance of the RSVs and bioavailability of metals, risk to aquatic plants from antimony, cadmium, copper, lead, nickel, and zinc in sediment is possible at the 0.5-acre Iona Island Hudson River Shoreline exposure area.

7.10 AE10: BENTHIC INVERTEBRATE COMMUNITY

The refined sediment screen for benthos using RSVs is provided in **Table 7-3**. When the sediment EPCs for each aquatic DU (Iona Island Hudson River Shoreline, Riprap Drainage Swale, and Tidal Wetland Swale) were compared to the RSVs, the following COPECs had HQs greater than 1:

Insert 7-5. Risk Characterization for Benthic Invertebrates.

Receptor	Exposure Area	COPEC	HQ	Risk Characterization Conclusions
Benthic Invertebrates	Iona Island Hudson River Shoreline	Antimony	5	Potential for risk
		Cadmium	2	Potential for risk
		Copper	68	Potential for risk
		Lead	147	Potential for risk
		Nickel	3	Potential for risk
		Zinc	9	Potential for risk
	Riprap Drainage Swale	Zinc	3	No risk due to AVS/SEM results

None of the COPECs in the Tidal Wetland Swale had HQs greater than 1. Only one COPEC, zinc, has an HQ greater than 1 in the Riprap Drainage Swale. Zinc in this area may be attributed to the metal debris (e.g., rebar, old fencing, and other metal pieces) observed in the drainage swale. AVS/SEM results from the Riprap Drainage Swale are less than 130 µmol/g_{oc}, which indicates that the metals in sediment are unlikely to be bioavailable; therefore, zinc is not expected to pose risk to benthic invertebrates in the Riprap Drainage Swale exposure area.

At Iona Island Hudson River Shoreline, AVS/SEM results combined with low TOC content and sandy sediments indicate that the area provides suitable conditions for metals in sediment to be bioavailable. During the Shoreline Reconnaissance, benthic organisms were observed beneath large boulders and riprap along the shoreline, but none were observed within the river shoreline sediments during sampling. The area is primarily gravel, riprap, and course-grained sand with the exception of pockets of deposited sediment (EA 2020); thus, limited habitat may be present for benthic invertebrates. A benthic community assessment on the Hudson River Shoreline sediments would need to be completed in order to confirm the lack of benthos and lack of suitable habitat. The lack of observed benthic organisms in the sediment could also be an indicator that concentrations of COPECs in the sediment are contributing to benthic organism toxicity.

This exposure area is spatially limited to one-half acre, immediately adjacent to the Former Dump Area. Just beyond this shallow shelf, river bathymetry indicates a steep slope leading to a deep river channel. Concentrations of metals in surface water are low, indicating dilution from the Hudson River current or that metals are not desorbing from sediment particles and are not dissolving into surface water at concentrations that would cause adverse effects

Due to the exceedance of the RSVs and bioavailability of metals, risk to benthic invertebrates from antimony, cadmium, copper, lead, nickel, and zinc in sediment is possible.

7.11 AE11: ZOOPLANKTON COMMUNITY

Zooplankton were evaluated by comparing surface water concentrations to freshwater surface water quality criteria. There were no exceedances of any water quality criteria; therefore, risks to the zooplankton community are not expected.

7.12 AE12: DEMERSAL FISH COMMUNITY

Demersal fish (i.e., benthic-feeding fish) were evaluated by comparing EPCs for sediment to RSVs and by comparing surface water concentrations to water quality criteria. There were no exceedances of any water quality criteria. The HQs for six metals in sediment at Iona Island Hudson River Shoreline (antimony, cadmium, copper, lead, nickel, and zinc) exceeded 1. As highlighted above, the AVS/SEMs results coupled with sandy sediments and low organic carbon at Iona Island Hudson River Shoreline suggest that metals may be bioavailable.

Evaluating risk to demersal fish from the drainage swales may be a conservative evaluation as the areas may be dry for at least part of the year. However, aerial images show drainage swales connecting to water (Figure 3-3). With the available information, use of the drainage swales by these receptors cannot be dismissed. Only zinc exceeded its RSV in the Riprap Drainage Swale with an HQ of 3. Zinc in this area may be attributed to the metal debris (e.g., rebar, old fencing, and other metal pieces) observed in the drainage swale. AVS/SEM results from the Riprap Drainage Swale indicate that metals in sediment are unlikely to be bioavailable; therefore, zinc is not expected to pose risk in the Riprap Drainage Swale exposure area. No concentrations of metals exceeded RSVs in the Tidal Wetland Swale. Therefore, demersal fish are not at risk in the Riprap Drainage Swale or the Tidal Wetland Swale.

Demersal fish will not use the Former Dump Area as habitat. Thus, the Former Dump Area is not evaluated as an exposure area for this receptor. As previously mentioned, the small shelf area at Iona Island Hudson River Shoreline adjacent to the Former Dump Area is lined with boulders and riprap. Beyond the rocky shoreline, sandy sediments that lack organic matter are prevalent. As a result, there may be a lack of sufficient habitat for infaunal benthic invertebrate communities and aquatic plants. Without this base of the food web for foraging and sufficient habitat for spawning, small benthic-feeding fish (i.e., demersal fish) are also unlikely to inhabit this area, minimizing the potential for exposure and risk in these receptor groups.

Concentrations of metals in surface water are low, indicating dilution from the Hudson River current or that metals are not desorbing from sediment particles and are not dissolving into surface water at concentrations that would cause adverse effects. As discussed above in Section 7.10, metals in sediments are bioavailable based on AVS/SEM results and low TOC content. Due to the exceedance of the RSVs and bioavailability of metals, risk to demersal fish from antimony, cadmium, copper, lead, nickel, and zinc in sediment is possible.

The endangered Atlantic sturgeon and shortnose sturgeon are demersal fish. Atlantic sturgeon migrate up the Hudson River from the Atlantic beginning in April for reproduction and migrate back to the ocean in the late summer through fall (NOAA 2023a, New York Heritage Program

2023a). Shortnose sturgeon spawn in the Hudson River using large rocky substrate (New York Heritage Program 2023b), which is found at the littoral zone of the Iona Island Hudson River Shoreline. Juvenile shortnose sturgeon may remain at the saltfront during maturation. Within the Hudson River the saltfront is dynamic and is identified by specific conductance at 500 µS cm^{-1}. The United States Geological Survey defines the saltfront and provides daily and historical measurements of the river as supported by the Hudson River Saltfront Data and Project (https://ny.water.usgs.gov/projects/dialerplots/saltfront.html).

Juvenile Atlantic sturgeon have been harvested near and south of Iona (Peterson et al. 2000; Sweka 2007) indicating they could be present at the Iona Island Hudson River Shoreline. Adult sturgeon are likely to be transient in nature and thus risks to that lifestage may be limited; however, juvenile sturgeon could be at risk due to lead in the sediment at Iona Island Hudson River Shoreline.

7.13 AE13: PELAGIC FISH COMMUNITY

Pelagic fish inhabit the water column. They were evaluated by comparing surface water concentrations to water quality criteria. There were no exceedances of any water quality criteria; therefore, risks to the pelagic fish community are not expected.

7.14 AE14: AQUATIC HERBIVOROUS BIRDS

Potential risks to herbivorous birds were evaluated using a food web model for mallard duck (**Table G-6**). Ingestion doses were calculated for each aquatic DU (Iona Island Hudson River Shoreline, Riprap Drainage Swale, and Tidal Wetland Swale) based on the EPC in sediment, which was also used to predict a concentration in plant tissue that would be consumed by ducks. The dose from sediment and the dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. Mallard duck has a large habitat/foraging range (1,075 acres) and, therefore, the AUF was adjusted to account for the expected proportion of time the species would spend in 0.5-acre DUs. HQs greater than 1 indicate potential risk. None of the constituents in any DU had NOAEL or LOAEL-based HQs greater than 1; therefore, risks to aquatic herbivorous birds are not expected.

7.15 AE15: AQUATIC HERBIVOROUS MAMMALS

Potential risks to herbivorous mammals were evaluated using a food web model for muskrat (**Table G-7**). Ingestion doses were calculated for each aquatic DU (Iona Island Hudson River Shoreline, Riprap Drainage Swale, and Tidal Wetland Swale) based on the EPC in sediment, which was also used to predict a concentration in plant tissue that would be consumed by muskrat. In addition, muskrat was evaluated in the Former Dump Area (DUs 17,18, and 19) because this area is frequently inundated and contains an abundance of *Phragmites australis*, which could be consumed by muskrat (**Table G-8**). Ingestion doses were calculated for the Former Dump Area based on the soil EPC, which was also used to predict concentrations in plant tissue.

The dose from sediment/soil and the dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. HQs greater than 1

indicate potential risk. None of the constituents in the Riprap Drainage Swale, Tidal Wetland Swale, or the Former Dump Area had NOAEL or LOAEL-based HQs greater than 1; therefore, there is no potential risk to herbivorous mammals. The HQs (HQ_{NOAEL} and HQ_{LOAEL}) as well as risk characterization conclusions for all COPECs in exceedance of the NOAEL-based TRV at Iona Island Hudson River Shoreline for aquatic herbivorous mammals are presented in the following table.

Insert 7-6. Risk Characterization for Aquatic Herbivorous Mammals.

Receptor	Exposure Area	COPEC	HQ_{NOAEL}	HQ_{LOAEL}	Risk Characterization Conclusions
Aquatic herbivorous mammals (muskrat)	Iona Island Hudson River Shoreline	Antimony	5	<1	No risk, HQ_{LOAEL}<1
		Copper	2	1	No risk, HQ_{LOAEL}≤1
		Lead	4	2	No risk due to low HQ and habitat considerations

When the doses from Iona Island Hudson River Shoreline are compared to the NOAEL-based TRVs, antimony, copper, and lead, exceed 1. When the doses are compared to the LOAEL-based TRVs, the HQ for antimony falls below 1, and to a value of 1 for copper. Therefore, risk to aquatic herbivorous mammals is not expected due to antimony and copper in sediment.

The shoreline area consists of sandy sediment and lacks aquatic vegetation due to the high-energy environment, which is subject to scouring. It is unlikely that muskrat would spend 100 percent of its time in this area (as the food web models assume due to a relatively small range of 0.33 acre) when there are areas such as the Former Dump Area with vegetation nearby. Habitat suitability studies have shown that muskrat burrows and foraging are positively related to aquatic vegetation coverage, with muskrat occupancy also negatively related to percent sand in soil (Cotner and Schooley 2011; Nadeau et al. 1995). Taking this into account with the relatively low HQs based on comparison to the LOAEL-based TRV (HQ of 2), risk to aquatic herbivorous mammals from lead is not expected.

7.16 AE16: AQUATIC INSECTIVOROUS BIRDS

Potential risks to insectivorous birds were evaluated using a food web model for lesser scaup (**Table G-9 in Attachment G**). Ingestion doses were calculated for each aquatic DU (Iona Island Hudson River Shoreline, Riprap Drainage Swale, and Tidal Wetland Swale) based on the EPC in sediment, which was also used to predict a concentration in invertebrate tissue that would be consumed by scaup. The dose from sediment and the dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. Lesser scaup has a large habitat/foraging range (219 acres) and, therefore, the AUF was adjusted to account for the expected proportion of time the species would spend in 0.5-acre DUs.

HQs greater than 1 indicate potential risk. When the doses were compared to the NOAEL-based TRVs, HQs were less than 1 except for the HQ for lead at Iona Island Hudson River Shoreline only which was 6. The HQ for lead dropped to 3 when the dose was compared to the LOAEL-based TRV. Based on the exceedance of the LOAEL-based TRV, there is potential for risk to

insectivorous birds due to lead at the Iona Island Hudson River Shoreline. As highlighted above in Section 7.15, AVS/SEM results, low TOC content, and sandy sediments indicate that the area provides conditions for metals in sediment to be bioavailable. Thus, it is concluded that potential risks to aquatic insectivorous birds may be present. The HQs (HQ_{NOAEL} and HQ_{LOAEL}) as well as risk characterization conclusions for lead at Iona Island Hudson River Shoreline for aquatic insectivorous birds are presented in the following table.

Insert 7-7. Risk Characterization for Aquatic Insectivorous Birds.

Receptor	Exposure Area	COPEC	HQ_{NOAEL}	HQ_{LOAEL}	Risk Characterization Conclusions
Aquatic insectivorous birds (lesser scaup)	Iona Island Hudson River Shoreline	Lead	6	3	Potential for risk

The lesser scaup was selected as a surrogate receptor for the pied-billed grebe, a protected species that prefers wetland habitats with both open water and aquatic vegetation cover available. The Iona Island Hudson River Shoreline does not provide suitable habitat for the species. Therefore, the pied-billed grebe is not likely to use the exposure area for nesting and foraging and is unlikely to be at risk due to lead in sediment.

As highlighted previously, effects at the population-level cannot be determined based on the magnitude of HQ exceedances, though effects at this level are considered possible based on the exceedances of TRVs derived from studies of reproductive effects. Additional data collection and modeling approaches would be necessary to fully elucidate the potential for population-level effects on aquatic insectivorous birds at the Iona Island Hudson River Shoreline.

7.17 AE17: PISCIVOROUS MAMMALS

Potential risks to piscivorous mammals were evaluated using a food web model for river otter (**Table G-10 in Attachment G**). Ingestion doses were calculated for the site based on the EPC in sediment for each aquatic DU (Iona Island Hudson River Shoreline, Riprap Drainage Swale, and Tidal Wetland Swale). Concentrations in fish tissue were calculated using surface water concentrations and BCFs. The dose from sediment and the dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. River otter have a large habitat/foraging range (859 acres) and, therefore, the AUF was adjusted to account for the expected proportion of time the species would spend in 0.5-acre DUs. HQs greater than 1 indicate potential risk. None of the HQs exceeded the threshold of 1; therefore, risk to piscivorous mammals is not expected.

7.18 AE18: PISCIVOROUS BIRDS

Potential risks to piscivorous birds were evaluated using a food web model for great blue heron (**Table G-11 in Attachment G**). Ingestion doses were calculated for the site based on the EPC in sediment for each aquatic DU (Iona Island Hudson River Shoreline, Riprap Drainage Swale, and

Tidal Wetland Swale). Concentrations in fish tissue were calculated using surface water concentrations and BCFs. The dose from sediment and the dose from biota were summed to calculate a total dose, which was then compared to NOAEL and LOAEL-based TRVs to calculate an HQ. Great blue heron habitat/foraging range is expected to be approximately 11 acres and, therefore, the AUF was adjusted to account for the expected proportion of time the species would spend in 0.5-acre DUs. HQs greater than 1 indicate potential risk. None of the HQs exceeded the threshold of 1; therefore, risk to piscivorous birds is not expected.

The great blue heron was selected as a surrogate receptor for the following protected species: least bittern, bald eagle, and osprey. Since no risks to piscivorous birds are expected, no risks to the protected species are expected.

7.19 SUMMARY AND CONCENTRATION COMPARISONS

Potential risk identified is limited to the Former Dump Area and Iona Island Hudson River Shoreline exposure areas. In contrast to the size of Iona Island (approximately 125 acres), the exposure areas are small. In the Former Dump Area, risk is generally limited to two of three of the 1-acre DUs (DU-17 and DU-18), so risk is limited to a total area of about two acres. Given the size of the area, it is unlikely that populations of receptors will spend all their time inhabiting or foraging only in these DUs. Site characteristics at the Former Dump Area including inundation and dense stands of *Phragmites* may reduce foraging for soil invertebrates by receptors which is assumed in the food web models. However, review of the literature found that receptors that have been recorded on site may favor the use of *Phragmites* dominated habitat (Benoit and Askins 1999; Whyte et al. 2015); thus, occupancy and foraging at the Former Dump Area is possible.

Even with the consideration of the low bioavailability of metals in the soil as discussed in Section 7, concentrations of COPECs in the soil indicate potential risk to ecological receptors. For perspective of the magnitude of metal concentrations in the Former Dump Area, the table below presents the comparison of 95UCL background concentrations (Table C-2), the Former Dump Area EPC used in the food web models (Attachment G), and the range of EPCs for DU-17 and DU-18 used in the SLERA (Table 4-4). Maximum EPCs from DU-17 and DU-18 range from approximately 15 (chromium and mercury) to over 200 times (copper) the 95UCL background concentrations.

Insert 7-8. Comparison of Background and Dump Area Soil Concentrations.

COPEC	95UCL Soil Background Concentration (mg/kg)	Former Dump Area EPC used in ERA (Combined surface and subsurface soil from DU-17, DU-18, and DU-19) (mg/kg)	Range of DU-17 and DU-18 surface and subsurface soil EPCs used in SLERA (mg/kg)
Chromium	30	82	14 – 411
Copper	28	1,538	219 – 6070
Lead	82	1,825	1,580 – 4,150
Mercury	0.35	1.7	1 – 6.33
Zinc	69	3,413	3,520 – 10,200

The Iona Island Hudson River Shoreline exposure area is approximately half an acre. The range of the mean background sediment concentrations from Con Hook Marsh Shoreline and Con Hook Hudson River Shoreline (Table D-2) are presented with the Iona Island Hudson River Shoreline EPCs (Table 4-5) in the table below. EPCs from Iona Island Hudson River Shoreline range from 5 (nickel) to 330 times (lead) the 95UCL background concentrations.

Insert 7-9. Comparison of Background and Iona Island Sediment Concentrations.

COPEC	Range of 95UCL Background Sediment Concentrations (mg/kg)	Iona Island Hudson River Shoreline EPC (mg/kg)
Antimony	0.63 – 1.1	123
Cadmium	0.80 – 1.3	9.86
Copper	38 – 50	10,100
Lead	57 – 67	18,800
Nickel	29 – 38	140
Zinc	155 – 176	3,930

The potential for risk following exposure to the metals noted above is demonstrated both quantitatively and qualitatively using multiple lines of evidence; however, elevated concentrations do not necessarily indicate risk to populations. There are a number of uncertainties inherent in the assessment of risks that should be considered in interpretation of results. One of the greatest uncertainties inherent to risk assessment is the assumption that effects on individuals, as indicated by benchmark exceedances, are indicative of population-level effects. For wildlife, the LOAEL-based TRVs are derived in part from studies focusing on reproductive effects (EPA 2005g, 2007c); thus, it is reasonable to assume that exceedance of these levels could indicate a reduction in reproductive output and subsequent population-level impacts on these receptors due to copper and lead exposures. However, based on the available information, population-level impacts could not be confirmed.

8. REFINED SCREENING-LEVEL ECOLOGICAL RISK ASSESSMENT CONCLUSIONS

The ERA evaluated both terrestrial and aquatic receptors. After the completion of the SLERA, only those receptors potentially at risk were evaluated using a site-specific RSLERA.

The terrestrial exposure areas were: 1) Iona Island Exposure Area; and 2) Former Dump Exposure Area. Representative terrestrial receptor categories included plants, soil invertebrates, herbivorous mammals (representative species meadow vole), insectivorous birds (representative species American robin), insectivorous mammals (representative species short-tailed shrew), carnivorous birds (representative species red tailed hawk), carnivorous mammals (representative species red fox), and herptiles.

The aquatic exposure areas were: 1) Iona Island Hudson Shoreline; 2) riprap drainage swale; and 3) tidal wetland swale. Representative aquatic receptor categories included plants, benthic invertebrates, zooplankton, demersal fish, pelagic fish, herbivorous birds (representative species mallard duck), herbivorous mammals (representative species muskrat), insectivorous birds (representative species lesser scaup), piscivorous mammals (representative species river otter) piscivorous birds (representative species great blue heron), and herptiles.

No receptors were found to be at risk in the terrestrial Iona Island exposure area, which does not include the Former Dump Area. These risk findings apply also to two federal/state-listed species of bats (i.e. Indiana bat, northern long-eared bat) and two state listed species of insectivorous birds (i.e. cerulean warbler and golden-winged warbler). No risks to aquatic receptors were found in the riprap drainage swale or the tidal wetland swale exposure areas.

In the Former Dump Area soil exposure area, plants, soil invertebrates, insectivorous mammals, insectivorous birds, and herptiles are potentially at risk from metals (chromium, copper, lead, mercury, and/or zinc), with risk being driven by avian exposure to lead. This risk potentially extends to two federal/state-listed species of bats (i.e. Indiana bat, northern long-eared bat) and two species of insectivorous birds which are New York State listed species of special concern (i.e. cerulean warbler and golden-winged warbler). In the Iona Island Hudson Shoreline sediment exposure area, plants, benthic invertebrates, demersal fish, herptiles and insectivorous birds are potentially at risk from metals (antimony, cadmium, copper, lead, nickel and zinc), with risk being driven by exposure to lead. This risk from sediment potentially extends to two species of endangered demersal fish (juvenile sturgeon) (i.e. Atlantic sturgeon, short-nosed sturgeon).

Risk from soil in the Former Dump Area is mitigated for common species by the small spatial extent of the area (< 2 acres), dense phragmites stands and twice daily inundation during tidal cycles; population level effects are unlikely from soils in this area. Similarly, population level risk is unlikely for common species due to the small extent of sediment in shoreline areas immediately adjacent to the Former Dump Area. The attenuation of risk these factors is not as clear for the two listed bats species, two listed bird species and two endangered fish species (listed because of preferred riverine habitat by the Former Dump Area for a juvenile life stage), as value is put on a single individual in these instances.

Insert 8-1. Summary of Risk Characterization for All Receptors.

Habitat Type	Exposure Area	Media	COPEC	Receptors
Terrestrial	Iona Island	No receptors are at risk due to COPECs in soil.		
	Former Dump Area	Soil (surface and subsurface)	Chromium	• Terrestrial plants • Soil invertebrates • Herptiles
			Copper	• Terrestrial plants • Soil invertebrates • Terrestrial Insectivorous Birds (including 2 NY species of special concern) • Terrestrial Insectivorous Mammals (including 2 federal and state-listed endangered bat species) • Herptiles
			Lead	• Terrestrial plants • Terrestrial Insectivorous Birds (including 2 NY species of special concern) • Terrestrial Insectivorous Mammals (including 2 federal and state-listed endangered bat species) • Herptiles
			Mercury	• Terrestrial plants • Soil invertebrates • Herptiles
			Zinc	• Terrestrial plants • Soil invertebrates • Herptiles
Aquatic	Iona Island Hudson Shoreline	Sediment	Antimony, Cadmium, Copper, Lead, Nickel, and Zinc	• Aquatic plants • Benthic invertebrates • Demersal fish (including 2 species of endangered sturgeon) • Herptiles
			Lead	• Aquatic insectivorous birds
	Riprap Drainage Swale	No receptors are at risk due to COPECs in surface water or sediment.		
	Tidal Wetland Swale	No receptors are at risk due to COPECs in surface water or sediment.		

The purpose of the RSLERA was to incorporate easily obtained site specific information to refine the ecological risk evaluation. With the introduction of these sub-tiers of evaluation, the SLERA was refined to provide fewer generic conclusions of ecological risk; however, even with these refinements, hazard calculations show potentially significantly greater risks in this isolated area due to the presence of federal/state-listed or endangered species in the Former Dump Area. These species include two federal/state-listed species of bats (i.e. Indiana bat, northern long-eared bat) and state listed/Special Concern avian species (cerulean warbler and golden-winged warbler), as well as two endangered species of fish (shortnose sturgeon and Atlantic sturgeon) potentially

exposed to sediments at the waterline in front of the Former Dump Area along the shoreline of Iona Island on the Hudson River.

The risk conclusions of the SLERA/RSLERA after these sub-tiers of evaluation show that potential risks are confined to a small area of the site with a sharply defined lateral extent of contamination due to island topography and the Hudson River, as well as a sharply defined vertical extent of contamination due to bedrock at approximately three (3) ft bgs based on test pitting and shoreline bathymetric data. Size notwithstanding, based upon current nature and extent information, the Former Dump Area represents on-going source area due to the presence of ash from the former on-site incinerator, as encountered during test pitting.

HTRW Areas of Concern		
AOC #	**Building(s)/Area**	**Historical Use**
1	Former Building 103	Paint and Oil Storage
2	Former Building 121	Incinerator
3	Former Building 123	Garage Building
4	Former Buildings 124 to 128	Sewage Disposal Plant (and Suspected Outfall)
5	Former Building 207	Marine Garage Building
6	Former Building 213	Paint Locker for Building 202
7	Former Building 215	Garage Building
8	Former Building 219	Garage Building
9	Former Building 220	Garage Building
10	Former Building 406	Tin, Electrical and Annealing Shop Building
11	Former Building 407	Paint Shop and Pipe Shop
12	Former Building 410	Power House
13	Area A	One Former Fuel Oil AST (2,500 gallons) located near Former Building 233
14	Area B	One Former Fuel Oil AST (size unknown) located near Dock 131
15	Area C	Two Former Fuel Oil ASTs (size unknown) located near Former Building 417
16	Area D	Dumping Area
17	Area E	Former Coal Trestle and Storage Area – located near Former Building 410
18	Area F	Former Coal Storage Area – located near Former Building 215
19	Transformers 1, 2, 3	Three Former Transformers
Former Buildings with Significant Potential for Explosive Hazard		
Building		**Historical Use**
Former Building 609		Mine Loading Plant
Former Building 506		Filling House #3 (Bombproof)
Former Building 503		Filling House #6
Former Building 404		Filling House #1
Former Building 307		Filling House #5
Former Building 306		Filling House #2
Former Building 202		Shell House #5 & D Plant

Exposure Media[2]:	Exposure Routes[3]:	Terrestrial Plants	Soil Invertebrates	Terrestrial Birds and Mammals[4,5]	Herptiles[6]	Aquatic Plants	Benthic Invertebrates	Zooplankton	Demersal Fish	Pelagic Fish	Aquatic Birds and Mammals[4,7]
Terrestrial Biota[9]	Ingestion	○	○	●	●	○	○	○	○	○	○
Surface and Subsurface Soil[1]	Ingestion	○	●	●	●	○	○	○	○	○	◐
	Direct Contact	●	●	◐	●	○	○	○	○	○	◐
Surface Water	Ingestion	○	○	◐	◐	○	◐	●	●	●	◐
	Direct Contact	○	○	◐	●	◐	◐	●	●	●	◐
Aquatic Biota[10]	Ingestion	○	○	○	●	○	○	○	◐	◐	●
Sediment	Ingestion	○	○	○	●	○	●	○	●	◐	●
	Direct Contact	○	○	○	●	●	●	○	●	◐	◐

NOTES

1. Surface soil = 0 to 6 inches below ground surface, and subsurface soil = 6 to 36 inches below ground surface. Surface and subsurface soil are normally considered separately. Since the surface soil layer is so shallow the two were grouped together in the evaluation of areas where subsurface soil was collected.
2. Groundwater exposure is not complete for any ecological receptors and is not shown as exposure media in the CSM. Exposure to porewater for aquatic plants and benthic invertebrates is a complete pathway but since porewater was not sampled, it is not shown here for simplicity.
3. The inhalation pathway is complete but not significant compared to ingestion pathways (EPA 2007a) and, therefore, is not quantitatively evaluated in the ERA.
4. Direct contact pathways for mammals and birds is limited by fur and feathers and is considered in incidental soil ingestion during grooming.
5. Mammals such as voles, shrews, and foxes may be exposed to subsurface soil during burrowing activities.
6. Herptiles are evaluated qualitatively using other receptors as surrogate species due to the lack of ecotoxicity values for these receptors. Risks to any receptor could indicate potential risks to herptiles.
7. Aquatic birds and mammals may be exposed to soil when burrowing or foraging on the bank, but exposure to these receptors expected to be less than that captured by exposure to terrestrial birds and mammals. Primary abiotic media of concern to aquatic wildlife is sediment.
8. Only bioaccumulation directly into biota that will be consumed by a receptor is shown here for simplicity, though there can be several trophic levels.
9. Terrestrial biota identified as terrestrial plants, soil invertebrates, and small wildlife.
10. Aquatic biota identified as aquatic plants, benthic invertebrates, and demersal fish.

● Complete Pathway; confirmed receptor and media interaction (i.e., a source, migration route, and receptor have been identified). Exposure is evaluated quantitatively.

◑ Complete Pathway, but not Significant; There is confirmed receptor and media interaction. However, pathway is not significant and exposure is not evaluated quantitatively.

○ There is no receptor and media interaction. No evaluation is conducted.

HTRW Areas of Concern		
AOC #	**Building(s)/Area**	**Historical Use**
1	Former Building 103	Paint and Oil Storage
2	Former Building 121	Incinerator
3	Former Building 123	Garage Building
4	Former Buildings 124 to 128	Sewage Disposal Plant (and Suspected Outfall)
5	Former Building 207	Marine Garage Building
6	Former Building 213	Paint Locker for Building 202
7	Former Building 215	Garage Building
8	Former Building 219	Garage Building
9	Former Building 220	Garage Building
10	Former Building 406	Tin, Electrical and Annealing Shop Building
11	Former Building 407	Paint Shop and Pipe Shop
12	Former Building 410	Power House
13	Area A	One Former Fuel Oil AST (2,500 gallons) located near Former Building 233
14	Area B	One Former Fuel Oil AST (size unknown) located near Dock 131
15	Area C	Two Former Fuel Oil ASTs (size unknown) located near Former Building 417
16	Area D	Dumping Area
17	Area E	Former Coal Trestle and Storage Area – located near Former Building 410
18	Area F	Former Coal Storage Area – located near Former Building 215
19	Transformers 1, 2, 3	Three Former Transformers
Existing Structures / Not FUDS Eligible		
Building		**Historical Use**
Building 201		Empty Projectile Magazine
Building 212		Former Marine Barracks
Building 217		Fire Station and Labor Office Building
Building 222		Miscellaneous Storage Building
Building 508		Bag Charge Magazine
Building 603		Pyrotechnic Magazine

Table 2-1
Ecological Risk Assessment and Measurement Endpoints

Assessment Endpoint Number	Assessment Endpoints	Representative Receptors	Measurement Endpoints
AE1	Protection and maintenance (i.e., survival, growth, and reproduction) of terrestrial plant community from adverse effects to survival, growth, or reproduction from exposure to COPECs in soil	Terrestrial Plant community	Comparison of site soil EPCs to EcoSSLs protective of plants Comparison of site EPCs to BTVs for soil Evaluation of soil pH, TOC, and CEC to predict bioavailability potential of metals in soil
AE2	Protection and maintenance (i.e., survival, growth, and reproduction) of soil invertebrate community from adverse effects to survival, growth, or reproduction from exposure to COPECs in soil	Soil Invertebrate community	Comparison of site soil EPCs to EcoSSLs protective of soil invertebrates Comparison of site EPCs to BTVs for soil Evaluation of soil pH, TOC, and CEC to predict bioavailability potential of metals in soil
AE3	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of herbivorous mammals, represented by meadow vole (*Microtus pennsylvanicus*), from exposure to COPECs in soil and biota (i.e., plant tissue)	Meadow vole	HQs calculated by comparing modeled food web doses using soil EPCs to TRVs for mammals Evaluation of soil pH, TOC, and CEC to predict bioavailability potential of metals in dietary items Biota tissue EPCs used in food web model calculated using plant BAFs
AE4	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of insectivorous birds, represented by American robin (*Turdus migratorius*), from exposure to COPECs in soil and biota (i.e., earthworms)	American robin	HQs calculated by comparing modeled food web doses using soil EPCs to TRVs for birds Evaluation of soil pH, TOC, and CEC to predict bioavailability potential of metals in dietary items Biota tissue EPCs used in food web model calculated using soil invertebrate BAFs
AE5	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of insectivorous mammals, represented by short-tailed shrew (*Blarina brevicauda*), from exposure to COPECs in soil and biota (i.e., earthworms)	Short-tailed shrew	HQs calculated by comparing modeled food web doses using soil EPCs to TRVs for mammals Evaluation of soil pH, TOC, and CEC to predict bioavailability potential of metals in dietary items Biota tissue EPCs used in food web model calculated using soil invertebrate BAFs
AE6	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of carnivorous (predatory) mammals, represented by red fox (*Vulpes vulpes*), from exposure to COPECs in soil and biota (i.e., small mammal tissue)	Red fox	HQs calculated by comparing modeled food web doses using soil EPCs to TRVs for mammals Evaluation of soil pH, TOC, and CEC to predict bioavailability potential of metals in dietary items Biota tissue EPCs used in food web model calculated using small mammal BAFs
AE7	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of carnivorous (predatory) birds, represented by red-tailed hawk (*Buteo jamaicensis*), from exposure to COPECs in soil and biota (i.e., small mammal tissue).	Red-tailed hawk	HQs calculated by comparing modeled food web doses using soil EPCs to TRVs for birds Evaluation of soil pH, TOC, and CEC to predict bioavailability potential of metals in dietary items Biota tissue EPCs used in food web model calculated using small mammal BAFs

Table 2-1
Ecological Risk Assessment and Measurement Endpoints

Assessment Endpoint Number	Assessment Endpoints	Representative Receptors	Measurement Endpoints
AE8	Protection of and maintenance (i.e., survival, growth, and reproduction) of populations of herptiles (amphibians and reptiles) from exposure to COPECs in soil, surface water, and sediment (qualitative evaluation due to minimal toxicological endpoints)	Herptile populations	Qualitative evaluation based upon: Amphibians: comparison of surface water EPCs to relevant screening values Reptiles: comparison of modeled food web doses for other receptors (i.e., birds) to TRVs. Evaluation of supplemental soil and sediment parameters to predict bioavailability potential of metals
AE9	Protection and maintenance (i.e., survival, growth, and reproduction) of aquatic plant community from exposure to COPECs in sediment and surface water	Aquatic plant community	Comparison of site sediment EPCs to effects level concentrations for benthos Comparison of surface water EPCs to site-specific freshwater chronic surface water quality criteria Evaluation of grain size, AVS/SEM, and TOC to predict bioavailability potential of metals in sediment
A10	Protection and maintenance (i.e., survival, growth, and reproduction) of benthic invertebrate community from COPECs in sediment	Benthic invertebrate community	Comparison of site sediment EPCs to effects level concentrations for benthos Comparison of site EPCs to BTVs for sediment Evaluation of grain size, AVS/SEM, and TOC to predict bioavailability potential of metals in sediment

Table 2-1
Ecological Risk Assessment and Measurement Endpoints

Assessment Endpoint Number	Assessment Endpoints	Representative Receptors	Measurement Endpoints
AE11	Protection and maintenance (i.e., survival, growth, and reproduction) of zooplankton community from exposure to COPECs in surface water	Zooplankton community	Comparison of surface water EPCs to site-specific freshwater chronic surface water quality criteria Comparison of site EPCs to BTVs for surface water
AE12	Protection and maintenance (i.e., survival, growth, and reproduction) of demersal fish community from exposure to COPECs in surface water and sediment	Demersal fish community	Comparison of surface water EPCs to site-specific freshwater chronic surface water quality criteria Comparison of site EPCs to BTVs for surface water
			Comparison of sediment EPCs to effects level concentrations for benthos Comparison of site EPCs to BTVs for sediment
AE13	Protection and maintenance (i.e., survival, growth, and reproduction) of pelagic fish community from exposure to COPECs in surface water	Pelagic fish community	Comparison of surface water EPCs to site-specific freshwater chronic surface water quality criteria
			Comparison of site EPCs to BTVs for surface water
AE14	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of herbivorous birds, represented by mallard duck (*Anas platyrhynchos*), from exposure to COPECs in sediment and biota (i.e., plant tissue)	Mallard duck	HQs calculated by comparing modeled food web doses using sediment EPCs to TRVs for birds
			Biota tissue EPCs used in food web model calculated using plant BAFs
AE15	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of herbivorous mammals, represented by muskrat (Ondatra zibethicus), from exposure to COPECs in sediment and biota (i.e., plant tissue)	Muskrat	HQs calculated by comparing modeled food web doses using sediment EPCs to TRVs for mammals
			Biota tissue EPCs used in food web model calculated using plant BAFs
AE16	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of insectivorous birds, represented by lesser scaup (*Aythya affinis*), from exposure of COPECs in sediment and biota (i.e., benthic invertebrates)	Lesser scaup	HQs calculated by comparing modeled food web doses using sediment EPCs to TRVs for birds
			Biota tissue EPCs used in food web model calculated using BSAFs
AE17	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of piscivorous mammals, represented by river otter (*Lontra canadensis*), from exposure to COPECs in sediment and biota (i.e., fish tissue)	River otter	HQs calculated by comparing modeled food web doses using sediment EPCs to TRVs for mammals
			Biota tissue (i.e., fish) EPCs used in food web model calculated using BCFs
AE18	Protection and maintenance (i.e., survival, growth, and reproduction) of populations of piscivorous birds, represented by great blue heron (*Ardea herodias*), from exposure to COPECs in sediment and biota (i.e., fish tissue)	Great blue heron	HQs calculated by comparing modeled food web doses using sediment EPCs to TRVs for birds
			Biota tissue (i.e., fish) EPCs used in food web model calculated using BCFs

NOTE:
AVS/SEM = acid volatile sulfides/simultaneously extracted metals
BAF = bioaccumulation factor
BCF = bioconcentration factor
BSAF = biota sediment accumulation factor
BTV= background threshold value
CEC = cation exchange capacity
COPEC = constituent of potential ecological concern
EcoSSL = ecological soil screening level
EPC = exposure point concentration
HQ = hazard quotient
TOC = total organic carbon
TRV = toxicity reference value

Total PCBs	40	0.33	0.371	0.041
1,3-Dinitrobenzene (DNB)	--	0.034	0.072	0.079

Notes:

1. Supplemental values for LMW PAH, HMW PAH, and chromium from Efroymson et al. 1998a, 1998b

2. Chromium and mercury based on total

3. LMW and HMW PAH values not available for birds. Value for LMW PAHs is based on naphthalene from Los Alamos National Laboratory (LANL; 2018). Value for HMW PAHs based on benzo(a)anthracene from LANL.

-- indicates no value is available

HMW = High molecular weight

mg/kg = Milligram(s) per kilogram

LMW = Low molecular weight

PAH = Polycyclic aromatic hydrocarbon

Notes:

Ecological screening values for freshwater, chronic exposure. **Bold values selected.** Hierarchy for selected values is as follows:

1. NRWQC, current values. available: https://www.epa.gov/wqc/national-recommended-water-quality-criteria-aquatic-life-criteria-table

2. Values from the publication by Suter et al. 1996. Toxicological benchmarks for screening potential contaminants of concern for effects on aquatic biota: 1996 Revision. ES/ER/TM-96/R2. https://rais.ornl.gov/documents/tm96r2.pdf. This source was used when no other values were available.

3. Great Lakes Initiative (GLI), Clearinghouse Resources Tier II criteria revised 2013. Available: https://www.epa.gov/gliclearinghouse. These values were selected over Canadian Council of Ministries of the Environment (2003), per USACE NAE.

µg/L = Microgram(s) per liter

EPA = U.S. Environmental Protection Agency

*The following NRWQC were hardness adjusted using a 95%LCL of 71 mg/L $CaCO_3$ for hardness:

Cadmium: EXP[0.7977 x ln(71)-3.909] x [1.101672-(ln(71) x 0.041838)] = 0.6 µg/L

Chromium: EXP[0.819 x ln(71)+0.6848] x 0.86 = 56 µg/L

Lead: EXP[1.273 x ln(71)-4.705] x [1.46203-[(ln(71) x 1.45712)] = 1.73 µg/L

Nickel: EXP[0.846 x ln(71) + 0.0584] x 0.997 = 38.9 µg/L

Zinc: EXP[0.8473 x ln(71) + 0.884] x 0.986 = 88.4 µg/L

Table 4-4. Constituents of Potential Ecological Concern in Soil

Notes:
1. Calcium, magnesium, iron, potassium, and sodium eliminated as essential nutrients.
2. Aluminum, barium, cobalt, manganese, and vanadium eliminated as non-CERCLA metals.
3. DUs 17, 18, and 19 contain both surface (SS) and subsurface (SB) soil. Intervals screened separately.
4. Methods for the comparison to background described in the text (Section 4.3.1 and results presented in Attachment F).
Y = Yes, when exceeds screening level or background, cell is highlighted orange. When exceeds screening level and background, highlighted blue.
N = No, not a COPEC
95UCL = 95th upper confidence limit of the mean
mg/kg = Milligram(s) per kilogram
CERCLA = Comprehensive Environmental Response, Compensation, and Liability Act
COPEC = Constituent of potential ecological concern
Bold type indicates where a constituent exceeded background and screening level and was carried through to the RSLERA

Notes:

µg/L = Microgram(s) per liter

COPEC = Constituents of potential ecological concern

EPC = Exposure point concentration

HQ = Hazard Quotient; rounded to one significant digit.

NA = Not available

Bold type indicates analytes identified as COPECs where HQ>1 and concentrations exceed background, based on statistical comparisons

Table 5-1. Wildlife Exposure Parameters – Terrestrial Receptors

Exposure Parameter	Value	Units	Notes
MEADOW VOLE (*Microtus pennsylvanicus*) Surrogate for Small Herbivorous Mammals			
Body Weight	0.033	Kg	Average of common range of weights (EPA 1993)
Food Ingestion Rate	0.023	kg dry wt./kg-day	Converted assuming 85% plant moisture (EPA 2007)
Food Ingestion Rate	0.15	kg wet wt./kg-day	Green and Millar 1987
Diet Proportion	100	% plant	EPA 1993
Incidental Soil Ingestion Rate	2	% of total mass of diet	Beyer et al. 1994
Habitat Range	1	Acre	Assumed (EPA 1993)
AMERICAN ROBIN (*Turdus migratorius*) Surrogate for Insectivorous Birds			
Body Weight	0.077	Kg	EPA 1993 (mean in Pennsylvania)
Food Ingestion Rate	0.14	kg dry wt./kg-day	Converted assuming 84% prey moisture (EPA 2007)
Food Ingestion Rate	0.89	kg wet wt./kg-day	EPA 1993 (mean in California)
Diet Proportion	93/7	% invert/veg	EPA 1993 (eastern US). Spring diet proportions used for most sensitive life stage and use as surrogate for protected species.
Incidental Soil Ingestion Rate	10.5	% of total mass of diet	Value base on woodcock (Sample and Suter 1994)
Site Use Factor	0.67	Unitless	Assumed to be migratory 8 of 12 months
Habitat Range	1	Acre	Assumed (EPA 1993)
SHORT-TAILED SHREW (*Blarina brevicauda*) Surrogate for Small Carnivorous Mammals			
Body Weight	0.017	Kg	EPA 1993, average of reported range
Food Ingestion Rate	0.099	kg dry wt./kg-day	Converted assuming 84% prey moisture (EPA 2007)
Food Ingestion Rate	0.62	kg wet wt./kg-day	EPA 1993 (Ohio lab)
Diet Proportion	78/17/5	% invert/plant/mammal	EPA 1993 (proportions for insects, vegetable matter, and small mammals from Hamilton 1941)
Incidental Soil Ingestion Rate	3	% of total mass of diet	EPA 2007 (90^{th} percentile)
Habitat Range	1	Acre	Assumed (EPA 1993)
RED-TAILED HAWK (*Buteo jamaicensis*) Surrogate for Predatory Birds			
Body Weight	1.2	Kg	EPA 1993 (Ohio)
Food Ingestion Rate	0.032	kg dry wt./kg-day	Converted assuming 68% prey moisture (EPA 2007)
Food Ingestion Rate	0.1	kg wet wt./kg-day	Average of ingestion rates (EPA 1993)
Diet Proportion	100	% small mammal	EPA 1993
Incidental Soil Ingestion Rate	5.7	% of total mass of diet	EPA 2007 (90^{th} percentile)
Habitat Range	500 to >2,000	Acre	EPA 1993 (range presented)
RED FOX (*Vulpes vulpes*) Surrogate for Predatory Mammals			
Body Weight	4.5	Kg	Average of common range of weights (EPA 1993)
Food Ingestion Rate	0.045	kg dry wt./kg-day	Converted assuming 68% prey moisture (EPA 2007)
Food Ingestion Rate	0.14	kg wet wt./kg-day	Sample and Suter 1994
Diet Proportion	100	% small mammal	EPA 1993
Incidental Soil Ingestion Rate	2.8%	% of total mass of diet	Value from Beyer et al. 1994
Habitat Range	125 - 740	Acre	EPA 1993 (range presented)

Notes: % = Percent
EPA = U.S. Environmental Protection Agency
kg = Kilogram(s)
wt. = Weight

Table 5-2. Wildlife Exposure Parameters - Aquatic Receptors

RIVER OTTER (PISCIVOROUS MAMMAL)	Value	Unit	Notes
Body Weight	7.43	kg	EPA, 1993 average of adult male and female body weights for eastern US.
Food Ingestion Rate	0.0481	kg dry wt/kg-day	EPA, 1993 allometric equation for all mammals [Equation 3-7]
Incidental Sediment Ingestion Rate	2.00%	% of total mass of diet	Assumed, conservative estimate
Habitat Range	859	acres	EPA, 1993 average of adult male and female ranges for Texas, converted to acres
Water Ingestion Rate	0.081	L/kg-day	EPA 1993, average of male and female rates
GREAT BLUE HERON (PISCIVOROUS BIRD)			
Body Weight	2.229	kg	EPA, 1993, value for eastern North America
Food Ingestion Rate	0.0360	kg dry wt./kg-day	Converted assuming 80% fish moisture (Holcombe 1976)
Food Ingestion Rate	0.18	kg wet wt./kg-day	EPA, 1993
Incidental Sediment Ingestion Rate	2.00%	% of total mass of diet	Assumed, conservative estimate
Habitat Range	11	acres	EPA, 1993, average of values provided
Water Ingestion Rate	0.045	L/kg-day	EPA, 1993
MUSKRAT (HERBIVOROUS MAMMAL)			
Body Weight	1.17	kg	EPA 1993, average of adult male and female weights given throughout year
Food Ingestion Rate	0.045	kg dry wt./kg-day	EPA 1993, converted assuming 85% plant moisture (EPA 2007)
Food Ingestion Rate	0.3	kg wet wt./kg-day	EPA 1993, average of greens and green and corn ingestion rates
Incidental Soil Ingestion Rate	2.00%	% of total mass of diet	Beyer et al. 1994, value for woodchuck
Habitat Range	0.33	acres	EPA, 1993, average of values provided
Water Ingestion Rate	0.975	L/kg-day	EPA 1993, average of male and female rates
MALLARD DUCK (HERBIVOROUS BIRD)			
Body Weight	1.134	kg	EPA 1993, average of adult male and female weights given throughout year
Food Ingestion Rate	0.049	kg dry wt./kg-day	Calculated using allometric equation for all birds from Nagy 2001
Incidental Soil Ingestion Rate	3.30%	% of total mass of diet	Beyer et al. 1994
Habitat Range	1075	acres	EPA 1993, average of values provided
Water Ingestion Rate	0.0565	L/kg-day	EPA 1993, average of adult male and female rates
LESSER SCAUP (INSECTIVOROUS BIRD)			
Body Weight	0.815	kg	EPA, 1993 average of male and female body weights in US
Food Ingestion Rate	0.0625	kg dry wt/kg-day	EPA, 1993 allometric equation for all birds [Equation 3-3]
Incidental Sediment Ingestion Rate	2.00%	% of total mass of diet	Assumed, conservative estimate
Habitat Range	219	acres	EPA, 1993 converted to acres
Water Ingestion Rate	0.0630	L/kg-day	EPA, 1993 average of adult male and female rates

Notes:

% = Percent

EPA = U.S. Environmental Protection Agency

kg = Kilogram(s)

kg dry wt./kg-day = kilograms dry weight/kilograms body weight per day

L = Liter(s)

HMW PAH	ln(Cp) = 0.9469*ln(Cs)-1.7026	EPA 2007a	2.6	EPA 2007a	0	EPA 2007a
Total PCBs	log(Cp)=1.588-0.578*LogKow	Travis and Arms 1988	ln(Cw) = (1.410+1.361*ln(Cs))	Sample et al 1998a	log(Cm)=-7.6+LogKow	Travis and Arms 1988

Notes:

1. Sources are original sources as presented in EPA (2007a)
2. For PCBs: values are based on average Kow of several Aroclors:

PCB	LogKow
Aroclor 1242	6.335
Aroclor 1254	6.9795
Aroclor 1268	6.8
Average	6.7

Cm = concentration in mammal
Cp = concentration in plant
Cw = concentration in worm
BAF = bioaccumulation factor
COPEC = Constituent of potential ecological concern
EPA = U.S. Environmental Protection Agency
HMW = High molecular weight
LMW = Low molecular weight
ln = Natural log
mg/kg = Milligram(s) per kilogram
PAH = Polycyclic aromatic hydrocarbon
PCB = Polychlorinated biphenyl

Table 5-4. Aquatic Uptake Factors

COPEC	Plant BAFs	Plant BAFs Source	Benthic Invertebrate BCFs ([mg COPC/Kg tissue wet wt]/[mg COPC/kg sediment])[c]	Benthic Invertebrate Uptake ([mg COPC/kg tissue dry wt]/[mg COPC/kg sediment])[d]	Fish BCFs ([mg COPC/Kg tissue wet wt]/[mg COPC/L])[c]	Fish Uptake ([mg COPC/kg tissue dry wt]/[mg COPC/L])[e]
Antimony	ln(Cp) = 0.938 * ln(Cs) - 3.233	a	0.9	5.39	40	200
Arsenic	Cp = 0.03752 * Cs	b	0.9	5.39	114	570
Beryllium	ln(Cp) = 0.7345 * ln(Cs) - 0.5361	a	0.9	5.39	62	310
Cadmium	ln(Cp) = 0.546 * ln(Cs) - 0.475	b	3.4	20.36	907	4535
Chromium	Cp = 0.041 * Cs	b	0.39	2.34	19	95
Copper	ln(Cp) = 0.394 * ln(Cs) + 0.668	b	0.3	1.80	710	3550
Lead	ln(Cp) = 0.561 * ln(Cs) - 1.328	b	0.63	3.77	0.09	0.45
Nickel	ln(Cp) = 0.748 * ln(Cs) - 2.223	b	0.9	5.39	78	390
Selenium	ln(Cp) = 1.104 * ln(Cs) - 0.677	b	0.9	5.39	129	645
Silver	Cp = 0.014 * Cs	b	0.9	5.39	87.71	438.55
Zinc	ln(Cp) = 0.554 * ln(Cs) + 1.575	b	0.57	3.41	2059	10295

Notes:

a - Regression derived from measured data by EPA (2007)

b - Bechtel-Jacobs 1998a

c - Invertebrate and Fish BCF (US EPA 1999)

d - Invertebrate BCFs converted to mg/kg dry weight assuming a moisture content of 83.3% (Pietz et al. 1984)

e - Fish BCFs converted to mg/kg dry weight assuming a moisture content of 80% (Holcombe 1976)

COPEC = Contaminant of potential ecological concern

mg/L= Milligram(s) per liter

mg/kg dry wt = Milligram(s) per kilogram dry weight

Table 5-5. Summary of Physical Parameters in Soil

	Location	DU-4	DU-7	DU-9	DU-11	DU-13	DU-17	DU-18	DU-19
	Unit	Mean	Mean	Mean	Mean	Mean	Mean	Mean	Mean

CEC Analytical[1]	MEQ/100g	NA	NA	NA	NA	NA	NA	NA	NA
CEC Calculation[2]	MEQ/100g	106.38	174.71	90.79	286.05	94.57	588	135	133
CEC Re-analysis[3]	MEQ/100g	33	24	28	27	36	38	53	33
Grain Size									
Gravel	%	9.2	9.66	6.84	2.01	6.17	9.97	3.97	1.86
Sand Coarse	%	1.8	5.25	0.70	1.72	5.48	11.8	10.5	1.73
Sand Medium	%	18.1	25.8	15.4	28.2	29.7	36.1	61.3	32.1
Sand Fine	%	23.9	20.1	26.2	19.8	19.9	14.4	7.7	23
Silt	%	39.7	30.0	46.9	45.4	36.7	26.2	14.6	39.5
Clay	%	7.32	9.12	4.01	2.89	1.98	1.5	1.97	1.73

Notes:

1. Initial laboratory CEC results were deemed abnormally high by several orders of magnitude. Analytical results were rejected during data validation.
2. CEC for onsite soil was calculated using Phase I metals analytical results (calcium, magnesium, potassium, sodium).
3. The laboratory re-analyzed CEC samples after correcting an error with reagents. Analytical results are from re-analysis. However, laboratory holding times and conditions are unknown.

% = Percent

CEC = cation exchange capacity

g = Gram(s)

MEQ = milliequivalents

mg/kg = Milligram(s) per kilogram

mV = Millivolt(s)

NA = Not available

Notes:

µmoles/g = Micromole(s) per gram
AVS = Acid volatile sulfide
CAS = Chemical Abstracts Service
EPA = U.S. Environmental Protection Agency
f_{OC} = Fraction organic carbon
ID = Identification
in. = Inch(es)
J = Estimated: The analyte was positively identified; the quantitation is an estimation
NA = Not applicable
No. = Number
SEM = Simultaneously extracted metals
TOC =Total organic carbon
UJ = Analyte not detected, and associated numerical value (Limit of Detection or Limit of Quantitation) is approximate
Red font indicates SEM:AVS ratio > 1
Highlighted cells indicate $(\sum SEM\text{-}AVS)/f_{OC}$ > 3000 µmoles/g and metals are bioavailable/toxic (EPA 2005)

USACE New England District Ecological Risk Assessment Flowcharts

This page intentionally left blank

Figure 1: Screening Level Ecological Risk Assessment (SLERA) Flow Chart

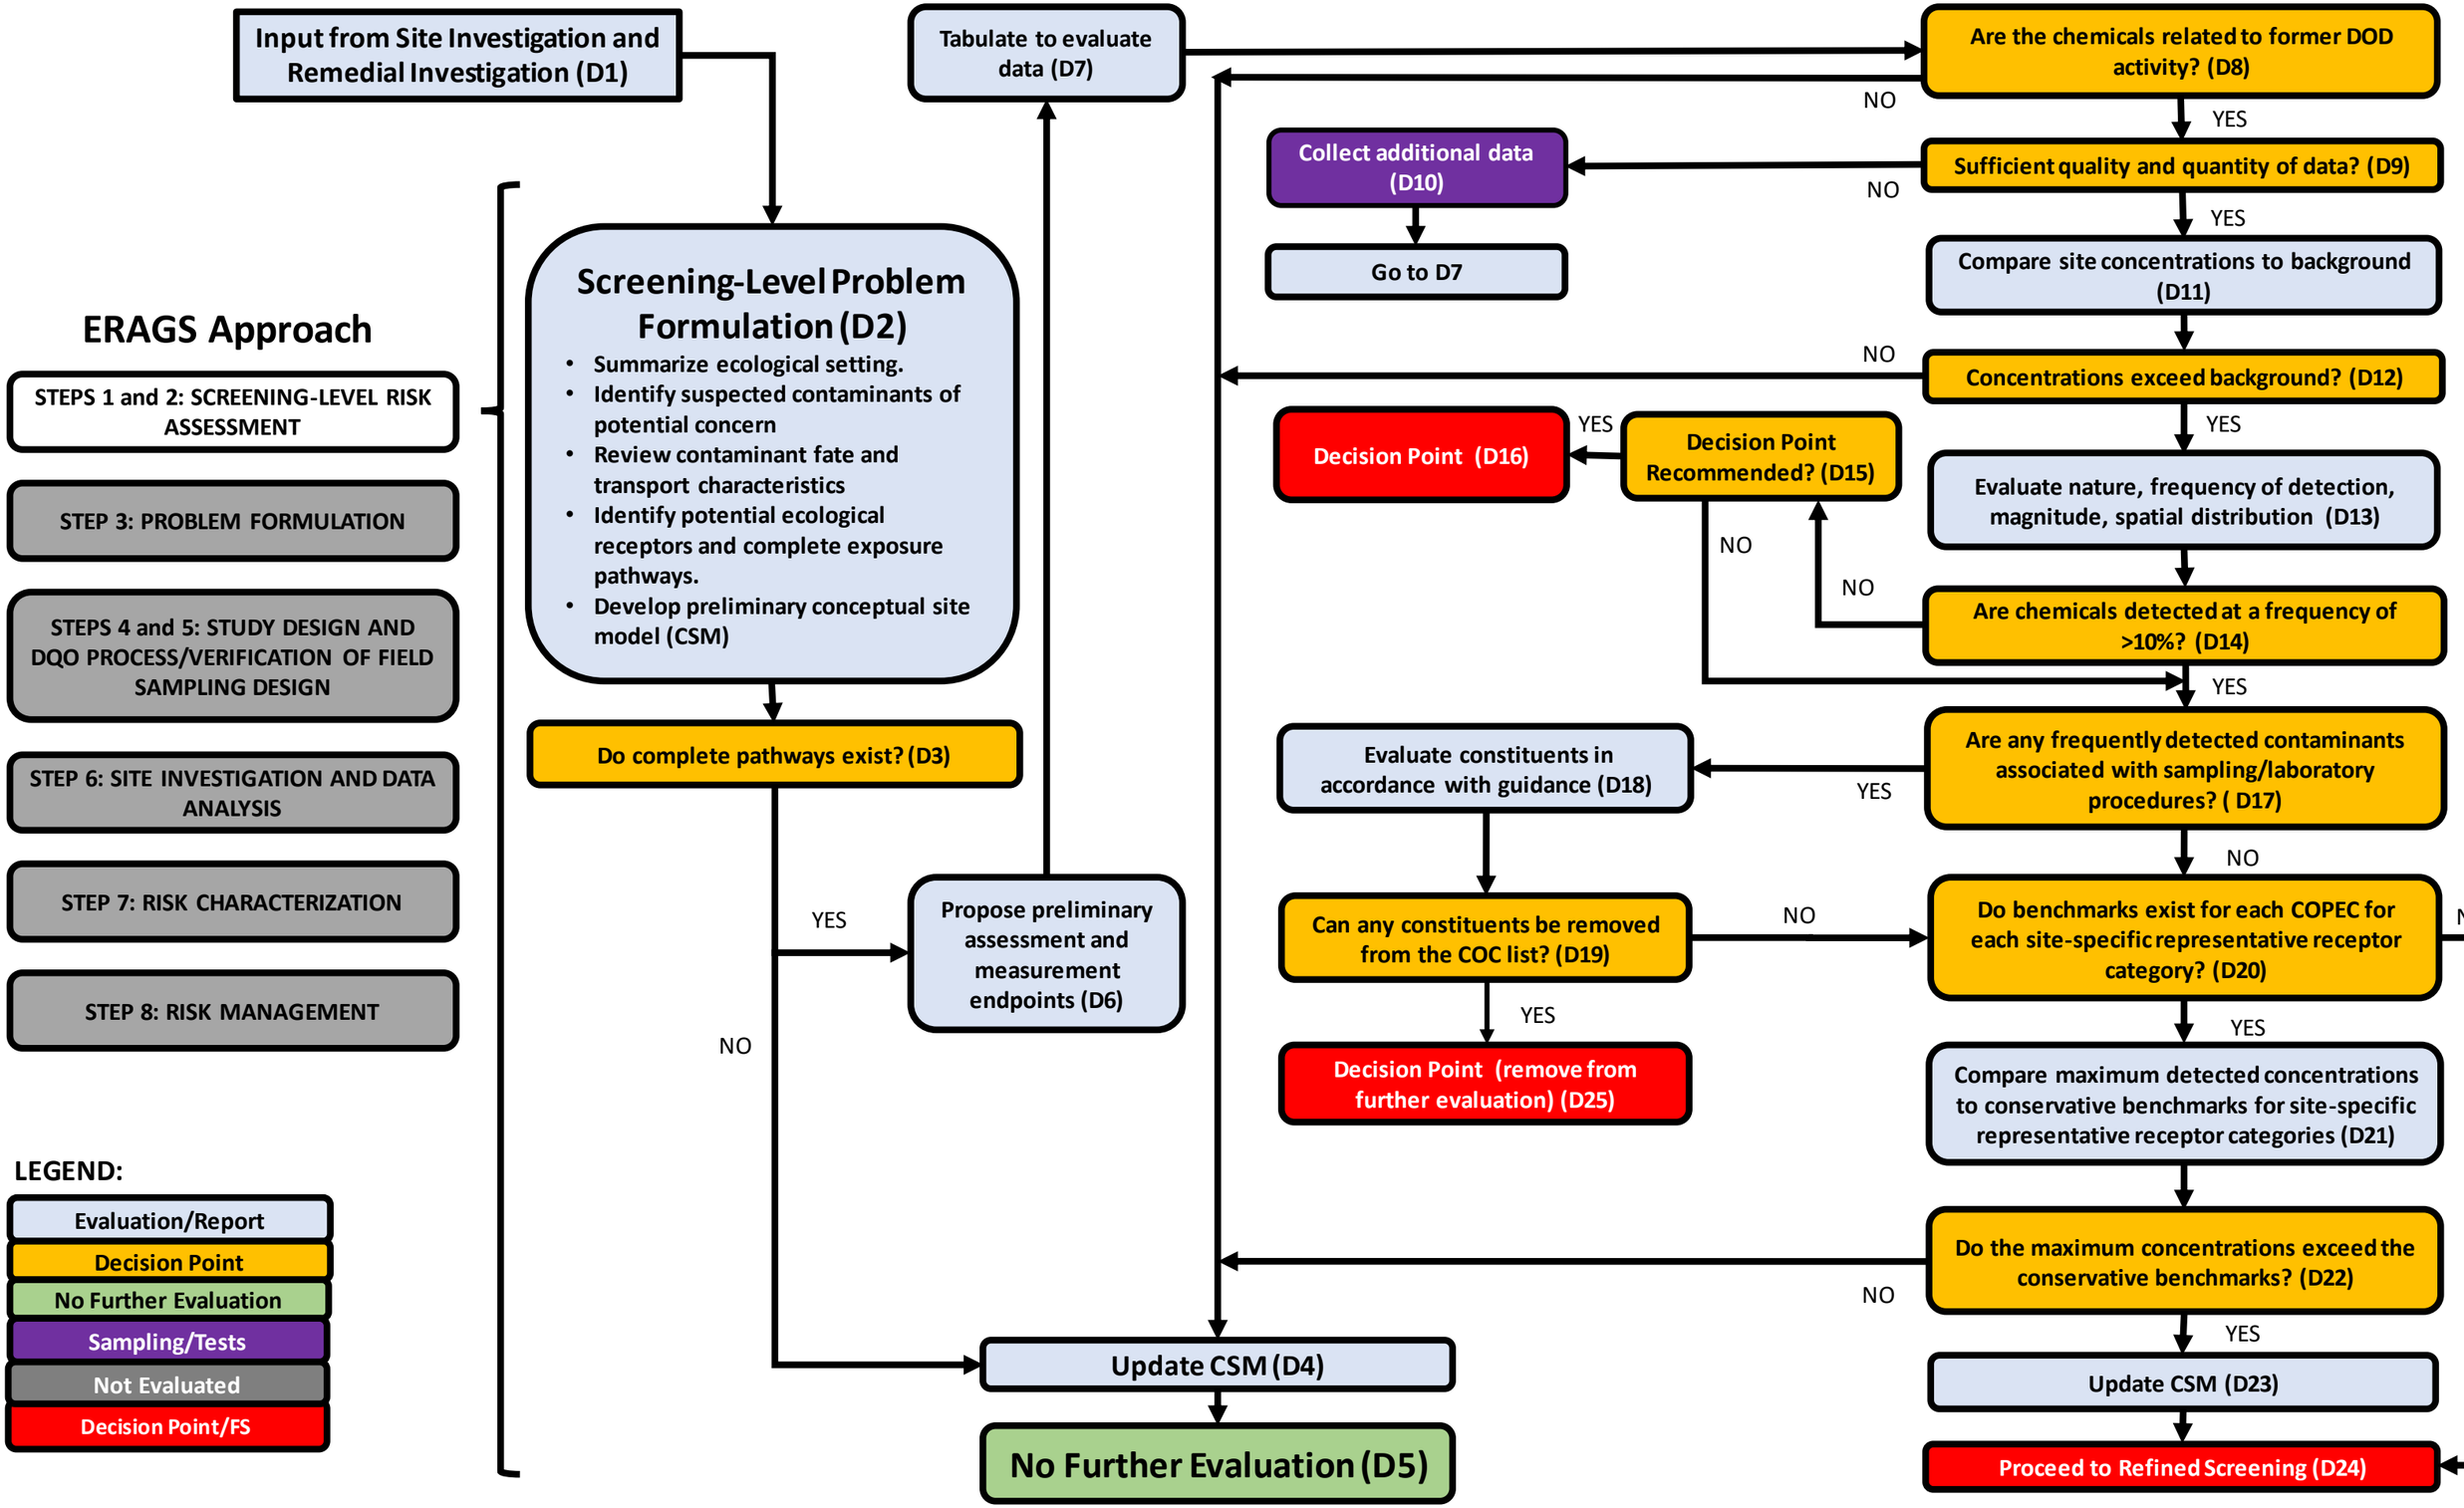

Figure 2: Refined Screening Level Ecological Risk Assessment (RSLERA) Flow Chart

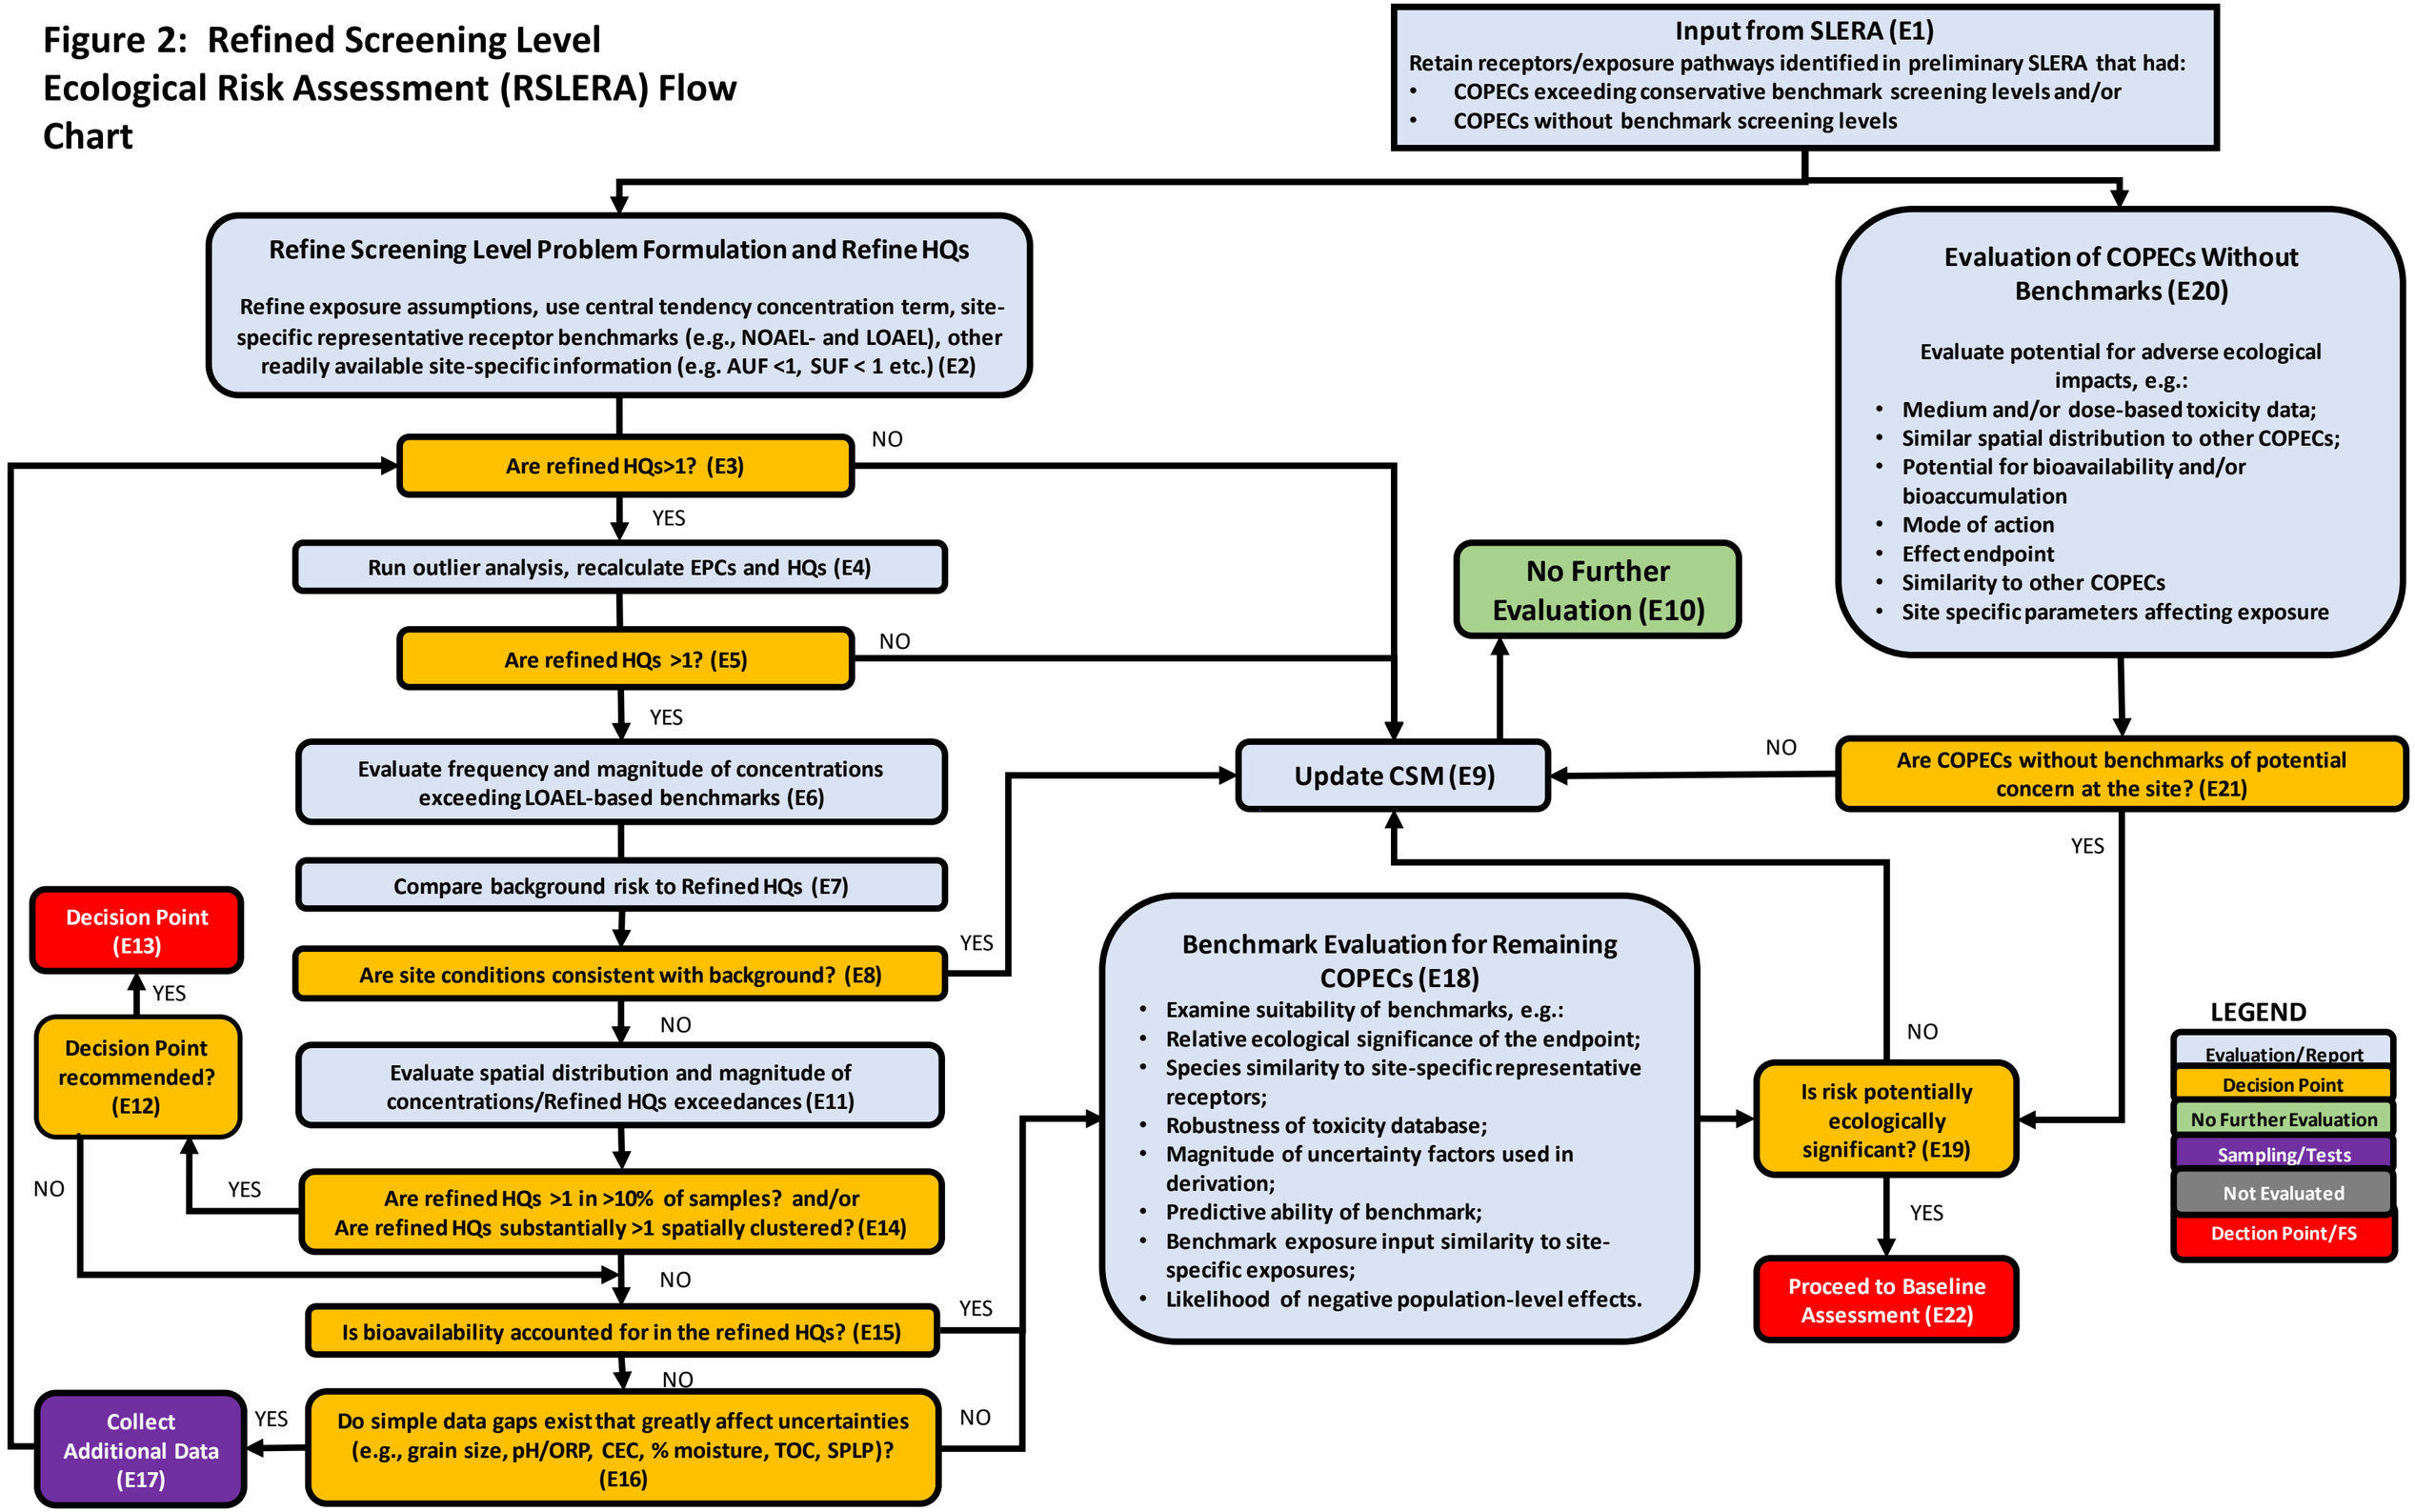

Figure 3: Baseline Ecological Risk Assessment (BERA) Flow Chart

ERAGS Approach

- STEPS 1 and 2: SCREENING-LEVEL RISK ASSESSMENT
- STEP 3: PROBLEM FORMULATION
- STEPS 4 and 5: STUDY DESIGN AND DQO PROCESS/VERIFICATION OF FIELD SAMPLING DESIGN
- STEP 6: SITE INVESTIGATION AND DATA ANALYSIS
- STEP 7: RISK CHARACTERIZATION
- STEP 8: RISK MANAGEMENT

Input from RSLERA (F1)
Evaluate receptors and pathways for COPECs that indicate the potential for ecologically significant risk.

Perform a Baseline Problem Formulation, e.g.: evaluate toxicity and bioaccumulation; determine final assessment and measurement endpoints; complete exposure pathways; refine conceptual site model; and ask questions/form hypotheses to direct data collection, analyses, and risk evaluation (F2)

Develop sampling and analysis plan based upon completed exposure pathways (F3)

Surface Water (F4)

Data Collection Options
e.g.,
- Toxicity testing (survival, growth, reproduction)
- Bioaccumulation evaluation
- Tissue analysis (epibenthic, fish)
- Community assessment (epibenthic, fish)
- Fish health profile
- Fish growth and age metrics evaluation
- Biomarker assessment

Sediment (F5)

Data Collection Options
e.g.,
- Toxicity testing (survival, growth, reproduction)
- Bioaccumulation evaluation
- Tissue analysis (benthic, fish)
- Community assessment (benthic, fish)
- Toxicity Identification Evaluation (TIE)

Soil (F6)

Data Collection Options
e.g.,
- Toxicity testing (survival, growth, reproduction)
- Bioaccumulation evaluation
- Tissue analysis (plant, invertebrate, bird, mammal)
- Vegetative community analysis
- Assess populations (numbers, biomass)
- Dietary tissue analysis

Using the various lines of evidence, evaluate if a risk exists for each Assessment and/or Measurement Endpoint (F7)

Is risk potentially ecologically significant? (F8)

NO

YES

Update CSM (F9)

No Further Evaluation (F10)

Develop Preliminary Remediation Goals (PRGs)/Perform Feasibility Study for Retained Receptors (F11)

LEGEND:

- Evaluation/Report
- Decision Point
- No Further Evaluation
- Sampling/Tests
- Not Evaluated

Amanda Kohn, EA

SUBJECT: Iona Island Shoreline Reconnaissance Survey

On 6-7 April 2020, two scientists from EA Engineering, Science, and Technology, Inc., PBC (EA) conducted a Shoreline Reconnaissance Survey at the Iona Island Naval Ammunition Depot, Formerly Used Defense Site. The project site is located in Stony Point, Rockland County, New York (Figure 1). Prior to conducting the survey, four "Recon Areas" were established (Figure 2) in the Hazardous Toxic and Radioactive Waste (HTRW) Remedial Investigation (RI) Uniform Federal Policy (UFP) - Quality Assurance Project Plan (QAPP) for the project site (EA, 2020). These areas include:

- Area 1 – Hudson River Shoreline
- Area 2 – Iona Marsh Shoreline
- Area 3 – Western Shoreline between Iona and Round Island
- Area 4 – CSX Railroad Tracks (West and East side)

In addition to surveying the four identified shoreline Recon Areas, EA personnel also generally characterized the upland conditions throughout Iona and Round Islands and conducted a reconnaissance of potential background sediment sampling locations.

The purpose of the Shoreline Reconnaissance Survey was to identify potential areas of sediment accumulation that could be suitable for sampling along the shoreline, identify and document habitat areas for potential ecological receptors, and identify potential preferential pathways to the shoreline from the upland portion of the island.

Should the results of the Phase I soil sampling investigation on the uplands portion of Iona Island indicate source-pathway-receptor interaction, including a pathway from Iona Island to the shoreline, potential habitat and/or receptors, and if physical parameters indicate a sink of contaminants, then sediments samples will be collected for chemical parameters as part of the Phase II investigation to evaluate potential site impacts to the Iona Island shoreline that are representative of significant habitat, could present a potential exposure pathway to human or ecological receptors, and could potentially be impacted by site-related contaminants.

During the survey, EA personnel traversed the shoreline areas on foot to identify potential areas of interest. EA marked areas of interest with orange and white survey flagging which were also recorded with a sub-meter accurate GPS unit. The areas of interest were geo-referenced on an aerial photograph provided in Appendix A (Figure 3). Photographs of key features are presented in Appendix B and the location of each photograph was mapped on Figure 4.

Area 1 – Hudson River Shoreline

Recon Area 1 consists of the shoreline along the Hudson River, which is located on the east side of Iona Island. The majority of the shoreline in this Recon Area consists of a stone river wall which was measured as approximately 6 feet in height (Photo 5). EA identified approximately 1,100 feet of river wall, although the wall is not contiguous along the shoreline—three large breaks in the wall were identified where the wall has partially collapsed (Photo 6). Additionally, small gaps between the stones were also observed along the length of the wall where the Hudson River passes through the wall at high tide and forms pockets of water behind the wall. EA observed large areas of cobble and boulder-sized stone at the northern and southern ends of the river wall as well as at the identified wall breaks. The large stones were mostly submerged during high tide but exposed during low tide (Photos 1 and 2). EA identified amphipods and aquatic snails on the underside of many of the large stones when flipped over (Photos 3 and 4). However, there was little silty or fine sediment in this area, with the majority of the substrate consisting of cobble and course-grained sand.

The majority of the area along the river wall consists of exposed bedrock (Photo 11) and gravel with the exception of some small pockets of sediment deposition. EA identified three small distinct areas of sediment deposition along the shoreline of Recon Area 1 (Photos 14 and 17). Each of these areas was identified for sediment sampling for grain size and total organic carbon (TOC). Sediment sampling was conducted on 7 April 2020.

EA also identified 6 potential outfall pipes along the river wall area of Recon Area 1. Pipe 1 was identified as an 18-inch concrete pipe located on the northern end of the river wall (Photo 6). This outfall pipe extends approximately 8 feet into the Hudson River during high tide. Pipe 2 was identified as a 12-inch steel pipe located in the central portion of Recon Area 1, near the historic causeway/pier (Photo 8). Additional steel piping and cables were observed in this area. It was unclear during the survey if this 12-inch pipe was part of the causeway road infrastructure (conduit piping) or an outfall discharge pipe. Approximately 30 feet south of Pipe 2, three additional discharge pipes were observed—two 8-inch steel pipes were identified in the wall and one 10-inch terracotta pipe was identified partially exposed in the ground above the wall (Photos 9 and 10). Lastly, Pipe 3 is a 14-inch concrete pipe identified at the southern end of the wall (Photo 12).

The pipes were identified as potential preferential pathways leading to the shoreline although their origins could not be identified at the time of the field survey. Based on the locations of mapped former buildings/structures identified on Figure 2, Pipes 1 and 3 appear to be in the areas of former buildings/structures. Pipe 2 does not appear to be in an area with former buildings/structures.

Area 2 – Iona Marsh Shoreline

Recon Area 2 consists of the shoreline area along the west side of Iona Island. This area is divided by a railroad embankment which supports an active CSX rail line. The western side of the railroad tracks and south of the entrance road consists of a tidal marsh (Photo 23) dominated by cattails (*Typha spp.*); the area east of the railroad tracks (Photo 18) is dominated by an extremely dense monotypic stand of common reed (*Phragmites australis*). The western side of the railroad tracks and north of the entrance road is dominated by phragmites as well. Recon Area 2 consists of typical tidal marsh areas common along the Hudson River. A fine-grained sediment bottom is present throughout the marsh (Photo 30). Three sediment sample locations were selected in this area to document sediment characteristics.

Although no outfall pipes were identified during the recon survey along the shoreline of Recon Area 2, a potential preferential pathway was identified. One groundwater seep was observed on the northwestern portion of Recon Area 2, in the vicinity of the entrance road to Iona Island (Photo 23). This groundwater seep was identified along the upland slope between the marsh and the existing railroad tracks. EA staff observed groundwater discharge along the upland slope into the marsh and a sediment sample was taken at this location. An outfall pipe was not observed in this location.

Area 3 – Western Shoreline Between Iona and Round Island

Recon Area 3 consists of the shoreline area on the southwest side of Iona Island and western portion of Round Island. This area includes the low portion of land between the two islands. Unlike Recon Areas 1 and 2, this area is not a true shoreline, as historic fill and disturbance has significantly altered this area. Recon Area 3 consists of a mix of *Phragmites* tidal wetland on the southern and western end of the area, a tidal wetland swale consisting of various plant species, and a rip-rap filled drainage swale.

Although no outfall pipes were identified during the survey along the shoreline of Recon Area 3, two potential preferential pathways were identified. The southern end of Iona Island appears to drain down towards the *Phragmites* dominated low point between Iona Island and Round Island. This area slopes slightly to the south east to a rip-rap filled drainage swale (Photo 20) that directs flow to the south, towards the tidal marsh associated with Recon Area 2. A tidal wetland swale also identified along Recon Area 3 appears to convey flow to the west toward the tidal marsh associated with Recon Area 2.

Just north of Recon Area 3, EA identified a *Phragmites* filled wetland depression on the north side of the Iona Island perimeter road. This depression appears to collect surface runoff from Iona Island, but EA staff were unable to identify a culvert beneath the road connecting this depression to the tidal wetland swale within Recon Area 3.

Area 4 – CSX Railroad Tracks (West and East Side)

Recon Area 4 includes the areas along the east and west side of the railroad track embankment and primarily consists of rip-rap along an upland embankment. The northern portion of Recon Area 4 includes a scrub-shrub upland along the edge of the rip-rap (Photo 24); the southern end of the recon area includes a transition from rip-rap to existing marsh areas associated with Recon Area 2 (Photo 19).

EA did not identify any discharge outfall pipes along Recon Area 4. No culverts were identified beneath the railroad embankment that could connect drainage from Iona Island on the east of the railroad embankment to the marsh on the western side of the railroad embankment. EA identified only one hydrological connection through the railroad embankment, connecting the cattail marsh to the west with the *Phragmites* marsh on the east. This connection is located outside the project area at an embankment opening (i.e., shallow bridge) approximately 1,500 feet away, across the marsh from Round Island.

Flora and Fauna Observations

In addition to identifying potential pathways and characterizing the shoreline conditions of the site, EA's environmental scientists also documented wildlife to determine potential ecological receptors at the site. Wildlife observations included incidental observations and did not include a formal survey for specific species. In general, the observations made are consistent of what would be expected for the habitat areas described above. A list of wildlife observations along with the general recon area depicting where each species was identified is provided in Table 1.

Table 1. Wildlife Observations

Common Name	Scientific Name	Recon Area Observed				
		Area 1	Area 2	Area 3	Area 4	Upland
White tailed deer	*Odocoileus virginianus*		X	X		X
Grey squirrel	*Sciurus carolinensis*				X	X
Northern water snake	*Nerodia sipedon*			X		
Black rat snake	*Panthrophis obsoletus*		X	X		
Painted turtle	*Chrysemys picta*		X			
Terrestrial snail	--	X				
Aquatic snail	--	X				
Amphipod	--	X				
Turkey vulture	*Cathartes aura*	X	X	X	X	X
Osprey	*Pandion haliaethus*	X	X	X		X
American crow	*Corvus brachyrhynchos*	X			X	X
Red-winged blackbird	*Agelaius phoeniceus*		X	X		
Mourning dove	*Agelaius phoeniceus*					X
Northern cardinal	*Cardinalis cardinalis*					X
Northern bluejay	*Cyanocitta cristata*			X		X
Great scaup	*Aythya marila*	X				
Pileated woodpecker	*Dryocopus pileatus*					X
Ring-billed gull	*Larus delawarensis*	X				X

As previously mentioned, *Phragmites* and cattail were the dominant aquatic vegetation. The upland habitat consists primarily of invasive species including Japanese barberry (*Berberis thunbergii*), multiflora rose (*Rosa multiflora*), wineberry (*Rubus phoenicolasius*), and Japanese honeysuckle (*Lonicera japonica*). Other dominant species located within the upland areas included maples (*Acer spp.*), *Forsythia spp*., devil's walkingstick (*Aralia spinosa*), and red cedar (*Juniperus virginiana*). Milkweed (*Asclepias syriaca*) was also identified.

Sediment Sampling

EA collected sediment samples on 7 April 2020 from areas identified as depositional. EA identified seven sediment sampling locations, including three locations in Recon Area 1 (SD 04, SD 05, and SD 06), three locations in Recon Area 2 (SD 01, SD 02, SD 03), and one location in Recon Area 3 (SD 07). The seven sediment locations are depicted on Figure 3. Sediment samples were collected for analysis of grain size and TOC. Grain size appears to vary from coarse sand and cobbles in Recon Area 1 to fine silts and clays in Recon Areas 2 and 3.

Potential Sediment Background Locations

EA identified two potential upstream background sediment sampling locations (Figure 5). The first potential background sampling location was identified as Constitution Island, which is located approximately 7 miles upstream of Iona Island on the eastern bank of the Hudson River. The island consists of approximately 175 acres of upland habitat and another 240 acres of marsh, similar to that of Iona Island. A gate prevented access to the island and signs indicated it is government property with restricted access and is believed to be part of West Point Military Academy.

The second potential background location was identified as Con Hook, which is a peninsula located approximately 3 miles upstream of Iona Island on the western side of the Hudson River. It consists of approximately 7 acres of upland

habitat and another 12 acres of a *Phragmites*-dominated marsh land, similar to that of Iona Island. Access appears only possible via boat. A boat ramp is located approximately 2 miles south of Con Hook in Mine Dock Park.

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

1. Northernmost portion of Recon Area 1 at high tide, before start of river wall.

2. Northernmost portion of Recon Area 1 at low tide.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

3. Amphipod observed under shoreline rocks during low tide.

4. Snail observed under shoreline rocks during low tide.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

5. River wall located along the majority of Recon Area 1.

6. Pipe #1 identified along the northern portion of Recon Area 1.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

7. Sediment area observed at low tide at sample area SD-06.

8. Pipe #2 observed along Recon Area 1.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

9. Terracotta pipe identified partially buried near the historic causeway in Recon Area 1.

10. Two additional metal pipes identified along the river wall, near the historic causeway in Recon Area 1.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

11. Sample location SD-05 located between the exposed bedrock and beach area in Recon Area 1.

12. Pipe #3 located along the river wall in Recon Area 1.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

13. Coarse sand, beach glass and pebble material along the beach area on the southern portion of Recon Area 1.

14. Southernmost portion of Recon Area 1 at high tide at sediment location SD-04.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

15. Southernmost portion of Recon Area 1 at low tide.

16. Water depth of approximately 5 feet along the river wall in Recon Area 1 at high tide.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

17. Northern shoreline of Round Island.

18. *Phragmites* dominated marsh in Recon Area 2, on the eastern side of railroad tracks.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

19. Rip-rap slope and water depth of three feet along the eastern side of railroad tracks, across from Round Island.

20. Potential pathway located between Round Island and the existing fill area.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

21. View of Recon Area 3 from Round Island.

22. View of *Phragmites* dominated marsh between Iona Island and Round Island.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

23. Potential groundwater seep area along Recon Area 2 (Location of SD 02).

24. Typical view of railroad tracks in Recon Area 4.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

25. Top of river wall with evidence of historic railing or fence posts.

26. Typical metal piping observed in Recon Areas 1 and 3 which appear to be from historic railing or fence structure.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

27. Observed fence and wall drainpipe identified on Round Island.

28. Sediment sample location SD-01.

EA Engineering, Science, and Technology, Inc., PBC

Photographic Record

Shoreline Reconnaissance Photographs – Iona Island
6-7 April 2020

29. Sediment Sample Location SD-03 at hightide.

30. Sediment sample location SD-07 at low tide.

1. EPA Region 4 Ecological Risk Assessment Supplemental Guidance. Scientific Support Section Superfund Division EPA Region 4. March 2018. Screening values are further detailed in Appendix E, Ecological Risk Assessment Work Plan

DU-8 (AOC #5: Former Building 207 – Marine Garage Building) was not sampled because it would not be possible to separate metals and PAH contaminants originating from former Building 207, from contaminants originating from drums and other debris observed in DU-8.

Notes:

% = Percent
CAS = Chemical Abstracts Service
EPA = U.S. Environmental Protection Agency
HMW = High molecular weight
in. = Inch(es)
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LMW = Low molecular weight
LOD = Limit of detection
LOQ = Limit of quantitation
mg/kg = Milligram(s) per kilogram
N/A = Not applicable
ND = Not detected
No. = Number
NS = No standard
PAH = Polycyclic aromatic hydrocarbon
PCB = Polychlorinated biphenyl
RSD = Relative standard deviation
RSL = Regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- = Bias low
+ = Bias high

Validation Reason Codes:

A Serial dilution
C LCS Recovery
D MS RPD
H2 Prep Hold Time
I Surrogate recovery outside project limits
L Lab Blank
M MS Recovery
M2 Post Spike
P1 Column RPD
TR Trace Level Detect
V2 CCV

Concentrations highlighted in blue exceed EPA Region 4 Ecological Soil Screening Levels.

1. EPA Region 4 Ecological Risk Assessment Supplemental Guidance. Scientific Support Section Superfund Division EPA Region 4. March 2018. Screening values are further detailed in Appendix E, Ecological Risk Assessment Work Plan

Notes:

% = Percent
CAS = Chemical Abstracts Service
EPA = U.S. Environmental Protection Agency
in. = Inch(es)
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LMW = Low molecular weight
LOD = Limit of detection
LOQ = Limit of quantitation
mg/kg = Milligram(s) per kilogram
N/A = Not applicable
ND = Not detected
No. Number
NS = No standard
PAH = Polycyclic aromatic hydrocarbon
PCB = Polychlorinated biphenyl
RSD = Relative standard deviation
RSL = regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high

Validation Reason Codes:

A Serial dilution
C LCS Recovery
D MS RPD
H2 Prep Hold Time
I Surrogate recovery outside project limits
L Lab Blank
M MS Recovery
M2 Post Spike
P1 Column RPD
TR Trace Level Detect
V2 CCV

Concentrations highlighted in blue exceed EPA Region 4 Ecological Soil Screening Levels.

DU-24 (T2 near AOC #16 – Area Dumping Area) was not sampled. The majority of DU-24 contained exposed bedrock with little to thin soil cover. Any PCBs that may have been released from former transformers would have been transported via runoff and overland flow across the bedrock outcrop of Round Island to the Hudson River. While sediment and soil was noted along the northeastern edge of DU-24 off the bedrock outcrop of Round Island, this sediment/soil was along the shoreline of the tidally influenced Hudson River. The Hudson River itself is a PCB source. Therefore, collecting PCBs from soil/sediment along the Hudson River would not provide information that could be used to evaluate a potential release related to former transformers.

1. EPA Region 4 Ecological Risk Assessment Supplemental Guidance. Scientific Support Section Superfund Division EPA Region 4. March 2018. Screening values are further detailed in Appendix E, Ecological Risk Assessment Work Plan

Notes:
% = Percent
CAS = Chemical Abstracts Service
EPA = U.S. Environmental Protection Agency
in. = Inch(es)
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
mg/kg = Milligram(s) per kilogram
N/A = Not applicable
ND = Not detected
No. Number
NS = No standard
RSD = Relative standard deviation
RSL = Regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high

Validation Reason Codes:
A Serial dilution
C LCS Recovery
D MS RPD
H2 Prep Hold Time
I Surrogate recovery outside project limits
L Lab Blank
M MS Recovery
M2 Post Spike
P1 Column RPD
TR Trace Level Detect
V2 CCV

Concentrations highlighted in blue exceed EPA Region 4 Ecological Soil Screening Levels.

1. EPA Region 4 Ecological Risk Assessment Supplemental Guidance. Scientific Support Section Superfund Division EPA Region 4. March 2018. Screening values are further detailed in Appendix E, Ecological Risk Assessment Work Plan

Notes:
CAS = Chemical Abstracts Service
EPA = U.S. Environmental Protection Agency
HMW = High molecular weight
in. = Inch(es)
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LMW = Low molecular weight
LOD = Limit of detection
LOQ = Limit of quantitation
mg/kg = Milligram(s) per kilogram
N/A = Not applicable
No. Number
NS = No standard
PAH = Polycyclic aromatic hydrocarbon
PCB = Polychlorinated biphenyl
R = The data are unusable The sample results are rejected due to serious deficiencies in meeting the QC criteria The analyte may or may not be present in the sample
RSL = regional screening level
U = Analyte not detected Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate
- Bias low
+ Bias high

Validation Reason Codes:

A	Serial dilution
C	LCS Recovery
D	MS RPD
H2	Prep Hold Time
I	Surrogate recovery outside project limits
L	Lab Blank
M	MS Recovery
M2	Post Spike
P1	Column RPD
TR	Trace Level Detect
V2	CCV

Concentrations highlighted in blue exceed EPA Region 4 Ecological Soil Screening Levels.

Ecological screening values for freshwater, chronic exposure. Hierarchy for selected values is as follows:

1. NRWQC, current values. available: https://www.epa.gov/wqc/national-recommended-water-quality-criteria-aquatic-life-criteria-table

2. Values from the publication by Suter et al. 1996. Toxicological benchmarks for screening potential contaminants of concern for effects on aquatic biota: 1996 Revision. ES/ER/TM-96/R2. https://rais.ornl.gov/documents/tm96r2.pdf. This source was used when no other values were available.

3. Great Lakes Initiative (GLI), Clearinghouse Resources Tier II criteria revised 2013. Available: https://www.epa.gov/gliclearinghouse. These values were selected over Canadian Council of Ministries of the Environment (2003), per USACE NAE.

NOTES:
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated

Concentrations highlighted in blue exceed Ecological Screening Levels.

Validation Reason Codes:

A	Serial dilution
L	Lab Blank
TR	Trace Level Detect

Ecological screening values for freshwater, chronic exposure. Hierarchy for selected values is as follows:

1. NRWQC, current values. available: https://www.epa.gov/wqc/national-recommended-water-quality-criteria-aquatic-life-criteria-table

2. Values from the publication by Suter et al. 1996. Toxicological benchmarks for screening potential contaminants of concern for effects on aquatic biota: 1996 Revision. ES/ER/TM-96/R2. https://rais.ornl.gov/documents/tm96r2.pdf. This source was used when no other values were available.

3. Great Lakes Initiative (GLI), Clearinghouse Resources Tier II criteria revised 2013. Available: https://www.epa.gov/gliclearinghouse. These values were selected over Canadian Council of Ministries of the Environment (2003), per USACE NAE.

NOTES:

CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
RSL = regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated

Validation Reason Codes:
A Serial dilution
L Lab Blank
TR Trace Level Detect

Concentrations highlighted in blue exceed Ecological Screening Levels.

Ecological screening values for freshwater, chronic exposure. Hierarchy for selected values is as follows:

1. NRWQC, current values. available: https://www.epa.gov/wqc/national-recommended-water-quality-criteria-aquatic-life-criteria-table

2. Values from the publication by Suter et al. 1996. Toxicological benchmarks for screening potential contaminants of concern for effects on aquatic biota: 1996 Revision. ES/ER/TM-96/R2. https://rais.ornl.gov/documents/tm96r2.pdf. This source was used when no other values were available.

3. Great Lakes Initiative (GLI), Clearinghouse Resources Tier II criteria revised 2013. Available: https://www.epa.gov/gliclearinghouse. These values were selected over Canadian Council of Ministries of the Environment (2003), per USACE NAE.

NOTES:
CAS = Chemical Abstracts Service
EPA = United States Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = not applicable
ND = not detected
NS = No standard
RSL = regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate

Concentrations highlighted in blue exceed Ecological Screening Levels.

Validation Reason Codes:
L Lab Blank
TR Trace Level Detect

Notes:

Ecological screening values for freshwater, chronic exposure. Hierarchy for selected values is as follows:

1. NRWQC, current values. available: https://www.epa.gov/wqc/national-recommended-water-quality-criteria-aquatic-life-criteria-table
2. Values from the publication by Suter et al. 1996. Toxicological benchmarks for screening potential contaminants of concern for effects on aquatic biota: 1996 Revision. ES/ER/TM-96/R2. https://rais.ornl.gov/documents/tm96r2.pdf. This source was used when no other values were available.
3. Great Lakes Initiative (GLI), Clearinghouse Resources Tier II criteria revised 2013. Available: https://www.epa.gov/gliclearinghouse. These values were selected over Canadian Council of Ministries of the Environment (2003), per USACE NAE.

µg/L = Microgram(s) per liter
CAS = Chemical Abstracts Service
EPA = U.S. Environmental Protection Agency
J = Estimated: The analyte was positively identified; the quantitation is an estimation
LOD = Limit of detection
LOQ = Limit of quantitation
N/A = Not applicable
ND = Not detected
NRWQC = National Recommended Water Quality Criteria
No. = Number
NS = No standard
RSL = Regional screening level
U = Analyte not detected. Numerical value is LOD or LOQ, as indicated
UJ = Analyte not detected, and associated numerical value (LOD or LOQ) is approximate

Concentrations highlighted in blue exceed Ecological Screening Levels.

Validation Reason Codes:

L	Lab Blank
TR	Trace Level Detect

Notes:
1. Initial laboratory CEC results were deemed abnormally high by several orders of magnitude. Analytical results were rejected during data validation.
2. CEC for onsite soil was calculated using Phase I metals analytical results (calcium, magnesium, potassium, sodium).
3. The laboratory re-analyzed CEC samples after correcting an error with reagents. Analytical results are from re-analysis. However, laboratory holding times and conditions are unknown.

3120											
3121	**Gamma ROS Statistics using Imputed Non-Detects**										
3122	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs										
3123	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)										
3124	For such situations, GROS method may yield incorrect values of UCLs and BTVs										
3125	This is especially true when the sample size is small.										
3126	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

4603						**Gamma ROS Statistics using Imputed Non-Detects**							
4604						GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs							
4605						GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)							
4606						For such situations, GROS method may yield incorrect values of UCLs and BTVs							
4607						This is especially true when the sample size is small.							
4608						For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

5946						GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs							
5947						GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)							
5948						For such situations, GROS method may yield incorrect values of UCLs and BTVs							
5949						This is especially true when the sample size is small.							
5950						For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

7428				Mean (detects)	0.15							
7429												
7430	**Gamma ROS Statistics using Imputed Non-Detects**											
7431	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
7432	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
7433	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
7434	This is especially true when the sample size is small.											
7435	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

7716												
7717						**Gamma ROS Statistics using Imputed Non-Detects**							
7718						GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs							
7719						GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)							
7720						For such situations, GROS method may yield incorrect values of UCLs and BTVs							
7721						This is especially true when the sample size is small.							
7722						For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

8393												
8394	**Suggested UCL to Use**											
8395					95% Student's-t UCL	85.56						
8396												
8397	Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.											
8398	Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.											
8399	However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.											
8400												
8401	**Result (tws-sw-zinc)**											
8402												
8403	**General Statistics**											
8404					Total Number of Observations	10	Number of Distinct Observations	2				
8405					Number of Detects	1	Number of Non-Detects	9				
8406					Number of Distinct Detects	1	Number of Distinct Non-Detects	1				
8407												
8408	**Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!**											
8409	**It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).**											
8410												
8411	**The data set for variable Result (tws-sw-zinc) was not processed!**											
8412

Notes:

1. Kaplan-Meier estimator used for datasets with non-detect results.

2. Difference between site and background means reported as an interval if either site or background mean is a non-detect.

3. Right-tailed probability of permutation test of difference between site and background means. Adjusted p-values computed with Benjamini-Hochberg procedure for controlling false discovery rate (FDR). Asterisks indicate significance level (<0.05, <0.01, <0.001).

µg/L = Microgram(s) per liter

CAS = Chemical Abstracts Service

CHHRS = Con Hook Hudson River Shoreline

CHMS = Con Hook Marsh Shoreline

DU = decision unit

IHRS = Iona Hudson River Shoreline

mg/kg = Milligram(s) per kilogram

No. = Number

RRDS = Rip rap drainage swale

SE = Sediment

TWS = Tidal wetland swale

WS = Surface water

Notes:
COPEC = Constistuent of potential ecological concern
EPC = Exposure point concentration
HQ = Hazard quotient
kg = Kilogram(s)
L = Liter(s)
LOAEL = Lowest observed adverse effects level
mg/kg bw-day = Milligram(s) per kilogram of body weight per day
NA = Not available
NOAEL = No observed adverse effects level
TRV = Toxicity reference value
wt = Weight
Hazard quotients >1 are bold font

Table G-10. Food Web Model for River Otter

RIVER OTTER (PISCIVOROUS MAMMAL)	Value	Unit
Body Weight	7.43	kg
Food Ingestion Rate	0.0481	kg dry wt/kg-day
Incidental Sediment Ingestion Rate	2.00%	% of total mass of diet
Incidental Sediment Ingestion Rate	0.00096	kg dry wt/kg-day
Habitat Range	859	acres
Area use factor	0.0006	0.5/859
Diet - fish	100	%
