1.0 INTRODUCTION

In the New England region, disposal of dredged material in the marine environment is generally controlled by management procedures requiring dumping at a disposal buoy under the supervision of a federal inspector. This procedure is quite expensive, particularly in manpower logistics, and often limited in accuracy and flexibility since buoys typically have a large watch circle and cannot be readily moved from one point to another. A different approach to disposal management, utilizing a computerized navigation system, has recently been employed with excellent results at the Boston Foul Ground in Massachusetts Bay. This report presents a description of the disposal control system installed aboard the 250 foot hopper dredge SUGAR ISLAND and an evaluation of the results attained over a series of 65 separate dumping operations between January 11 and February 1, 1983.

2.0 DISPOSAL CONTROL SYSTEM

A prototype version of a computerized disposal control system was installed on the bridge of the SUGAR ISLAND. A block diagram of the system, which closely resembles the unit installed on tugs at New Haven to control capping operations during the Stamford/New Haven project in 1980, is presented in Figure 2.0-1. The system consists of a Northstar 6000 Loran-C receiver interfaced to an Apple II computer through a Northstar 6700, RS-232-C interface unit. Software within the Apple II processes the raw Loran-C time delay data using a Kalman filter algorithm and presents a ship track display on a video monitor (Fig. 2.0-2). This display provides the helmsman with sufficient data

Figure 2.0-2

to accurately position the ship for point dumping operations.

In addition to ship control, the system continuously records position data at a preset interval (5 min. for this operation) on a magnetic disk to permit later reconstruction of the ships track. When a special function key is initialized indicating disposal is occurring, a flag is set and the system records position continuously for one minute to provide accurate definition of the location and velocity of the ship during disposal. An example of the printout generated by the system is presented in Figure 2.0-3.

An important feature of the system installed on the SUGAR ISLAND was the simplicity of the operating procedures. In order to operate the system, the Corps inspector simply inserted a disk and turned the unit on. As the ship left the harbor a key was pressed when the vessel passed a designated buoy which checked the calibration of the Loran-C receivers. When disposal occurred, the inspector pressed a second key to indicate the event. All recording procedures, graphic display changes and calibration checks were conducted automatically by the computer.

2.1 System Software

The program developed for operation of the disposal control system had to perform the following functions:

- initialize the system, including disposal point, calibration point, Loran-C chain, Loran-C slaves, etc.
- acquire Loran-C time delay data from RS-232-C interface
- acquire initial calibration of the Loran-C receiver and maintain calibration through the duration of the disposal trip
- present position and other pertinent data on video display for ship control

- record position data as required on magnetic disk

The software to accomplish these tasks contained several unique features, including a Kalman filter to smooth the Loran-C data prior to display on the video monitor and recording on disk. The Kalman filter reduces the scatter of the Loran data and actually improves the accuracy of navigation through calculation of the best estimate of position using the past history of ship motion as well as current measurements from the Loran-C.

A second feature of the software that is essential to reliable operation is the calibration subroutine. Loran-C receivers have a potential error source, that can occur when the processor "locks" on to the wrong pulse of the Loran signal. This causes a 10 μ sec shift in the time delay measurement which results in a large position error of several hundred meters to more than a mile depending on the geometry of the Loran net. This error can be detected and removed if a calibration point is established and checked during each transit to the disposal point.

On this project the sea buoy at the mouth of Boston Harbor was designated as the calibration point and the Loran-C time delays observed at the buoy on the first trip to the site were input to the program. On subsequent trips to the disposal area a special function key was pressed as the ship passed the buoy and the observed Loran-C readings were compared with the initial time delays. If the observed values were less than 5 sec from the initial values the system was considered to be calibrated; if not, a flag was set and a warning displayed on the

video monitor to indicate that the receiver should be adjusted to correct the 10μ sec jump. Once the Loran receiver was in calibration the system monitored the Loran data and displayed a similar warning should a jump of 10μ sec or more occur during transit to the disposal site. With this safeguard, the certainty of position for disposal location was greatly increased and spread of material due to Loran-C errors essentially eliminated.

2.2 Video Display

Control of the hopper dredge was maintained through use of graphic displays on a video monitor which provided continuous information to the helmsman in the format shown in Figure 2.0-2. On this display the disposal point is the center of the grid which has an automatically varying scale as designated in the upper left corner of the screen (200m per tick mark as shown in this example). The ships track relative to the disposal point is shown as a continuous line with the latest position indicated as a cross.

Below the graphic display, alphanumeric data are presented indicating the range in meters and the bearing in either true or magnetic degrees to the disposal point. A third quantity, the course made good over the bottom, is presented in the lower right (0.00; since it was not implemented on this example). By steering the ship so that the bearing and course made good values are identical, the helmsman can steer directly to the disposal point.

Finally, the time of day is displayed in the lower left corner as general information to the user and as a continuous indication that the system is operational. If the computer were

to hang, or if data were not properly transmitted from the Loran, then the time of day display will stop updating, thus providing an immediate indication of system malfunction.

2.3 Loran-C Navigation

Loran-C was chosen as the positioning system for integration to the disposal control system for several reasons, including:

- Availability - Loran-C chains are operational anywhere along the coast of the U.S.
- Operation Logistics - Loran-C does not require installation of any shore stations
- Precision - Depending on location, the precision of Loran-C is generally on the order of ± 20 to ± 50 meters
- Cost - Loran-C receivers are generally available aboard ship or can be installed for less than \$5000

It is important to distinguish between the accuracy and precision of Loran-C data. Although the precision may be less than ± 50 meters, the accuracy may be on the order of ± 1 km depending on distortion caused by overland pathlength.

Therefore, the system must be initialized by measuring the Loran-C time delay values at the disposal point prior to any dumping operation. If complete geodetic accuracy is required, this must be done using an accurate positioning system such as a trisponder, mini ranger, or equivalent. If relative positions are adequate, simple designation of observed Loran-C delays observed at a point can be used. It is essential, however, that readings be taken from the designated point since values plotted on a standard nautical chart are not corrected for the overland path and generally do not intersect at sea at the desired

location.

For this operation, the disposal point was designated at $42^{\circ}25.399'N$, $70^{\circ}34.549'W$ as determined by measuring Loran-C time delays at a taut-wire moored buoy used for disposal of Boston Harbor sediment. When this buoy was re-located to control additional disposal, the Loran-C system was installed aboard the SUGAR ISLAND. Table 2.3-1 presents the parameters of the Loran-C network at the disposal point. At this location the W (Caribou, ME) and X (Nantucket, MA) slaves of the 9960 chain provide the best resolution or precision for disposal control. The effective resolution of a Loran receiver is $.1 \mu\text{sec}$ which results in a spatial resolution of 27.5 m. Should the $10 \mu\text{sec}$ jump occur, then the error in position could be as much as 2 km.

3.0 RESULTS

The location of the SUGAR ISLAND was recorded on disk at five minute intervals during transit to the site and continuously for one minute following initiation of the disposal operation. Printouts of all data obtained during the operation are included as Appendix I to this report. The transit routes followed by the dredge are presented in Figures 3.0-1 through 4. From these plots it is apparent that the vessel followed a consistent course to the site, generally staying within one half mile of the direct course. As the ship neared the disposal point, she frequently swung to the north to make her approach heading southeast into the prevailing wind and sea.

Figure 3.0-5 shows the location of the ship at initiation of each disposal operation, relative to the designated

point and a circle of 50m radius. It is important to note that all but 7 of the 65 dumps fell within the 50m radius, in fact, as shown in Figure 3.0-6, more than half were within 25m of the designated point. Because of the large scale of Figure 3.0-5, the resolution of the Loran-C grid is apparent from the linear distribution of points in a southeast orientation. The constant separation represents a change of 1 μ sec on the Loran-C receiver.

Table 3.0-1 presents the exact location of each disposal operation conducted with the system along with a range and bearing to the designated point and the ships course and speed at the time of disposal. The ship was generally travelling at five knots or less in a southeasterly direction, which substantiates the southeasterly bias of disposal points seen in Figure 3.0-5.

4.0 SUMMARY

In general, the disposal control system for the SUGAR ISLAND was a success. After becoming familiar with the unit, both the inspectors and crew of the ship were able to operate the system and utilize the output. Some problems were experienced due to changing scales on the video display, however, these were corrected after the first several trips and no further complications were observed. The Loran-C receiver performed flawlessly and no calibration problems were encountered during the entire operation.

Probably the most significant aspect of this project, however, is the overall precision of the disposal control. The ability to restrict 90% of the dumps to within a 50m radius using

a large ship such as the SUGAR ISLAND means that procedures such as point dumping or capping are feasible at relatively low cost even at some distance from shore. Furthermore, with slight modifications to make this system automatic, the potential exists for reducing the large labor costs associated with Corps inspectors, since the recording of transit routes and disposal locations provides an automatic surveillance capability.
